Saraswati Sukumar
Ian Thompson

Symposia Director
Rich Markow

Meeting Profile
For thirty-four years, the mission of the San Antonio Breast Cancer Symposium has been to provide state-of-the-art information on breast cancer research. The symposium aims to achieve a balance of clinical, translational, and basic research, providing a forum for interaction, communication, and education for a broad spectrum of researchers, health professionals, and those with a special interest in breast cancer.

In 2007, the Cancer Therapy & Research Center (CTR) at UT Health Science Center San Antonio and the American Association for Cancer Research (AACR) announced a collaboration for the future of the San Antonio Breast Cancer Symposium. The symposium has been renamed the CTRC-AACR San Antonio Breast Cancer Symposium. Complementing the clinical strengths of the highly regarded annual San Antonio Breast Cancer Symposium, the AACR’s scientific prestige in basic, translational, and clinical cancer research will create a unique and comprehensive scientific meeting that will advance breast cancer research for the benefit of patients.

In 2005, Baylor College of Medicine became a joint sponsor of the symposium and will remain a part of the CTRC-AACR collaboration.

Future Meeting Dates
December 4–8, 2012
December 10–14, 2013
December 9–13, 2014

Copyright and Permissions
As a collaborating partner, the AACR is publishing the abstracts of the San Antonio Breast Cancer Symposium in this Supplement to Cancer Research on behalf of the Symposium organizers. Permission to reprint or re-use any abstract in this Supplement must be obtained from the copyright holder. For more information, contact the Symposia Director (below).

Publishing Information: Cancer Research

Cancer Research [ISSN 0008-5472; CNRE8] is published twice a month, one volume per year, by the American Association for Cancer Research, Inc. Postage paid at Philadelphia, PA, and additional mailing offices. POSTMASTER: Send address changes to Member Services, AACR, 615 Chestnut St., 17th Floor, Philadelphia, PA 19106-4404; or E-mail: membership@aacr.org. Copyright 2011 by the American Association for Cancer Research. Inc. Printed on acid free paper in the United States of America.

Subscription Information
AACR Members. Subscription options are print with online access or see http://www.aacr.org and go to the membership page for further information.

Institutions and Nonmembers.
E-mail contact is primary, and the decision to print is based on the decision of the institutional administrator. Subscriptions are payable in advance and include both old and new addresses. Member subscribers should contact AACR Membership Services, 615 Chestnut St., 17th Floor, Philadelphia, PA 19106-4404; or E-mail: membership@aacr.org. Nonmember subscribers contact Turpin Distribution, The Bleachery, 143 West Street, New Milford, CT 06776; e-mail turpin@turpin-distribution.com, or Turpin Distribution, Pegasus Drive, Stratton Business Park, Biggleswade, Bedfordshire SG18 8TQ, United Kingdom; e-mail custserv@turpin-distribution.com.

Claims. Claims for missing issues must be made within 90 days of the issue’s publication date and will be honored while supplies last. Member subscribers should contact membership@aacr.org. Nonmember subscribers contact Turpin Distribution, The Bleachery, 143 West Street, New Milford, CT 06776; e-mail turpin@turpin-distribution.com, or Turpin Distribution, Pegasus Drive, Stratton Business Park, Biggleswade, Bedfordshire SG18 8TQ, United Kingdom; e-mail custserv@turpin-distribution.com.

Change of Address. Send change of address notifications 60 days in advance and include both old and new addresses. Member subscribers should contact AACR Membership Services, 615 Chestnut St., 17th Floor, Philadelphia, PA 19106-4404; or E-mail: membership@aacr.org. Nonmember subscribers should contact Turpin Distribution, The Bleachery, 143 West Street, New Milford, CT 06776; e-mail turpin@turpin-distribution.com, or Turpin Distribution, Pegasus Drive, Stratton Business Park, Biggleswade, Bedfordshire SG18 8TQ, United Kingdom; e-mail custserv@turpin-distribution.com.

Single Issue Sales. Single issues and back stock of the journal may be ordered from the AACR main office by calling 866-423-3965 (toll-free) or 215-440-9300. Prices are available upon request.

Copyright and Permissions
As a not-for-profit organization incorporated in the United States, AACR adheres to U.S. copyright law (PL 94-553), which became effective January 1, 1978. The law stipulates that copyright for works is vested in the author from the moment of creation and remains the property of the author until legally transferred. Authors who wish to publish articles and other material in AACR journals must formally transfer copyright to AACR. The copyright transfer form must be signed by all authors before AACR can proceed with publication. Appropriate forms for transfer of copyright will be requested from all authors after a manuscript has been deemed potentially acceptable.

To read the complete version of AACR’s Copyright and Permissions Policy, please visit http://www.aacr.org/home/scientists/publications-of-the-aacr/copyright-and-permissions-policy.aspx. This policy includes further information on authors’ rights of usage, permission requests from third parties, free access to AACR journals, funding agency requirements, and the National Institutes of Health Public Access Policy.

Cancer Research is abstracted or indexed in Biological Abstracts, Biochemistry & Biophysics Citation Index, Basic Biosis, BIOSIS Previews (R) Database, Chemical Abstracts, Index Medicus, MEDLINE, Current Contents/Clinical Medicine, Reference Update, and Science Citation Index (expanded).

No responsibility is accepted by the Editors or by AACR, Inc. for the opinions expressed by contributors or for the content of the advertisements.

CONFERENCE GRANT
American Cancer Society, Texas Division

SABCS gratefully acknowledges
Susan G. Komen for the Cure® for generous support of
AACR Outstanding Investigator Award
for Breast Cancer Research,
CTCR-AACR San Antonio Breast Cancer Symposium
Educational Sessions,
AACR Scholars-in-Training Awards
SABCS wishes to thank Avon Foundation for support of the
Avon Foundation-AACR International
Scholar-In-Training Grants

FUTURE SYMPOSIUM MEETING DATES
35th Annual SABCS  December 4–8, 2012
36th Annual SABCS  December 10–14, 2013
37th Annual SABCS  December 9–13, 2014
**2011 CTRC-AACR
SAN ANTONIO BREAST CANCER SYMPOSIUM
PROGRAM SCHEDULE**

(At press time)
Refer to www.sabcs.org for the most current information.

Room Locations
Exhibit Halls A, B, C & D: Street Level
Ballrooms A & B: Street Level
Bridge Hall: Street Level

**TUESDAY, DECEMBER 6, 2011**

12:00 pm–7:30 pm
REGISTRATION
Bridge Hall
Pre-registered attendees can obtain materials. Those who have not yet registered may do so.

2:00 pm–7:30 pm
EDUCATIONAL SESSIONS
Ballrooms A & B and Exhibit Hall D
Supported by an educational grant from
Susan G. Komen for the Cure®
An update on advances in the technologies available for translational research. Sessions are to provide people with a better understanding of the talks they hear using the techniques described. They also provide researchers with a guide to the techniques they should be considering for their studies.

2:00 pm–3:30 pm
Treatment of Metastatic Breast Cancer – Breast Cancer as a Chronic Disease
Ballroom A
Moderator: Kathleen Pritchard, MD, FRCPC
University of Toronto
Toronto, CANADA

ER positive
Kathleen Pritchard, MD, FRCPC
University of Toronto
Toronto, CANADA

Triple negative breast cancer
Vered Stearns, MD
The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins
Baltimore, MD

HER2 positive
Ian E. Krop, MD, PhD
Dana-Farber Cancer Institute
Boston, MA

Mouse Models of PI3K-Dependent and Basal-Like Breast Cancer
Ballroom B
Moderator: Carlos L. Arteaga, MD
Vanderbilt-Ingram Cancer Center
Vanderbilt University
Nashville, TN

P13K mouse models of breast cancer
Ramon E. Parsons, MD, PhD
Institute for Cancer Genetics
Columbia University
New York, NY

Mouse models of basal-like breast cancer
Jos Jonkers, PhD
Netherlands Cancer Institute
Amsterdam, NETHERLANDS

Patient-derived xenograft models for preclinical breast cancer research: Not just “basal” anymore
Michael T. Lewis, PhD
Baylor College of Medicine
Houston, TX

4:00 pm–5:30 pm
Controversies in Early Breast Cancer
Exhibit Hall D
Moderator: Peter M. Ravdin, MD, PhD
UT Health Science Center San Antonio
San Antonio, TX

Controversies in early breast cancer: Small tumors
Peter M. Ravdin, MD, PhD
UT Health Science Center San Antonio
San Antonio, TX

Chemotherapy benefit in ER positive breast cancer – Mixed messages
Kathy Albain, MD, FACP
Loyola University Chicago Stritch School of Medicine
Maywood, IL

Adjuvant therapy in patients with a borderline HER-2 status
Angelo Di Leo, MD, PhD
Hospital of Prato
Prato, ITALY

New Technologies in Biomarker Discovery for the Clinician
Ballroom A
Moderator: Trey Westbrook, PhD
Baylor College of Medicine
Houston, TX

Metabolomics as a tool to study cancer progression
Arun Sreekumar, PhD
Baylor College of Medicine
Houston, TX

Proteomics
Gordon Mills, MD, PhD
UT MD Anderson Cancer Center
Houston, TX

The potential of epigenetic therapy in breast cancer
Stephen Baylin, MD
Johns Hopkins University
Baltimore, MD

Breast Cancer Trials in Developing Countries - Opportunities and Challenges
Ballroom B
Moderator: Ismail Jatoi, MD, PhD, FACS
UT Health Science Center San Antonio
San Antonio, TX

Challenges in the design and implementation of breast cancer clinical trials in developing countries
Sudeep Gupta, MD, DM
Tata Memorial Hospital
Mumbai, INDIA

Practicality, promise and pitfalls in industry-sponsored trials (in developing countries)
Sandra J. Horning, MD
Genentech, Inc.
South San Francisco, CA
Novel approach to breast cancer in low income countries
David J. Kerr, CBE, MA, MD, DSc FRCP (Glas & Lon), FRCPG (Hon), FMedSci
University of Oxford
Oxford, UNITED KINGDOM

6:00 pm–7:30 pm
Challenges in the Care of Special Populations with Breast Cancer
Exhibit Hall D
Moderator: Mothaffar Rimawi, MD
Baylor College of Medicine
Houston, TX

Oncofertility: Translation in multidimensions
Teresa K. Woodruff, PhD
Northwestern University
Chicago, IL

Treatment of young women with breast cancer
Ann H. Partridge, MD, MPH
Dana-Farber Cancer Institute
Boston, MA

Treatment of older women with breast cancer
Antti Hurria, MD
City of Hope
Duarte, CA

What Makes a Good Target?
Ballroom A
Moderator: Mark D. Pegram, MD
Miller School of Medicine of University of Miami
Miami, FL

Target, identification and drug discovery: What is druggable?
Stephen W. Fesik, PhD
Vanderbilt University Medical Center
Nashville, TN

Clinical validation of new therapeutic targets in breast cancer
Mark D. Pegram, MD
Miller School of Medicine of University of Miami
Miami, FL

Study design considerations in the development of drugs and the diagnostic tests that can guide their use
Steve Shak, MD
Genomic Health, Inc
Hillsborough, CA

Reconstruction
Ballroom B
Moderator: Richard L. Crownover, MD, PhD
Cancer Therapy and Research Center at UT Health Science Center San Antonio
San Antonio, TX

Breast reconstruction with implants and post-mastectomy irradiation: Algorithms and outcomes
Peter G. Cordeiro, MD, FACS
Memorial Sloan-Kettering Cancer Center
New York, NY

Strange bedfellows: Radiation therapy and breast reconstruction
Richard C. Zellars, MD
Johns Hopkins University
Baltimore, MD

Measuring outcomes in breast reconstruction: The patient perspective
Andrea L. Pusic, MD, MHS, FRCS
Memorial Sloan-Kettering Cancer Center
New York, NY

WEDNESDAY, DECEMBER 7, 2011

7:00 am–5:15 pm
REGISTRATION
Bridge Hall

6:45 am–8:15 am
CAREER DEVELOPMENT FORUM: A NETWORKING SESSION FOR YOUNG INVESTIGATORS
Ballroom B
Networking and career development opportunities for early career scientists. The session is open to early-career scientists, defined as graduate students, postdoctoral or clinical fellows, or medical students and residents, who are registered attendees of the SABCS. Space in the workshop is limited to 200 participants; registrations will be accepted on a first-come, first-served basis and is free of charge.

Discussion topics at press time
(Program subject to change)
1. Balancing Research and Clinical Practice
   Ann H. Partridge, Dana-Farber Cancer Institute, Boston, MA
   Judy E. Garber, Dana-Farber Cancer Institute, Boston, MA

2. Balancing Research and Clinical Practice

3. Careers in Industry
   Malte Peters, Novartis, Basel, Switzerland

4. Careers in Industry
   Steven Shak, Genomic Health, Inc., Redwood City, CA

5. Careers in Translational Research
   Rachel Schiff, Baylor College of Medicine, Houston, TX

6. Grant Writing – Clinical/Translational
   Lisa A. Carey, University of North Carolina Lineberger Comprehensive Cancer Center, Chapel Hill, NC

7. Grant Writing – Basic/Translational
   Joan S. Brugge, Harvard Medical School, Boston, MA

8. How to Become a Clinical Trialist
   Hope S. Rugo, UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, CA

9. How to Get the Most Out of your Fellowship Years – Translational
   Nancy U. Lin, Dana-Farber Cancer Institute, Boston, MA

10. How to Get the Most Out of your Fellowship Years – Clinical
   Rong Li, University of Texas Health Science Center, San Antonio, TX

11. How to Get the Most Out of your Predoctoral Experience
   Valerie M. Weaver, University of California San Francisco Medical Center, San Francisco, CA

12. Leadership Skills
   Carlos L. Arteaga, Vanderbilt-Ingram Cancer Center, Nashville, TN

13. Making the Transition from Fellowship to Faculty
    Pepper Jo Schedin, University of Colorado, Aurora, CO

14. Making the Transition to Independence
    Valerie M. Weaver, University of California San Francisco Medical Center, San Francisco, CA

15. Making the Transition to Independence
    Eric P. Winer, Dana-Farber Cancer Institute, Boston, MA

16. Mentoring and Supervising
    Douglas Yee, University of Minnesota Masonic Cancer Center, Minneapolis, MN

17. Negotiating a Job Offer
    Matthew J. Ellis, Washington University Siteman Cancer Center, St. Louis, MO

Cancer Res; 71(24 Suppl.) December 15, 2011
Cancer Research
December 6-10, 2011

Program Schedule

8:30 am–8:45 am
OPENING REMARKS
Exhibit Hall D

8:45 am–9:15 am
PLENARY LECTURE 1
Exhibit Hall D

Endocrine Therapy for Breast Cancer: Looking Into the Future
Eric P. Winer, MD
Dana-Farber Cancer Institute
Boston, MA

9:15 am–11:30 am
GENERAL SESSION 1
Exhibit Hall D

Moderator: Kathy D. Miller, MD
Indiana University School of Medicine
Indianapolis, IN

9:15
S1-1. A Phase III randomized trial of anastrozole versus tamoxifen in postmenopausal women with metastatic breast cancer: SWOG S0226
Mehta RS, Barlow WE, Albain KS, Vandenberg T, Dakhil SR, Tirumali NR, Lew DL, Hayes DF, Gralow JR, Livingston RB, Hortobagyi GN. University of California at Irvine; Chao Family CCC, Orange, CA; SWOG, Seattle, WA; Loyola University Chicago Stritch School of Medicine, Maywood, IL; London Regional Cancer Program, London, ON, Canada; Wichita CCOP, Wichita, KS, NW Permanente, Portland, OR, University of Michigan, Michigan; Seattle Cancer Care Alliance, Seattle, WA; Arizona Cancer Center, Tucson, AZ; University of Texas/MD Anderson Cancer Center, Houston, TX.

9:30
S1-2. Long-term follow-up in ABCSG-12: Significantly improved overall survival with adjuvant zoledronic acid in premenopausal patients with endocrine-receptor–positive early breast cancer
Gnant M, Milinker B, Luschin-Ebgren G, Stoeger H, Dubsky P, Jakesz R, Singer C, Eidtmann H, Fesl C, Eiermann W, Marth C, Greil R. Medical University of Vienna, Vienna, Austria; Paracelsus Medical University Salzburg, Salzburg, Austria, Medical University of Graz, Graz, Austria; University of Schleswig-Holstein, Kiel, Germany; Austrian Breast and Colorectal Cancer Study Group, Vienna, Austria; Red Cross Women’s Hospital, Munich, Munich, Germany; Medical University of Innsbruck, Innsbruck, Austria.

9:45
S1-3. Long-term survival outcomes among postmenopausal women with hormone receptor-positive early breast cancer receiving adjuvant letrozole and zoledronic acid: 5-year follow-up of ZO-FAST
de Boer R, Bundner N, Eidtmann H, Neven P, von Minckwitz G, Martin N, Modi A, Coleman R. Royal Melbourne Hospital, Victoria, Australia; University Hospital of South Manchester NHS Foundation Trust, Manchester, United Kingdom; University Frauenklinik, Kiel, Germany; UZ Gasthuisberg, Leuven, Belgium; German Breast Group, Frankfurt, Germany; Novartis Oncology, East Hanover, NJ, University of Sheffield, Sheffield, United Kingdom.

10:00
Discussion
James N. Ingle, MD, Mayo Clinic College of Medicine, Rochester, MN

10:15
S1-4. Retrospective analysis of study EGF30008 by mass-spectrometry based serum assay (VeriStrat®)

10:30
S1-5. Modulation of cancer and stem cell biomarkers by the Notch inhibitor MK-0752 added to endocrine therapy for early stage ER+ breast cancer

10:45
S1-6. Characterization of breast cancer distant metastasis based on outcome over time using a gene expression profiling approach and identification of pathway activities of late relapse

11:00
S1-7. Molecular tumor characteristics influence adjuvant endocrine treatment outcome
Bianchini G, PuzzaI L, Ismaiel T, Kelly CM, Zambetti M, Caralo A, Del Conte G, Santapia L, Symmans WF, Gianni L. San Raffaele Comprehensive Cancer Center, Milan, Italy; University of Texas, MD Anderson Cancer Center, Houston, TX; Mater Misericordiae University Hospital, Dublin, Ireland; Hospital of Prato and Istituto Toscana Tumori, Prato, Italy.

11:15
S1-8. Molecular signaling distinguishes early ER positive breast cancer recurrences despite adjuvant tamoxifen

11:30 am–12:00 pm
AACR DISTINGUISHED LECTURESHIP IN BREAST CANCER RESEARCH
Exhibit Hall D

Protective Adaptive Responses to Breast Cancer Therapies
Joan S. Brugge, PhD
Harvard Medical School
Boston, MA

12:00 pm–1:35 pm
LUNCH

12:15 pm–1:15 pm
PRODUCT THEATRE
Exhibit Hall C – Exhibit Area

Updates in Breast Cancer in Diagnostic Testing
Sponsored by Clement, A GE Healthcare Company

12:30 pm–1:35 pm
CLINICAL SCIENCE FORUM
Medical Economics - The Cost of Care Ballroom A

Moderator: Eric P. Winer, MD
Dana-Farber Cancer Institute
Boston, MA

The cost of cancer care: How much do we spend and how can we spend it better?
Bena Elkin, PhD
Memorial Sloan-Kettering Cancer Center
New York, NY

Health care reform and cost control: Practical and ethical considerations for cancer care providers
Michael Hassett, MD, MPH
Dana-Farber Cancer Institute
Boston, MA

www.aacrjournals.org
2:30  S2-2. Luminal A subtype predicts radiation response in patients with T1N0 breast cancer enrolled in a randomized trial of tamoxifen with or without breast radiation

2:45  S2-3. NSABP protocol B-34: A clinical trial comparing adjuvant clodronate vs. placebo in early stage breast cancer patients receiving systemic chemotherapy and/or tamoxifen or no therapy — final analysis
Paterson AHG, Anderson SJ, Lembersky BC, Felehrenbacher L, Falkson CI, King KM, Weir LM, Brufsky AM, Dalhui S, Lad T, Baez-Diaz L, Gralow JR, Robidoux A, Perez EA, Zheng P, Geyer CE, Swain SM, Costantino JP, Mamounas EP, Wolmark N. National Surgical Adjuvant Breast and Bowel Project (NSABP), Tom Baker Cancer Centre; University of Pittsburgh Graduate School of Public Health; University of Pittsburgh Cancer Institute School of Medicine; Kaiser Permanente, Northern California; University of Alabama at Birmingham/ECOG; Cross Cancer Institute; British Columbia Cancer Agency; University of PittsburghMagee Women’s Hospital; Cancer Center of Kansas; Stroger Hospital Cook County MBCCP; San Juan MBCCP; University of Washington/SWOG; Centre Hospitalier de l’Université de Montréal; Mayo Clinic Jacksonville/NCCTG; Allegheny General Hospital; Washington Cancer Institute, Washington Hospital Center; Aultman Health Foundation.

3:00  S2-4. GAIN (German Adjuvant Intergroup Node Positive) study: A phase-III multicenter trial to compare dose dense, dose intense ETC (iddETC) vs. EC-TX and Ibandronate vs. observation in patients with node-positive primary breast cancer – 1st interim efficacy analysis

3:15  S2-5. An anti-HER3 antibody that stabilizes the inactive conformation inhibits both HER2 and ligand driven tumor growth
Gamer AP, Bialucha CU, Chen D, Elis W, Kunz C, Li S, Munier J, Saxena P, Sineshchekova O, Sprague E, Ettenberg S. Novartis Institutes for Biomedical Research, Cambridge, MA; Morphosys AG, Munich, Germany; Sanofi-Aventis, Cambridge, MA.

3:30  S2-6. ErbB3 expression is required for maintenance of normal and transformed luminal breast epithelial cells
Cook RS, Soko JM, Rineshart C, Miller TW, Poljak K, Prat A, Perou CM, Arteaga CL. Vanderbilt University, UNC Lineberger Comprehensive Cancer Center, Dana Farber Cancer Institute.

3:45  S2-7 Mechanisms of action and biological significance of HER2 mutations in HER2 overexpressing breast cancer
Boulbes DR, Jin Q, Arold ST, Ladbury JE, Yu D, Estaeva FJ. University of Texas – MD Anderson Cancer Center, Houston, TX; Mynad Genetics, Salt Lake City, UT.

4:00 pm–5:00 pm  SUSAN G. KOMEN FOR THE CURE® BRINKER AWARDS FOR SCIENTIFIC DISTINCTION LECTURES
Exhibit Hall D
The Basic Science award is presented to a researcher who has added substantively to our understanding of the basic biology of, or development of, methodologies that further our ability to unravel the genetic and molecular basis of breast cancer. This year the award is being presented to:...
P1-01-01  A Rat Monoclonal Antibody Against Bone Sialoprotein II Is Active in Preventing and Treating Tumor Growth and Osteolytic Lesions in Nude Rats Induced by MDA-MB-231 Breast Cancer Cells
Berger MR, Zepp M, Armburster FP. DKFZ, Heidelberg, Germany; Immunodiagnostics Comp, Bensheim, Germany.

P1-01-02  T Cell Is a Key Player in the Establishment of Cancer Associated Pre-Metastatic Bone Disease

P1-01-03  The Cytotoxicity of Select Neutrophils in Cancer Patients and the Role of Chemokines in Inducing Neutrophil Cytotoxicity
Comer E, Granot Z, Norton L, Beneza R. Memorial Sloan-Kettering Cancer Center, New York, NY.

P1-01-04  Immunological Effects of Bisphosphonates on γδT Cells in Breast Cancer
Sugie T, Tanaka Y, Toi M, Minato N. Graduate School of Medicine, Kyoto University, Kyoto, Japan.

P1-01-05  Conditioning by the Tumor Environment Turns Invariant Natural Killer T Cells into Negative Regulators of Anti-Tumor Immunity Elicited by Treatment
Pilones KA, Demaria S. NYU School of Medicine, New York, NY.

P1-01-06  Mechanisms of Tumor Immune Escape in Triple-negative Breast Cancers (TNBC) with and without Mutated BRCA1
Segerer SE, Kapp M, Hahne JC, Dietl J, Engel JB. Medical University of Vienna, Wurzburg, Wurzburg, Germany.

P1-01-07  ErbB-2 Peptide Vaccination Suppresses Spontaneous Tumorigenesis and Tumor Stem Cell Expansion in MMTV-PyVT Transgenic Mouse
Park KH, Gil EY, Choi YJ, Kim ST, Cho K, Seo JH, Lee ES, Kim IS, Disis ML. Korea University College of Medicine, Seoul, Korea; Korea University College of Medicine; University of Washington, Seattle, WA.

P1-01-08  Expression of Interleukin-15 (IL-15) and the IL-15 Receptor in Human Breast Cancer
Sanders AJ, Ye L, Wei XQ, Marsel RE, Jiang WY. Cardiff University School of Medicine, Cardiff, Wales, United Kingdom; Cardiff University, Cardiff, Wales, United Kingdom.

P1-01-09  A Focused Immune Response Targeting the Homotypic Binding Domain of the Carcinoembryonic Antigen Blocks the Establishment of Tumor Foci in Vivo
Gatgey J, Abdul-Wahid A. University of Toronto, Toronto, ON, Canada; Sunnybrook Research Institute, Toronto, ON, Canada.

P1-01-10  Immune Suppression of Regulatory T Cells and M2 Macrophage in Breast Cancer Patients
Imoto S, Sakamura N, Kamma H, Nakatsuura T. School of Medicine, Kyorin University, Mitaka, Japan; Research Center Organization, National Cancer Center Hospital East, Kashiwa, Japan.

P1-01-11  CD4+CD25+CD127+ Regulatory T Cells Have Immunosuppressive Function in Patients with Breast Cancer
Sakamura N, Nakatsumawa M, Ito H, Isaka H, Imai K, Tazaki E, Miyamoto K, Wada N, Imoto S, Nakatsuura T. Graduate School of Medicine, Kyorin University, Mitaka Tokyo, Japan; National Cancer Research Center Hospital East, Kashiwa Chiba, Japan.

P1-01-12  Mesoporous Silicon Particles for the Presentation of Tumor Antigens and Adjuvant for Anti-Cancer Immunity
Menzel IM, Melendez B, Gu J, Serda RE. Methodist Hospital Research Institute, Houston, TX.

P1-01-13  Prognostic Impact of CD8 in Node-Negative Breast Cancer
Schmidt M, Chen Z, Hellwig B, Böhm D, Liebrecht A, Gebhard S, Gehrmann M, Koebl H, Hengstler JG. University Hospital, Mainz, Germany; Technical University, Dortmund, Germany; Bayer GMBH, Leverkusen, Germany.

P1-01-14  Gene Expression of Immune Mediators within Nipple Aspirate Fluid and Ductal Lavage from Normal and Cancerous Breasts
Love SM, Ruffell B, Nguyen T, Mills D, Coussens LM. Dr. Susan Love Research Foundation, Santa Monica, CA; University of California-San Francisco, San Francisco, CA.

P1-01-15  Do Serum Cytokines Predict Breast Cancer Behavior?
Lush E, Dedert E, Daup M, Dhabhar F, Spiegel D, Tille J, Mccmasters K, Sephton SE, Chappar A. University of Louisville; Duke University Medical Center, Veterans Affairs Medical Center, Stanford University School of Medicine; James Graham Brown Cancer Center, University of Louisville School of Medicine, Yale School of Medicine.

P1-01-16  Detecting a Breast Carcinoma-Deriving B-Cell Response: An Immunoproteomics Biomarker Approach
Keller K, Boehm DJ, Grus FH, Koebl H. University Medical Center Mainz, Germany.

Tumor Cell Biology: Epithelial-Mesenchymal Transition

P1-02-01  c-Jun N-Terminal Kinase 1 (JNK1) Inhibits Tumor Growth and Metastasis by Downregulating Epithelial to Mesenchymal Transition (EMT) and Stem Cell-Related Genes
Ebelt ND, Van Den Berg CL. The University of Texas, Austin, TX.

P1-02-02  Zoledronic Acid Reverses the Epithelial-Mesenchymal Transition While Inhibiting the Tumor Initiating Cell Population of Highly Tumorigenic Breast Cancer Cell Lines
Schech AJ, Gilani RA, Kazi AA, Brodie JH. University of Maryland, Baltimore, Baltimore, MD.

P1-02-03  The Reciprocal Roles of E-Cadherin and ZEB1 Demonstrate the Mesenchymal-Epithelial Transition as a Primary Characteristic of Inflammatory Breast Cancer
Chu K, Boley KM, Luo AZ, Ye Z, Wright MC, Freiter EM, Robertson FM. The University of Texas MD Anderson Cancer Center, Houston, TX.

P1-02-04  Estrogen Receptor beta Inhibits Breast Cancer EMT by Regulating the Expression of miR-200
Invasive Lobular Carcinoma - A Luminal Breast Cancer
Histotype Enriched for Epithelial-to-Mesenchymal Transition Features

P1-02-06
Silencing of IGF-1R Has Paradoxical Effects in Triple Negative Breast Cancer Phenotypes
Talaiferro-Smith LD, Oberlick EM, Liu T, Eggers C, Kline ER, Nagaraju GP, Marcus A, O'Regan R. Winship Cancer Institute at Emory University, Atlanta, GA; Grady Memorial Hospital, Atlanta, GA.

Epithelial-Mesenchymal Transition Correlated with Serum Cytokine Profiling in Breast Cancer Patients
Giordano A, Cohen EN, Anfossi S, Gao H, Lee B-N, Mego M, Sandra T, Valero V, Alvarez RH, Cristofanilli M, De Placido S, Hertogaboy GN, Woodward W, Ueno NT, Reuben JM. The University of Texas MD Anderson Cancer Center, Houston, TX; University Federico II of Naples, Naples, Italy; Fox Chase Cancer Center, Philadelphia, PA; National Cancer Institute, Bratislava, Slovakia (Slovak Republic).

Modulation of EMT by Targeting E-Cadherin Restores Radiation Sensitivity in Human Breast Cancer Cells
Munshi A, Yuan Y, Liu J, Meyn RE. University of Oklahoma Health Sciences Center, Oklahoma City, OK; Baylor College of Medicine, Houston, TX; The University of Texas M.D. Anderson Cancer Center, Houston, TX.

Epigenetics-Regulated microRNAs Related with Epithelial-Mesenchymal Transition of Breast Cancer Cells
Sato F, Ito T, Tsuchiya S, Kawaguchi-Sakita N, Shimizu K, Tsujimoto G, Toi M. Graduate School of Medicine, Kyoto University, Kyoto, Japan; Graduate School of Pharmaceutical Sciences, Kyoto University, Kyoto, Japan.

Vimentin Expression: as a Prognostic Factor and a Possible Molecular Target of Triple Negative Breast Cancer

The BCL2 Antagonist of Death, baD is Down-regulated in Fibroadenomatoid Changes with a higher occurrence rate in Middle-aged benign breast disease patients with the trend retained in cancer Patients
Munshi A, Yuan Y, Liu J, Meyn RE. University of Oklahoma Health Sciences Center, Oklahoma City, OK; Baylor College of Medicine, Houston, TX; The University of Texas M.D. Anderson Cancer Center, Houston, TX.

The p120ctn is a key effector of Ras-PKCε-mediated oncogetic signaling

EBCM Stiffness and Breast Tumor Histology and Treatment Phenotype
Acerbi I, Au C, Chen Y-Y, Park C, Huang S, Weaver V. Center for Bioengineering and Tissue Regeneration, University of California, San Francisco, San Francisco, CA; Carol Buck Breast Cancer Center, University of California San Francisco, San Francisco, CA; University of California San Francisco, San Francisco, CA; Institute of Regeneration Medicine, University of California San Francisco, San Francisco, CA; University of California at San Francisco, San Francisco, CA.

The Norton-Simon Hypothesis and Cancer Stem Cells: How Cancer Stem Cells May Explain the Effectiveness of Dose-Dense Chemotherapy
Landis MD, Dobrolecki LE, Wong H, Lai Q, Vahdat LT, Chang JC. The Methodist Hospital Research Institute, Houston, TX; Weill Cornell Medical College, New York, NY.

Adaptive Exploitation of Stromal Cell Metabolism by Tumor Cells

In Vitro Characterization of a Breast Cancer Microenvironment with Epithelial-to-Mesenchymal Transition (EMT) Characteristics
Casbas-Hernandez P, Roman-Perez E, Mani SA, Treoester MA. School of Medicine, UNC, Chapel Hill, NC; Gillings School of Public Health, UNC, Chapel Hill, NC; UNC Hospitals, Chapel Hill, NC; University of Texas MD Anderson Cancer Center, Houston, TX.

Fibrocytic Changes Have Different Age-Dependent Patterns in Benign, In S itu, and Invasive Breast Cancer Patients
Bekhash A, Kovatich AJ, Chen Y, Hooke JA, Kvecher L, Mural RJ, Shriver CD, Hu H. Windber Research Institute, Windber, PA; Walter Reed Army Medical Center, Washington, DC; MDR Global Systems LLC, Windber, PA.

Fibroblastic Changes Have a Higher Occurrence Rate in Middle-Aged Benign Breast Disease Patients with the Trend Retained in Breast Cancer Patients
Bekhash A, Hooke JA, Chen Y, Kovatich AJ, Kvecher L, Mural RJ, Shriver CD, Hu H. Windber Research Institute, Windber, PA; Walter Reed Medical Center, Washington, DC; MDR Global Systems LLC, Windber, PA.

Subtype-Specific Gene Expression Signatures in Peritumoral Non-Neoplastic Breast Tissue
Williams T, Roman-Perez E, Rein JL, Amos KD, Troester MA. University of North Carolina-Chapel Hill, Chapel Hill, NC.

Adipose Tissue in Breast Cancer: Not an Idle Bystander but an Active Participant in Breast Cancer Progression

Significance of FAP, SMA and CD31 Expression in the Strom a of Breast Cancer

S100a7 enhances breast tumor progression and metastasis through activation of pro-metastatic and inflammatory pathways
Ganjura RK, Nasser MW, Qamri Z, Deol YS, Schwendener RA, Leone G, Wolf R, Yuspa S. The Ohio State University Medical Center, Columbus, OH; University of Zurich, Zurich, Switzerland; Ludwig Maximilian University, Munich, Germany; National Institutes of Health, Bethesda, MD.

The Mechanism of Anti-Breast Cancer TICs Effect of Pyrvinium Pamoate Is through WNT/beta-Catenin Signaling

In Vitro Qualification and Quantification of murine mammary tumor Cell biology: Stem/progenitor Cells

P1-04-03  The Effect of Survivin Downregulation on Radiosensitization of Breast Cancer Cell Lines Grown under Adherent and Stem Cell Promoting Culture Conditions
Debeb BG, Larson R, Xu W, Lacerda L, Reuben JM, Buchholz TA, Ueno NT, Woodward WA. Morgan Welch witchford Breast Cancer Clinic and Research Group, The University of Texas M.D. Anderson Cancer Center, Houston, TX.

P1-04-04  Focal Adhesion Kinase Plays a Major Role in the Regulation of Human Ductal Carcinoma In Situ (DCIS) Stem Cell Activity
Williams KE, Bundjed NJ, Farnie G. University of Manchester, Paterson Institute for Cancer Research, Manchester, United Kingdom; University Hospital of South Manchester, Manchester, United Kingdom.

Honig A, Diessner J, Dietl J, Wischhusen J. University of Wuerzburg, Wuerzburg, Germany.

P1-04-06  Ionizing Radiation Reprograms Non-Tumorigenic Cancer Cells into Cancer Stem Cells
Chann L, Vlasi E, Lorenza DD, Dekremzan C, Pajonk F. University of California, Los Angeles, CA.

P1-04-07  Poly (ADP-Ribose) Polymerase-1 (PARP-1) Is Overexpressed in Human Breast Cancer Stem Cells: Results from a Proteomic-Based Approach
Gilbert M, Ginestet C, Audebert S, Pophillat M, Torion Y, Birnbaum D, Borg J-P, Charafe-Jauffret E, Goncalves A. Institut Paoli-Calmettes, Marseille, France; U91 INSERM, Marseille, France; Université de la Méditerranée, Marseille, France; Centre d’Immunologie Marseille-Luminy, Marseille, France.

P1-04-08  Distribution of ALDH1 Positive Stem Cells in Benign Mammary Tissue from Women with and without Breast Cancer
Iffoss BL, Holmqvist B, Alm P, Olsson H. Telemark Hospital, Sken, Lund University, Lund, Sweden.

P1-04-09  Biphasic Effects of Docetaxel and Hedgehog Signaling Antagonists on Breast Cancer Tumor-Initiating Cells In Vivo
Zhang X, Moraes RC, Landis MW, Wu M-F, Hilsenbeck SG, Cairo MM, Tofigar R, Chang JC, Lewis MT. Baylor College of Medicine, Houston, TX; Karolinska Institutet, Novum, Sweden.

Tumor Cell Biology: Epigenetics

P1-05-01  PELP1 Oncogenic Functions Involve Regulation of Histone Arginine Methylation
Mann M, Cortez V, Yang BW, Telma RR, Vadlamudi RK. University of Texas Health Science Center at San Antonio, San Antonio, TX; University of Southern California, Los Angeles, CA.

P1-05-02  Epigenetic Regulation by Alcohol Reactivates Estrogen Receptor alpha in Estrogen Receptor alpha-Negative Cells
Wong AW, Nunez N. University of Texas at Austin, Austin, TX.

P1-05-03  Relationship between Polycomb Repressive Complex EZH2/CBX7, Large Non-Coding RNA ANRIL and Stem Cells Biomarkers in Triple Negative Breast Carcinomas: Important Role in Carcinogenesis through an Epigenetic Silencing Process and New Clues for Targeted Therapies

P1-05-04  Distinct Patterns of Promoter CpG Island Methylation of Breast Cancer Subtype Are Associated with Different Stem Cell Phenotype
Park SY, Kwon HJ, Choi Y, Lee HE, Kim S-W, Kim JH; Kim IA, Jung N, Cho N-Y, Kang GH. Seoul National University Bundang Hospital; Seoul National University Hospital; Cancer Research Institute, Seoul National University.

P1-05-05  Prognostic Utility of Histone Modifier Gene Expression Profiles in Human Breast Cancer
Patani N, Jiang WG, Newbold RF, Mobbel K. The London Breast Institute, The Princess Grace Hospital, London, United Kingdom; University Department of Surgery, Cardiff University School of Medicine, Cardiff, United Kingdom; Brunel Institute of Cancer Genetics and Pharmacogenomics, Brunel University, London, United Kingdom.

P1-05-06  Hypermethylation 14-3-3-Sigma Promoter as a Biomarker to Screening for Metastasis and Potential Prognostic Factor in Breast Cancer Patients
Martinez-Galan J, Torres-Torres B, Gonzalez-Vicente A, Ruiz-Vozmediano J, Delgado-Perez JR. Hospital Universitario Virgen de las Nieves, Granada, Spain; Centro de Investigaciones Biomédicas, Granada, Spain.

Prognosis/Response Predictions: Response Predictions – I
P1-06-01  Withdrawn

P1-06-02  Correlation between Gene Variants in CYP19 (Aromatase) and TCL1A with Disease and Tolerability Endpoints in the ATAC Trial
Ray C, Regnier C, Lidereau R, Bieche I. Institut Curie Hôpital Rene Huguenin, St Cloud, France.

P1-06-03  Predictive Value of HER2, Topoisomerase-IIa (Topo-II) and Tissue Inhibitor of Metalloproteinases (TIMP-1) for Efficacy of Taxane-Based Chemotherapy in Intermediate Risk Breast Cancer - Results from the EC-Doc Trial
Gluz O, Erber R, Kates R, Kreipe H, Barlet A, Liedtke C, Pelz E, Hueber J, Kuhn W, Nitz U, Hartmann A, Harbeck N, Brunner N. West German Study Group, Muenchegendabach, Germany; University Hospital Erlangen, Erlangen, Germany; Medizinische Hochschule Hannover, Hannover, Germany; University Copenhagen, Copenhagen, Denmark; University Hospital Muenster, Muenster, Germany; Pathology Practice, Viersen, Germany; University Hospital Tuebingen, Tuebingen, Germany; Kantonsspital St. Gallen, St. Gallen, Switzerland; University Hospital Bonn, Bonn, Germany; University Hospital Cologne, Cologne, Germany.

P1-06-04  PAM50 Prognostic Index Predicts Response to Weekly Adjuvant Paclitaxel in Node-Positive Operable Breast Cancer
Martin M, Rodriguez-Lescure A, Stijlemans U, Munárriz B, Ruiz-Borrego M, Davis C, Crespo C, Rodríguez CA, Ebbert MTW, Alvarez I, Furido V, Bastien RRL, Garcia AM, Cheung MC, Palacios J, Ellis MJC, Carrasco E, Casas MI, Caballero R, Perez CM, Bernard PS. Hospital General Universitario Gregorio Marañon, Madrid, Spain; Hospital Universitario de Elche, Elche, Spain; University of Utah Health Sciences Center/ Huntsman Cancer Institute, Salt Lake City, UT; Hospital Universitario La Fe, Valencia, Spain; Hospital Universitario Virgen del Rocio, Sevilla, Spain; Hospital Universitario Ramon y Cajal, Madrid, Spain; Hospital Clinico Universitario de Salamanca, Salamanca, Spain, The ARLP Institute for Clinical and Experimental Pathology, Salt Lake City, UT; Hospital de Donostia, San Sebastian, Spain; Hospital Universitario San Carlos, Madrid, Spain; University of North Carolina at Chapel Hill; Washington University in St Louis, St Louis, Spain; Spanish Breast Cancer Research Group, GECAM, San Sebastian de los Reyes, Madrid, Spain.

P1-06-05  Withdrawn

P1-06-06  The Importance of CCK10 and CCKR3-A in Breast Cancer
Hilborn E, Sivik T, Kot A, Fomander T, Skoog L, Nordensjöld B, Stål O, Jansson A. Faculty of Health Sciences, Linköping, Sweden; Karolinska Institutet.
P1-06-07  TIMP-1 in Combination with HER2 and TOP2A for Prediction of Benefit from Adjuvant Anthracyclines in High Risk Breast Cancer Patients
Hertel PB, Tu D, Ejlertsen B, Jensen M-B, Bagduse E, Jiang S, O’Malley FP, Pritchard KJ, Shepherd LE, Bartels A, Brünnner N, Nielsen TO, Faculty of Life Sciences, Univ of Copenhagen, Copenhagen, Denmark; National Cancer Institute of Canada, Kingston, ON, Canada; Rigshospitalet, Copenhagen, Denmark; Danish Breast Cancer Cooperative Group, Copenhagen, Denmark; Herlev Hospital, Herlev, Copenhagen, Denmark; Mount Sinai Hospital, Toronto, ON, Canada; University of Toronto, Toronto, ON, Canada; University of British Columbia Vancouver, Vancouver, BC, Canada.

P1-06-08  Effect of Treatment Emergent Symptoms on Relapse Free Survival: NCIC CTG MA.12 a Randomized Placebo-Controlled Trial of Tamoxifen after Adjuvant Chemotherapy in Pre-Menopausal Women in Early Breast Cancer
Chapman J-AW, Shepherd LE, Le Maitre A, Pritchard KJ, Graham BC, Gelmon KA, Bramwell VH. NCIC Clinical Trials Group, Queen’s University, Kingston, ON, Canada; University of Toronto, ON, Canada; University of British Columbia Vancouver, Vancouver, BC, Canada; Tom Baker Cancer Centre, Calgary, AB, Canada.

P1-06-09  Patient-Specific Integrative Pathway Analysis Using PARADIGM Identifies Key Activities in I-SPY 1 Breast Cancer Patients (CALGB 150007/150012; ACRIN 6657)

P1-06-10  Lobular Breast Cancer and NAC: Combined Results from the NKI and I-SPY 1 Trial

P1-06-11  Comparison of Community and Central Her2 Assessment on Outcome of Neoadjuvant Chemotherapy in the I-SPY 1 Trial
DeMichele A, Yau C, Zhu J, Wu H, Kuhle J, Lomburg M, Buxton M, Davis S, Mies C, Livasy C, Chin K, Gray J, Carey L, Esserman L, Petricoin E. Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA; University of California, San Francisco, CA; George Mason University, Fairfax, VA; University of California, Santa Cruz, CA; Carolina HealthCare System, Charlotte, NC; Oregon Health Sciences University, Portland, OR; The University of North Carolina at Chapel Hill, Chapel Hill, NC; University of Pennsylvania, Philadelphia, PA.

P1-06-12  Circulating Tumor Cells (CTC) Monitoring during Phase II Study with Lapatinib (L) and Capecitabine (C) in Patients with Brain Metastases from HER2-Positive (+) Metastatic Breast Cancer (MBC) before Whole Brain Radiotherapy (WBR): LANDSCAPE Study

P1-06-13  An Amplicon-Driven Aromatase Inhibitor Response (ADAIR) Signature Provides an Orthogonal Risk Classifier for ER+ Breast Cancer

P1-06-14  Topoisomerase II alpha (Top2a) Protein Expression Is a Predictor for Response to Anthracycline-Based Chemotherapy (ATC-CT): Is It Due to Gene Amplification, HER2-Coamplification or a Summation of Pathways Leading to This Highly Proliferative Phenotype?
Abdel-Fatah TMA, Lambros MB, Vatcheva R, Ball G, Dickinson PD, Moseley P, Green AR, Ellis IO, Reis-Filho JS, Chan S. Nottingham University City Hospital, NHS Trust, Nottingham, Nottinghamshire, United Kingdom; The Institute of Cancer Research, London, United Kingdom; School of Molecular Medical Science, Nottingham University, Nottingham; Nottingham Trent University, Nottingham.

P1-06-15  A Genomic Predictor Developed from Breast Cancer Cell Line Pre-Survs Both Disease-Free Survival and Overall Survival in Breast Cancer Patients Treated with Doxorubicin and Cyclophosphamide: A Collaborative Project of the NSABP and Precision Therapeutics

P1-06-16  BRCA2 Mutation Carriers Respond Poorly to Conventional Anthracylins/Taxanes-Based Neo-Adjuvant Chemotherapy

P1-06-17  A New Pathological Response Index (PRI) for Neoadjuvant Chemotherapy Accurately Predicts Clinical Outcomes of Locally Advanced Breast Cancers (LAPBC)
Abde-Fatah TMA, Moseley P, Lee A, Balls G, Ellis IO, Chan S. Nottingham University City Hospital, Nottingham, Nottinghamshire, United Kingdom; Nottingham University, Nottingham, United Kingdom; The Institute of Cancer Research, London, Nottingham Trent University.

P1-06-18  Loss of E-Cadherin Expression in Clinical Breast Cancer Is Associated with an Adverse Outcome on Tamoxifen
Hiscox S, Rahka E, Smith C, Farnow L, Gandahara S, Green A, Ellis I, Barrett-Lee P, Nicholson RI, Gee J. Cardiff University, Cardiff, Wales, United Kingdom; Nottingham University Hospital, Nottingham, United Kingdom; Velindre Hospital, Cardiff, Wales, United Kingdom.

P1-06-19  Absence or Low Levels of c-Jun NH2-Terminal Protein Kinase (JNK) Mitogen Activated Protein Kinase (MAPK) Is Related to a Luminal B Subtype and an Impaired Survival in Patients with an ER Positive Breast Cancer Treated with Adjuvant Tamoxifen
Linderholm BK, Sanchez-Chavez B, Hellborg H, Johansson UM, Leuwensroh R, Viktorsson K, Kanter L. Institution of Oncology, Sahlgrenska University Hospital, Gothenburg, Sweden; Institution of Oncology and Pathology, Karolinska Institute, Stockholm, Sweden; Institution of Pathology, Herlev, Denmark.

P1-06-20  Response to Neo-Adjuvant Chemotherapy and Outcomes for I-SPY 1 Patients Stratified by the 70-Gene Prognosis Signature (MammaPrint) and Molecular Subtyping (Blueprint)
Gluck S, de Snoo F, Tian S, Glas A, van’t Veer L. Miller School of Medicine, University of Miami, Miami, FL; Agenda, Amsterdam, Netherlands; HDFC Cancer Center, UCSI, San Francisco, CA.
P1-06-21 Relationship between Body Mass Index and Preoperative Treatment Response to Aromatase Inhibitor Exemestane in Postmenopausal Patients with Primary Breast Cancer

Takada M, Saji S, Masuda N, Kuroi K, Sato N, Takei H, Yamamoto Y, Ohno S, Yamashita H, Hisamatsu K, Aogi K, Iwata H, Ueno T, Sasano H, Toi M. Graduate School of Medicine, Kyoto University, Japan; Saitama Medical University, International Medical Center, Japan; Osaka National Hospital, Japan; Tokyo Metropolitan Cancer and Infectious Diseases Center, Komagome Hospital, Japan; Niigata Cancer Center Hospital, Japan; Saitama Cancer Center, Japan; Kumamoto University, Japan; National Kyushu Cancer Center, Japan; Nagaoy City University Hospital, Japan; Hiroshima City Asa Hospital, Japan; National Shikoku Cancer Center, Japan; Aichi Cancer Center Hospital, Japan; Tohoku University Hospital and School of Medicine, Japan.

P1-06-22 Identification of Biomarkers in Breast Cancer for Prediction of Response to PARP Inhibitor Olaparib

P1-06-23 Changes in Gene Expression after One Dose of Trastuzumab (T) in HER2+ Breast Cancer Cell Lines Predict Novel Pathways of Response in HER2 Positive Early Stage Breast Cancer

Sprecher E, Lezon-Geya K, Sarkar S, Bossuyt V, Narayaan M, Kumar A, Krop I, Winer E, Tuck D, Kleinstein S, Harris L. Yale University, New Haven, CT; Yale University; Beckman Coulter, Stony Brook University Hospital, Stony Brook, NY; Dana-Farber Cancer Institute, Boston, MA.

P1-06-24 Nuclear Localization of Stat5a predicts Response to Antiestrogen Therapy and Prognosis of Clinical Breast Cancer Outcome

Peck AR, Witkiewicz AK, Liu C, Klimowicz AC, Stringer GA, Pequignot E, Freydin B, Yang N, Tran TH, Rosenberg AL, Hooke JA, Kovatch AJ, Shriver CD, Rimm DL, Magliocco AM, Hyslop T, Rui H. Thomas Jefferson University, Philadelphia, PA; Tom Baker Cancer Center, Calgary, AB, Canada; Walter Reed Army Medical Center, Washington, DC, MDR Global Systems, LLC, Windber, PA; Yale University School of Medicine, New Haven, CT.

P1-06-25 Changes in FDG PET SUV Correlates with Ki-67 Following 2 Weeks of Aromatase Inhibitor Therapy in ER+ Early Stage Breast Cancer, a Pilot Imaging Study

Gadi VK, Kurland BF, Specht JM, Rodller E, Korde LA, Peterson LM, Schubert EK, Chai X, Mankoff DA, Lindem HM. University of Washington, Seattle, WA; Fred Hutchinson Cancer Research Center, Seattle, WA.

P1-06-26 The EndoPredict Score Is a Response Predictor for Neoadjuvant Chemotherapy in ER-Positive, HER2-Negative Breast Cancer

Brase JC, Gehrmann MC, Petry C, Weber KE, Schmidt M, Kobl H, Brauch H, Schwab M, Muller J, Janicke F, Roda A, Kaufmann M, Filippis M, Grant M, Denkert C, Loibl S, von Minckwitz G, Kronenwett R. Svidon Diagnostics, Cologne, Germany; Bayer Technology Services GmbH, Leverkusen, Germany; University of Mainz, Germany; Dr. Margarete Fischer-Bosch Institute of Clinical Pharmacology Stuttgart and University Tubingen, Germany; University Medical Center Hamburg-Eppendorf, Germany; J.W. Goethe University, Frankfurt, Germany; Medical University of Vienna, Austria; Charite - University of Berlin, Germany; German Breast Group, Neu-Isenburg, Germany.

Prognosis/Response Predictions: Biomarkers – Methods

P1-07-01 Comparison of Four HER2 Testing Methods in the Detection of HER2-Positive Breast Cancer: Results from the FinHer Study Cohort

Huang W, Wirtz R, Weidler J, Lie Y, Sherwood T, Leinenho M, Bono P, Isola J, Kellokumpu-Lehtinen P-L, Joensuu H. Monogram Biosciences Inc., So. San Francisco, CA; STRATIFYER Molecular Pathology GmbH, Cologne, Germany; Pharma, Turku, Finland; Helsinki University Central Hospital, Helsinki, Finland; Institute of Medical Technology, University of Tampere and Tampere University Hospital, Tampere, Finland; Tampere University Hospital, Tampere, Finland.

P1-07-02 Discordance between Central and Local Laboratory HER2 Testing from a Large HER2-Negative Population in VIRGO, a Metastatic Breast Cancer Registry

Vogel CL, Bloom K, Burris H, Galraw JR, Mayer M, Pegam M, Rugo HS, Swain SM, Yandley DA, Chau M, Lalla D, Brammer MG, Kaufman PA. Sylvester Comprehensive Center at Deerfield, Miller School of Medicine, University of Miami, Miami, FL; Clariant, Inc., Aliso Viejo, CA; Sarah Cannon Research Institute, Nashville, TN. Tennessee Oncology, PLLC, Nashville, TN; University of Washington Medical Oncology, Seattle Cancer Care Alliance, Seattle, WA; Patient Advocate, New York, NY; University of California San Francisco Comprehensive Cancer Center, San Francisco, CA; Washington Cancer Institute, Washington Hospital Center, Washington, DC; Genentech, Inc., South San Francisco, CA; Norris Cotton Cancer Center, Dartmouth-Hitchcock Medical Center, Lebanon, NH.

P1-07-03 Preanalytical Variables Affect Protein Expression in Formalin Fixed Paraffin Embedded Tissue - Assessment of Intrinsic Controls To Define Tissue Quality for Immunohistochemical Analysis

Neumeister VM, Lostritto K, Siddiqui S, Anagnostou V, Vasiliakopoulou M, Zarrella EA, Molinaro AR, Hicks DG, Rimm DL. Yale University School of Medicine, New Haven, CT; Rochester University, School of Medicine, Rochester, NY.

P1-07-04 Gene Expression Module Biomarkers To Stratify Multiple Clinical and Therapeutic Endpoints for Universal Breast Cancer Companion Diagnostic

P1-07-05 HER2 Status Resolution in FISH and IHC “Double Equivocal” Breast Carcinomas by Quantitative Real-Time PCR

Porter BP, Wang Z, Downs-Kelly E, Budd GT, Lanigan C, Tubbs RR. Cleveland Clinic, Cleveland, OH; Taussig Cancer Center, Cleveland Clinic, Cleveland, OH.

P1-07-06 High Concordance of Protein (by IHC), Gene (by FISH; HER-2 Only) and Microarray Readout (by TargetPrint) of ER/PR/HER2: Results from the MINDACT Trial

Viale G, Bogaerts J, van’t Veen L, Rutgers E, Piccart M, de Snoo F, Engelen K, Russo L, Dell’Orto F, Glas A, Cardoso F, on behalf of the TRANSBIG Consortium & the MINDACT Investigators. European Institute of Oncology, Milan, Italy; European Organisation of Research and Treatment of Cancer, Brussels, Belgium; Netherlands Cancer Institute, Amsterdam, Netherlands; Institute Jules Bordet, Brussels, Belgium; AgendiaNV, Amsterdam, Netherlands, Champalimaud Cancer Center, Lisboa, Portugal.

P1-07-07 Assessing Two Methods of Meta-Analysis in Studies of Patients with Breast Cancer: Individual Patient Data-Based (IPD) Versus Literature Based Abstracted Data (AD) in 5 Meta-Analyses Including over 28,000 Patients. Are There Results Differences of Concern?

Gralla RJ, Brita E, Raftopoulos H, Spirduso I, Giannarelli D, Cognetti F. Hofstra North Shore - LI School of Medicine, Lake Success, NY; Regina Elena National Cancer Institute, Rome, Italy.
P1-07-08  PCR Genomic Grade in Breast Cancer: A New Tool for Daily Practice

P1-07-09  Estrogen Receptor (ER) mRNA and ER-Related Gene Expression in Breast Cancers That Are 1%-10% ER-Positive by Immunohistochemistry
Iwamoto T, Booser D, Valero V, Murray JL, Koenig K, Esteva FJ, Ueno NT, Zhang J, Shi W, Qi Y, Matsuoka J, Hortsobagyi GN, Haitz C, Symmans WF, Pusztai L. The University of Texas MD Anderson Cancer Center, TX; Okayama University, Okayama, Japan; Nueva Biosciences Inc, MA.

P1-07-10  Validation of a Diagnostic Molecular Signature (EHT Dx14) on Fine-Needle Aspirate Samples from Breast Tumors

P1-07-11  Consistency and Control in Clinical Assay Technology over Time: The Oncotype DX Recurrence Score and Assessment of Single Gene Expression Levels

P1-07-12  Assessment of Real World HER2 Status by Immunohistochemistry (IHC) and Fluorescence In Situ Hybridization (FISH) in Breast Cancers: Comparison with HERMark®, a Validated Quantitative Measure of HER2 Protein Expression
Huang W, Paquet A, Sivaraman S, Pesano R, Goodman L, Shenwood T, Lie Y, Hickey J, Walworth C, Haddad M, Anderson S, Bates M, Weidler J. Monogram Biosciences Inc, South San Francisco, CA; Incyte Corporation, Wilmington, DE; Quest Diagnostics Nichols Institute, San Juan Capistrano, CA; Affymetrix, Santa Clara, CA; Gilead Sciences, Inc, Foster City, CA; Cepheid, Sunnyvale, CA.

P1-07-13  Efficiency of a Laboratory Developed HER2 FISH Test on Circulating Tumor Cells

P1-07-14  Quantum Dot-Labelled Antibodies To Assess HER2 Expression in Breast Cancer
Zona S, Blackbaum E, Hjojatoleslami AS, Brown IR, Gulwic WJ. University of Kent, Canterbury, Kent, United Kingdom.

Mizuno Y, Takayanagi H, Sato K. Tokyo-West Tokushukai Hospital, Akishima-city, Tokyo, Japan.

P1-07-16  Number Needed To Count: A Novel Model for Ki67 Assessment in Breast Cancer
Bendahl P-O, Romero Q, Grabau D, Borgquist S. Institution of Clinical Sciences, Lund University, Sweden; Institution of Clinical Sciences, Lund University, Sweden.

P1-07-17  Multiplex Plasma Biomarkers Associated with Bone Metastasis from Breast Cancer
Leitzel K, All S, Bisen A, Lomakin A, Simonyan V, Lipton A. Penn State Hershey Medical Center, Hershey, PA; Lebanon VA Medical Center, Lebanon, PA; Massachusetts Institute of Technology, Cambridge, MA; BioCompanion LLC, Rockville, MD.

P1-07-18  Expanding an Online Tool for Genome-Wide Validation of Survival-Associated Biomarkers in Breast and Ovarian Cancer Using Microarray Data of 3,862 Patients
Gyorffy B, Lanczky A, Szallasi Z. Semmelweis University, Budapest, Hungary; Harvard Medical School, Boston.

P1-07-19  Analysis of HER2-Status in Breast Cancer by Mass Spectrometry in Archival, Formalin-Fixed Tissues
Sanders M, Sprang R, Harr A, Sanchez V, Manning S, Anteaga C, Liebler D. Vanderbilt University Medical Center, Nashville, TN.

P1-07-20  Consistent High False Negative Rate of HER2 qRT-PCR of Oncotype DX® in Comparison to ASCO/CAP Recommended Combined IHC/FISH Method
Dabbs DJ, Bhargava R. Magee-Women’s Hospital of UPMC, Pittsburgh, PA.

P1-07-21  Analysis of Molecular Markers by Immunohistochemistry (IHC) Method on Formalin Fixed Paraffin Embedded (FFPE) Tissues Could Predict Shorter Recurrence Free Survival (RFS) and Overall Survival (OS) among Patients Who Have Received Adjuvant Chemotherapy for Early Breast Cancer
Moe M, Gee J, Finlay P, Mansel R, Adams R. Singleton Hospital, Swansea, United Kingdom; Velindre Hospital and Cardiff University, Cardiff, United Kingdom; Cardiff University, Cardiff, United Kingdom.

P1-07-22  A Venezuelan Study of Breast Cancer Estrogen Receptor, Progesterone Receptor and HER2 Receptor Expression by the Standard Method, Immunohistochemistry (IHC), Compared to a New Method, Quantitative Reverse Transcription Polymerase Chain Reaction (RT-PCR)
Marin C-EM, Ramirez AC, Baehner FL, Yoshizawa C, Acosta MM. Fundacion BADAN, Caracas, Miranda, Venezuela; Genomic Health, Redwood City, CA.

P1-07-23  Absolute Quantification of Estrogen Receptor alpha in Breast Cancer

P1-07-24  Quantitative and Immunohistochemical Detection of Breast Cancer Cells in Blood Samples

P1-08-01  Survival in Metastatic Breast Cancer (MBC): No Evidence for Improved Survival Following Distant Recurrence after Adjuvant Chemotherapy
Tevaanwerk AJ, Gray R, Schneider BP, Smith HL, Wagner LI, Miller KD, Sparano JA. University of Wisconsin-Carbone Cancer Center, Indiana University-Simon Cancer Center, Northwestern University, Chicago, IL; Dana-Farber Cancer Institute, Research Advocacy Network; Albert Einstein University-Monffore Medical Center.

P1-08-02  Pre-Diagnosis Body Mass Index and Breast Cancer Prognosis and Survival: Report from the after Breast Cancer Pooling Project
Kwak ML, Chen WY, Weltzien E, Beasley JM, Lu W, Nechuta SJ, Querebbery CP, Prence JP, Shu XO, Caan BJ. Kaiser Permanente Division of Research; Brigham and Women’s Hospital and Harvard Medical School; Fred Hutchinson Cancer Research Center; Shanghai Institute of Preventive Medicine; Vanderbilt University; University of California, San Diego.

P1-08-03  Huge Improvement in Relapse-Free Breast Cancer Survival over the Last 25 Years
Geurts SME, van Dijk JAAM, de Veet F, Paraguay Y, Siesling S, Verbeek ALM, Tjan-Heijnen VCG. Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; Hospital Bernhoven, Oss, Netherlands; Comprehensive Cancer Centre, Netherlands; Maastricht University Medical Centre, Maastricht, Netherlands.
**P1-08-04** Obesity, Adjuvant Therapy, and Survival Outcomes in Early-Stage Breast Cancer
Ina-Lisentorp S, Wang T, Rimawi MF, Nangia JR, Schiff A, Giordano SH, Pollak MN, Chenault CC, Osborne CK, Hilsenbeck SG. Baylor College of Medicine, Houston, TX; M.D. Anderson Cancer Center, Houston, TX; McGill University, Montreal, Canada.

**P1-08-05** Age and Survival in Women with Early Stage Breast Cancer: An Analysis Controlling for Tumor Subtype
Partidges AH, Hughes ME, Otterson R, Wong Y-N, Edge SB, Theriault RL, Blayney DW, Nalind JC, Winer EP, Weeks JC, Tamimiri RM. Dana-Farber Cancer Institute, Boston, MA; City of Hope, Duarte, CA; Fox Chase Cancer Center, Philadelphia, PA; Roswell Park Cancer Institute, Buffalo, NY; University of Texas MD Anderson Cancer Center, Houston, TX; Stanford Cancer Center, Palo Alto, CA; Brigham and Women's Hospital, Boston, MA.

**P1-08-06** Breast Cancer among Patients with Diabetes, Obesity and Abnormal Blood Lipids - A Population-Based Register Study in Sweden

**P1-08-07** Survival in US Women Following an Indication of Metastatic Breast Cancer Diagnosis and Chemotherapy Initiation: A SEER-Medicare Analysis
Rugo H, Taylor D, Sanon M, Clemmons K, Balu S, Faria C, Teitelbaum A. University of California San Francisco, OptumInsight; Eisa Inc.

**P1-08-08** Higher Prediagnostic Serum 25-Hydroxyvitamin D Is Associated with Substantially Lower Incidence of Breast Cancer: Prospective Study
Mohr SB, Garrah EM, Garland CF, Grant WB, Baggerly L. University of California San Diego, La Jolla, CA; SUNLIGHT and Nutrition Research Center, San Francisco, CA; GrassrootsHealth, San Diego, CA.

**P1-08-09** Increased Mortality in Swedish Women Diagnosed with Breast Cancer during and Shortly after Pregnancy
Lambre M, Johansson ALV, Andersson TM-L, Chatingius S, Hsieh C-C. Karolinska Institutet, Stockholm, Sweden; University of Massachusetts Medical School, Worcester; Regional Oncologic Center, Uppsala, Sweden.

**P1-08-10** Invasive Lobular Breast Cancer - No Increased Risk of Contralateral Disease
Langlands F, Horgan K, Kearns O, Burns R, Dodwell D. The General Infirmary at Leeds, Leeds, United Kingdom; The University of Birmingham, Birmingham, United Kingdom; Level 6, Bexley Wing (Institute of Oncology), Leeds, United Kingdom; St James University Hospital, Leeds, United Kingdom.

**P1-08-11** Differences in Recurrence Dynamics between Lobular and Ductal Invasive Breast Cancer
Siedling S, Kwas ABG, Grandjean I, Ho V, van der Sanger MJC, Menke-Pluymers MBE, Tian-Heijnen VCG. Comprehensive Cancer Centre the Netherlands, Utrecht, Netherlands; Catharina Hospital, Eindhoven, Netherlands; Erasmus Medical Centre, Rotterdam, Netherlands; Maastricht University Medical Centre, Maastricht, Netherlands.

**P1-08-12** Hormonal Therapy Compliance and Mortality in Metastatic Breast Cancer
Baron TI, Kennedy MJ, Sharp L, Bennett K. Trinity College, University of Dublin, Dublin, Ireland; St James' Hospital and Trinity College Dublin, Dublin, Ireland; National Cancer Registry Ireland, Cork, Ireland.

**P1-08-13** Determinants of Risk, Characteristics and Prognosis of Breast Cancer Occurring after Hodgkin Lymphoma

**P1-08-14** Arsenic Methylation Is Associated with Breast Cancer Risk in Northern Mexico
Lopez-Carrillo L, Hernandez-Ramirez U, Torres-Sanchez L, Gandolfi J, Ornelas-Aguirre JM, Cebreros-ME. Mexico National Institute of Public Health, Cuernavaca, Morelos, Mexico; University of Arizona, Tucson, AZ; Hospital de Especialidades Instituto Mexicano del Seguro Social, Cd. Obreron, Sonora, Mexico; Centro de Investigation y Estudios Avanzados (Cinvestav), Mexico DF, Mexico.

**P1-08-15** Pattern of Cardiac Monitoring and Risk of Trastuzumab Associated-Cardiac Dysfunction in a Clinical Practice: A Population Based Study
Lee-Ying R, Ubhi C, Roberts S, Lim H, Bhatt H, Gesy K, Ahmed S. University of Saskatchewan, Saskatoon, SK, Canada; University of Saskatchewan; Saskatchewan Cancer Agency.

**P1-08-16** Benign Breast Disease (BBD) and Breast Cancer in African American Women
Fehmi RA, Cote M, Ruttenber J, Alish B, Bandyopadhyay S, Alibashti B, Frost M, Hartmann L, Visscher D. Wayne State University/ Karmanos Cancer Institute/DMIC, Detroit, MI; Wayne State University/ Karmanos Cancer Institute, Detroit, MI; Mayo Clinic Cancer Center, Rochester, MN.

**P1-08-17** Pregnancy-Associated Breast Cancer Does Not Have a Worse Outcome in the 4912 Women with Breast Cancer of the AMAZONA Project
Liedeke PER, Szymonifika J, Simon SD, Banios CH, Bines J, Finkelstein D, Goss PE. Massachusetts General Hospital, Boston, MA; Universidade Federal de São Paulo (UNIFESP), São Paulo, Brazil; Pontificia Universidade Católica do RS (PUCRS), Porto Alegre, Rio Grande do Sul, Brazil; Instituto Nacional do Cancer (INCA), Rio de Janeiro, Brazil; Brazilian Breast Cancer Study Group (GBECAM), São Paulo, Brazil.

**P1-08-18** Aspirin Exposure and Nodal Status at Diagnosis in Women with Stage I-III Breast Cancer
Baron TI, Sharp L, Bennett K, Visvanathan K. Trinity College, University of Dublin, Dublin, Ireland; National Cancer Registry Ireland, Cork, Ireland; Johns Hopkins School of Public Health, Baltimore, MD.

**P1-08-19** Withdrawn

**P1-08-20** Parity Interferes with the Effect of Age at Diagnosis on the Frequency Breast Cancers Are Triple-Negative

**P1-08-21** Demographic and Clinical Characteristics of Metastatic Breast Cancer Patients and Biomarker-Based Prevalence in the UK, Germany, France, Spain and Italy (EUROBRECA) Study
Garguili A, Diefkens M, Bonthapally V, Lee WC, Ray S, Abbott Laboratories, Abbott Park, IL; IMS Consulting Group, Alexandria, VA.

**P1-08-22** Treatment Patterns and Clinical Outcomes in Elderly Patients with HER2-Positive Metastatic Breast Cancer from the registHER Observational Study
Kaufman PA, Brujulis AM, Mayer M, Rugo HS, Tripathy D, Ulicicjko Yood M, Feng S, Wang LL, Brammer MG, Yardley DA. Norris Cotton Cancer Center, Dartmouth-Hitchcock Medical Center, Lebanon, NH; University of Pittsburgh Cancer Center, Pittsburgh, PA; Patient Advocate, New York, NY; University of California San Francisco Comprehensive Cancer Center, San Francisco, CA; University of Southern California/Norris Comprehensive Cancer Center, Los Angeles, CA; EpiSource, LLC, Boston, MA; Boston University School of Medicine, Boston, MA; Genentech, Inc., South San Francisco, CA; Sarah Cannon Research Institute, Nashville, TN; Tennessee Oncology, PLLC, Nashville, TN.
P1-08-23 Characteristics of De Novo Stage IV Breast Cancer Presentation and Comparison with Stage IV Disease Relapse after Adjuvant Therapy

P1-08-24 Clinical and Pathologic Characteristics of Diabetic Breast Cancer Patients in a Tertiary Care Safety Net Hospital
Loch MM, Eapen A, Ross AA, Rosenberg C, Blanchard RA. Boston University Medical Center, Boston, MA; Boston University, Boston, MA.

P1-08-25 Breast Cancer Burden, Risks and Outcomes in Latin America

P1-08-26 Assessment of the impact of ineffective treatments on metastatic breast cancer - a US managed care perspective
Montero AJ, Eapen S, Gorin B, Waryas CM, Adler P. Sylvester Comprehensive Cancer Center, University of Miami, Miami, Florida; Analysis Group, Inc, Boston, MA; Veriindex, LLC, Ranjan, NJ.

P1-08-27 Assessment of the economic burden of metastatic breast cancer - a US managed care perspective
Montero AJ, Eapen S, Gorin B, Waryas CM, Adler P. Sylvester Comprehensive Cancer Center, University of Miami, Miami, Florida; Analysis Group, Inc, Boston, MA; Veriindex, LLC, Ranjan, NJ.

P1-08-28 Differences in long-term survival for Hispanic and non-Hispanic white women with breast cancer
Baumgartner KB, Pinkston CM, Denhoff SR, Baumgartner RN. School of Public Health & Information Sciences, University of Louisville, Louisville, KY.

Epidemiology, Risk, and Prevention: Epidemiology – Genetic and Molecular

P1-09-01 Effect of Obesity on Gene Expression in Invasive Breast Tumors
Ellsworth RE, Croft DT, Ellsworth DL, Shriver CD, Henry M. Jackson Foundation, Windber, PA; Windber Research Institute, Windber, PA; Walter Reed Army Medical Center, Washington, DC.

P1-09-02 HDL-Cholesterol and Low-Penetrance Gene CYP17 rs2486758 Influence Daily Estrogen Levels. The EBBa-I Study
Iversen A, Thune I, McTienan A, Makart MV, Wilsgaard T, Ellison PT, Jasienska G, Floro V, Poole E, Furburg A S. University of Tromsø, Tromsø, Norway; Oslo University Hospital, Oslo, Norway; Fred Hutchinson Cancer Research Center, Seattle, WA; Harvard University, Cambridge, MA; Medical College, Krakow, Poland; Channing Laboratory, Boston, MA; University Hospital of North Norway, Tromsø, Norway.

P1-09-03 Prevalence of Germline TP53 Mutations in Young Women with HER2-Positive Breast Cancer
Dick MG, Mascian S, Miron A, Miron P, Foley K, Gelman R, Dillon DA; Richardson AL, Versels SJ, Lypas G, Krop IE, Garber JE. Dana Farber Cancer Institute, Boston, MA; Brigham and Women’s Hospital, Boston, MA.

P1-09-04 A Genetic Predictor for Breast Cancer Risk in a Japanese Population
Sueta A, Ito H, Iwata H, Hosono S, Watanabe M, Iwase H, Tajima K, Tanaka H, Matsuoka K. Aichi Cancer Center Research, Nagoya, Japan; Kumamoto University Graduate School of Medical Science, Kumamoto, Japan; Aichi Cancer Center Central Hospital, Nagoya, Japan; Nagoya University Graduate School of Medicine, Nagoya, Japan.

P1-09-05 A 3'UTR Functional Variant in BRCA1: A Predictor of Poor Outcome in Breast Cancer
Donaraj JJ, Miller N, Newell J, Kerin MJ, Weedhaas JB. National University of Ireland, Galway, Ireland; Yale University, New Haven, CT.

P1-09-06 Single Nucleotide Polymorphisms in the BRMS1 and SIPA1 Metastasis Suppressor Genes as Prognostic Markers in Breast Cancer Patients
Roberts MR, Hong C-C, Edge SB, Yao S, Nesline M, Ambrosone CB. Roswell Park Cancer Institute, Buffalo, NY.

P1-09-07 Contribution of TP53 p.R337H Mutation to Breast Cancer Incidence in Brazil

P1-09-08 Association of Hypoxia-Inducible Factor-1 with Breast Cancer Risk: A Meta-Analysis of Published Studies
Yin W, Liu G, Lu J, Shen Z, Shao Z. Fudan University Shanghai Cancer, Shanghai, China.

P1-09-09 Fetal Microchimerism and In Situ Breast Cancer
Eur JG, Kadi P. University of Washington, Seattle, WA; Fred Hutchinson Cancer Research Center, Seattle, WA.

P1-10-01 Utility of Routine Cardiac Ejection Fraction (CEF) Measurement Prior to Anthracycline-Based Chemotherapy (ABC): A Study of 466 Patients with Early-Stage HER2-Negative Invasive Breast Cancer
Policenati SM, Go RS, De Maiffe BM, Gudmun JD, McHugh VL. Gundersen Lutheran Medical Foundation, La Crosse, WI; Gundersen Lutheran Medical Centre, La Crosse, WI; Gundersen Lutheran Medical System, La Crosse, WI.

P1-10-02 Burden of Brain Metastases in HER2-Positive Breast Cancer: Healthcare Use and Costs from a French Observational Retrospective Multicenter Study
Baffert S, Cottu PH, Kirova Y, Bachetot T, Le Rhen E, Mercier F, Levy C, Guitierrez M, Madrange N, Moldovan C, Guiu S, Serin D, Cotte FE, Benjamin L, Simondi C, Mailhard C, Laihure-Vigné S, Durand-Zaleski I. Institut Curie, Paris, France; Centre Léon Bérard, Lyon, France; Centre Oscar Lambret, Lille, France; Stat Process, Fort Mort, France; Centre François Baclesse, Caen, France; Institut Curie; Saint-Cloud, France; Institut Bergoné, Bordeaux, France; Centre Henri Becquerel, Rouen, France; Centre GF Leclerc, Dijon, France; Institut Sainte Catherine, Avignon, France; GlaxoSmithKline, Marly Le Roi, France; Ceri Medical, Garches, France; CHU Henri Mondor, Créteil, France.

P1-10-03 Colony Stimulating Factor Use with Taxane-Based Therapy for Metastatic Breast Cancer: Claims Analysis of Prophylaxis, Treatment, and Costs
Force RW, Pugimire BA, Culbertson VL, ImproveRX, LLC, Pocatello, ID; Idaho State University, Pocatello, ID.

P1-10-04 Cost-Utility of the 21-Gene Breast Cancer Assay (Oncotype DX®) in the Irish Healthcare Setting
Lacey L, Chien R, Homberger J. Lacey Solutions Ltd, South Strand, Skerries, County Dublin, Ireland; Cedar Associates LLC, Menlo Park, CA; Columbia University, New York, NY; Stanford University, Stanford, CA.

P1-10-05 Is the 21-Gene Breast Cancer Test (Oncotype DX®) Cost-Effective?
Pronzato P, Plun-Favre J. Istituto Naz.le Ricerca Cancro, Genova, Italy; Genomic Health International Srl, Geneva, Switzerland.

P1-10-06 Economic Analysis of Chemotherapy Costs for Adjuvant Therapy in Breast Cancer in France
P1-10-07  Comparing Breast Cancer Screening Guidelines: A Stage-Survival-Cost Model in a Public Hospital
Friedman DT, Baskind-Had C, Adams K, Beck e E, Habets I, D’Oni C, Gundry K, Birdsong G, Gabram-Mendola S. Emory University, Atlanta, GA.

Psychosocial, Quality of Life, and Educational Aspects: Disparities and Barriers to Care

P1-11-01  Strong Socioeconomic Disparities in Breast Cancer Quality of Care in Switzerland

P1-11-02  Racial/Ethnic Differences in Adjuvant Trastuzumab Receipt for Women with Breast Cancer within the National Comprehensive Cancer Network
Freedman RA, Hughes ME, Ottesen RA, He Y, Weeks JC, Wong Y-N, Theriault RL, Keating NL. Dana-Farber Cancer Institute, Boston, MA; City of Hope, Duarte, CA; Harvard Medical School, Boston, MA; Fox Chase Cancer Center, Philadelphia, PA; University of Texas MD Anderson Cancer Center, Houston, TX; Brigham and Women’s Hospital, Boston, MA.

P1-11-03  Breast Conserving Surgery or Mastectomy - An Urban Bias? A Rural Surgical Patient Population and Factors That Lend to Therapeutic Decisions in Breast Cancer
Wooldridge RD, Borgstrom DC. Bassett Medical Center, Cooperstown, NY.

P1-11-04  Breast Cancer Treatment Resources and Guideline-Concordant Treatment in Appalachia
Yao N, Hillemeier MM, Anderson RT, Matthews SA. Penn State, University Park, PA; Penn State, Hershey, PA.

P1-11-05  Investigation of Epidemiological Factors as Barriers to Indicated Radiation Therapy in Post-Mastectomy Breast Cancer Patients in South Carolina
Rhome RM, Wahlgquist A, Garrett-Mayer E, Harper J. Medical University of South Carolina, Charleston, SC.

P1-11-06  Barriers to Enrollment in Cancer Therapeutic Clinical Trials: A Comprehensive Cancer Center Experience
Bourdeau L, Niland J, Stiller T, Swain-Cabiales S, Somlo G. City of Hope Medical Center, Duarte, CA.

P1-11-07  Impact of Reduction in Cost-Sharing on Screening Mammography Utilization among Rural U.S. Women

P1-11-08  Breast Cancer Screening Resources and Stage at Diagnosis in Appalachia: A Geospatial Perspective
Yao N, Hillemeier MM, Anderson RT. Penn State, University Park, PA; Penn State, Hershey, PA.

P1-11-09  Effects of a Multidisciplinary Breast Cancer Clinic in an Appalachian Based Medical Center
Ingham JA, Cremeans DK, Daugherty SL, Myhand RC, Sever WE. Adena Health System, Comprehensive Breast Care Program, Chillicothe, OH.

P1-11-10  Quality of Breast Cancer Care in a Boston Area Patient Navigator Program
Raj A, Ko N, Battaglia T, Moy B. Massachusetts General Hospital, Boston, MA; Boston Medical Center, Boston, MA.

P1-11-11  Wait Times for Breast Cancer Care in Manitoba 2009-2010. Time To Face the Challenge
Carpenter-Kellett T, Nashed M. CancerCare Manitoba, Winnipeg, MB, Canada.

P1-11-12  Patterns of Care of Newly Diagnosed Patients with Breast Cancer in Mexico
Chavarrí-Guerra Y, Ljedak PER, Syecko H, Hammond EE, Higgins MJ, Finkelstein D, Goss PE. Massachusetts General Hospital, Boston, MA.

P1-11-13  Improvement in the Quality of Care for Patients with Locally Advanced Breast Cancer through Implementation of an Integrated Electronic Care Pathway
Hoogleveen S, Han D, George RL, Sweet-Goldstein M, Dinnwell RE, Muradali D, Brezden CB, Haq R, Simmons CE. St. Michael’s Hospital; Princess Margaret Hospital.

P1-11-14  Gender and Sexual Orientation of Clients Who Were Linked to Breast Cancer Screening Services through Outreach and Education Supported by the Avon Breast Health Outreach Program

Treatment – Therapeutic Strategies: HER2-Targeted Therapy

P1-12-01  Pregnancy during and Following Adjuvant Trastuzumab in Patients with HER2-Positive Breast Cancer: An Analysis from the HERA Trial (BIG 01-01)
Azim Jr HA, Metzger-Filho O, de Azambuja E, Loibl S, Focant F, Gresko E, Procter M, Piccart-Gebhart M. Institut Jules Bordet, Brussels, Belgium; German Breast Group, Frankfurt, Germany; F. Hoffmann-La Roche, Basel, Switzerland; Frontier Science, Kincraig, United Kingdom.

P1-12-02  Patient-Reported Outcomes (PROs) from a Randomized Phase II Study (TDM4450g/BO21976) of Trastuzumab Emtansine (T-DM1) vs Trastuzumab Plus Docetaxel (HT) in Previously Untreated HER2-Positive Metastatic Breast Cancer (MBC)
Bianchi GV, Kocis J, Diix L, Tongoe Y, Lalla D, Tong YB, Guardino AE, Hurvitz SA. Fondazione IRCCS Istituto Nazionale Tumori, Milan, Italy; Semmelweis University Budapest, Budapest; Sint-Augustinus Antwerp, Genentech, UCL/A/Translational Oncology Research International.

P1-12-03  Combined Targeting of the PI3K Pathway and HER2 Overcomes Acquired and De Novo Trastuzumab Resistance
O’Brien NA, McDonald K, Von Eeuw E, Conklin D, Kalous O, Di Tomaso E, Finn RS, Slamon DJ. University of California at Los Angeles, Los Angeles, CA; Novartis-Oncology, Cambridge, MA.

P1-12-04  EBPSO - A Novel Biomarker for Resistance to Endocrine and HER2-Targeted Therapies in Breast Cancer
Gu G, Covington RR, Fernandez NM, Ando’ S, Fuqua SAW. Baylor College of Medicine, Houston, TX; University of Calabria, Arcavacata di Rende, Cosenza, Italy.

P1-12-05  Complete Pathological Response of Ductal Carcinoma In Situ after Treatment with Neoadjuvant Herceptin Chalmers CR, Mallon EA, Touqan N, Horgan KJ, MacPherson I, Doughty JC. The Western Infirmary, Glasgow, Scotland, United Kingdom; Leeds General Infirmary, Leeds, Yorkshire, United Kingdom.

P1-12-06  The Role of MAPK and PI3K/AKT/mTOR Signaling in Innate Lapatinib Resistance
McDermott M, O’Brien N, McDonald K, Crown J, O’Donovan N, Slamon D. Dublin City University, Glasnevin, Dublin 9, Ireland; University of California Los Angeles, Los Angeles, CA; St. Vincents University Hospital, Elm Park, Dublin 4, Ireland.

P1-12-07  Pharmacokinetics (PK) of Trastuzumab Emtansine and Paclitaxel or Docetaxel in Patients with HER2-Positive MBC Previously Treated with a Trastuzumab-Containing Regimen
Lu D, Modi S, Elias AD, Agarwal P, Yi H, Guardino AE, Athaous BL, Ginsh S. Genentech, South San Francisco, CA; Memorial Sloan-Kettering Cancer Center, New York, NY; University of Colorado, Aurora, CO.
P1-12-08 Induction of Adhesion Molecules on Target Cells Maximizes Antibody-Dependent Cell-Mediated Cytotoxicity of Anti-Her2 Therapeutic Antibody with High Fucosyl Saccharide Jia X, Wong P-Y, Gazzano-Santojo H. Genentech Inc., South San Francisco, CA.

P1-12-09 Safety and Efficacy of Naretinib in Combination with Cephalotaxine in Patients with IB2-Positive Breast Cancer Saura C, Garcia-Saizco JA, Xu B, Harb W, Morosoe P, Piuard T, Kiger C, Germa C, Wang K, Kim S-B. Breast Cancer Unit, Vall d’Hebron University Hospital, Barcelona, Spain; Hospital Clinico San Carlos, Madrid, Spain; Cancer Hospital, Chinese Academy of Medical Sciences, Beijing, China; Horizon Oncology Center, Lafayette, IN; Florida Hospital Cancer Institute, Orlando, FL, Washington University School of Medicine, St Louis, MO, Pfizer Global Research and Development, Paris, France, Pfizer Inc, Pearl River, NY, Asan Medical Center, Seoul, Korea.

P1-12-10 Phase II Study Evaluating Laptuzumab (L) in Combination with Albumin Bound Paclitaxel (ab-Pac) in Women Who Have Received 0-1 Chemotherapy Regimen for HER2 Overexpressing (HER2+) Metastatic Breast Cancer (MBC) Yardley D, Hart T, Bosserman L, Saleh MN, Waterhouse DM, Richards P, Hagan MK, Del Silvio ML, Mahoney JM, Nagy M, Sarah Cannon Research Institute; Tennessee Oncology, PLLC; Florida Cancer Specialists; Willshire Oncology Medical Group; Georgia Cancer Specialists, Oncology & Hematology Care, Inc.; Virginia Cancer Care, Oncology & Hematology Associates of SW, GlaxoSmithKline, Collegeville, PA.

P1-12-11 Neoadjuvant Chemotherapy-Trastuzumab Versus Neoadjuvant Chemotherapy Followed by Post-Operative Trastuzumab: A Multicentre Study Palmieri C, Yan K, Owadally W, Shah D, Gogis Q, North B, Riddle P, Ahmad R, Lewanski C, Coombes RC, Cleator S, Howell S, Beresford M. Imperial College Healthcare NHS Trust, London, United Kingdom; Bristol Haematology and Oncology Centre, Bristol, United Kingdom; Third Faculty of Medicine, Charles University, Prague, Czech Republic; Imperial College London, London, United Kingdom; The Christie NHS Foundation Trust, Manchester, United Kingdom.

P1-12-12 Evaluation of Ile655Val HER2 Polymorphism Associated with Cardiac Toxicity Following the Administration of Trastuzumab in Women with Non-Metastatic Breast Cancer Dinoia C, Lermieux J, Côté M-A, Provencher L, Nadeau-Larochelle C, Jacob S, Demers É, Tremblay-Lemay R, Saint-Pierre C, Beauchemin M, Barabé F, Laflamme C. Centre de Recherche FRSQ du CHA de Laval, Laval, Quebec; Quebec City, QC; Canada; Hospital du Saint-Sacrement, Quebec City, QC, Canada; Université Laval, Quebec City, QC, Canada; Hospital of the Saint-Sacrement, Quebec City, QC, Canada; Centre Hospitalier de l’Université Laval, Quebec City, QC, Canada; Centre Hospitalier Universitaire de Québec, Quebec City, QC, Canada.

P1-12-13 Comparative Pharmacokinetics (PK) of Trastuzumab Emtansine (T-DM1) in Patients Who Have or Who Have Not Received Prior Treatment for Human Epidermal Growth Factor 2 (HER2)-Positive Metastatic Breast Cancer (MBC) Wang B, Conte P, Casanova LA, Vinholes JDF, Saad OM, Yi J-H, Gupta M, Song C, Olsen SR, Perez EA, Grish S. Genentech, South San Francisco, CA; University of Modena and Reggio Emilia, Modena, Italy; Instituto Oncologico Mafra, Lima, Peru; Clinica Porto Alegre, Brazil; Mayo Clinic, Jacksonville, FL.

P1-12-14 Genetic Ablation or Pharmacological Inhibition of Autophagy Suppresses Intrinsic Resistance of Breast Cancer to HER2-Targeted Therapies Cuff S, Oliveras-Ferraros C, Vazquez-Martin A, Sauni-Nadal T, Del Barco S, Martín-Castillo B, Lopez-Bonet E, Menendez JA. Catalan Institute of Oncology, Girona, Catalonia, Spain; Girona Biomedical Research Institute (IDIBG), Girona, Catalonia, Spain; University Hospital of Girona Dr. Josep Trueta, Girona, Catalonia, Spain.

P1-12-16 HER-2 Testing and Treatment - Is Age a Factor? Singh JK, Ewing K, Howell S, Howe M, Cramer A, Bunded NJ. School of Cancer and Enabling Sciences, University of Manchester; Paterson Institute for Cancer Research, Manchester, United Kingdom; University Hospital of South Manchester, Wythenshawe Hospital, Manchester, United Kingdom; The Christie NHS Foundation Trust, Manchester, United Kingdom.

P1-12-17 Fluorescent In Situ Hybridization Evaluation of HER2 Status in Tumors with Chromosome 17 Polysomy Pietri E, Medri L, Farolfi A, Sarti S, Maltoni R, Cecconetto L, Ibrahim T, Paioli A, Serra L, Amadori D, Rocca A. Istituto Scientifico Romagnolesi for Clinical Research (I.R.S.T), Meldola, (FC), Italy; Morgagni-Pierantoni Hospital, Forli, (FC), Italy.

P1-12-18 Change in HER2 Status in HER2 Positive Operable Breast Cancer Patients Treated with Neoadjuvant Chemotherapy with or without Anti-HER2 Therapy: Analysis of Two Consecutive Cohorts Barbieri E, Picentini F, Dieci MV, Ferrara G, Bettelli S, Conte P, Guarnieri M. Modena University Hospital, Modena, Italy.

P1-12-19 Phase I Study of Single Agent Trastuzumab Emtansine in Japanese Patients with Human Epidermal Growth Factor Receptor2 (HER2)-Positive Metastatic Breast Cancer (J022591) Aogi K, Ando M, Iwata H, Hara F, Matsubara M, Fujiwara Y. National Hospital Organization Shinokaku Cancer Center, Matsuyama, Ehime, Japan; National Cancer Center Central Hospital, Chuo-ku, Tokyo, Japan; Chuo Hospital Aichi Cancer Center, Nagoya, Aichi, Japan; Chugai Pharmaceutical Co. Ltd, Chuo-ku, Tokyo, Japan.

P1-12-20 The Safety and Tolerability of Vorniostat in Combination with Lapatinib in Advanced Solid Tumors Churmsri S, Tait NS, Mediros BM, Bauer KS, Betts K-M, Lewis JC, Bao T, Feigenberg SJ, Kesmodel SB, Steams V, Edelman ML, Sausville EA, Tkaczuk KHR. University of Maryland Greenebaum Cancer Center, Baltimore, MD; The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD; University of Maryland, Baltimore, MD.

P1-12-21 Adjuvant Trastuzumab Treatment Without Adjuvant Chemotherapy in Early Breast Cancer Dall P, Koch T, Lenzen G, Kuhn T, Hielscher C, Reichert D, Maasberg M, Ehscheidt P, Eustermann H, Fischer G. Städt. Klinikum, Lüneburg, Germany; Osnabrück, Germany; Brustzentrum, Stuttgart, Germany; Praxis, Stralsund, Germany; Praxis, Westerstedte, Germany; Praxis, Mayen, Germany; Praxis, Neuwied, Germany; WISP, Langenfeld, Germany; Landkreis Mittweida Khs., Mittweida, Germany.

P1-12-22 Impact on Survival of the Level of HER2/neu Gene Amplification in Patients with HER2-Positive (HER2+)
Advanced Breast Cancer (AdvBrCa) Treated with Trastuzumab (H) Gullo G, Betto D, Zuradelli M, Masci G, Giordano L, Bareggi C, Salvini P, Runza L, Santoro A. St. Vincent’s University Hospital, Dublin, Ireland; Istituto ClinicoHumanitas, Rozzano, Milano, Italy; Humanitas Cancer Centre, Rozzano, Milano, Italy; Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milano, Italy; Cliniche Humanitas Gavazzeni, Bergamo, Italy.
P1-12-23  HER4 Coexpression Is Associated with Improved Recurrence Free Survival in HER2-Positive, Herceptin Treated Patients
Brockhoff G, Macleod A, Piendl G, Seegers S, Sassen A, Diermeier-Daucher S, Buchholz S, Ottmann O. University Medical Center
Regensburg, Regensburg, Bavaria, Germany.

P1-12-24  Adherence and Persistence with Lapatinib in Women with Metastatic Breast Cancer Who Were Previously Treated with Trastuzumab
Delea TE, Kartashov A, Sharma P. Policy Analysis Inc. (PAI), Brooklyn, MA; GlaxoSmithKline, Philadelphia, PA.

P1-12-25  Evaluation of PTEN, EGFR and Ki-67 Expression as Predictors of Response to a Trastuzumab-Containing Neoadjuvant Chemotherapy Regimen in a HER-2 Over-Expressing Locally Advanced Breast Cancer (LABC) Trial
BC, Canada; British Columbia Cancer Research Centre, Vancouver,
BC, Canada; British Columbia Cancer Agency, Kelowna, BC, Canada;
British Columbia Cancer Agency, Victoria, BC, Canada; British Columbia Cancer Agency, Surrey, BC, Canada.

P1-12-26  Global Patterns of Care for HER2/neu Overexpressing Breast Cancer

Treatment – Therapeutic Strategies: Immunotherapy

P1-13-01  An Update of a Phase II Trial of the HER2 Peptide AE37 Vaccine in Breast Cancer Patients To Prevent Recurrence
Peoples GE, Mittendorf EA. Brooke Army Medical Center, Ft. Sam Houston, TX; Saint Savas Cancer Hospital, Athens, Greece;
Naval Medical Center San Diego, San Diego, CA; Uniformed Services University of the Health Sciences, USMCI, Bethesda, MD, UT M.D. Anderson Cancer Center, Houston, TX.

P1-13-02  Long-Term Clinical Benefit of Adjuvant Breast Cancer Vaccine: 5 Year Efficacy of E75 with Multiple Booster Inoculations
Vreeland TJ, Clifton GT, Sears AK, Hale DF, Patil R, Olive KS, Holmes JP, Mittendorf EA, Ponniah S, Peoples GE. Brooke Army Medical Center, Ft. Sam Houston, TX; Windber Medical Center, Windber, PA; Naval Medical Center San Diego, San Diego, CA; UT M.D. Anderson Cancer Center, Houston, TX; Uniformed Services University of the Health Sciences, USMCI, Bethesda, MD.

P1-13-03  Zoledronic Acid Induces an Immune Response in Breast Cancer Patients through Stimulation of Central Memory and Effector Memory gamma/delta T-Cells

P1-13-04  Phase II Study of Topical Imiquimod and Abraxane for Treatment of Breast Cancer Cutaneous Metastases

Treatment – Therapeutic Strategies: Antiangiogenic Therapy

P1-14-01  Randomized Phase II Trial of Weekly vs. q 2-Weekly vs. q 3-Weekly Nanoparticle Albumin-Bound Paclitaxel with Bevacizumab as First-Line Therapy for Metastatic Breast Cancer
Seidman AD, Conlin AK, Bach A, Forero-Torres A, Wright G, Hackney MH, Clasonion A, Schofield D, Igleias J, Hudis CA. Memorial Sloan-Kettering Cancer Center, New York, NY; Providence Cancer Center, Portland, OR; University of Alabama - Birmingham, Birmingham, AL; Florida Cancer Institute, Hudson, FL; Virginia Commonwealth University, Richmond, VA; Celgene Corporation, Summit, NJ.

P1-14-02  Correlation of Circulating Tumor Cells (CTC) and Circulating Endothelial Cells (CEC) with Pathological Complete Response (pCR) during Neoadjuvant Chemotherapy (CT) Combined with Bevacizumab in HER2 Negative Inflammatory Breast Cancer (IBC): Ancillary Study of Phase II Trial BEVERLY 1
Pierga J-Y, Bidard F-C, Andre F, Petit T, Dalenc F, Delazer T, Romieu G, Bonnettere J, Ferrero J-M, Kerbrat P, Lemonnier J, Viens P. Institut Curie, Paris, France; Institut Gustave Roussy, Villejuif, France; Centre Paul Strauss, Strasbourg, France; Centre Claudius Regaud, Toulouse, France; Centre François Baclesse, Caen, France; Centre Val d’Aurelle, Montpellier, France; Centre Oscar Lambret, Lille, France; Centre Antoine Lacassagne, Nice, France; Centre Eugène Marquis, Rennes, France; UniFrance, Paris, France; Centre Paoli Calmettes, Marseille, France.

P1-14-03  AVALUZ Study: First Line with Bevacizumab in Combination with Paclitaxel (P) and Gemcitabine (G) in Patients with HER-2 Negative Recurrent or Metastatic BC: PFS Analysis
Salvador J, Ciruelos E, Codeds de Villena M, Jaen A, Gil M, Galan A, Murias J, Kara C, de la Haba J, Baena JM, Villanueva MJ, Bayo J, Blancas I, Gonzalez E, Perez D, Mel JR, Manso L. Hospital U. de Valme, Seville, Spain; Hospital 12 de Octubre, Madrid, Spain; Hospital Virgen Macarena, Seville, Spain; Hospital de Jaen, Jaen, Spain; ICO, Bellvitge, Spain; Hospital de Sagunto, Sagunto, Spain; Hospital Insular de Gran Canaria, Gran Canaria, Spain; Fundacion Hospital de Alcorcon, Alcorcon, Spain; Hospital Reina Sofia, Cordoba, Spain; Hospital Puerta del Mar, Cadiz, Spain; Hospital Meixoeiro, Vigo, Spain; Hospital Juan Ramon Jimenez, Huelva, Spain; Hospital San Cecilio, Granada, Spain; Hospital Virgen de las Nieves, Granada, Spain; Hospital Costa del Sol, Marbella, Spain; Hospital Lucas-Augusti, Lugo, Spain.

P1-14-04  Prolonged (≥1 Year) Exposure to First-Line Bevacizumab Combined with Paclitaxel in Patients with HER2-Negative Metastatic Breast Cancer Treated in a Routine Oncology Practice Study
Kuemmell S, Schneeweiss A, Foerster FG, Geberth M, Tesch H, Klare P, Schumacher C, Hollburg W, Soelings U, Schmidt M, Klassen Essen-Mitte, Essen, Germany; National Center for Tumor Diseases, Heidelberg, Germany; University of Applied Sciences Zweickau, Zweickau, Germany; SPGO-Mannheim, Mannheim, Germany; Oncological Practice Bethanien, Frankfurt, Germany; Oncology Practice Krebsklinikuale für Frauen, Berlin, Germany; St Elisabeth-Hospital, KölN, Germany; HOPA (Hämatologisch-Onkologische Praxis Altona) im Struenseehaus, Hamburg, Germany; Practice, Kassel, Germany; University Hospital Mainz, Mainz, Germany.

P1-14-05  Surgical Complications from the geparQuinto trial of patients with HER2-positive metastatic breast cancer
Steinmann et al. Universitätsklinikum, Frankfurt; German Breast Group, Neu-Isenburg; St. Barbara-Klinik, Heessen; St. Elisabeth-Hospital, Gelsenkirchen; St. Barbara-Klinik, Essen; Universitätsklinikum, Freiburg; Henrietten Stiftung, Rheinfelden; Universitätsklinikum, Greifswald; Helios Klinikum Berlin Buch, Berlin; Universitätsklinikum, Kiel; Praxisklinik, Berlin; Luisenkrankenhaus, Regensburg, Regensburg, Bavaria, Germany.

HER2

OT1-02-01 Phase II Neoadjuvant Trial of Anthracycline Based Regimens Followed by a Combination with Nanoparticle Alumunium-Bound Paclitaxel and Trastuzumab in Patients with Operable T2-3,N0-1,Her2 Positive Breast Cancer

OT1-02-02 HALT MBC: HER2 Suppression with the Addition of Lapatinib to Trastuzumab in HER2-Positive Metastatic Breast Cancer (LPT112515)
OT1-02-03  EGFR14299: Safety and Efficacy of an Aromatase Inhibitor (AI) in Combination with Lapatinib (L), Trastuzumab (T) or Both for the Treatment of Hormone Receptor-Positive (HR+), HER2+ Metastatic Breast Cancer (MBC)

OT1-02-04  Adjuvant Pertuzumab and Herceptin in [In][T]rial Therapy of Breast Cancer: APHINITY (BIG 4-11/B025126/TOC4939g)
vom Minckwitz G, Baselga J, Bradbury I, de Azambuja E, Scullion MJ, Ross G, Saini KS, Picart-gebhart M. German Breast Group, Neu-Isenburg, Germany; Massachusetts General Hospital, Boston, MA; Frontier Science and Technology Research Foundation, Scotland; Breast Center, Jules Bordet Institute, Brussels, Belgium; Roche, Welwyn Garden City, UK; Breast International Group Headquarters, Brussels, Belgium; Breast International Group, Brussels, Belgium.

OT1-02-05  A Phase III Clinical Trial Comparing Trastuzumab Given Concurrently with Radiation Therapy to Radiation Therapy (RT) Alone for Women with HER2-Positive DCIS Resected by Lumpectomy: NSABP B-43
Julian TB, Anderson SJ, Cobleigh MA, Szili-koukou KP, Arthur DW, Zheng P, Mamounas EP, Pajon ER, Behrens RI, Chu L, Leasure NC, Atkins JN, Polkoff J, Seay TE, McCaskill-Stevens W, Rabinovitch MJ, Ross G. National Surgical Breast & Bowel Project (NSABP, Pittsburgh, PA; Allegheny General Hospital, Pittsburgh, PA; University of Pittsburgh Graduate School of Public Health and NSABP Biostatistical Center, Pittsburgh, PA; Rush University Medical Center, Chicago, IL; Northwestern University Feinberg School of Medicine, Chicago, IL; Virginia Commonwealth University, Richmond, VA; Aultman Health Foundation, Canton, OH; Colorado Cancer Research Program, Denver, CO; Iowa Oncology Research Association, Des Moines, IA; Florida Cancer Specialists, Sarasota, FL; Reading Regional Cancer Center, West Reading, PA; SCCC-CCOP, Goldsboro, NC; Kaiser Permanente Southern California, San Diego, CA; Atlanta Regional Community Clinical Oncology Program, Atlanta, GA; National Cancer Institute, Rockville, MD; University of Colorado, Aurora, CO.

OT1-02-06  DETECT III - A Multicenter, Randomized, Phase III Study To Compare Standard Therapy Alone Versus Standard Therapy Plus Lapatinib in Patients with Initially HER2-Negative Metastatic Breast Cancer and HER2-Positive Circulating Tumor Cells
Melcher CA, Janni W, Oettmann U, Jäger B, Rack B, Müller V, Schneeweiss A, Pantic-K, Solomayer E-F, Fehm T. University Hospital Duesseldorf, Duesseldorf, Germany; University Hospital Munich, Munich, Germany; National Center for Tumor Diseases Heidelberg, Heidelberg, Germany; University Hospital Hamburg, Hamburg, Germany; University Hospital Hamburg, Homburg/Saar, Germany; University Hospital Tuebingen, Tuebingen, Germany; University Hospital Hamburg-Eppendorf, Hamburg-Eppendorf, Germany.

OT1-02-07  NSABP B-47: A Randomized Phase III Trial of Adjuvant Therapy Comparing Chemotherapy Alone (Six Cycles of Docetaxel Plus Cyclophosphamide or Four Cycles of Doxorubicin Plus Cyclophosphamide Followed by Weekly Paclitaxel) to Chemotherapy Plus Trastuzumab in Women with Node-Negative or High-Risk Node-Negative HER2-Low Invasive Breast Cancer
Fehrenbacher L, Jeong J-H, Rastogi P, Geyer CE, Paik S, Ganz PA, Land SR, Costantino JP, Swain SM, Mamounas EP, Wolmark N. National Surgical Adjuvant Breast and Bowel Project (NSABP) Operations and Biostatistical Centers; Kaiser Permanente, Northern California; University of Pittsburgh Graduate School of Public Health; University of Pittsburgh Cancer Institute, University of Pittsburgh School of Medicine; Allegheny General Hospital, Monroeville Comprehensive Cancer Center, Pittsburgh, PA; Washington Cancer Institute, Washington Hospital Center, Aultman Health Foundation.

OT1-02-08  The PERSEPHONE Trial: Duration of Trastuzumab with Chemotherapy in Women with HER2 Positive Early Breast Cancer. Changing the Randomisation Point To Address Potential Barriers to Recruitment

OT1-02-09  A Phase II Randomized Trial of Lapatinib with Either Vinorelbine or Capecitabine as First- and Second-Line Therapy for HER2-Overexpressing Metastatic Breast Cancer
Janni W, Pikiel J, Terakawa T, Kaszeska W, Papadimitriou CA, Schwedler K, Alvarez Enallo J, Caruso M, Herve RA, Lau MR, Williams LS, Briggs K, Sapunar FJ. Heinrich-Heine-Universität, Chalmers lobaricentrum, Stockholm, Sweden; Department of Medical Oncology, University Hospital Hamburg, Hamburg, Germany; Department of Breast Cancer, University Hospital Tuebingen, Tuebingen, Germany; Department of Medical Oncology, University Hospital Homburg, Homburg/Saar, Germany; Department of Medical Oncology, University Hospital Hamburg, Hamburg, Germany; Division of Medical Oncology, University Hospital Munich, Munich, Germany; Division of Medical Oncology, University Hospital Hamburg-Eppendorf, Hamburg, Germany; Department of Medical Oncology, University Hospital Hamburg, Hamburg, Germany; Department of Medical Oncology, University Hospital Hamburg, Hamburg, Germany; Breast Cancer, Department of Medical Oncology, University Hospital Hamburg, Hamburg, Germany; Department of Medical Oncology, University Hospital Hamburg-Eppendorf, Hamburg, Germany; Department of Medical Oncology, University Hospital Hamburg, Hamburg, Germany.

OT1-02-10  Phase I-II Study of HER2 Vaccination with Poly(I) : Poly(C) (Ampligen®) as an Adjuvant in Optimally Treated Breast Cancer Patients
Higgins DM, Childs J, Parker S, Guthrie KA, Ditsis ML, Salazar LG. University of Washington, Seattle, WA; Fred Hutchinson Cancer Research Center, Seattle, WA.

OT1-02-11  Mother: A Registry Developed for Women with Breast Cancer Who Have Received Trastuzumab within 6 Months Prior to Conception or during Pregnancy

OT1-02-12  Early Detection of Cardiotoxicity by Advanced Cardiac Imaging and a Novel Biomarker in Breast Cancer Patients Undergoing Chemotherapy

OT1-02-13  Cardiac Biomarkers on Trastuzumab (CABOT Trial): Determining the Cardiac Biomarker Profile in Breast Cancer Patients Receiving Adjuvant Trastuzumab Therapy
Kumar VNC, Kavakas P, Rask S, Mukherjee SD, Ellis P, Dhees-Third B. Sunnybrook Odette Cancer Centre, Toronto, ON, Canada; Juravinski Hospital, Hamilton, ON, Canada; Juravinski Cancer Centre, Hamilton, ON, Canada.

Prognostic and Predictive Markers

OT1-03-01  A Randomized Phase III Clinical Trial of Standard Adjuvant Endocrine Therapy +/- Chemotherapy in Patients (pts) with 1-3 Positive Nodes, Hormone Receptor (HR)-Positive and HER2-Negative Breast Cancer with Recurrence Score (RS) of 25 or Less: SWOG S1007
Gonzalez-Angulo AM, Barlow WE, Gralow JR, Menic-Bernstam F, Hayes DF, Moopour CM, Ramsey SD, Schott AF, Sparks DB, Albain KS, Hortobagyi GN. MD Anderson Cancer Center, Houston, TX; Cancer Research and Biostatistics, Seattle, WA; Seattle Cancer Care Alliance/University of Washington, Seattle, WA; University of Michigan, Ann Arbor; MD, Fred Hutchinson Cancer Research Ctr, Seattle, WA; University of Michigan and SWOG, Ann Arbor, MI; SWOG, San Antonio, TX; Loyola Univ Chicago Stritch School of Medicine, Maywood, IL.

OT1-03-02  SAFIR01: A Molecular Screening Trial for Metastatic Breast Cancer Patients
Andre F, Peletetekan C, Jimenez M, Ferrero, Delaloge S, Roman Roman S, Dessen P, Bonnefoi H, Gustave Roussy Institute; Univac'urie; Curie Institute; Bergonie Institute; Centre antoine lacassagne, Nice, France.
P2-01-23  Seprase Promotes the Growth and Impairs the Migratory Ability of Breast Cancer Cells
Jia J, Martin TA, Jiang W. Peking University, Beijing, China; Cardiff University School of Medicine, Cardiff, United Kingdom.

P2-01-24  Triple-Negative Breast Cancer Emerges from the Luminal Progenitor Compartment
Nogi H, Kario M, Kato K, Kawaase K, Toriumi Y, Takeyama H, Uchida K. The Jikei University School of Medicine, Tokyo, Japan.

P2-01-25  Truncated p110 ERBB2 (CTF611) Increases Migration and Invasion of Breast Epithelial Cells by Inhibiting STAT5b Activation

P2-01-26  TIMPv: a novel downstream transcriptional target gene that underpins CD146-suppressed breast tumor invasion
Ouhit A, Abdelmageed Z, Fernando A, Gaur RL, Raj MHG. College of Medicine & Health Sciences, Sultan Qaboos University, Muscat, Oman; Louisiana State University Health Sciences Center; Stanley S Scott Cancer Center, New Orleans, LA.

P2-01-27  Withdrawn

Tumor Cell Biology: Oncogenes/Tumor Suppressor Genes

P2-02-01  A Novel Inflammatory Breast Cancer-Specific Oncogene, Tazarotene-Induced Gene 1, Promotes Tumorigenicity and Invasiveness through the Receptor Tyrosine Kinase Axl
Wang X, Saslo H, Iwamoto T, Pusztai L, Gong Y, Woodward WA, Reuben JM, Hortobagyi GN, Ueno NT. Morgan Welch Inflammatory Breast Cancer Clinic, The University of Texas MD Anderson Cancer Center, Houston, TX; University of Texas MD Anderson Cancer Center, Houston, TX.

P2-02-02  Mutation of the APC Tumor Suppressor Stimulates Breast Cancer Cell Proliferation through Hyperactivation of FAK/Src/JNK Signaling
Prosperi JR, Yang FF, Goss KH. University of Chicago, Chicago, IL.

P2-02-03  MAP3K3, Amplified in Human Breast Cancer, Promotes Breast Tumor Progression and Defines Poor Prognosis
Dong J. Baylor College of Medicine, Houston, TX.

P2-02-04  Novel Functions of vps34 in Non-Transformed Epithelial Cells: Regulation of Cell Proliferation and Tumorigenesis
Su H, Xu T, Ganapathy S, Yuan Z-M. UTHealthSA, San Antonio, TX.

P2-02-05  Molecular Mechanism for Src Homology Phosphotyrosyl Phosphatase 2 Cell Motility and Migration
Hartman ZR, Agazie YM. West Virginia University School of Medicine, Morgantown, WV.

P2-02-06  Inhibition of CDK4 Phosphorylation of Smad3 Decreases Cyclin D Overexpressing Breast Cancer Cell Proliferation and Migration
Tarasewicz E, Hardy A, Straela H, Foucar C, Zelivianski S, Jerus J. Northwestern University Feinberg School of Medicine, Chicago, IL.

P2-02-07  Regulation of mTOR Signaling by Proto-Oncogene PELP1
Gonugunta VK, Cortez V, Rethman C, Nair BC, Sareddy GR, Vadlamudi RK. UTHSCSA, San Antonio, TX.

P2-02-08  Int6 Regulates Both Proteasomal Degradation and Translation Initiation and Is Critical for Proper Formation of Acini by Human Mammary Epithelium
Suo J, Snider SJ, Lloyd RE, Chang EC. BCM.

P2-02-09  TP53 Mutation Patterns in Breast Cancer Subgroups

P2-02-10  Differential Targeting of the RB-Pathway To Expand the Therapeutic Index in the Treatment of Triple Negative Breast Cancer

Tumor Cell Biology: Growth Factors

P2-03-01  Genetic Reduction of Circulating Insulin-Like Growth Factor (IGF)-I Differentially Impacts the Effects of Diet-Induced Obesity and Calorie Restriction on Mammary Tumor Progression
Ford NA, Nunez NP, Perkins SN, Hursting SD. University of Texas at Austin, Austin, TX; National Cancer Institution, Rockville, MD.

P2-03-02  An IGF1R Antibody Does Not Inhibit Growth of Tamoxifen Resistant MCF-7 Cells
Fagan DH, Yee D. University of Minnesota, Minneapolis, MN.

P2-03-03  An Insulin-Like Growth Factor I (IGF-I)-Induced Gene, Solute Carrier Family 7 Member 11 (SLC7A11)/xCT, Mediates IGF-I-Induced Biological Behaviors in Breast Cancer Cells
Yang Y, Becker MA, Yee D. University of Minnesota, Minneapolis, MN.

P2-03-04  Novel Pathways Underlying the Initiation and Transition of DCIS to IDC of HER2-Overexpressing Breast Cancer Model
Pradeppe CR, Koester W, Laurola M, Nair H, Rao R, Mills GB, Yarden Y. MD Anderson Cancer Centre, Houston, TX; Weizmann Institute of Science, Rehovot, Israel; Southwest National Primate Research Center, San Antonio, TX; University of Texas Health Science Center San Antonio, San Antonio, TX.

P2-03-05  Attenuation of TGF-beta Signaling Suppresses Premature Senescence in a p21-Dependent Manner and Promotes Oncogenic ras-Mediated Metastatic Transformation in hTERT-Immortalized Basal-Like Human Mammary Epithelial Cells
Lin S, Yang J, Elkahoul AG, Bandopadhayay A, Wang L, Cornell JE, Yeh I-T, Agyn JK, Sun L-J. University of Texas Health Science Center, San Antonio, TX; NHGRI-NIH, Bethesda, MD.

P2-03-06  Endothelin-1/Endothelin A Receptor Signalling in Breast Cancer
Tamkis D, Leece C, Gallo K, Madhukar BV, Dmitrov N. Michigan State University (MSU).

Tumor Cell Biology: Apoptosis and Senescence

P2-04-01  Extracellular PAI-1 - t-PA – IGFBP3 Cascade Mediates Chemotherapy-Induced Senescence of Breast Cancer Cells
Shio Y, Elzi DJ, Song M, Hakala K, Weitstraub ST. The University of Texas Health Science Center, San Antonio, TX.

P2-04-02  Identification of a Novel Glycocalyxtransferase-Like Gene as an Autophagic Inducer in Human Mammary Carcinoma Cells Via Down Regulation of BCL-2

Tumor Cell Biology: Angiogenesis

P2-05-01  Acquired Tamoxifen Resistance Promotes Angiogenic Responses in ER+ Breast Cancer Cells
Hayes E, Smith C, Nicholson RI, Gee J, Hiscox S. Cardiff University, Wales, United Kingdom.
P2-05-02  PGC1, Peroxisome Proliferator Activated Receptor-gamma (PPAR-gamma) Coactivator-1, Is Necessary in PPAR-gamma Modulated Angiogenesis
Jiang WG, Li X, Mansel RE. Cardiff University School of Medicine, Cardiff, Wales, United Kingdom.

P2-05-03  Is Breast Cancer Trypsinase a Novel Anti-Angiogenic Molecular Target?

P2-05-04  Mapping the Specific Gene Families Activated in the Lymphangiogenesis and Vasculogenic Mimicry Exhibited by Inflammatory Breast Cancer
Liu H, Luo AZ, Mu Z, Chu K, Ye Z, Alpbaugh RK, Fernandez S, Boley KM, Jin J, Wright MC, Cristofanilli M, Robertson FM. The University of Texas, MD Anderson Cancer Center, Houston, TX, Fox Chase Cancer Center, Philadelphia, PA.

P2-05-05  Receptor-Like Protein Tyrosine Phosphatase Kappa (PTPRK) and Its Biological Role in Angiogenesis
Sun P-H, Ye L, Mason MD, Jiang WG. Cardiff University School of Medicine, Cardiff, United Kingdom.

P2-05-06  Role of Repulsive Guidance Molecule b (RGMb) in HGF Mediated Angiogenesis
Sanders AJ, Ye L, Mason MD, Jiang WG. Cardiff University School of Medicine, Cardiff, United Kingdom.

P2-05-07  Combined Antiangiogenic and Anti-Estrogen Therapy in Breast Cancer. Molecular Mechanisms Involved
de la Haba J, Berciano M, Cañabate M, Porras I, Valverde A, Cañas A, Rodríguez A, Aranda E. Hospital Universitario Reina Sofia, Institute for Biomedical Research Maimonides IMIBIC, Cordoba, CO, Spain; Hospital General Universitario, Ciudad Real, CR, Spain.

P2-05-08  Expression of VE-Statin/egfl7 in Breast Cancer
Lauridant-Philippin G, Baranelli M-C, Fourrier C, Samson C, Soncin F, Bonnette J. Centre Oscar Lambret, Lille, France; Institut de Biologie de Lille - CNRS UMR 8161, Lille, France; Université Lille Nord de France, Lille, France.

P2-05-09  Secondary Inflammatory Breast Cancer: A Possible Model for Post-Surgical Dissemination of Cancer
Hashmi S, Zolfaghari L, Levine PH. George Washington University, Washington, DC.

P2-05-10  Brain-Derived Neurotrophic Factor, BDNF, and Its Biological Impact on Vascular Endothelial Cells
Jiang WG, Ye L, Yang X, Mansel RE. Cardiff University School of Medicine, Cardiff, Wales, United Kingdom; Capital Medical University, Beijing, China.

Tumor Cell Biology: Genetics – Somatic Changes

P2-06-01  Genomic Instability in Breast Cancers from Atomic Bomb Survivors: An Analysis of Microarray-Comparative Genomic Hybridization with Old Archived Tissues
Oikawa M, Yoshura K-I, Kondo H, Miura S, Kurashige T, Nagayasu T, Yano H, Nakashima M. Atomic Bomb Disease Institute, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan; Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan.

P2-06-02  FOXO3a Genotype Predicts Age of Breast Cancer Onset and Correlates with Lymph Node Involvement

Grizzle WE, Steg AD, He Q, Steciuk MR, Byun-Parker S, Johnson MR, Grunda JM. University of Alabama at Birmingham, Birmingham, AL; Tuskegee University, Tuskegee, AL.

P2-06-04  Phosphatidylinositol-3-Kinase Pathway Mutations Are Common in Breast Columnar Cell Lesions
Truxell ML, Brunner AL, Montgomery K, Zhu SX, Neff T, Warrick A, Beadling C, Corless CL, West RB. Oregon Health & Science University, Portland, OR; Stanford University, Stanford, CA.

Tumor Cell Biology: Genetics – Germline Changes

P2-07-01  Copy Number Variants in Early-Onset-Breast Cancer
Ludwig S, Ivanovich J, Graubert TA. Goodfellow PJ. Washington University in St.Louis, SOM, St. Louis, MO.

P2-07-02  Germline Genetic Variants Disturbing the Let-7/LIN28 Double-Negative Feedback Loop Alter Breast Cancer Susceptibility
Yu K-D, Shao Z-M, Chen A-X. Fudan University Shanghai Cancer Center, Shanghai, China.

P2-07-03  Collective Evidence Suggests Neutrality for BRCA1 V1687i, a Novel Sequence Variant in the Conserved THO Motif of the First BRCT Repeat
Cortesi L, De Nicolai A, Medic V, Marino M, Turchetti D, Pradella LM, Rossi G, Parisini E, Federico M. University of Modena and Reggio Emilia, Modena, Italy; Dana-Farber Cancer Institute, Boston, MA; Harvard Medical School, Boston, MA; University of Bologna, Bologna, Italy; Italian Institute of Technology, Milan, Italy.

Detection and Diagnosis – Imaging and Screening: Breast Imaging – MRI

P2-08-01  Impact of Aromatase Inhibitors on Background Parenchymal Enhancement and Amount of Fibroglandular Tissue on Breast MRI

P2-08-02  Magnetic Resonance Imaging as a Predictor of Pathologic Response in Patients Treated with Neoadjuvant Systemic Treatment for Operable Breast Cancer (TCRC 017)
De los Santos J, Cantor A, Mcguire K, Golshan M, Merci-Bemstam F, Horton J, Nanda R, Amos K, Forero A, Hudis C, Meszoely I, Hwang S. Hospital General Universitario, Ciudad Real, CR, Spain; University of North Carolina Chapel Hill, Chapel Hill, NC; Dana-Farber Cancer Institute, Boston, MA; Duke University Medical Center, Durham, NC; Memorial Sloan Kettering Cancer Center, New York, NY; University of Pittsburgh Medical Center, Pittsburgh, PA; MD Anderson Cancer Center, Houston, TX; Vanderbilt University, Nashville, TN; University of Chicago, Chicago, IL; University of California at San Francisco, San Francisco, CA.

P2-08-03  Quantitative MRI for Noninvasive Prediction of Prognostic Markers in Breast Cancer
Parisian S, Sun R, Kurland BF, Rahbar H, Allison KH, Specht JM, DeMartini WB, Lehrman CD, Partridge SC. University of Washington, Seattle, WA; Fred Hutchinson Cancer Research Center, Seattle, WA.

P2-08-04  Computer-Derived Breast MRI Features Have Complementary Value for Preoperative Selection of Systemic Drug Therapy in Node-Negative Stage-I/II Breast Cancer Patients
Ghilijus KGA, Pengel KE, Dimitriev I, Paape A, Rutgers EEl; Wesseling J, Loo CE. The University Medical Center Utrecht, Utrecht, Netherlands; The Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands.
P2-08-05  Use of Dynamic Contrast-Enhanced MR Imaging To Predict Pathological Response in Primary Breast Cancer

P2-08-06  Improved Spatial Resolution Diffusion-Weighted Imaging for Characterizing Tumors and Treatment Response in Patients with Invasive Breast Cancer

P2-08-07  Ex-Vivo High Resolution MRI of Sentinel Lymph Nodes Following Subcutaneous Injection of Superparamagnetic Iron Oxide Nanoparticles

P2-08-08  Benefit of Preoperative Breast MRI in Patients with Newly Diagnosed Breast Cancer
Miesbauer M, Sheu H, Schiessingegr A, Kirchweger B, Waldenberger P. St. Vincent Hospital, Linz, Austria.

P2-08-09  The Impact of Preoperative Breast MRI in Newly Diagnosed Breast Cancer. A Prospective Study of Treatment Outcome in Patients Selected for Breast-Conserving Surgery in a Norwegian Multidisciplinary Breast Cancer Clinic
Robben T, Rodegerdts E, Bachmann H, Funder V. Department of Surgery, Nordland Hospital, Bodø, Norway; Department of Radiology, Nordland Hospital, Bodø, Norway; Faculty of Health Sciences, University of Tromsø, Tromsø, Norway.

P2-08-10  Withdrawn

P2-08-11  Correlation of Mammography, Ultrasound and MRI in Patients with Nipple Discharge
Deshmane VH, Mulan S, Lodh N, Pungavkar S, Bhaduri A, Deshpande R, Madiwale C. P. D. Hinduja National Hospital, Mumbai, Maharashtra, India; Nanavati Hospital, Mumbai, Maharashtra, India.

P2-08-12  Additional Lesion Found in Preoperative Breast MRI; Is Routine Use Justified?

Detection and Diagnosis – Imaging and Screening: Molecular, Functional, and Novel Imaging

P2-09-01  First-in-Human Whole-Body HER2-Receptor Mapping Using Affibody Molecular Imaging

P2-09-02  Predicting Response to Bevacizumab in Primary Breast Cancer Using 18F-Fluorothymidine (FLT) and 18F-Misonidazole (MISO) Positron Emission/Computed Tomography (PET/CT) as Imaging Biomarkers

P2-09-03  Breast Cancer Detection Using a Novel Functional Imaging Device Equipped with Multiparametric Computer Analysis
Sella T, Sklar-Levy M, Maya C, Rozen M, Tanim A, Maisa S, Libson E, Ishaky D. Hadassah Hebrew University Medical Center, Jerusalem, Israel; Chaim Sheba Medical Center, Tel Hashomer, Israel; Rabin Medical Center, Petach Tikva, Israel; Assuta Medical Center, Tel-Aviv, Israel; Kaplan Medical Center, Rehovot, Israel; Meir Medical Center, Kfar Sava, Israel; Real Imaging Ltd., Airport City, Israel.

P2-09-04  Near Infra Red Quantum Dots as Novel Probes for Sentinel Lymph Node Biopsy

P2-09-05  Molecular Imaging of Hedgehog Induced Epithelial-Stromal Interactions
Woodward W, Sims-Mourtada J, Yang DJ, Twerorswka I, Larson R, Smith D, Mourtada F. RadioMedix, Inc, Houston, TX; The University of Texas M.D. Anderson Cancer Center, Houston, TX.

P2-09-06  Relevance of Breast Cancer Subtypes in Response Monitoring with 18F-FDG PET/CT during Neoadjuvant Chemotherapy

P2-09-07  Metabolic Response by FDG-PET in Patients (pts) Receiving Trastuzumab (T) and Lapatinib (L) for HER2+ Metastatic Breast Cancer (MBC): Correlative Analysis of TBCRC 003
Yap JT, Locascio T, Najita JS, Mayer IA, Hobday TJ, Falkson CI, Dees EC, Gelman RS, Rimawi MF, Nanda R, Berkowitz J, Franchetti Y, Wolff AC, Winer EP, Lin N, Van den Abbeele AD. Dana-Farber Cancer Institute, Boston, MA; Vanderbilt-Ingram Cancer Center, Nashville, TN; Mayo Clinic, Rochester, MN; University of Alabama, Birmingham, AL; University of North Carolina at Chapel Hill, Chapel Hill, NC; Baylor College of Medicine, Houston, TX; University of Chicago, Chicago, IL; Johns Hopkins Kimmel Cancer Center, Baltimore, MD.

P2-09-08  FDG-PET in the Staging of the Axilla in Women with Breast Cancer Treated with Primary Chemotherapy

P2-09-09  Dynamic FDG PET and DCE-MRI To Assess Tumor Metabolism and Blood Flow in Response to Neoadjuvant Sunitinib and Paclitaxel Followed by AC + G-CSF in Patients with Locally-Advanced (LABC) and/or Inflammatory Breast Cancer (IBC)
Schecht JM, Kurland BF, Dunnwald LK, Doot RK, Eun JK, Schubert EK, Partridge SC, Ellis GK, Gadi VK, Gralow JR, Linden HM, Rodler ET, Mankoff DA. University of Washington, Seattle, WA; Fred Hutchinson Cancer Research Center, Seattle, WA; Seattle Cancer Care Alliance, Seattle, WA.

P2-09-12 High Resolution Diffusion MRI Characterizes Tumor Stromal Boundaries McLaughlin RL, Newitt DC, Wilmes LS, Sinha S, Wisner DJ, Hylton NM. UC Berkeley and UCSF, Berkeley and San Francisco, CA; UCSF, San Francisco, CA.

P2-09-13 The Value of FDG PET/CT in Screening Detected Breast Cancer Patients Koo HR, Moon WK, Cho N, Chang JM, Kang KW, Yi A. Seoul National University Hospital, Seoul, Korea.

P2-09-14 Evaluation of Angiogenesis Using Synchrotron Radiation in Xenograft Mouse Models of Breast Cancer Gu S-m, Zhang X, Li R-m, Jin W, Shen Z-z, Shao Z-m, Xu X-m, Wu J. Cancer Hospital/Institute, Fudan University, Shanghai, China; Shanghai Jiao Tong University, Shanghai, China.

Detection and Diagnosis – Imaging and Screening: Breast Imaging – Other Methods

P2-10-01 Extracellular Matrix Stiffness and Mammographic Density in the Human Breast Acerbi L, Au A, Chen Y-y, Hwang S, Weaver V. Center for Bioengineering and Tissue Regeneration, University of California San Francisco, San Francisco, CA; University of California San Francisco, San Francisco, CA; Eli and Edythe Broad Center of Regeneration Medicine and Stem Cell Research, and Helen Diller Family Comprehensive Cancer Center, UCSF, San Francisco, CA.

P2-10-02 Assessment of Tumor Response to Neoadjuvant Chemotherapy Using Ultrasound-Guided Near Infrared Light Zhu Q, DeFusco P, Tannenbaum S, Ricci A, Cronin E, Hegde P, Kane M, Tavakoli B, Xu Y. University of Connecticut; Storrs, CT; Hartford Hospital; Hartford, CT; University of Connecticut Health Center, Farmington, CT.

P2-10-03 Non-Invasive In Vivo Characterization of Cancer-Cell Proliferation & Angiogenesis in Cancer-Cell-Surrounding Stromal Microenvironment In-Vivo Using Diffuse Optical Tomography Chung SH, Feldman M, Choe R, Martinez D, Yodh AG. University of Pennsylvania; Hospital of the University of Pennsylvania; The Children's Hospital of Philadelphia, University of Rochester.

P2-10-04 3D Mapping of Total Choline in Human Breast Cancer Using High-Speed MR Spectroscopic Imaging at 3T: A Feasibility Study Posse S, Royce M, Dayao ZR, Zhang T, Zhao C, Sillerud L, Lopez S, Casey L, Eberhardt SC, Lomo L, Lee S-J, Rosenberg R, Rainey A, Bolan P. University of New Mexico School of Medicine, Albuquerque, NM; University of New Mexico Cancer Center, Albuquerque, NM; New Mexico Cancer Center, Albuquerque, NM; University of Minnesota, Minneapolis, MN.

P2-10-06 Prospective Ultrasonographic Prediction of Sentinel Lymph Node Metastasis by Real-Time Virtual Sonography Constructed with Three-Dimensional Computed Tomography-Lymphography in Breast Cancer Patients Yamamoto S, Maeda N, Yoshimura K, Oka M. Yamaguchi University Graduate School of Medicine, Ube, Yamaguchi, Japan.

P2-10-07 Triple-Negative Breast Cancer May Have Ultrasonographic Features Mimicking Nonmalignant Lymph Nodes Wojcinski S, Farrokh A, Schmidt J, Hillemanns P, Degenhardt F. Franziskus Hospital, Bielefeld, Germany, Hannover Medical School, Hannover, Germany.

P2-10-08 Electrical Impedance Imaging Characteristics of Nodular and Edematous-Infiltrative Forms of Breast Cancer Korotkova M, Karpov A, Bulatov A, Frzyuk A. Clinical Hospital 9, Yaroslavl, Russian Federation.

P2-10-09 Detecting Breast Cancer with Dynamic Diffuse Optical Tomographic Imaging Flexman ML, Kim HK, Lim E, Desperito E, Barbour RL, Hershman DL, Hielscher AH. Columbia University, New York, NY; State University of New York, Brooklyn, NY.

Prognosis/Response Predictions: Prognostic Factors and Biomarkers – Preclinical

P2-11-02 Brain-Derived Neurotrophic Factor Expression Is Associated with Poor Prognosis in Human Breast Cancer Patani N, Jiang WG, Mokbel K. The London Breast Institute, The Princess Grace Hospital, London, United Kingdom; University Department of Surgery, Cardiff University School of Medicine, Cardiff, United Kingdom; Brunel Institute of Cancer Genetics and Pharmacogenomics, Brunel University, London, United Kingdom.

P2-11-03 High Expression of CX3CL1 by Tumor Cells Correlates with a Good Prognosis and Increased Infiltrating CD8+ T Cells, Natural Killer Cells, and Dendritic Cells in Breast Carcinoma Lee JS, Park MH, Yoon JH. Chonnam National University Medical School, Gwangju, Republic of Korea.

P2-11-04 TMEPAI Is a Feedback Regulator of TGF-β Signaling during Breast Cancer Progression Singhia PK, Pandeswarra S, De La Chapa JJ, Venkatachalam MA, Saikumar P. UT Health Science Center at San Antonio, San Antonio, TX.
P2-11-05 Stromal Matrix Metalloproteinase-14 Expression Correlates with the Grade and Biological Behavior of Mammary Phyllodes Tumors
Lee JS, Park MH, Yoon JH. Chonnam National University Medical School, Gwangju, Republic of Korea.

P2-11-06 PTEN Loss in Asian Triple Negative Breast Cancer Is a Frequent Event Associated with Basal Markers, Tumour Grade and Younger Age of Onset
Dean S, Rhodes A, Holly J, Perks C, Loci L-AM, Mun KS, Taib NA, Yip CH. University of the West of England, Bristol, United Kingdom; University of Bristol, Bristol, United Kingdom; University of Malaya, Kuala Lumpur, Malaysia.

P2-11-07 Expression of Selected Predictive Markers in African American Women with Atypical Hyperplasia of the Breast
Bandopadhyay S, Cote M, Visscher DW, Rutberbus J, Albashiti B, Alosl B, Frost MH, Hartmann LC, Fehmi RA. Wayne State University/KCI, Detroit, MI; Wayne State University/KCI, Detroit, MI; Mayo Clinic Cancer Center, Rochester, MN.

P2-11-08 Clinical Value of Combination Assay for Quantitative Determination of Cancer Biomarkers C2p and uPA/PAI-1 for Disease Recurrence Prediction of Early Breast Cancer Patients
Schmitt M, Kiechle M, Schwarz-Boeger U, Langer R, Nakayama S, Matsuhash T, Ishihata H. Technical University of Munich, Munich, Germany; Sysmex Corporation, Kobe, Japan.

P2-11-09 EGFR Overexpression in Triple Negative Breast Cancer (TNBC) and Its Association with the Prognosis
Liu W, Zhang L, Ma K, Han B, Li S, Xu G, Fan Z, Liu N, Shi A. The First Hospital of Jilin University, Changchun, Jilin, China; The 208 Hospital of People’s Liberation Army, Changchun, Jilin, China; The Central Hospital of Siping, Siping, Jilin, China; The Second Hospital of Jilin University, Changchun, Jilin, China.

P2-11-10 Low Toll-Like Receptor 9 Expression Is Required for the Aggressive Behavior of Triple Negative Breast Cancer Cells in Hypoxia
Selander KS, Tuomela J, Sandholm J, Kanihalta P, Pressey C, Ilvesar J, Vuopala K, Kaupilla JH, Kaupilla S, Harris KW, Graves D, Jurkasla-Vuoren J. University of Alabama at Birmingham, Birmingham, AL; Oulu University Hospital, Oulu, Finland; University of Oulu, Oulu, Finland.

P2-11-11 IGBP-2 Ratio Confers Resistance to IGF Targeting and Correlates with Increased Invasion and Poor Outcome in Breast Tumors
Becker MA, Hou X, Harrington SC, Carbini JM, Gottardis MM, Haluska F, Mayo Clinic, Rochester, MN; Bristol Myers Squibb Pharmaceutical Research Institute, Princeton, NJ.

P2-12-03 A Prospective Study of the Prognostic Implications of Being a BRCA1 Carrier for Young Onset Breast Cancer Patients
Erick DM, Diet L, Gemy SM, Altman D, Copson ER, Simononds PD, Durcan L, Ward D. University of Southampton, Southampton, Hampshire, United Kingdom; Oxford University, Oxford, United Kingdom; Southampton University Hospitals NHS Trust, Southampton, Hampshire, United Kingdom; Salisbury District Hospital, Salisbury, Wiltshire, United Kingdom.

P2-12-04 RACGAP1 mRNA Assay Outperforms Ki-67 as a Proliferation Marker in the FinHer Study Cohort
Wirtz RM, Leinonen M, Bono P, Isola J, Kellokumpu-Lehtinen P-L, Kataja V, Turpeenniemi-Hujanen T, Jyrkkio S, Huang W, Eids T, Joensuu H. STRATIFYER Molecular Pathology GmbH, Cologne, Germany; Pharma, Finland; Helsinki University Central Hospital and University of Helsinki, Finland; University of Tampere and Tampere University Hospital, Finland; Tampere University Hospital, Finland; Kuopio University Hospital, Finland; Oulu University Hospital, Finland; Turku University Hospital, Finland; Monogram Biosciences, Inc.; Institute of Pathology at the St-Elisabeth-Hospital, Germany.

P2-12-05 Correlation between Quantitative HER2 Protein Expression and Risk of Brain Metastases in HER2-Positive Advanced Breast Cancer Patients Receiving Trastuzumab-Containing Therapy
Duchnowska R, Bianetti W, Szostakiewicz B, Spierde J, Piette F, Haddad M, Paquet A, Lie Y, Czartoryska-Arlukowicz B, Wysocz P, Jankowski T, Radecka B, Fozszycka-Kloda M, Liwinski M, Delska S, Weidler J, Huang W, Buyse M, Bates M, Jassem J. Military Institute of Medicine, Warsaw, Poland; Medical University of Gdansk, Gdansk, Poland; Monogram Biosciences, South San Francisco, CA; International Drug Development Institute, Louvain-la-Neuve, Belgium; Bialystok Oncology Center, Bialystok, Poland; Great Poland Cancer Center, Poznan, Poland; Lublin Oncology Center, Lublin, Poland; Opole Oncology Center, Opole, Poland; West Pomeranian Oncology Center, Szczecin, Poland; Poznan University of Medical Sciences, Poznan, Poland; Regional Cancer Center, Lodz, Poland; Ceghein, Sunyvalle, CA.

P2-12-06 Nomogram To Predict Subsequent Bone Metastasis in Patients with Non Metastatic Breast Carcinomas
Louqui R, Delpech Y, Roussier R, Gispon J, Hui L, Barranger E, Puzaite L, Uzan S, Hortobagyi GN, Courant C, Ibrahim NK. Lariboisiere Hospital, AP-H, Paris, France, Metropolitan; Tenon Hospital, AP-H, Paris, France, Metropolitan; The University of Texas M.D. Anderson Cancer Center, Houston, TX; Georges Francois Leclerc Cancer Center, Dijon, France, Metropolitan.

P2-12-07 Pooled Analysis of Outcomes of T1a/BNO, HER2-Amplified Breast Cancer
Amir E, Seruga B, Ocan A, Carlsson L, Bedard P. Princess Margaret Hospital, Toronto, Canada; Institute of Oncology Ljubljana, Ljubljana, Slovenia; Albacete University Hospital, Albacete, Spain.

P2-12-08 Bcl-2 as a Prognostic Marker in Breast Cancer Patients Receiving Endocrine Therapy
Larsen MS, Bjerre KD, Laenholm A-V, Giobbie-Hurder A, Ejertsen B, Lykkefeldt AE, Rasmussen BB. Herlev Hospital, Herlev, Denmark; Rigshospitalet, Copenhagen, Denmark; Dana-Farber Cancer Institute, Boston, MA, Danish Cancer Society, Inst of Cancer Biology, Copenhagen, Denmark.

P2-12-09 Prediction of Risk of Recurrence (RRR) after 5-Years of Follow-Up by Ki-67 and IHC4: A TransATAC Study
Pineda S, Cuzick J, Salter J, Zabaglo L, Howell A, Buzdar A, Forbes JF, Dowsett M. Queen Mary University of London, London, United Kingdom; Royal Marsden Hospital and Breakthrough Breast Cancer Centre, London, United Kingdom; Christie Hospital, Manchester, United Kingdom; University of Texas, Texas; University of Newcastle, Newcastle, NSW, Australia.

www.aacrjournals.org Cancer Res; 71(24 Suppl.) December 15, 2011
P2-12-10 Low TCR Diversity (Divpenia) Is a Prognosis Factor of Overall Survival in Metastatic Breast Cancer

P2-12-11 Clinical Relevance of a IL-8/B-Cell Gene Signature Identified from Trigle Negative Breast Cancer (TNBC) in Intrinsic Breast Cancer Subtypes
Rodr G, Holtrich U, Ruckhaeberle E, Radossa J, Juhasz-Boess I, Solomayer EF, Kaufmann M, Karm T, Saarland University, Homburg, Germany; Goethe-University, Frankfurt, Germany.

P2-12-12 Prognostic Utility of Breast Cancer Index for Late Relapse in Patients with Early Stage Breast Cancer

P2-12-13 Topoisomerase 2 alpha (TOP2A) RNA Expression Provides Prognostic Information in Hormone Receptor Positive Breast Cancer That Is Complementary to a Simulated Algorithm for Recurrence Score
Sparano JA, Goldstein LJ, Davidson NE, Sledge, Jr GW, Gray R. Albert Einstein College of Medicine, Montefiore Medical Center, Bronx, NY; Fox Chase Cancer Center, Philadelphia, PA; University of Pittsburgh, Pittsburgh, PA; Indiana University, Indianapolis, IN; Eastern Cooperative Oncology Group, Brookline, MA.

P2-12-14 Prognostic Value of HER2 Positivity and Negative Hormonal Status in Patients with Small Tumor (<1cm) and Node-Negative Breast Cancer
Meattini I, Livi S, Saieva C, Agresti B, Scotti V, Nori J, Sanchez LJ, Vezzosi V, Bianchi S, Cataliotti L, Biti G. Florence University, Florence, Italy; Cancer Prevention and Research Institute, Florence, Italy.

P2-12-15 GAINS: A Breast Cancer Prognostic Index Utilizing Lymph Node Ratio
Doranj JI, Wall D, Newell J, Blamey RW, Sweeney KJ, Ball G, Kerm M. National University of Ireland, Galway, Ireland; Breast Institute, Nottingham City Hospital, Nottingham, United Kingdom; Nottingham Trent University, Nottingham, United Kingdom.

P2-12-16 HER2 Expression Is the Major Risk Factor for Recurrence in pT1a-b,N0 Breast Cancer: A French Regional Population-Based Study of 671 Patients

P2-12-17 Prospective Evaluation of the Conversion Rate of HER2, ER and PR between Primary Tumours and Corresponding Metastases.
CONVERTER/GEICAM 2009-03 Study
Martinez de Dueñas E, Lluch A, Guerrero A, Chacon JJ, Perez R, Antolin S, Blancas I, Ferrer-Lozano J, Burgues O, Lopez A, Gonzalez-Angulo AM. P2-13-04 Testing Women with Invasive Lobular Breast Cancer for BRCA Mutations

Turco DL, Elsayegh N, Litton J, Hortobagyi GN, Arun B. MD Anderson Cancer Center, Houston, TX.

P2-13-05 Breast Cancer, BRCA Mutations and Attitudes Regarding Pregnancy and Preimplantation Genetic Diagnosis

Litton JK, Ezel C, Jackson MA, Muse JJ, Turco D, Schover LR, ThanEUart RL, Mattar D, Lu KH, Hortobagyi GN, Arun BK. The University of Texas MD Anderson Cancer Center, Houston, TX.

P2-13-06 Withdrawn

P2-13-07 Prevalence of Germline BRCA1 and BRCA2 Deletions Mutations in Brazilian Patients with High-Risk of Breast and Ovarian Cancer

Diz MDPE, Escobar KA, Guindalini CSC, Pasini FS, Snitkovski IM, Maistro S, Hof PMG, Federico MHH. Instituto do Cancer do Estado de Sao Paulo, Sao Paulo, Brazil; Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil.

P2-13-08 A Retrospective Study on Surveillance Behaviour and Prophylaxis after Genetic Testing for Hereditary Breast and Ovarian Cancer among High-Risk Chinese Females

Kwong A, Chu ATW. The University of Hong Kong, Hong Kong; The Hong Kong Hereditary Breast Cancer Family Registry, Hong Kong.

P2-13-09 First Statewide Experience with Telephone Delivery of Cancer Genetic Counseling

P2-13-10 Detection, Visualization and High Resolution Physical Mapping of Large Rearrangements by Molecular Combing in the Hereditary Breast Cancer Genes BRCA1 and BRCA2

P2-13-11 Follow Up of BRCA1/2 Carriers: The Spectrum of Cancer Diagnoses in Healthy at Risk Individuals (HTR), and in Cancer Survivors (CS)

P2-13-12 The impact of a directive counseling procedure in families with a BRCA1/2 gene mutation: uptake of predictive genetic testing and general outcome

Epidemiology, Risk, and Prevention: Ethnic/Racial Aspects

P2-14-01 Race, Response to Chemotherapy, and Outcome within Clinical Breast Cancer Subtypes
Tichy JP, Deal AM, Anders CK, Carey LA. UNC, Chapel Hill, NC.

P2-14-02 NCIC CTG MA.27: Clinical Tolerability and Overall Survival of Racial and Ethnic Minority Women on Aromatase Inhibitor Therapy
MoY B, Shepherd LE, Chapman J-AW, Le Maitre A, Gelmon KA, Elliott C, Ingle JN, Goss PE. Massachusetts General Hospital, Boston, MA; National Cancer Institute of Canada Clinical Trials Group, Kingston, ON, Canada; British Columbia Cancer Agency, Vancouver, BC, Canada; Mayo Clinic, Rochester, MN.

P2-14-03 A Comparison of Biologic Differences in Tumors in a Matched Cohort of Hispanic and Caucasian Women with Early-Stage Breast Cancer Using the 21-Gene Recurrence Score Assay
Lim EA, Hershman DL, Greenleese H, Crew KD, Mauer MA, Hibshoosh H, Kalinsky K. Columbia University Medical Center, New York, NY; Mailman School of Public Health, New York, NY.

P2-14-04 The Influence of Demographic, Psychosocial and Emotional Barriers to Screening for Colorectal and Ovarian Cancer among Latina Breast Cancer Survivors
Ramirez AG, Holden AE, San Miguel SL, Galloin KJ. UT Health Science Center at San Antonio, San Antonio, TX.

P2-14-05 Racial Differences in the Use of Adjuvant Chemotherapy for Breast Cancer in a Large Urban Integrated Health System
Simon MS, Lamerato L, Krajenta R, Booza J, Rutertbusch J, Kunz S, Schwartz K. Karmanos Cancer Institute at Wayne State University, Detroit, MI; Henry Ford Health System, Detroit, MI; Wayne State University, Detroit, MI.

P2-14-06 Clinical and Pathologic Characteristics of Haitian Breast Cancer Patients in a Tertiary Care Safety Net Hospital
Loch MM, Ross AA, Rosenberg C, Blanchard RA. Boston University Medical Center, Boston, MA; Boston University, Boston, MA.

P2-14-07 Ethnic Differences in Breast Cancer Molecular Subtypes and Survival Outcomes in a Multi-Ethnic Singaporean Population

P2-14-08 Hormone Receptor Status and Breast Cancer Survival among Hispanic and Non-Hispanic White Women over 10 Years of Follow-Up
Denkhoﬀ SR, Baumgartner KB, Yang D, Pinkston CM, Baumgartner RN. University of Louisville, Louisville, KY.

P2-14-09 Comparison between Spanish and Peruvian Patients with Early Breast Cancer

P2-14-10 Are There Variations in Invasive Tumour Characteristics between Different Ethnic Groups?
Barri B, Lo M, Gandamihardja T, Lewis J, Hogben K. Imperial College Healthcare NHS Trust, Charing Cross Hospital, London, United Kingdom.

P2-15-01 Surgical Patterns of Care after Magnetic Resonance Imaging in the Academic Setting in Patients with Operable Breast Cancer Treated with Neoadjuvant Systemic Therapy: A Secondary Analysis of TBRC 017
De Los Santos J, Cantor A, Mcguire K, Golshan M, Meric-Bernstam F, Horton J, Nanda R, Amos K, Forero A, Hudis C, Meszoely I, Hwang S. University of Alabama at Birmingham, Birmingham, AL; University of North Carolina Chapel Hill, Chapel Hill, NC; Dana-Farber Cancer Institute, Boston, MA; Duke University Medical Center, Durham, NC; Memorial Sloan Kettering Cancer Center, New York, NY; University of Pittsburgh Medical Center, Pittsburgh, PA; MD Anderson Cancer Center, Houston, TX; Vanderbilt University, Nashville, TN; University of Chicago, Chicago, IL; University of California at San Francisco, San Francisco, CA.

P2-15-02 Are We Performing More Mastectomies on Women Diagnosed with Invasive Breast Cancer?
Lo MCI, Hariri B, Gandamihardja T, Lewis J, Hogben K. Imperial College Healthcare NHS Trust, Charing Cross Hospital, London, United Kingdom.

P2-15-03 Nipple-Sparing Mastectomy for Breast Cancer in Japanese Experience: An Assessment from Long Follow-Up Data of Complication and Cancer Control in 806 Patients
Sakurai T, Sakurai T, Inuma T, Jinta E, Suzuma T, Yoshimura G. Wakayama Medical University Kihoku Hospital, Ito, Wakayama, Japan; Sakurai Breast Clinic, Wakayama, Japan; Kiwa Hospital, Japan; Kushimoto Ando Hospital, Japan; Kishiwada Shimin Hospital, Japan.

P2-15-04 Clinical Significance of Resection with Curative Intent for Isolated Pulmonary Metastases from Breast Cancer. Multi-Institutional Study in Japan
Sato N, Ohsumi S, Iwase T, Inaji H, Muzutani M, Nishimura R, Mukai H. Niigata Cancer Center Hospital, Niigata, Japan; National Hospital Organization Shikoku Cancer Center, Matsuyama, Japan; Cancer Institute Hospital, Tokyo, Japan; Osaka Medical Center for Cancer and Cardiovascular Diseases, Osaka, Japan; National Hospital Organization Osaka National Hospital, Osaka, Japan; Kumamoto City Hospital, Kumamoto, Japan; National Cancer Center East, Kashiwa, Japan.

P2-15-05 Excision of the Primary Tumour in Patients with Metastatic Breast Cancer - Will E2108 Provide the Deﬁnitive Answer?

P2-15-06 Breast Cancer Liver Metastases - Possibilities and Limits of Surgical Treatment
Narsanska A, Treskova I, Treskova V, Skalicky T, Sutnar A. University Hospital and Medical Faculty Pilsen, Charles University Prague, Pilsen, Czech Republic.

P2-15-07 The Need for Additional Surgeries to Adequately Excise Early Breast Cancers May Have a Negative Impact on Local Recurrence

P2-15-08 New Trends for Surgical Treatment of Large Breast Tumors
Zucca Matthes AG, Vieira RAC, Maki S, Menezes AC, Alvesca MA, Uemura G. Barretos’Cancer Hospital, Barretos, SP, Brazil; School of Medicine of Botucatu - UNESP, Botucatu, SP, Brazil; USP, Sao Paulo, SP, Brazil; University Barão de Mauá, Ribeirão Preto, SP, Brazil.

P2-15-09 Prospective Randomized Comparison of Conventional Instruments and the Harmonic Focus® Device in Breast-Conserving Therapy for Primary Breast Cancer
Bohm D, Kubita A, Lebrecht A, Schmidt M, Kolb H. University Medical Centre, Mainz, Germany.
P2-15-10 Do Patients with Incurable Advanced Breast Tumor and Distant Metastasis Derive Any Benefit from Primary Tumor Resection? 

P2-15-11 Outcomes of Corrective Procedure with Vycryl Mesh as an Oncoplastic Repair of the Breast 
Lim YA, Lee YO, Kim HY, Kim HS, Kang HJ, Kim LS. Hallym Sacred Heart Hospital, College of Medicine, Hallym University, Anyang, Gyeonggi-do, Korea.

P2-15-12 Management Strategy of Early-Stage Breast Cancer Patients: With or without Axillary Lymph Node Dissection 
Yamamoto D, Tanaka K, Tsubota Y, Yosida H, Kanematsu S. Kansai Medical University, Hirakata, Japan; Ribbon-Roze Tanaka Kanji Clinic, Osaka, Japan.

P2-15-13 Oncologic and Cosmetic Outcome in Breast Cancer Patients Who Underwent “Moving Window” Operation 
Ohno Y, Noguchi M, Nakano Y, Noguchi M, Kosaka T. Kanazawa Medical University, Japan.

P2-16-01 A Multi-Centre Prospective Cohort Study Evaluating Health Related Quality of Life after Types of Immediate Latissimus Dorsi (LD) Breast Reconstruction 

P2-16-02 How Well Do Medical Oncologists and Plastic Surgeons Communicate about Their Patients? 
Milucky J, Deal A, Wu R, McNally RS, Anders C, Lee C. University of North Carolina at Chapel Hill, Chapel Hill, NC.

P2-16-03 Outcomes of Nipple-Sparing Mastectomy (NSM) and Immediate Reconstruction 
Chidester JR, Olson JR, Poruk KE, Marenco JJ, Matsen CB, Neumayer L, Agarwal J, Loma Linda University Medical Center, Loma Linda, CA; University of Utah School of Medicine, Salt Lake City, UT.

P2-16-04 Abdominal Wall Stability and Flap Complications Are Unaltered Following Deep Inferior Epigastric Perforator (DIEP) flap Breast Reconstruction Despite Increasing Body Mass Index: Analysis of 418 Patients and 639 Flaps 
Ochoa O, Chrysopoulo M, Nastala C, Ledoux P, Pisano S. Plastics Reconstruction and Microsurgical Associates of South Texas, San Antonio, TX.

P2-16-05 Delay of Adjuvant Chemotherapy after Elective Mastectomy and Immediate Reconstruction in Breast Conservation Candidates: A Matched-Pair Analysis 
Batty PN, Riley EC, Pan J, Crew JB, Lee K, Jain D, Kruse BJ, Quillo AR, Rai S, Dragun AE. James Graham Brown Cancer Center, University of Louisville School of Medicine, Louisville, KY.

P2-16-06 A Systematic Review of Standardised Clinical Outcomes and Patient Reported Outcome Measures (PROMS) in Breast Reconstruction 
Winters ZE, Chaudhry A, Benson JR. University Hospitals Bristol NHS Foundation Trust, Bristol, South West, United Kingdom; Cambridge University Hospitals NHS Foundation Trust, Cambridge, East Anglia, United Kingdom.

P2-16-09 Nipple-Areolar Sparing Mastectomy: Utility of the Lateral Inframammary Incision in Immediate Implant-Based Reconstructions 

P2-16-10 Practice Variations in Post-Mastectomy Breast Reconstruction: What Are the Roles of Clinical Factors, Access Barriers, and Delayed Reconstruction? 
Cox D, Milucky J, Dominik R, Lee C. University of North Carolina at Chapel Hill, Chapel Hill, NC.

P2-16-11 Role of Proper Patient Counselling in Combination with Effect of Socioeconomic Deprivation on the Rate of Immediate Breast Reconstruction after Mastectomy 
Chakrabarti M, Fitzgerald C, Obbond C, Weiler-Mithof E, Doughty J, Romics, JrL. Victoria Infirmary Glasgow; Glasgow Royal Infirmary; Western Infirmary Glasgow.

P2-16-12 Skin Reducing Nipple Sparing Mastectomy - A Treatment Option for Patients with Significant Ptosis or Macromastia 
Ott Young A, Alizadeh K, Hodyl C, Pronovost M, Davenport T, Yale New Haven Health System, Fairfield, CT; Long Island Plastic Surgical Group, Garden City, NY; South Nassau Communities Hospital, Oceanside, NY.

P2-16-13 Life after Mastectomy without Breast Reconstruction - Are the Needs of Caribbean Women Different? 

P2-16-14 Skin Sparing Mastectomy and Immediate Latissimus Dorsi Flap Reconstruction: Patient Reported Outcome and Factors Affecting the Highest Patient Satisfaction 

P2-16-15 Oncological Safety and Survival Rate According to Reconstruction Surgery in Advanced Breast Cancer after Neoadjuvant Chemotherapy 
Kim WW, Lee JJ, Nam KH, Jung JH, Chae YS, Yang JD, Lee YH, Park HY. Kyungpook National University, Hyoysung Hospital.

P2-16-16 Nipple Sparing Mastectomy and Immediate Breast Reconstruction: Critical Appraisal of Five Year, Single Centre Outcomes 
Westbroek D, Karat I, Min-Hui H, Gukas I, Daoud R, Laidlaw IJ. Frimley Park Hospital, Portsmouth Road, Frimley, Surrey, United Kingdom.

P2-16-07 A Randomised Controlled Trial To Evaluate the Role of Tisseel, a Fibrin Sealant on Seroma Formation in Latissimus dorsi Breast Reconstruction 

P2-16-08 Expander-Implant-Reconstruction - Aesthetic Outcome and Patients' Satisfaction in a 10-Year-Period 
Kern PA, Zarth F, Rainer K, Scherag AS, Mahdi R. Breast Center Dusseldorf Louis Hospital, Dusseldorf, North Rhine Westfalia, Germany; University Clinic of Essen, Essen, North Rhine Westfalia, Germany; University of Duisburg-Essen, Essen, Germany.

P2-16-07 A Randomised Controlled Trial To Evaluate the Role of Tisseel, a Fibrin Sealant on Seroma Formation in Latissimus dorsi Breast Reconstruction 

P2-16-08 Expander-Implant-Reconstruction - Aesthetic Outcome and Patients' Satisfaction in a 10-Year-Period 
Kern PA, Zarth F, Rainer K, Scherag AS, Mahdi R. Breast Center Dusseldorf Louis Hospital, Dusseldorf, North Rhine Westfalia, Germany; University Clinic of Essen, Essen, North Rhine Westfalia, Germany; University of Duisburg-Essen, Essen, Germany.

P2-16-09 Nipple-Areolar Sparing Mastectomy: Utility of the Lateral Inframammary Incision in Immediate Implant-Based Reconstructions 

P2-16-10 Practice Variations in Post-Mastectomy Breast Reconstruction: What Are the Roles of Clinical Factors, Access Barriers, and Delayed Reconstruction? 
Cox D, Milucky J, Dominik R, Lee C. University of North Carolina at Chapel Hill, Chapel Hill, NC.

P2-16-11 Role of Proper Patient Counselling in Combination with Effect of Socioeconomic Deprivation on the Rate of Immediate Breast Reconstruction after Mastectomy 
Chakrabarti M, Fitzgerald C, Obbond C, Weiler-Mithof E, Doughty J, Romics, JrL. Victoria Infirmary Glasgow; Glasgow Royal Infirmary; Western Infirmary Glasgow.

P2-16-12 Skin Reducing Nipple Sparing Mastectomy - A Treatment Option for Patients with Significant Ptosis or Macromastia 
Ott Young A, Alizadeh K, Hodyl C, Pronovost M, Davenport T, Yale New Haven Health System, Fairfield, CT; Long Island Plastic Surgical Group, Garden City, NY; South Nassau Communities Hospital, Oceanside, NY.

P2-16-13 Life after Mastectomy without Breast Reconstruction - Are the Needs of Caribbean Women Different? 

P2-16-14 Skin Sparing Mastectomy and Immediate Latissimus Dorsi Flap Reconstruction: Patient Reported Outcome and Factors Affecting the Highest Patient Satisfaction 

P2-16-15 Oncological Safety and Survival Rate According to Reconstruction Surgery in Advanced Breast Cancer after Neoadjuvant Chemotherapy 
Kim WW, Lee JJ, Nam KH, Jung JH, Chae YS, Yang JD, Lee YH, Park HY. Kyungpook National University, Hyoysung Hospital.

P2-16-16 Nipple Sparing Mastectomy and Immediate Breast Reconstruction: Critical Appraisal of Five Year, Single Centre Outcomes 
Westbroek D, Karat I, Min-Hui H, Gukas I, Daoud R, Laidlaw IJ. Frimley Park Hospital, Portsmouth Road, Frimley, Surrey, United Kingdom.

P2-17-01 Influence of Delayed Zoledronic Acid Initiation on Disease-Free Survival in Postmenopausal Women with Endocrine Receptor-Positive Early Breast Cancer Receiving Adjuvant Letrozole: Exploratory Analyses from the ZO-FAST Trial 
Coleman R, De Boer R, Eidtmann H, Neven P, von Minckwitz G, Martin N, Modi A, Bunded N. University of Sheffield, Sheffield, United Kingdom; Royal Melbourne Hospital, Victoria, Australia; University Frauenklinik, Kiel, Germany; UZ Gasthuisberg, Leuven, Belgium; German Breast Group, Frankfurt, Germany; Novartis Oncology, East Hanover, NJ; University Hospital of South Manchester NHS Foundation Trust, Manchester, United Kingdom.
**P2-17-02** Increased Progression Free and Overall Survival in Breast Cancer Patients with Menopausal Symptoms or Arthralgia/Myalgia during Adjuvant Treatment with Exemestane or Tamoxifen - Results of the German TEAM Trial
Hadji P, Kieback DG, Hasenburg A, Tams J, Ziller M, Philippus University, Marburg, Germany; Eiblandkliniken, Meissen, Germany; University Hospital Freiburg, Freiburg, Germany; ICRC-Weyer GmbH, Berlin, Germany.

**P2-17-03** Incomplete Uptake and Diminished Adherence to Endocrine Therapy in Women with Hormone Receptor Positive Breast Cancer 4 Years from Diagnosis: An Australian Cohort Study
Bell RJ, Fradkin P, Schwarz M, Davis SR. Monash University, Melbourne, VIC, Australia; Alfred Health, Melbourne, VIC, Australia.

**P2-17-04** Induction of Tamoxifen Metabolism by Rifampicin: A Worrying Drug-Drug Interaction
Binkhorst L, Loos WJ, de Jongh FE, Hamberg P, Goboai Moghadam-Helmantel IM, Jager A, Seynaeve C, Verweij J, van Gelder T, Mathijssen RH. Erasmus University Medical Center, Rotterdam, Netherlands; Erasmus University Medical Center - Daniel den Hoed Cancer Center, Rotterdam, Netherlands; Iziak Hospital, Rotterdam, Netherlands; Sint Franciscus Gasthuis, Rotterdam, Netherlands.

**P2-17-05** Antiprogestin Prolexel Suppresses Proliferation of Aromatase Overexpressing and Letrozole Resistant T47D Breast Cancer Cells

**P2-17-06** Patterns of Bone Density Evaluation in a Community Population Treated with Aromatase Inhibitors

**P2-17-07** Construction of a Predictive Model of Probability of Ovarian Function Recovery in a Series of Premenopausal Breast Cancer Patients with Chemotherapy-Induced Amenorrhea Switched to an Aromatase Inhibitor (AI) after Adjuvant Tamoxifen Perez-Fidalgo JA, Bermejo B, Pons V, Guzman C, Bosch A, Lluch A. Hospital Clinico Universitario, Valencia, Spain; Pfizer Spain, Alcobendas (Madrid), Spain.

**P2-17-08** Prospective Study of Aromatase Inhibitor Induced Bone Loss and Lipid Levels in Early Postmenopausal (PM) Hormone Receptor Positive (HR+) Breast Cancer (BC) Patients Treated with Adjuvant Letrozole Extended beyond 5 Years (yrs)

**P2-17-09** A Prospective Assessment of Loss of Grip Strength by Baseline BMI in Breast Cancer Patients Receiving Adjuvant Aromatase Inhibitors or Tamoxifen

**P2-18-01** The Magnitude of Trastuzumab Benefit in HER2-Positive (HER2+) Lobular Breast Carcinoma (BC): Results of a HERA Trial Sub-Group Analysis
Metzger O, Ploeger M, de Azambuja E, Viale G, Leyland-Jones B, Dowsett M, Gelber R, Gregoir E, Lui S, Sotiroiu C, Piccart M. Institut Jules Bordet, Université Libre de Bruxelles, Brussels, Belgium; Frontier Science (Scotland) Ltd, Kincraig, Kingsussie, United Kingdom; European Institute of Oncology, Milan, Italy; Emory University, Atlanta, Royal Marsden Hospital and Institute of Cancer Research, London, United Kingdom; Dana-Farber Cancer Institute, Boston; Roche, Basel, Switzerland.

**P2-18-02** Cardiovascular Outcomes of Patients on Adjuvant Weekly Paclitaxel (T) and Trastuzumab (H) for Node Negative, HER2 Positive Breast Cancer (BCA)
Dang C, Tolaney S, Najita J, Gelman R, Yardley D, Marcom K, Albain K, Rugo H, Miller K, Ellis M, Shapira I, Wolff A, Carely L, Vahdat L, Burdette-Radoux S, Budd T, Krop I, Burstein H, Hudis C, Winer E. Memorial Sloan-Kettering Cancer Center; Dana-Farber Cancer Institute; Tennessee Oncology and Sarah Cannon Research Institute; Duke University; Loyola University Medical Center; University of California-San Francisco Comprehensive Cancer Center; Indiana University; Washington University; North Shore-Long Island Jewish Medical Center; Johns Hopkins University; University of North Carolina; Weill Cornell Medical College; University of Vermont; Cleveland Clinic Taussig Cancer Institute Case.

**P2-18-03** Systemic Adjuvant Treatment of T1a and T1b N0M0 HER2+ Breast Carcinomas; an AERIO/UNICANSEY Study

**P2-18-04** Pilot Evaluation of Bevacizumab (Bev) in Combination with Docetaxel (T) and Cyclophosphamide (C) as Adjuvant Treatment (AdjRx) for Patients (pts) with Early Stage (ES) Breast Cancer (BrCa)

**P2-18-05** Cardiotoxicity Risks of Adjuvant Trastuzumab in Asian Breast Cancer Patients
Shih V, Chan A, Sim MH, Teo C, Chen W, Wong ZW. National Cancer Centre, Singapore; National University of Singapore, Singapore.

**P2-18-06** Conventional Trastuzumab Is an Antagonist of Natural Killer Cells: Making the Case for Fucose-Depleted Trastuzumab
Listinskij JJ, Siegal GP, Listskiny CM. University of Alabama at Birmingham, Birmingham, AL; Case Western Reserve University, Cleveland, OH.

**P2-19-01** Impact of Zoledronic Acid on Fractures, Bone Mineral Density and Bone Remodeling in the AZURE Trial (BIG 01-04)
Coleman R, Woodward E, Turner L, Marshall H, Collinson M, Dodwell D, Davies C, Bell R, Cameron D, Brown J. University of Sheffield, Sheffield, United Kingdom; University of Leeds, Leeds, United Kingdom; Andrew Love Cancer Centre, Geelong, Victoria, Australia; Western General Hospital, Edinburgh, United Kingdom.

**P2-19-02** Multidisciplinary Treatment of Pregnancy-Associated Breast Cancer
Meisel JL, Economy KE, Zabicki-Calvillo K, Gelber S, Kereakoglow S, Winer EP, Partridge AH, Mayer EL, Brigham and Women’s Hospital, Boston, MA; Dana-Farber Cancer Institute, Boston, MA.
**PD03-02** Prognostic and Predictive Predictors for Triple Negative Breast Cancer
Karn T, Pusztai L, Ruckhaberle E, Liedtke C, Schmidt M, Müller V, Galá T, Hänker L, Ahr A, Holtrich U, Ahr A, Kaufmann M. Goethe University, Frankfurt, Germany; University of Texas MD Anderson Cancer Center, Houston, TX; Institut Paoli-Calmettes (IPC), Marseille, France; World IBC Consortium; Contributed Equally.

**PD03-03** Identification of Transcription Factors Critical for the Growth of Basal Breast Cancer
Shepherd JH, Mazumdar A, Tsimelzon A, Hilsenbeck SG. Brown Phil. Baylor College of Medicine, Houston, TX; The University of Texas MD Anderson Cancer Center, Houston, TX.

**PD03-04** SuperPathway Analyses of Luminal and Basaloid Breast Cancers from the Cancer Genome Atlas (TCGA) Program
Yau C, Benz S, Sanborn JZ, Stuart J, Hausler D, Benz C. Buck Institute for Research on Aging, Novato, CA; UC Santa Cruz, Santa Cruz, CA.

**PD03-05** Withdrawn

**PD03-06** Basal-Like Breast Tumors Are Associated with Frequent Micro Genomic Aberrations in Important Cancer Genes
Chao H-H, He X, Perez CM. University of North Carolina - Chapel Hill, Chapel Hill, NC.

**PD03-07** Breast Cancer Heterogeneity and Treatment Resistance: Clues from Metaplastic Tumors
Felding-Habermann B, O’Sullivan DM, Lorger M, MacDermid D, Fernandez-Santidrian A, Steele JB, Telli ML, Jeffrey SS, Murray S, Torkamani A, Cunillie H, Vaughn S. The Scripps Research Institute, La Jolla, CA; Scripps Clinic, La Jolla, CA; Stanford University, Stanford, CA; Translational Genomics Research Institute, Phoenix, AZ.

**PD03-08** BRCA1-Like Triple Negative Tumors: Clinicopathological Variables and Chemosensitivity to Alkylating Agents
Wesseling J, Lips EH, Donk AMM, Smits RM, van Rijn CCM, Mulder L, Laddach N, Savola SA, Wessels LFA, Nederlof PM, Rodenhuis S, Imholz ALT. Netherlands Cancer Institute-Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands; Deventer Hospital, Deventer, Netherlands; MRC-Holland, Amsterdam, Netherlands.

**PD03-09** Breast Cancer Recurrence Risk Probed by Whole Transcriptome Next Generation Sequencing in 136 Patients

**PD03-10** Gene Modules and Response to Neoadjuvant Chemotherapy in Breast Cancer: A Meta-Analysis

**PD04-01** Predictors of Recovery of Ovarian Function during Aromatase Inhibitor (AI) Therapy
Henry NL, Banerjee M, Hayden J, Yakim E, Schott AF, Steams V, Partridge AH, Hayes DF. University of Michigan Medical School, Ann Arbor, MI; Johns Hopkins School of Medicine; Dana Farber Cancer Institute.

**PD04-02** Recovery of Ovarian Function in Breast Cancer Patients with Chemotherapy-Induced Amenorrhea Receiving Anastrozole in the Dutch DATA Study
Tjan-Heijnen VC, Smorenburg CH, de Graaf H, Erdkamp F, Honkoop A, Wals J, van Gastel S, van der Sangen M, Seynaeve C, Nortier JW, Borm G. Maastricht University Medical Centre, Netherlands; Medical Centre Alkmaar, Netherlands; Medical Centre Leeuwarden, Netherlands; Orbis Medical Centre, Netherlands; Isala Clinics, Netherlands; Artrium Medical Centre, Netherlands; Comprehensive Cancer Centre Netherlands Nijmegen, Netherlands; Catharina-Hospital, Netherlands; Erasmus University Medical Centre, Netherlands; Leiden University Medical Centre, Netherlands; Redbud University Nijmegen Medical Centre, Netherlands.
PD04-05  Body Image Issues in Young Breast Cancer Patients: The Impact of Chemotherapy, Hormone Treatment, and Surgery
Rosenberg SM, Tamimi RM, Gelber S, Kenakaloglu S, Borgan V, Currie S, Schapira L, Winer E, Partridge A. Harvard School of Public Health, Boston, MA; Dana-Farber Cancer Institute, Boston, MA; University of Colorado Cancer Center, Denver, CO; Beth Israel Deaconess Medical Center, Boston, MA; Massachusetts General Hospital, Boston, MA.

PD04-06  A Randomised Controlled Trial of Quality of Life and Fatigue after Support Group Intervention in Primary Breast Cancer Patients
Granstam Bjomeklett H, Lindemalm C, Ojutkangas M-L, Berglund A, Letocha H, Strang P, Bergkvist L. Centre for Clinical Research, Västerås, Sweden; Cancer Centre Karolinska, Solna, Sweden; Centre for Clinical Research, Central Hospital, Västerås, Sweden; Karolinska Institute, STH, Stockholm, Sweden; Karolinska Institute, Stockholm, Sweden.

PD04-07  Cognitive Function and Reproductive Hormones in Women Receiving Anastrozole
Bender CM, Sereika SM, Ryan CM, Berga SL. University of Pittsburgh, Pittsburgh, PA; Emory University, Atlanta, GA.

PD04-08  Altered Neurocognitive Responses Prior to Adjuvant Therapy for Breast Cancer: A Functional MRI Analysis of the Impact of Worry and Fatigue
Cimprich B, Hayes DF, Askren MK, Jung MS, Berman MG, Therrien B, Reuter-Lorenz PA, Zhang M, Peltier S, Noll DC. University of Michigan, Ann Arbor, MI.

PD04-09  Self-Reported Cognitive Attributes and Fatigue Improve over Long-Term Follow-Up in Breast Cancer Survivors; Some Cognitive Attributes Are Worse in Breast Cancer Survivors Than in Non-Cancer Controls
Hsu T, Ennis M, Hood N, Goodwin PJ. University of Toronto, Toronto, ON, Canada; Applied Statistician, Markham, ON, Canada; Mount Sinai Hospital, Toronto, ON, Canada; Mount Sinai and Princess Margaret Hospitals, Samuel Lunenfeld Research Institute, University of Toronto, Toronto, ON, Canada.

9:00 am–9:30 am  PLENARY LECTURE 2
Exhibit Hall D

Macrophages as Novel Targets for Therapy in Breast Cancer
Lisa M. Coussens, PhD
University of California San Francisco
San Francisco, CA

9:30 am–11:15 am  GENERAL SESSION 3
Exhibit Hall D

9:30  S3-1. Update of International Breast Cancer Study Group trial 23-01 to compare axillary dissection versus no axillary dissection in patients with clinically node negative breast cancer and micrometastases in the sentinel node

9:45  S3-2. Neoadjuvant chemotherapy adapted by interim response improves overall survival of primary breast cancer patients – results of the GeparTrio Trial

10:00  S3-3. Association of PTEN loss and PIK3CA mutations on outcome in HER2- metastatic breast cancer patients treated with first-line lapatinib plus paclitaxel or paclitaxel alone
Xu B-H, Guan Z-Z, Shen Z-Z, Tong Z-S, Yang J-Y, DeSilvio M, Leith G, Ellis C. Cancer Hospital, CAMS & PUMC, Sun Yat-Sen Medical University Cancer Center, Shanghai Cancer Center, Fudan University; Tianjin Medical University Cancer Institute and Hospital; Hospital Affiliated to Military Medical Science; Beijing 301 PLA Hospital; GlaxoSmithKline.

10:15  S3-4. ER downregulation with fulvestrant in combination with pan-PI3K inhibitor BKM120 synergizes against ER+/PI3K-mutant breast cancer xenografts in vivo
Miller TW, Fox EM, Balke JM, Meszoly IM, Sanders ME, Kuba MG, Wagle N, Garraway LA, Maira S-M, Arteaga CL. Vanderbilt University, Nashville, TN; Dana-Farber Cancer Institute, Boston, MA; Novartis Inst. for Biomedical Research, Basel, Switzerland.

10:30  S3-5. Next generation sequencing reveals co-activating events in the MAPK and p13k/akt pathways in metastatic triple negative breast cancers

10:45  S3-6. Neoadjuvant chemotherapy of paclitaxel with or without Rad001: Results of the non-responder part of the GEPRIQUINTO study (GBG 44)

11:00  S3-7. Everolimus for postmenopausal women with advanced breast cancer: updated results of the BOLERO-2 phase III trial
Hortobagyi GN, Piccart M, Rugo H, Harris C, Campone M, Noguchi S, Grant M, Pritchard KI, Vittori L, Mukhopadhyay P, Sahnoud T, Lebwohl D, Baselga J. The University of Texas, MD Anderson Cancer Center, Houston, TX; Jules Bordet Institute (Institut Jules Bordet), Brussels, Belgium; University of California, San Francisco Helen Diller Family Comprehensive Cancer Center, UCSF, San Francisco, CA; Sarah Cannon Research Institute, Nashville, TN; Institut de Cancérologie de l’Ouest - René Gauduchaud, Centre de Recherche en Cancérologie, Nantes Saint Herblain, France; Osaka University, Department of Breast and Endocrine Surgery, Osaka, Japan; Comprehensive Cancer Center, Medical University of Vienna, Vienna, Austria; Sunnybrook Odette Cancer Centre and the University of Toronto, Toronto, Canada; Novartis Pharma AG, Basel, Switzerland; Novartis Pharmaceuticals Corporation, East Hanover, NJ, Massachusetts General Hospital Cancer Center and Harvard Medical School, Boston, MA.
11:15 am–12:00 pm
WILLIAM L. MCGUIRE MEMORIAL LECTURE
Exhibit Hall D
Sponsored by Cancer Therapy & Research Center
Translating genomic insights into improved breast cancer management
Joe Gray, PhD
Oregon Health & Science University
Portland, OR

12:00 pm–1:35 pm
LUNCH

12:15 pm–1:15 pm
PRODUCT THEATRE
Exhibit Hall C – Exhibit Area
Abraxane
Sponsored by Celgene Corporation

12:30 pm–1:35 pm
CASE DISCUSSION 1
Ballroom A
Moderator: Mothaffar Rimawi, MD
Baylor College of Medicine
Houston, TX
Panelists:
John Benson, MD
Cambridge University
Cambridge, UNITED KINGDOM
Lisa Carey, MD
University of North Carolina
Chapel Hill, NC
Daniel Hayes, MD
University of Michigan
Ann Arbor, MI
Wendy Woodward, MD
MD Anderson Cancer Center
Houston, TX
Kay Wissmann
IL Deadline Action Network (NBCC)
Carbondale, IL

12:30 pm–1:35 pm
BASIC SCIENCE FORUM
Ballroom B
Estrogen Receptor
Moderator: Suzanne A.W. Fuqua, PhD
Baylor College of Medicine
Houston, TX
Steroid receptor cistromics
Myles Brown, MD
Dana-Farber Cancer Institute
Boston, MA
Nuclear receptor coactivators: Physiology and disease
Bert W. O’Valley, MD
Baylor College of Medicine
Houston, TX

1:45 pm–3:15 pm
MINI-SYMPOSIUM 1
Ballroom B
Tumor Heterogeneity and Metastasis
Moderator: Rachel Schiff, PhD
Baylor College of Medicine
Houston, TX
Imaging cancer invasion and experimental therapy response:
How to overcome resistance niches
Peter Friedl, MD, PhD
Radboud University Nijmegen
HB Nijmegen, NETHERLANDS
Tumor-engrained neutrophils inhibit breast cancer metastasis
seeding in the lung
Robert Beneza, PhD
Memorial Sloan-Kettering Cancer Center
New York, NY
Tumor heterogeneity and metastasis
Matthew J. Ellis, MB, BChir, PhD
Washington University School of Medicine
St. Louis, MO

1:45 pm–3:15 pm
MINI-SYMPOSIUM 2
Exhibit Hall D
Environmental Exposures, Epigenetics and Epidemiology
Moderator: Cheryl Lyn Walker, PhD
UT MD Anderson Cancer Center
Houston, TX
Epidemiology of preeclampsia and other early exposures on breast cancer risk
Michele R. Forman, PhD
UT Austin
Austin, TX
Environ exposures, epigenetics & epidemiology influence of environmental factors on pubertal maturation and breast cancer etiology
Robert A. Hiatt, MD, PhD
University of California, San Francisco
San Francisco, CA
Breast cancer and the environment: Developmental reprogramming of cancer susceptibility by early life environmental exposures
Cheryl Lyn Walker, PhD
UT MD Anderson Cancer Center
Houston, TX

3:15 pm–5:15 pm
GENERAL SESSION 4
Exhibit Hall D
Overdiagnosis in breast cancer screening: Methodological considerations of current estimates
Smith RA, Duffy SW. American Cancer Society, Atlanta, GA; Queen Mary University of London, London, United Kingdom.
Risk of contralateral breast cancer in BRCA1/2 carriers compared to non-BRCA1/2 carriers in an unselected cohort
van den Broek AJ, Schmidt MK, Tollenaar RAEM, van ’t Veer LJ, van Leeuwen FE. Netherlands Cancer Institute, Amsterdam, Netherlands; Leiden University Medical Center, Leiden, Netherlands.
3:45  S4-3. Prospective comparison of risk assessment tools in early breast cancer (recurrence score, uPA/PAI-1, central grade, and luminal subtypes): Final correlation analysis from the phase III WSG-plan B trial
Gluz O, Kreipe H, Degenhardt T, Kates R, Christgen M, Liedtke C, Shakh S, Clemens M, Markmann S, Uefer C, Augustin D, Thomssen C, Nitz U, Harbeck N. West German Study Group, Moenchengladbach, Germany; Medizinische Hochschule, Hannover, Germany; University of Muenster, Muenster, Germany; Genomic Health Inc, Redwood City; Klinikum Mutterhaus, Trier, Germany; Klinikum Suedstadt, Rostock, Germany; Gynecology Practice, Hildesheim, Germany; Klinikum Deggendorf, Deggendorf, Germany; University of Halle/Saale, Halle/Saale, Germany; Bethesda Clinics, Moenchengladbach, Germany; University of Cologne, Cologne, Germany.

4:00  S4-4. Clarifying the risk of breast cancer in women with atypical breast lesions
Coopey SB, Mazzola E, Buckley JM, Sharko J, Belli AK, Kim EMH, Polufriasgoff F, Parmigiani G, Garber JE, Smith BL, Gadd MA, Specht MC, Guidi AJ, Roche CA, Hughes KS. Massachusetts General Hospital, Boston, MA; Dana-Farber Cancer Institute, Boston, MA; Newton-Wellesley Hospital, Newton, MA; Wayne State University, Detroit, MI.

4:15  S4-5. Comparison of PAM50 risk of recurrence (ROR) score with oncostyoxDx and IH4C for predicting residual risk of DFS and distant DFS after endocrine therapy: A TransATAC study

4:30  S4-6. A quantitative multigene RT-PCR assay for predicting recurrence risk after surgical excision alone without irradiation for ductal carcinoma in situ (DCIS): A prospective validation study of the DCIS score from ECOG ES194
Solin LJ, Gray R, Baehner FL, Butler S, Badve S, Yoshizawa C, Shakh S, Hughes L, Sledge G, Davidson N, Perez EA, Ingle J, Sparano JA, Wood W. Albert Einstein Medical Center, Philadelphia, PA; Eastern Cooperative Oncology Group, Boston, MA; Genomic Health, Inc., Redwood City, CA; Indiana University, Indianapolis, IN; The Hope Center, Cartersville, GA; University of Pittsburgh, Pittsburgh, PA; Mayo Clinic Jacksonville, Jacksonville, FL; Mayo Clinic Rochester, Rochester, MN; Albert Einstein College of Medicine Bronx, NY; Emory University, Atlanta, GA.

4:45  S4-7. Results of a randomized, double-blind, multicenter, placebo-controlled study of adjuvant lapatinib in women with early-stage ErbB2-overexpressing breast cancer
Goss P, Smith I, O’Shaughnessy J, Ejlertson B, Kaufmann M, Boyle F, Buzdar A, Fumoleau P, Gradishar W, Martin M, Moyer B, Piccart-Gebhart M, Pritchard K, Aktan G, Rappold E, Williams L, Finkelstein D, Massachusetts Gen Hosp, Boston MA; Royal Marsden Hosp, London, UK; Baylor Sammons Cancer Ctr, Dallas TX; Rigshospitalet, Copenhagen, Denmark; JW Goethe-Universitat, Frankfurt, Germany; Royal North Shore Hosp, Sydney, Australia; UT MD Anderson Cancer Ctr, Houston TX; Centre GF Leclerc, Dijon, France; Northwestern Univ, Chicago IL; Hosp Univeristario San Carlos, Madrid, Spain; Jules Bordet Inst, Brussels, Belgium; Toronto-Sunnybrook Regional Cancer Ctr, Toronto, Ontario; GlaxoSmithKline, Collegeville PA and Uxbridge, UK.

5:00  S4-8. First results of AVEREL, a randomized phase III trial to evaluate bevacizumab (BEV) in combination with trastuzumab (H) + docetaxel (DOC) as first-line therapy for HER2-positive locally recurrent/metastatic breast cancer (LR/mBC)

5:15 pm–7:00 pm  POSTER SESSION 3 & RECEPTION
Exhibit Halls A-B

Tumor Cell Biology: Novel/Emerging Therapeutic Targets
P3-01-01  Geminin Overexpression Prevents the Completion of Topoisomerase Ila Chromosome Decatenation Leading to Aneuploidy in Human Mammary Epithelial Cells
Eshamy HM, Gardner L, Malik R, Shinmu Y, Mullins N. University of Mississippi Medical Center, Jackson, MS.

P3-01-02  EC 304: A Novel Progesterone Receptor (PR) Antagonist Inhibits Transcription and Induces Cell Cycle Arrest in T47D Breast Cancer Cells
Blakkaran JS, Kesavaram N, Nicksk JJ, VandeBerg JL, Nair HB. Texas Biomedical Research Institute, San Antonio, TX, Evestra, Inc., San Antonio, TX.

P3-01-03  The Hominoid-Specific Gene SHON Is Oncogenic in Human Mammary Carcinoma

P3-01-04  Differential Impact of Gefitinib and PLX4720 on Proliferation of MCF10A and Isogenic Lines as Measured with a Metastasis Expression Score

P3-01-05  Wnt Signaling: A New Target for Treatment and Prevention of Endocrine Resistant Breast Cancer?
Micaleff RA, Smith C, Barrow D, Nicholson RI, Gee JMW, Barratt-Lee PJ, Hiscox SE. Cardiff University, Cardiff, Wales, United Kingdom; Velindre NHS Trust, Cardiff, Wales, United Kingdom.

P3-01-06  NF-kB Inhibition Promotes Radiosensitivity of Breast Cancer Cells in Three-Dimensional Culture through Abating β1-Integrin Expression
Ahmed KM, Zhang H, Park CC. Ernest Orlando Lawrence Berkeley National Laboratory, Berkeley, CA.

P3-01-07  A Murine Xenograft Model for the Study of Ciclooxygenase-2 Expression and Function in Human Breast Cancer
Solano AR, Orlando UD, Garona J, Ripoli GV, Duarte AB, Maloberti PM, Avagnina MA, Alonso DF, Gomez DE, Pedesta EJ. School of Medicine University of Buenos Aires, Buenos Aires, Argentina; University of Quilmes, Quilmes, Buenos Aires, Argentina; Center of Medical Education and Clinical Investigation Norteño Quirino, Buenos Aires, Argentina.
P3-01-08  In Vitro and In Vivo Antitumor Activity of the Aurora and Angiogenic Kinase Inhibitor ENMD-2076 in Triple-Negative Breast Cancer Models
Diamond JR, Erkkhardt SG, Tan AC, Selby HM, Newton TP, Pitts TM, Bray MR, Fletcher GC, Tentler JJ. University of Colorado Cancer Center, Aurora, CO; EntreMed, Inc, Toronto, ON, Canada.

P3-01-09  Oncogenic Activation of HSF1 Enables the Malignant Progression of Breast Carcinoma
Mendillo ML, Santagata S, Koeva M, Fraenkel E, Ince TA, Whitessell L, Lindquist S. Whitehead Institute for Biomedical Research, Cambridge, MA; Brigham and Women’s Hospital, Boston, Boston, MA; Massachusetts Institute of Technology, Cambridge, MA; University of Miami Miller School of Medicine, Miami, FL; Howard Hughes Medical Institute, Cambridge, MA.

P3-01-10  DMBA-Breast Cancer in Diet Induced Obesity (DIO) and Lean Mice Is Related to Leptin Signaling
Gillespie C, Penichet MG, Colbert LS, McGlothen T, Guo S, Zhou W, Gonzalez-Perez RR. Morehouse School of Medicine, Atlanta, GA; Shenyang Medical College, Liaoning Pro, P.R., China.

P3-01-11  Increased Gene Copy Number of c-KIT and VEGFR2 at 4q12 in Primary Breast Cancer Is Related to an Aggressive Phenotype and Impaired Prognosis

P3-01-12  Prognostic Impact of RANK, RANKL and OPG Gene Expression in ER Positive Primary Breast Cancer
Ruckhaeberle E, Mueller V, Schmidt M, Saengar N, Hanker L, Gaetje R, Ahr H, Holtrich U, Karm T, Rooy A, Kaufmann M. Department of Gynecological Oncology, Frankfurt, Germany; Department of Obstetrics and Gynecology, Hamburg, Germany; Department of Obstetrics and Gynecology, Mainz, Germany; Department of Obstetrics and Gynecology, Hornburg/Saar, Germany.

P3-01-13  Leptin Modulates the Response to Tamoxifen Treatment in ER-Positive Breast Cancer Cell Lines
Yoon CK, Han W, Kim S-W, Kim DW, Kang E, Noh D-Y. Seoul National University Bundang Hospital, Seoul National University College of Medicine, Seongnam, Korea; Seoul National University College of Medicine, Seoul, Korea.

P3-01-14  RANK and RANK Ligand (RANKL) Expression in Invasive Breast Carcinoma and Human Breast Cancer Cell Lines

P3-01-15  The Role of Src Homology Phosphotyrosyl Phosphatase-2 in Basal-Type/Triple-Negative Breast Cancer - Implications for Targeted Therapy
Agase YM, Matafka F, Hartman ZR. West Virginia University School of Medicine, Morgantown, WV.

P3-01-16  Expression of Basal Markers in Correlation with PTEN and BRCA 1 in Triple Negative Breast Carcinomas (TN) Treated with Chemotherapy Versus PARP Inhibitors
Chisvukula M, Carter G, Puhalisa S, Magee Women’s Hospital of Pittsburgh, Pittsburgh, PA; Magee Women’s Hospital of UPMC, Pittsburgh, PA.

P3-01-17  Cadherin-11 as a therapeutic target in poor prognosis breast cancers
Assensia S, Gudny Audvil JM, Dakshnamurthy S, Hampel C, Brown M, Anastadiadis P, Brenner M, Byers SW. Lombardi Comprehensive Cancer Research Center, Georgetown University Medical Center, Washington, DC; Mayo Clinic, Jacksonville, FL; Brigham and Women’s Hospital, Harvard University, Boston, MA.

P3-01-18  Amplification of Anaplastic Lymphoma Kinase (ALK) as a common genetic alteration in Inflammatory Breast Cancer
Robertsion FM, Petricoin EF, Chu X, Mu Z, Jin J, Circo R, Fernandez SV, Albaum K, Zook M, Sun G, Wulkkhuji J, Liotta LA, Ye Z, Krishnamurthy S, Luo AZ, Lui H, Wright MC, Woodward WA, Banks SH, Cristofanilli M. The University of Texas MD Anderson Cancer Center, Houston, TX; George Mason University, Manassas, VA; Fox Chase Cancer Center, Philadelphia, PA; The University of Nevada School of Medicine and Nevada Cancer Institute, Reno and Las Vegas, NV.

P3-01-19  PEGPH20 depletion of pericellular hyaluronan sensitizes high hyaluronan-producing tumor cells in antibody-dependent cell-mediated cytotoxicity

Tumor Cell Biology: New Agents and Mechanisms

P3-02-01  A Novel Bispecific, Hexavalent, Antibody (HexAb) Inhibits Anchorage-Independent Growth and Reduces Invasiveness of Triple-Negative Breast Cancer Cell Lines In Vitro

P3-02-02  Novel Ranpirnase-Based ImmunorNases Display Potent Cytotoxicity in Diverse Human Breast Cancer Cell Lines

Tumor Cell Biology: MicroRNAs

P3-03-01  Low Expression of microRNA-210 Is an Independent Good Prognostic Factor in Japanese Triple-Negative Breast Cancer Patients
Toyama T, Kondo N, Endo Y, Sugihara H, Yoshimoto N, Iwasa M, Takahashi S, Iwase H, Fuji Y, Yamashita H. Nagoya City University Graduate School of Medical Sciences, Nagoya, Aichi, Japan; Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan.

P3-03-02  Higher Expression Levels of Circulating miR-21, miR-19a and miR-10b Are Associated with High Risk Features in Breast Cancer
Anfossi S, Giordano A, Cohen EN, Gao H, Cristofanilli M, Valero V, Alvarez RH, Hortobagyi GN, Woodward W, Ueno NT, Lee B-N, Reuben JM. The University of Texas MD Anderson Cancer Center, Houston, TX; Fox Chase Cancer Center, Philadelphia, PA.

P3-03-03  Congruence between Patterns of microRNA Expression and Histologic Grading of Invasive Breast Carcinomas
Ellsworth DL, Croft DT, Field LA, Deyarman B, Kane J, Ellsworth RE, Hooke JA, Shriver CD. Windber Research Institute, Windber, PA; George Mason University, Manassas, VA; Fox Chase Cancer Center, Philadelphia, PA.

P3-03-04  Targeted Modulation of HER Receptor Signaling in Breast Cancer Using miR-21

P3-03-05  Identification of miRNAs and Their Associated Target Genes Involved in Endocrine Resistance in Breast Cancer
Healy NA, Creighton CJ, Fu X, Tismatch A, Hilsenbeck SG, Miller N, Kerin MJ, Osborne CK, Schiff R. Baylor College of Medicine, Houston, TX; National University of Ireland, Galway, Ireland.
P3-03-06  Regulation of microRNA Expression by Autocrine Human Growth Hormone in Breast Cancer Cells
Pertzinger M, Shasti BG, Liu D-X, Zhu T, Lobe PE, Perry JK. University of Auckland, Auckland, New Zealand; University of Science and Technology of China, Hefei, Anhui, China; National University of Singapore, Singapore.

P3-03-07  A Novel Approach Integrating microRNA and mRNA Signatures of HMAPK Signaling Is Highly Predictive of ER-Status and Outcome in Breast Cancer - Role of HMAPK microRNAs in Repression of ER and p27
Miller P, Clarke J, Koru-Sengul T, Brinkman J, El-Ashy D. University of Miami, Miami, FL.

P3-03-08  microRNAs in Mammary Stem-Like Cells and Triple-Negative Breast Cancer; Conserved Functions and Treatment Potential
Williams C, Aydogdu E, Katchy A, Lin C-Y, Haldosen L-A, Helguro L. University of Houston, Houston, TX; Karolinska Institute, Stockholm, Sweden; University of Aveiro, Aveiro, Portugal.

P3-03-09  miR-944 is down-regulated in HER2 positive breast cancer tumors: identification of putative mRNA targets by transcriptome analysis
Forseca MA, Romero SL, Hidalgo A, Rodriguez S, Bautista V, Marchat LA, Perez-Plascencia C, Arechaga E, Lopez-Camarillo C. Universidad Autonoma de la Ciudad de Mexico, Mexico, DF, Mexico; Instituto Nacional de Medicina Genomica, Mexico, DF, Mexico; Instituto de Enfermedades de la mama FUCAM, Mexico, DF, Mexico; Escuela Nacional de Medicina y Homeopatia del IFN, Mexico, DF, Mexico; Instituto Nacional de Cancerologia, Mexico, DF, Mexico.

Tumor Cell Biology: Molecular Profiles

P3-04-01  Molecular Characterization of African Breast Cancer; Results from a Large Tissue Microarray Study
Shaaban A, Hatfield A, Omoniyi Esan GO, Komolafe AO, Daramola A, Pathak D, D’Cruz N, Alizadeh Y, Lewis P, Titloie NA. St James’s Institute of Oncology, Leeds, United Kingdom; Obafemi Awolowo Teaching Hospital Complex, Ille-Ife, Nigeria; Swansea School of Medicine, Swansea, United Kingdom; College of Medicine University of Lagos/University Teaching Hospital, Lagos, Nigeria.

P3-04-02  Bevacizumab Treatment Alters Intrinsic Subtypes in a VEGF-Reinforced Xenograf Model of ER-Positive Breast Cancer
Gokmen-Polar Y, Toroni RA, Goswami C, Sanders KL, Sirimalle U, Mehta R, Li L, Ivan M, Badve S, Sledge GW. Indiana University School of Medicine, Indianapolis, IN.

P3-04-03  Identification of Hormone-Responsive Genes as Biomarkers for Menstrual Cycle Phases and Menopausal Status

P3-04-04  Patterns of Distant Metastasis According to the Molecular Subtypes of Breast Cancer; Results of 529 Breast Cancer Patients
Hwang MJ, Seo YJ, Lee JH, Son GT, Choi JE, Bae YK, Kang SH, Lee SJ. Yeungnam University College of Medicine, Daegu, Republic of Korea.

P3-04-05  Expression Profiles of RANK and RANKL mRNA and Protein in the Mammary Gland of Female Cynomolagus Monkeys after Long-Term Treatment with Menopausal Hormone Therapy
Branstretter D, Wood CE, Rohrbach K, Borgenik H, Dougall WC. Amgen Inc., Seattle, CA; Wake Forest School of Medicine, Winston-Salem, NC.

P3-04-06  Comparison of MammaPrint, BluePrint, and TargetPrint with Clinical Outcomes in Patients with Breast Cancer: Findings from a Prospective United States Cohort
Nguyen B, Sinha R, Kerlin D, Barone J, Garcia A, Yao K, Rivera E, Stork-Sloots L, Deck K. Long Beach Memorial Health Care, Long Beach, CA; Rockwood Clinic, Spokane, WA; John Muir, Walnut Creek, CA; Comprehensive Breast Care of San Diego and Sharp Memorial Hospital, San Diego, CA; University of Southern California, Los Angeles, CA; North Shore University Health System, Chicago, IL; The Methodist Hospital/Weill Cornell University, Houston, TX; Agenda Inc, Irvine, CA; Saddleback Memorial Medical Center, Laguna Hills, CA.

P3-04-07  Physiological Concentrations of Genistein and 17β-Estradiol Inhibit MDA-MB-231 Breast Cancer Cell Proliferation by Increasing Bax/Bcl2 Ratio and Decreasing pERK1/2 Expression
Rajah TT, Peine KJ, Xu N, Serret CA. DePaul University, Chicago, IL.

P3-04-08  Increased cellular expression activity of minimal residual disease in breast cancer after surgery
Pachmann K, Carl S, Camara O. Friedrich Schiller University Jena, Jena, Germany.

Tumor Cell Biology: Tumor Heterogeneity/Molecular Subclassification

P3-05-01  Gene Profiling of Histopathologically Characterized Apocrine Breast Cancers

P3-05-02  Subtype-Specific Co-Occurrence of Atypical Hyperplasia and In Situ Carcinoma with Invasive Breast Cancers
Kovatch AJ, Kwecher L, Chen Y, Bekhash A, Hooke JA, Shriver CD, Mural RJ, Hu H. Windber Research Institute, Windber, PA; Walter Reed Army Medical Center, Washington, DC; MDR Global Systems LLC, Windber, PA.

P3-05-03  Transcriptomic Validation of Molecular Classification of Invasive Ductal Carcinoma Based on Immunohistochemical Markers and Grade

P3-05-04  Changes in Recurrence Risk of Breast Cancer Intrinsic Subtypes over Time

P3-05-05  Cyclin D1 Gene Amplification Is Rarely Heterogeneous in Breast Cancer

P3-05-06  Progression of Breast Cancer Molecular Subtypes through Different Clinical Stages

P3-05-07  Genetic Heterogeneity of Amplification Status in Breast Invasive Carcinoma with 2+ HER2 Immunostaining: What Can We Learn?
Valent A, Delaloge S, Fechoumi M, Bernheim A, Mathieu M-C. Institut Gustave Roussy, Villejuif, France, Metropolitan.
P3-05-08 Hormone Receptor Heterogeneity in Ductal Intraepithelial Neoplasia (Ductal Carcinoma In Situ) of the Breast
Sweedan M, Flynn G, Bossuyt V, Janzen D, Chagpar AB. Yale University School of Medicine, New Haven, CT.

P3-05-09 Comparison of Clinical Features and Patterns of Recurrence in Triple Negative Breast Cancers in Relation to Other Breast Cancers

P3-05-10 Standardized Quantitative Methods for Investigating the Intratumor Heterogeneity of HER2 in FFPE Breast Cancer Specimens Utilizing the Vectra System, inForm and AQUA Technology
Hoyt CC, Gustavson MD, Davis WL, Lane KA, Scott CG, Graves, Jr LL. Caliper Life Sciences, Hopkinton, MA, HistRx, Branford, CT.

Tumor Cell Biology: Genomics

P3-06-01 Next Generation RNA Sequencing Reveals Changes in Gene Expression and Alternative Splicing upon Brief Exposure to Therapy in Early Breast Cancer
Varadan V, Kamalakaran S, Jansenski A, Banerjee N, Leonz-Geyda K, Bossuyt V, Flowers D, Sikov W, Abu-Khalaf M, Rizack T, Dimitrova N, Harris LN. Philips Research North America, Briarcliff Manor, NY; Yale University School of Medicine, New Haven, CT, Brown University School of Medicine, Providence, RI.

P3-06-02 Identification of Redundant, Tumor Subtype Specific Fusion Transcripts in Primary Breast Tumors

P3-06-03 Hypodiploidy, 1pter Loss and Inactive X Chromosome Inactivation Are Associated with BRCA1 Somatic or Germline Determination and Other Basal-Like Breast Carcinomas: Proposal for a New BRCA1 Genomic Signature

P3-06-04 Sno/miRNA Expression Via Next Generation Sequencing: Variation in Patients before and after Treatment
Banerjee N, Kamalakaran S, Varadan V, Jansenski A, Leonz-Geyda K, Bossuyt V, Flowers D, Sikov W, Abu-Khalaf M, Rizack T, Harris LN. Philips Research North America, Briarcliff Manor, NY; Yale University School of Medicine, New Haven, CT, Brown University School of Medicine, Providence, RI.

P3-06-05 Comparison of Oncotype DX® Recurrence Scores between Surgical and Core Biopsy Specimens in Breast Cancer Patients
Stull TS, Goodwin MC, Anderson JM, Baehner FL, Sing AP, Yoshizawa CN, Barrio AV, Frazier TG. The Bryn Mawr Hospital, Bryn Mawr, PA; Genomic Health, Inc, Redwood City, CA.

P3-06-06 Comparison of Gene Expression Profiles of Lymph Node Positive and Lymph Node Negative ER Positive Breast Tumors in Pre- and Postmenopausal Women
Rapun PB, Brilliart G, Devarin B, Vranckx L, Hu H, Hooij JK, Shinver CD, Mural RJ. Windber Research Institute, Windber, PA; Walter Reed Medical Center, Washington, DC.

P3-06-07 Integrated Genomic and Pathway Analysis Reveals Key Pathways across Breast Subtypes
Benz S, Sanborn JZ, Vaske C. FireSc Genomics, LLC, Santa Cruz, CA.

P3-06-08 SCAN-B: An Accelerated Translational Pipeline from Profile to Prognosis, and Prediction for Individual Breast Cancer Patients

Detection and Diagnosis: Auxillary Staging and Sentinel Nodes

P3-07-01 Are the Findings of ASCO/Z0011 Applicable to District General Hospital Breast Unit - And How Should They Change Our Practice?

P3-07-02 Prediction of Non-Sentinel Lymph Node Status in Breast Cancer Patients with a Micrometastatic Sentinel Lymph Node Determined by the One Step Nucleic Acid Amplification (OSNA) Assay
Di Filippo C, Casini B, Gallo E, Terenato I, Botti C, Mottolese M, Pescarmona E, Marandino F, Buglioni S. Regina Elena National Cancer Institute, Rome, Italy; Regina Elena National Cancer Institute, Italy.

P3-07-03 One-Step Nucleic Acid Amplification (OSNA) for the Diagnosis of Sentinel Lymph Nodes of Breast Cancer - Results of the China Multicenter Study CBCSG-001c
Wang YS, Ouyang T, Wu J, Liu YH, Cao XC. Shandong Cancer Hospital & Institute, Jinan, Shandong, China; Beijing University Cancer Hospital, Beijing, China; Fudan University Cancer Hospital, Shanghai, China; Guangdong General Hospital, Guangzhou, Guangdong, China; Tianjin Medical University Cancer Hospital, Tianjin, China.

P3-07-04 Does Omission of Axillary Dissection after a Positive Sentinel Node Biopsy Influence Indication to Adjuvant Chemotherapy in Operable Breast Cancer Patients?

P3-07-05 Nomogram Incorporating SLN Metastasis Size Provides the Most Accurate Prediction of Non-SLN Involvement in Breast Cancer Patients

P3-07-06 Prognostic Utility of Upfront Nodal Staging Prior to Neoadjuvant Chemotherapy: The UAB Experience

P3-07-07 Effect of Sentinel Lymph Node Biopsy without Axillary Lymph Node Dissection on Overall Survival in Patients with T1 or T2 Node-Positive Breast Cancer: A Report from the Korean Breast Cancer Society
Park HS, Chae BJ, Song BJ, Jung SS, KBCS Investigators. The Catholic University School of Medicine, Seoul, Korea, Korean Breast Cancer Society.

P3-07-08 Accurate Staging of Axillary Lymph Nodes from Breast Cancer Patients Using a Novel Molecular Method

P3-07-09 Prediction of Additional Nodal Metastasis in Breast Cancer Patients with a Positive Sentinel Node Biopsy: A New Nomogram Including HER2 Status
P3-07-10 Sentinel Lymph Node Navigation Surgery Using Combination of Indocyanine Green Fluorescence and Blue Dye for Breast Cancer Patients
Takahashi M, Hayashida T, Jinno H, Kitagawa Y. Keio University School of Medicine, Tokyo, Japan.

P3-07-12 Value of Preoperative Ultrasound-Guided Axillary Lymph Node Biopsy for Preventing Futility Sentinel Node Procedures in Breast Cancer: A Systematic Review and Meta-Analysis
Diepstraten SC, Sever AR, Buckens CF, Veldhuis WB, van den Bosch MA, Mall WP, Verkooijen HM. University Medical Center Utrecht, Netherlands; Maidstone Hospital, United Kingdom.

P3-07-13 Validation and Comparison of Models To Predict Nonsentinel Lymph Node Metastasis in Chinese Breast Cancer Patients with Positive Sentinel Lymph Nodes
Chen K, Jia W, Zeng Y, Fan M, Su F, Li S. Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, Guangdong, China.

P3-07-14 Sensory Disturbance of the Ipsilateral Upper Arm after Breast Cancer Surgery with Sentinel Node Biopsy Alone Compared with Axillary Dissection - A Prospective Study
Ohsumi S, Kiyoto S, Takahashi M, Hara F, Takabatake D, Takashima S, Aogi K, Shimozuma K. NHK Shikoku Cancer Center, Matsuyama, Ehime, Japan; Ritsumeikan University, Kusatsu, Shiga, Japan.

P3-07-15 Sequential Peri-Areolar and Peri-Tumoural SPECT/CT Lymphoscintigraphy Has Identified High Rates of Discordance in Both Axillary and Internal Mammary Sentinel Lymph Node Mapping

P3-07-16 The Efficacy of Axillary Node Preserving Surgery Using Axillary Reverse Mapping for Preventing Lymphedema in Patients with Breast Cancer
See YJ, Hwang MJ, Lee JH, Son GT, Choi JE, Bae YK, Kang SH, Lee S.J. Yeungnam University College of Medicine, Daegu, Republic of Korea.

P3-07-17 Optimal Number of Sentinel Lymph Nodes That Could Avoid Completion of Axillary Lymph Node Dissection in Operable Breast Cancer
Salmon RJ, de Rieco Y, Falcou MC. Institut Curie, Paris, France.

P3-07-18 Withdrawn

P3-07-19 Long-Term Outcome of Internal Mammary Lymph Node Detected by Lymphoscintigraphy in Early Breast Cancer

P3-07-20 An Independent Assessment of Seven Nomograms for Predicting the Probability of Additional Axillary Nodal Metastasis after Positive Sentinel Lymph Node Biopsy in a Cohort of British Breast Cancer Population
Nadeem RM, Gudder LD, Saldan ZA. Lancashire Teaching Hospitals NHS Foundation Trust, Chorley, United Kingdom.

P3-07-21 Sentinel Lymph Node Metastasis Are More Likely To Develop in Triple Positive Breast Cancer Patients without Compromising Disease Free Survival

P3-07-22 Combined Approach for Staging the Axilla in Breast Cancer Patients with Clinically (-) Nodal Versus Sentinel Node Biopsy Alone
Patel RK, Krol VV, Cibull ML, McGrath PC, Fjallskog M-L, Pirruccello EA, Szabunio AL, Samayoa LM. University of Kentucky, Lexington, KY; Uppsala University, Uppsala, Sweden; VAMC, Lexington, KY.

P3-07-23 Intraoperative Molecular Analysis of Sentinel Lymph Nodes in Breast Cancer Using One Step Nuclease Acid Amplification (OSNA)

P3-07-24 Accuracy and Cost Effectiveness of Frozen Section Examination of the Sentinel Lymph Node (SLN) in Ductal Carcinoma In Situ (DCIS) of Breast
Balleharinna UK, Santoro E, Schaefer SS, Blackwood MM, Chamberlain RS. Saint Barnabas Medical Center, Livingston, NJ; Maimonides Medical Center, Brooklyn, NY; Saint George’s University School of Medicine, West Indies, Grenada; University of Medicine and Dentistry of New Jersey, Newark, NJ.

P3-07-25 Sentinel Lymph Node Mapping in Breast Cancer after Primary Chemotherapy
Bonardi S, Andreis D, Allevi G, Aggugini S, Milani M, Generali D, Bersiga A, Brizzi MP, Dogliotti L, Berruti A, Bottini A. Azienda Ospedaliera Istituti Ospitalieri, Cremona, Italy; Azienda Ospedaliera Universitaria San Luigi di Orbassano, Università di Torino, Orbassano, Torino, Italy.

P3-07-26 How Generalizable Is the Patient Population Enrolled in ACOSOG Z11?
Lannin DR, Killelea BK, Grube BJ, Horowitz N, Chagpar AB. Yale University School of Medicine, New Haven, CT.

P3-07-27 ROCK II Expression Can Be a Potential Marker of Non-Sentinel Lymph Node Metastasis in Breast Cancer Patients with Sentinel Lymph Node Involvement
Shigematsu H, Taguchi K, Shiozumi K, Kawaguchi H, Nishiyama K, Ohno S, Okada M. Hiroshima University Hospital, Hiroshima, Japan; National Kyushu Cancer Center, Fukuoka, Japan.

P3-07-28 One Step Nuclease Acid Amplification (OSNA) for Intraoperative Molecular Detection of Lymph Node Metastases and Micro-Metastases in Breast Cancer
Babar MM, Madani R, Jackson P, Irvine T, Layer G, Kissin M. Royal Surrey County Hospital, Guildford, SU, United Kingdom; University of Surrey, Guildford, SU, United Kingdom.

P3-07-29 Validating the Lymph Node Ratio as a Prognostic Indicator among South East Asian Breast Cancer Patients
Saxena N, Hartman M, Bhoi-Fathy N, Aziz R, Siew EL, Lee SC, Yip CH, Verkooijen HM. National University of Singapore, Singapore; Faculty of Medicine, University of Malaya, Kuala Lumpur, Malaysia; University Medical Center Utrecht, Utrecht, Netherlands; National University Cancer Institute, National University Health Systems, Singapore, Singapore.

P3-07-30 Applying the Findings of the Z11 Trial to a UK Practice
Chalmers CR, Mallon EA, Stallard S, Doughty JC, Wilson CR. Western Infirmary, Glasgow, Scotland, United Kingdom.

P3-07-31 Intra-Operative Assessment of Sentinel Lymph Nodes in Breast Cancer with Touch Imprint Cytology (TIC) in 460 Consecutive Patients

P3-07-32 The Role of Axillary Ultrasound in the Detection of Metastases from Primary Breast Cancers
Yamashta M, Little E, Fraley J, Hovanessian-Larsen L, Sener SF. Keck School of Medicine, University of Southern California, Los Angeles, CA.
P3-07-33 Are Single Node Metastases More Common in Patients with Breast Cancer in the Sentinel Node Era? 
Shetty G, Randhawa S, Mohammadi I, Hans S, Jones L, Clarke D. 
Warwick Hospital, Warwick, West Midlands, United Kingdom.

P3-07-34 Occult Metastasis in Sentinel Node: Should This Affect the Clinical Decision Making? A Systematic Review and Meta-Analysis

P3-07-35 Validation of Online Calculators To Predict Non-Sentinel Lymph Node Status in Sentinel Lymph Node-Positive Breast Cancer Patients
Tanaka S, Sato N, Fujioka H, Takahashi Y, Kimura K, Iwamoto M. 
Osaka Medical College, Takatsuki, Osaka, Japan.

P3-07-37 Clinical Characteristics and Treatment of Breast Cancer at Public and Private Institutions
Hegg R, Mattar A, Gebrim LH, Emerenciano K, Pinotti M, Perdicaris M, van Eyll B, Franke F, Pinczovskis H, Freitas, Jr R, Jendribova D, Borges G, Queiroz G, Nascimento YY, Gambel O, Mathias C, Budel V, Strepposos E, Delgado G. Perola Byington Hospital, Sao Paulo, SP, Brazil; II. Liga Norte Riograndeense; EGMAJAP, Instituto Santista de Oncologia; Instituto do Cancer Arnaldo Vieira de Canhalho; Hospital de Canadade de Ijuí; Faculdade de Medicina do ABC; Hospital das Clinicas de Goiania, Centro Goiano de Oncologia; Clinica de Neoplasias Litoral; Hospital Araujo Jorge; Cepon, Hospital do Servidor Publico do Estado de Sao Paulo; Nucleo de Oncologia da Bahia; Universidade Federal do Paraná; Hospital Sao Rafael; Hospital Santa Lucinda.

P3-07-38 Selective Omission of Blue Dye in Patients Undergoing Sentinel Lymph Node Biopsy for Breast Cancer
Waters JL, Iqbal M, Jones L, Harries S, Clarke D. Warwick Hospital, South West Warwickshire Foundation Trust, Warwick, West Midlands, United Kingdom.

P3-07-39 Where To Look for Sentinel Lymph Node in Breast Cancer
Durian A. Klinikum Bayreuth GmbH, Bayreuth, Bayern, Germany.

P3-07-40 Impact of the Sentinel Lymph Node Procedure on the Detection of Positive Lymph Nodes in Breast Cancer

P3-07-41 Sentinel Lymph Node Biopsy Is a Reliable Method for Lymph Node Evaluation in Neoadjuvant Chemotherapy Treated Breast Cancer Patients
Kaplan R, Oiu Q, Monni S, Swistel A, Shin S. The New York-Presbyterian Hospital-Weill Cornell Medical Center, New York, NY.

P3-07-42 Lymphovascular Invasion Best Correlates with Presence of Nodal Metastasis in Sentinel Lymph Node Biopsy
Abdiss MS, Adeleka MW, Patel E, Cotrell S. North Manchester General Hospital, Manchester, United Kingdom; University of Manchester, Manchester, United Kingdom.

P3-07-43 The Impact of Timing in Sentinel Lymph Node Biopsy in Primary Breast Cancer
Güth U, Schmid SM, Myrick ME, Oberrmann EC, Viehl CT, Rochlitz C, Forer F. University Hospital Basel, Basel, Switzerland.

P3-07-44 Feasibility of Axillary Reverse Mapping during Sentinel Lymph Node Biopsy in Breast Cancer
Noguchi M, Ohno Y, Nakano Y, Noguchi M, Kosaka T. Kanazawa Medical University, Kahoku, Ishikawa, Japan.

P3-07-45 Role of SPECT-CT in Detecting Sentinel Lymph Nodes in Patients with Ipsilateral Breast Cancer Recurrence and Previous Axillary Lymph Node Dissection

P3-07-46 Accuracy of SPIO-Enhanced MR Imaging Alone for the Diagnosis of Sentinel Node Metastases in Patients with Breast Cancer

P3-07-47 Validated Nomogram To Predict Sentinel Lymph Node Positivity in Breast Cancer Patients

P3-07-48 Axillary Imaging with Dynamic MRI Following Subcutaneous Injection of Superparamagnetic Iron Oxide Nanoparticles
Douek M, Johnson L, Parish J, Charles-Eduards G, Hall-Craggs M. King’s College London, London, London, United Kingdom; Guy’ and St Thomas’ Hospitals, London, United Kingdom; University College Hospital, London, United Kingdom.

P3-07-49 Microinvasive Breast Carcinoma: evaluation of status axillary is necessary?

P3-08-01 Effects of an Integrated Yoga Program on Mood States, Distress, Quality of Life, Diurnal Cortisol Rhythms and Natural Killer Cell Counts in Metastatic Breast Cancer Survivors
Gopinath SK, Rao RM, Sanjeevaavara VH, Diwakar RB, Basavanggila AS, Patil S, Raghuram N, Ramareo N, Ushariam RM. HGC - BIO Super Speciality Centre, Bangalore, Karnataka, India; Swami Vivekananda Yoga Anusandhana Samsthana, Bangalore, Karnataka, India.

P3-08-02 Evaluating the Impact of Educational Material on Anastrozole Treatment Adherence - The Final Results of the ARTEMIS Study
Nogaret J-M, Coibion M, Neven P, Soepenberg O, Graa M-PP, Deschamp V, Vanlereghem T. Jules Bordet Institute, Brussels, Belgium; CHC St-Vincent, Rocourt, Belgium; University Hospital Leuven, Leuven, Belgium; MariaZiekenhuis, Noord-Limburg, Belgium; CHC Saint-Joseph, Liege, Belgium; AstraZeneca Benelux, Brussels, Belgium.

P3-08-03 Exercise Increases Soluble Vascular Endothelial Growth Factor Receptor-1 (sFlt-1) in the Circulation of Adult Women
Makey K, Patterson SG, Robinson J, Loftin M, Waddell DE, Miele L, Chinchar E, Huang M, Smith AD, Weber M, Gu J-W. University of Mississippi Medical Center, Jackson, MS, University of Mississippi, Oxford, MS.

P3-08-04 “How Important is This for Me?” - The Role of Necessity Beliefs as Determinants of Breast Cancer Prevention Intentions among High-Risk Women
Verma S, Paquet L, Stacey D, Davis I, Bedard M, Lowry S, lanni L. The Ottawa Hospital Cancer Centre, Ottawa, ON, Canada; Carleton University, Ottawa, ON, Canada; University of Ottawa, Ottawa, ON, Canada.

P3-08-05 Internet-assisted weight loss for overweight/obese women at high risk for breast cancer
Epidemiology, Risk, and Prevention: Prevention – Nutritional Studies

P3-09-01 Change in Carbohydrate Intake and Breast Cancer Prognosis
Emond JA, Patterson RE, Pierce JP. UCSF Moores Cancer Center, La Jolla, CA; San Diego State University, San Diego, CA.

P3-09-02 Intermittent Dietary Carbohydrate Restriction Enables Weight Loss and Reduces Breast Cancer Risk Biomarkers
Harvie M, Wright C, Pegington M, Mitchell E, Evans DG, Jebb S, Clarke R, Goodacre R, Dunn W, Mattson M, Howell A. University Hospital of South Manchester, Manchester, United Kingdom; MRC Human Nutrition Research Group, Cambridge, United Kingdom; University of Manchester, Manchester, United Kingdom; National Institute of Aging, Baltimore, MD.

P3-09-03 Long-Chain Polysaturated Fatty Acid Intake and Its Relationship to Long-Chain Polysaturated Fatty Acids in Serum, Red Blood Cells and Breast Tissue
Harvey KE, Li S, Carlson SE, Sullivan DK, Klemp JR, Kimler BF, Fabian CJ. University of Kansas Medical Center, Kansas City, KS.

P3-09-04 Comparative Preventive Efficacy of Aqueous Extracts from Lycium Barbarum Bark and Fruit on Estrogen Receptor Positive Human Mammary Carcinoma MCF-7 Cells
Telang NT, Li G, Sepkovic DW, Bradlow LH, Song G, Song G, Telang NT. Palindrome Liaisons, Montvale, NJ; American Institute for Chinese Medicine, New York, NY; Hackensack University Medical Center, Hackensack, NJ.

P3-09-05 Understanding the Role of Estrogen in Sex Differences in Adipocyte Biology for Cancer Prevention
Stubbs RE, Holcomb VB, Hong J, Nunez NP. The University of Texas at Austin, Austin, TX.

P3-09-06 Changes of Serum Vitamin D According to the Breast Cancer Treatment
Kim HJ, Yi OV, Koh BS, Yu JH, Lee JW, Son BH, Ahn SH. Asan Medical Center, Seoul, Korea.

Epidemiology, Risk, and Prevention: Prevention – Preclinical Studies and Model Systems

P3-10-01 Alternative Dosing Regimens with the EGFR Inhibitors (Gefitinib and Lapatinib) in Mammary Cancer Models: Prevention and Therapeutic Efficacy
Lubet RA, Bode AM, Szabo E, Grubbs CJ. National Cancer Institute, Bethesda, MD; Hormel Institute, Austin, MN; University of Alabama at Birmingham, Birmingham, AL.

P3-10-02 Gene Expression Changes in Methylnitrosourea (MNU)-Induced ER+ Mammary Cancers Following Short-Term Treatment of Rats with the Aromatase Inhibitor Vorozole
Lubet RA, Grubbs CJ, Bode A, You M, Lu Y. National Cancer Institute, Bethesda, MD; University of Alabama at Birmingham, Birmingham, AL; Hormel Institute, Austin, MN; Medical College of Wisconsin, Milwaukee, WI.

P3-10-03 Bardoxolone (5MeCDDO) Inhibits Cancer Initiation but Promotes Progression in Rodent Models of Breast Cancer. What Does It Mean for the Antioxidant Response Element (ARE) as a Primary Prevention Target?
Lubet RA, Townsend R, Vedell P, Steele VE, Grubbs CJ. National Cancer Institute, Bethesda, MD; Washington University School of Medicine, Saint Louis, MO; Medical College of Wisconsin, Milwaukee, WI; University of Alabama at Birmingham, Birmingham, AL.

P3-10-04 Halting Early Breast Cancer Progression with Omega-3 Ethyl Esters: Altering Tumor Microenvironment in 21T Series Cell Lines
Chen CH, Rhodes ME, Fabian C, Hursting SD, deGraffenried LA. University of Texas at Austin, Austin, TX; University of Kansas Cancer Center, Kansas City, KS.
P3-12-03  A Prognostic Index of Ipsilateral Breast Tumor Recurrence in Patients Treated with Breast-Conserving Surgery after Preoperative Chemotherapy: Validation of M.D. Anderson Prognostic Index
Ohno S, Ohsumi S, Inaji H, Akiyama F, Akashi-Tanaka S, Sato N, Takahashi K, Dura S. National Kyushu Cancer Center, Fukuoka, Japan; National Shikoku Cancer Center, Matsuyama, Ehime, Japan; Osaka Medical Center for Medical and Cardiovascular Disease, Osaka, Japan; The Cancer Institute of the Japanese Foundation for Cancer Research, Tokyo, Tokyo, Japan; National Cancer Center Hospital, Tokyo, Tokyo, Japan; Niigata Cancer Center Hospital, Niigata, Japan; Shizuoka Cancer Center, Shizuoka, Japan; Wakayama Medical University, Wakayama, Japan.

P3-12-04  Involved Anterior Margins after Breast Conserving Surgery: Is Re-Excision Required?
Mullen R, Macaskill EJ, Khalil A, Elseedawy E, Brown DC, Lee AC, Purdie C, Jordan L, Thompson AM. Ninewells Hospital, Dundee, United Kingdom; Perth Royal Infirmary, Perth, United Kingdom.

P3-12-05  Breast Cancer Recurrence: 2nd Conservative Treatment Versus Mastectomy

P3-13-01  Boost Radiation Therapy Not of Value in Reducing IBTR of Invasive or Noninvasive Breast Cancers for Patients with DCIS: Results from the NSABP B-24 Trial
Julian TB, Vicini FA, Costantino JP, Arthur DW, Kickweil KM, Land SR, Mammounas EP, Wolmark N. National Surgical Adjuvant Breast & Bowel Project, Pittsburgh, PA; Allegheny General Hospital, Pittsburgh, PA; Beaumont Health System, Royal Oak, MI; Virginia Commonwealth University, Richmond, VA; Graduate School of Public Health, University of Pittsburgh, Pittsburgh, PA; Ulfman Health Foundation, Canton, OH.

P3-13-02  The Impact of Lymph Node Status on Clinical Outcomes Following Accelerated Partial Breast Irradiation
Shah C, Wilkinson JB, Wallace M, Vicini F. William Beaumont Hospital, Royal Oak, MI.

P3-13-03  Long-Term Symptoms after Radiotherapy of Supracavitary Lymph Nodes in Breast Cancer Patients

P3-13-04  Functional and Cosmetic Outcomes Following Post-Mastectomy Irradiation with Tissue Expander/Implant Reconstruction
Baschnagel A, Shah C, Wilkinson JB, Dekhene N, Margolis J, Arthur DW, Vicini F. William Beaumont Hospital, Royal Oak, MI; VCU Massey Cancer Center, Richmond, VA.

P3-13-05  Analysis of Heart Dose-Volume Parameters and Cardiac Events among Node Positive Breast Cancer (NPBC) Patients Treated with Three-Dimensional Conformal Radiation Therapy (3D-CRT)

P3-13-06  Cardiovascular Magnetic Resonance Imaging and Radiation-Induced Heart Disease Following Radiotherapy for Breast Cancer

P3-13-07  The TARGIT-A Trial Update Confirms No Increase in Local Recurrence
Vaidya JS, Baum M, Wenz F, Bulsara M, Tobias J, Alvarado M, Saunders C, Williams N, Joseph D, on Behalf of the TARGIT Trials Group. University College London, London, United Kingdom; University of Heidelberg, Mannheim, United Kingdom; University of Notre Dame, Fremantle, United Kingdom; University College Hospital and Whittington Hospital, London, United Kingdom; School of Surgery, University of Western Australia, London (All), United Kingdom; University of San Francisco, London (All), United Kingdom; Sir Charles Gairdner Hospital, London (All), United Kingdom.

P3-13-08  Survival Analysis and Recurrence Patterns in Locally Advanced Breast Cancer Following Neoadjuvant Chemotherapy and Preoperative Concurrent Chemo Radiotherapy
Shaw RJ, Lara F, Robles CD, Villar D. Instituto Nacional de Cancerologia, Mexico City, Mexico.

P3-13-09  Impact of Estrogen Receptor Negativity on Clinical Outcomes Following Accelerated Partial Breast Irradiation

P3-13-10  Does Lapatinib Increase Pulmonary Toxicity When Concurrently Used with Radiation Therapy? An Experimental Study with Wistar-Albino Rats

Horowitz DP, Nj J, Burri R. Columbia University Medical Center-New York Presbyterian Hospital, New York, NY.

P3-13-12  Electrons for Intraoperative Breast Radiotherapy in Selected Patients: Long-Term Results of the Montpellier Phase II Trial

P3-14-01  Panitumumab in Combination with FEC 100 (5-Fluorouracile, Epirubicin, Cyclophosphamide) Followed by Docetaxel (T) in Patients with Operable, Triple Negative Breast Cancer (TNBC): Final Results of a Multicentre Neoadjuvant Pilot Phase II Study
Nabholtz J-M, Weber B, Gilgore J, Moutet-Reynier M-A, Tredan H, Tubiana-Mathieu N, Abrial C, Kwiatkowski F, Planchat E, Chalabi N, Penault-Llorca F, Chollet P, Jean Perin Comprehensive Cancer Centre, Clermont-Ferrand, France; National Cancer Centre Hospital, Tokyo, Tokyo, Japan; National Cancer Centre Hospital, Osaka, Japan; The Cancer Institute of the Japanese Foundation, Tokyo, Tokyo, Japan; National Kyushu Cancer Center, Fukuoka, Japan; Niigata Cancer Center Hospital, Niigata, Japan; Shizuoka Cancer Center, Shizuoka, Japan; Wakayama Medical University, Wakayama, Japan.

P3-14-02  The TARGIT-A Trial Update Confirms No Increase in Local Recurrence
Vaidya JS, Baum M, Wenz F, Bulsara M, Tobias J, Alvarado M, Saunders C, Williams N, Joseph D, on Behalf of the TARGIT Trials Group. University College London, London, United Kingdom; University of Heidelberg, Mannheim, United Kingdom; University of Notre Dame, Fremantle, United Kingdom; University College Hospital and Whittington Hospital, London, United Kingdom; School of Surgery, University of Western Australia, London (All), United Kingdom; University of San Francisco, London (All), United Kingdom; Sir Charles Gairdner Hospital, London (All), United Kingdom.
P3-14-02  Sequential Versus Upfront Intensified Neoadjuvant Chemotherapy in Patients with Large Resectable or Locally Advanced Breast Cancer (INTENS), Toxicity Results from a Phase III Study of the Dutch Breast Cancer Trialsists’ Group (BOOG)

Vrins BE, Van de Vijver KK, Boetes C, van Gastel SM, Wals J, Smilde TJ, van Warmerdam LJ, van Laarhoven HW, van Spriens DJ, Born GF, Tjan-Heijnen VC. Maastricht University Medical Centre, Maastricht, Netherlands; Comprehensive Cancer Centre the Netherlands, Nijmegen, Netherlands; Atsum Medical Centre, Heerenlen, Netherlands; Jeroen Bosch Hospital, ’s Hertogenbosch, Netherlands; Catharina-Hospital, Eindhoven, Netherlands; Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; Canisius-Wilhelmina Hospital, Nijmegen, Netherlands.

P3-14-03  ABCB1 Single Nucleotide Polymorphisms a Possible Prognostic Factor in Breast Cancer Patients Receiving Docetaxel and Doxorubicin Neoadjuvant Chemotherapy on Systemic Treatment

P3-14-04  Assessment of Genomic Prognostic Signatures as Predictors of Response to Neoadjuvant Chemotherapy in Patients with Early Stage Breast Cancer

Culakova E, Poniewierski MS, Huang M, Kuderer NM, Ginsburg S, Barry W, Marcom PK, Ready N, Abernethy A, Lyman GH. Duke University, Durham, NC.

P3-14-05  Evaluation of Residual Cancer Burden Index (RCBI) as a Predictor of Disease Free Survival in a Non-Selected Cohort of Breast Cancer Patients Treated in the Neoadjuvant Setting

Perez-Fidalgo J-A, Martinez M, Ferrer J, Pons V, Bermejo B, Furriol J, Eroles P, Lluch A. Hospital Clinic, Barcelona, Spain; Hospital Arnau de Vilanova, Lleida, Spain; University of Lleida, Barcelona, Spain; Luisenkrankenhaus Düsseldorf, Düsseldorf, Germany; Ospedale Sacro Cuore, Negrar (Verona), Italy; Cliniques Universitaires St-Luc, Université Catholique de Louvain, Brussels, Belgium; Technischen Universität München, München, Germany; Centre Aexitis Vaurini, Vandoeuvre-Les-Nancy, France; Cephalon, Maisons-Alfort, France; Frauenklinik und Brustzentrum Rheinfelden, Rheinfelden, Germany.

P3-14-06  Combined Use of 18F-FDG PET/CT and MRI To Monitor Breast Cancer Response during Neoadjuvant Chemotherapy

Pengel KE, Koolen BB, Vogel W, Valdes Olmos R, Wesseling J, Vanrenck Peeters M-J, Loc CE, Higuys KG. Netherlands Cancer Institute, Amsterdam, Netherlands; Netherlands Cancer Institute, Amsterdam; University Medical Center Utrecht, Utrecht, Netherlands.

P3-14-07  Relative Risk of Recurrence (RR) over Time in ER Positive and Negative T4 Breast Cancer Patients Achieving Less Than pCR (<pCR) after Primary Chemotherapy: A Reversal Trend of Recurrence beyond 60 Months after Diagnosis

Ionta MT, Atzoni F, Pusceddu V, Notar F, Valle G, Guarzoni D, Chiappe M, Marangiu M, Minervia L, Massidda B. University Hospital, Cagliari, Italy; Hospital of Oncology Buisinco, Cagliari, Italy.

P3-14-08  A Phase II Study of Gemcitabine and Carboplatin (GC) Plus Iniparib (BSI-201) as Neoadjuvant Therapy for Triple-Negative and BRCA1/2 Mutation-Associated Breast Cancer

P3-14-09  A Phase II Preoperative Study of Dasatinib, a Multi-Targeted Tyrosine Kinase Inhibitor, in Locally Advanced “Triple-Negative” Breast Cancer Patients

Rimawi MF, Rodriguez AA, Yang WT, Gonzalez-Angulo AM, Nangia JR, Wang T, Speers C, Mills G, Hilsenbeck SG, Brown PH, Chang JC. Baylor College of Medicine, Houston, TX; The Methodist Hospital, Houston, TX; M.D. Anderson Cancer Center, Houston, TX.

P3-14-10  Early Predictive Value of Non-Responder to Docetaxel in Neoadjuvant Chemotherapy in Breast Cancer Using 18F-FDG-PET

Hirakata T, Fujisawa T, Yanaigiti H, Hiyoshi K, Oya N, Akyoishi T, Kinoshita T, Kuvano H. Gunma Prefectural Cancer Center, Ota, Gunma, Japan; Tsursuyaga Hospital, Isesaki, Gunma, Japan; Graduate School of Medicine, Gunma University, Maebashi, Gunma, Japan.

P3-14-11  Comparison of Two Nomograms To Predict Pathologic Complete Response to Neoadjuvant Chemotherapy - Evidence That HER2 Positive Tumors Need Specific Predictors

P3-14-12  Local Control of Primary Breast Cancer Treated with Radical Radiotherapy Alone after Neoadjuvant Chemotherapy

Makris A, Li SP, Ravichandran D, Ostler PJ, Pittman M. Mount Vernon Cancer Centre, Northwood, Middlesex, United Kingdom; Luton and Dunstable, Luton, United Kingdom.

P3-14-13  A Prospective Open-Label Randomized Phase II Neoadjuvant Study of Non-Pegylated Liposomal Doxorubicin (MYOCET®) Plus Cyclophosphamide and Trastuzumab Versus Conventional Doxorubicin Plus Cyclophosphamide Alone, Each Followed by Docetaxel and Trastuzumab, in HER2-Positive Breast Cancer Patients

Llombart-Cussac A, Perrin-Simon S, Rezai M, Hauschild M, Venturini M, Machels J-P, Paepe S, Luporsi E, Kasiskorski F, Kayaline L. Hospital Amava de Vilanova, Lleida, Spain; Hospital T’s Hospitalet de Llobregat, Barcelona, Spain; Luisenkrankenhaus Düsseldorf, Düsseldorf, Germany; Ospedale Sacro Cuore, Negrar (Verona), Italy; Cliniques Universitaires St-Luc, Université Catholique de Louvain, Brussels, Belgium; Technischen Universität München, München, Germany; Centre Aexitis Vaurini, Vandoeuvre-Les-Nancy, France; Cephalon, Maisons-Alfort, France; Frauenklinik und Brustzentrum Rheinfelden, Rheinfelden, Germany.

P3-14-14  Increased Prevalence of Low Vitamin D Level in Breast Cancer Patients during Neoadjuvant Chemotherapy

P3-14-15  Non-Randomized, Open Label Phase II Trial Evaluating the Safety and Efficacy of Taxotere (T) Followed by Myocet (M) + Cyclophosphamide (C) as First-Line Treatment for HER2-Negative Breast Cancer (BC)

Garcia-Mata J, Calvo L, Lopez R, Ramos M, Castellanos J, Heras L. Complexo Hospitalario de Ourense, Ourense, Spain; Complexo Hospitalario Universitario A Coruña, A Coruña, Spain; Hospital Clinico de Santiago, Santiago de Compostela, A Coruña, Spain: Complexo Hospitalario Universitario Xeral Cies, Vigo, Pontevedra, Spain; Hospital Sociosanitari de L’Hospitalet, Barcelona, Spain.

P3-14-16  Molecular Phenotype and the Use of HER-2 Targeted Agents Influence the Accuracy of Breast MRI after Neoadjuvant Chemotherapy

P3-14-17  Paclitaxel, Carboplatin, and Trastuzumab in a Neoadjuvant Regimen for HER2-Positive Breast Cancer: The TRAIN Study

Sonke GS, Barry W, Marcom PK, Ready N, Abernethy A, Lyman GH. Duke University, Durham, NC; BiPar Sciences, South San Francisco, CA.

P3-14-18  Primary Tumor Response to Neoadjuvant Chemotherapy Is Significantly Associated with Nodal Pathological Complete Response in Breast Cancer Patients with Cytologically Proven Axillary Node Metastasis

Hwang H, Park S, Lee JS, Kim S-J, Park B-W. Yonsei University College of Medicine, Seoul, Korea.
P3-14-19 Impact of Chemotherapy-Induced Amenorrhea on Response to Neoadjuvant Chemotherapy in Breast Cancer
Ahn SK, Moon HG, Kim JS, You JM, Shin Hc, Han W, Noh D-y. Seoul National University Hospital.

P3-14-20 Concomitant Taxane-Anthracyclin Regimen for Neoadjuvant Chemotherapy of Primary Breast Cancer: Experience from a Cohort of 223 Patients Treated in a Single Institution

P3-14-21 Neoadjuvant Therapy Response, Subtype and BRCA Status in an Underserved Population

P3-14-22 Response to Neoadjuvant Chemotherapy in Elderly Patients with Locally Advanced Breast Cancer

P3-14-23 Response to Neoadjuvant Chemotherapy and Survival in Japanese Patients with Triple-Negative Breast Cancer
Ohtani S, Kochi M, Ito M, Takada S, Matsuura H, Higaki K. Hiroshima City Hospital, Hiroshima, Japan.

P3-14-24 A Phase II Trial of TS-1 and Docetaxel Followed by 5-FU/Epirubicin/Cyclophosphamide (FEC) as Preoperative Treatment in Women with Stage II/III Breast Cancer
Hayashida T, Jinno H, Sakata M, Takahashi M, Kitagawa Y. Keio University School of Medicine, Tokyo, Japan.

P3-14-25 Neoadjuvant Trastuzumab and Paclitaxel Combination Increases a High Rate of Pathological Complete Responses in Locally Advanced Breast Cancer by Exploiting Host Antitumor Immunity

P3-14-26 The Effect of Biologic Subtype in Patients Treated with Neoadjuvant Chemotherapy: A UAB Experience
Keene KS, De Los Santos JF, Meredith R, Hinton B, Li Y, Krontritas H, Bland K, Carpenter JT, Forero A. University of Alabama at Birmingham, Birmingham, AL.

P3-14-27 Pegylated Liposomal Doxorubicin (PLD) as Primary Treatment in Estrogen Receptor (ER) and HER2 Poor Breast Cancer and Risk of Developing Cardiotoxicity or Elderly Patients (pt).

P3-14-28 ANZ 0502 NeoGem: A Phase II Trial Evaluating the Efficacy and Safety of Epirubicin and Cyclophosphamide Followed by Docetaxel with Gemcitabine (+ Trastuzumab If HER2 Positive) as Neoadjuvant Chemotherapy for Women with Large Operable or Locally Advanced Breast Carcinoma
McNulty N, Boyle B, Bull J, Leong E, Simpson A, Kannouakis G, Gebski V, Forbes JF, Wolkens N, Lindsay DF, Badger HD. Royal Brisbane and Women’s Hospital, Brisbane, Queensland, Australia; The Mater Hospital, Sydney, New South Wales, Australia; Wellington Hospital, Wellington, New Zealand; Ballarat Oncology and Haematology Service, Ballarat; Victoria, Australia; NHRMC Clinical Trials Centre, Sydney, New South Wales, Australia; University of Newcastle, Newcastle, New South Wales, Australia; Calvary Mater Newcastle, Newcastle; New South Wales, Australia; Westmead Hospital, Sydney, New South Wales, Australia; Australian New Zealand Breast Cancer Trials Group, Newcastle, New South Wales, Australia.

P3-14-29 Neoadjuvant Sunitinib Administered with Weekly Paclitaxel/Carboplatin in Patients with Locally Advanced Triple-Negative Breast Cancer: A Sarah Cannon Research Institute Phase II/II Trial

P3-14-30 Concurrent Celescoxi with FEC Followed by Docetaxel Shows Good Responses and Prognosis in a Neoadjuvant Breast Cancer Study
Chow LWC, Tung SY, Ng T-Y, Oh D-Y, Im S-A, Lee M-H, Yip AYS, Toi M, Glück S. Organisation for Oncology and Translational Research, Hong Kong; UNIMED Medical Institute, Hong Kong; Tuen Mun Hospital, Hong Kong; Seoul National University Hospital, Seoul, Korea; Soochunhyang University Hospital, Seoul, Korea; Kyoto University Hospital, Kyoto, Japan; University of Miami Leonard M. Miller School of Medicine, Miami, FL.

P3-14-31 Preoperative Chemotherapy and Bevacizumab for Locally Advanced HER-2 Negative Breast Cancer Followed by Prolonged Postoperative Bevacizumab for Those with Less Than Complete Pathologic Response
Carpenter JT, Forero A, Falkson CI, Nabeil LM, De Los Santos JF, Krontritas H, Bland K, Li Y. University of Alabama at Birmingham, Birmingham, AL.

P3-15-01 An Interim Efficacy Analysis of Neoadjuvant Letrozole in the New Primary Endocrine-Therapy Origination Study (NEOS/N-SAS BC06): A Randomized Study of Adjuvant Endocrine Therapy with or without Chemotherapy for Postmenopausal Breast Cancer Patients Who Responded to Neoadjuvant Letrozole
Iwata H, Yamaguchi T, Masuda N, Toyama T, Kashiwaba M, Yamamoto Y, Taia N, Saji S, Ohashi Y. Aichi Cancer Center, Nagoya, Japan; Tohoku University Graduate School of Medicine, Sendai, Japan; NHO Osaka National Hospital, Osaka, Japan; Nagoya City University Hospital, Nagoya, Japan; Iwate Medical University, Morioka, Japan; Kumamoto University Hospital, Kumamoto, Japan; Okayama University Hospital, Okayama, Japan; Satama Medical University International Medical Center, Hidakura, Japan; The University of Tokyo, Tokyo, Japan.

P3-15-02 The Change of Bone Turnover Markers during Neoadjuvant Anastrozole Versus Exemestane: A Randomized Single-Center Study
Jinno H, Shima K, Takahashi M, Hayashida T, Hirose S, Ikekda T, Kitagawa Y. Keio University School of Medicine, Shinjuku, Tokyo, Japan; Teikyo University School of Medicine, Itabashi, Tokyo, Japan.
P3-16-01  Safety Profile and Clinical Activity of Single-Agent BKM120, a Pan-Class I PI3K Inhibitor, for the Treatment of Patients with Metastatic Breast Carcinoma

Rodon J, Bendell JC, Abdul Razak AR, Homji N, Trandafir I, Quadt C, Graña-Suárez B, Siu LL, Di Tomaso E, Demanet D, Massacesi C, Hirawat S, Burns III HA, Baselga J. Vall d’Hebron University Hospital, Barcelona, Spain; Sarah Cannon Research Institute, Nashville, TN; Princess Margaret Hospital, Toronto, ON, Canada; Novartis Pharmaceuticals, Florham Park, NJ; Novartis Oncology, Paris, France; Novartis Pharma AG, Basel, Switzerland; Novartis Institutes for BioMedical Research Inc, Cambridge, MA, Massachusetts, Boston, MA.

P3-16-02  Targeting Tumor Initiating Cells with siRNA/Nanotherapy in Triple Negative Breast Cancer

Granados-Principal S, Deng X, Liu D, Chang JC, Shen H, Dave B. The Methodist Research Institute, Houston, TX; Baylor College of Medicine, Houston, TX.

P3-16-03  Enhancing Anti-IGF Directed Therapeutics by Co-Targeting Autophagy

Oh AS, LaPara K, Yee D. University of Minnesota, Minneapolis, MN.

P3-16-04  A Novel Monoclonal Antibody to Secreted Frizzled Related Protein 2 Inhibits Triple Negative Breast Carcinoma Growth Rate In Vivo

P3-16-05  A Phase II Trial Expansion Cohort of the PARP Inhibitor Veliparib (ABT888) and Temozolomide in BRCA1/2 Associated Metastatic Breast Cancer

Isakkoff SJ, Overmoyer B, Tung NM, Gelman RS, Habin K, Qian J, Giranda V, Shepherd S, Garber JE, Ellisien LW, Winer EP, Goss PE. Massachusetts General Hospital Cancer Center, Boston, MA; Dana Farber Cancer Institute, Boston, MA; Beth Israel Deaconess Medical Center, Boston, MA; Harvard Medical School, Boston, MA; Abbott Laboratories, Abbott Park, IL.

P3-16-06  Phase II Trial of T-1 in Combination with Oxaliplatin (SOX) in Patients with Metastatic Breast Cancer (MBC) Previously Treated with Anthracycline and Taxane Chemotherapy

Im S-A, Oh D-Y, Lee KS, Ahn J-H, Shin J, Ahn JS, Kim JH, Han SW, Lee MH, Lee KE, Lee K, Kim HJ, Keam B, Kim S-Y, Kim SB, Im YH, Ro J, Park H-S. Seoul National University Hospital, Seoul, Republic of Korea; National Cancer Center, Republic of Korea; Asan Medical Center, Seoul, Republic of Korea; YonSei University College of Medicine, Severance Hospital, Seoul; Samsung Medical Center, Seoul, Republic of Korea; Seoul National University Bundang Hospital, Seongnam, Republic of Korea; Inha University Hospital, Incheon, Republic of Korea; Ewha Womans University Medical Center, Seoul, Republic of Korea; Hanlim University Pyungchon Hospital, Pyungchon, Republic of Korea; Korea University; Kyung Hee University Hospital, Seoul, Republic of Korea; Soon Chun Hyang University Hospital, Seoul, Republic of Korea.

P3-16-07  Effect of Denosumab Treatment for Patients with Breast Cancer and Bone Metastases: Results from the Open-Label Extension Treatment Phase

Stopeck AT, Lipton A, Martin M, Body J-L, Paterson A, Steger GG, Tonkin K, De Boer RH, Fujiiwara Y, Yardley D, Jassem J, Takano T, Solal-Celigny P, Fan M, Braun A. Arizona Cancer Center, University of Arizona, Tucson, AZ; Penn State Milton S. Hershey Medical Center, Hershey, PA; Hospital General Universitario Gregorio Marañón, Madrid, Spain; CHU Brugmann, Université Libre de Bruxelles, Brussels, Belgium; Tom Baker Cancer Centre, Calgary, AB, Canada; Medical University of Vienna, Vienna, Austria; Cross Cancer Institute, Edmonton, AB, Canada; Royal Melbourne and Western Hospitals, Melbourne, Australia; National Cancer Center Hospital, Tokyo, Japan; Sarah Cannon Research Institute, Nashville, TN; Tennessee Oncology, PLLC, Nashville, TN; Akademickie Centrum Kliniczne Szpital Akademicki Medycznej w Gdaniku, Gdansk, Poland; Toranomon Hospital, Tokyo, Japan; Clinique Victor Hugo, Centre Jean Bernard, Le Mans, France; Argen, Inc., Thousand Oaks, CA.

P3-16-08  A Phase 2, Randomized Open-Label Study of Iniparib, Administered Either Weekly or Twice-Weekly in Combination with Gemcitabine Plus Carboplatin in Patients with mTNBC

Diéras V, Bonnefoi H, Alba E, Awada A, Coudert B, Pivot X, Gilgorev J, Jäger A, Giannini L, Lindeman G, Pham N, Su Y, Gao M, Mery-Mignard D, Pardiens R, Verweij J. Institut Curie, Paris, Cedex 05, France; Université de Bordeaux, Bordeaux, INSERM, France; Hospital Clínico Universitario Virgen de la Victoria, Málaga, Spain; Institut Jules Bordet, Centre des Tumeurs de l’Université Libre de Bruxelles, Brussels, Belgium; Centre Georges François Leclerc, Dijon, France; University Hospital Jean Minjoz, Besançon, France; University Paris VI, Paris, France; Erasmus University Medical Center, Daniel den Hoed Cancer Center, Rotterdam, Netherlands; HSR - San Raffaele, Milan, Italy; The Royal Melbourne Hospital and The Walter and Eliza Hall Institute of Medical Research, Melbourne, Victoria, Australia; Sanofi, Vitry, Paris, France; Sanofi, Great Valley, PA; Sanofi, Cambridge, MA; University Hospital Gasthuisberg, Catholic University of Leuven, Leuven, Belgium; Erasmus University Medical Center, Rotterdam, Netherlands.

P3-16-09  Endoxifen, a Newly Developed Breast Cancer Drug, Has Anabolic Actions on the Mouse Skeleton

P3-16-10  The Efficacy of Zoledronic Acid in Breast Cancer Adjuvant Therapy: A Meta-Analysis of Randomized Controlled Trials

Lu J, Yan Y, Zhui Q, Zhou L, Jiang Y, Diu Y, Shao Z. Fudan University Shanghai Cancer Center, Shanghai, China; Shanghai Medical College, Fudan University, Shanghai, China.

P3-16-11  Prospective Evaluation of Radiation Pneumonitis in Neoadjuvant Concurrent Docetaxel and Radiation Therapy for Locally Advanced Breast Cancer

P3-16-12  Cardiac Safety of Non-Pegylated Liposomal Doxorubicin and Docetaxel as 1st Line Treatment in Metastatic HER2 Negative Breast Cancer (Myotax Study)

P3-16-14  Effect of TG02, a Multikinase Inhibitor, on Triple Negative Breast Cancer Cells

Pandirri A, Ortiz-Ruiz MJ, Burrows F, Ocaña A, Espiria-Ogando A. Cancer Research Center, Salamanca, Spain; Hospital Universitario Albacete, Spain; Tragara Pharmaceuticals, San Diego, CA.
P3-16-15  Phase I Study with Biomarker Evaluation of Neoadjuvant Sunitinib in Combination with Exemestane in Post-Menopausal Women with Hormone-Sensitive, Her-2 Negative Primary Breast Cancer
Morales S, Gil M, Lломbart A, Garcia M, Uruticoechea A, Pernas S. University Hospital Arnau de Vilanova, Lleida, Cataluña, Spain; University Hospital ICO-Duran i Reynals, Barcelona, Cataluña, Spain.

P3-16-16  Overcoming EGFR Resistance Using Dasatinib in Combination with Cetuximab and Cisplatin in Triple Negative Breast Cancer Cell Lines
Kim EMH, Gartner E, Choi L, Boerner J. Wayne State University, Karmanos Cancer Center, Detroit, MI.

P3-16-17  The Identification of Novel Microtubule Stabilizing Taconalolides
Risinger AL, Li J, Peng J, Chen Z, Mooberry SL. University of Texas Health Science Center, San Antonio, TX; Shanghai Institute of Materia Medica, Shanghai, China.

P3-16-18  Phase 2, Open-Label Study of EZN-2208 (PEG-SN38) in Patients with Previously TreatedMetastatic Breast Cancer
O’Shaughnessy JA, Osborne CRC, Steinberg MA, Holmes FA, Kim HS, Kocs DM, Richards PD, Vukelja SJ, Berkowitz N, Buchbinder A. Texas Oncology - Baylor Charles A. Sammons Cancer Center, Dallas, TX; Virginia Oncology Associates, Norfolk, VA; Texas Oncology - Houston Memorial City, Houston, TX; Rocky Mountain Cancer Centers, Denver, CO; Texas Oncology - Austin Midtown, Austin, TX; Oncology & Hematology Associates of Southwest Virginia, Inc., Danville, VA; D.A. Blue Ridge Cancer Care, Salem, VA; Tyler Cancer Center, Tyler, TX; US Oncology; Enzon Pharmaceuticals, Inc., Piscataway, NJ.

Treatment – Therapeutic Strategies: Novel Drugs and Targeted Agents

P3-17-01  ApoE and Its Receptors (LRP8, VLDLR) Function as Growth Signals for Triple-Negative Breast Cancer and Represent a Novel Therapeutic Target

P3-17-02  Targeting the Autophagy Pathway for Drug Resistance of Breast Tumor-Initiating Cells
Zhao H, Li F, Cui K, Sheng J, Landis M, Chang J, Wong S, Dave B. The Methodist Hospital Research Institute, Weill Medical College, Cornell University, Houston, TX; The Methodist Hospital, Weill Medical College, Cornell University, Houston, TX.

P3-17-03  ADAM17: A Novel Therapeutic Target for Treatment of Triple Negative Breast Cancer
McGowan PW, Mulloylo M, Sukor S, Madden S, McDermott E, Pierce A, Crown J, O’Donovan N, Duffy MJ. St. Vincent’s University Hospital, Dublin, Ireland; University College Dublin, Dublin, Ireland; Dublin City University, Dublin, Ireland; Molecular Therapeutics Cancer Ireland, Dublin, Ireland.

P3-17-04  CKCR1/2 Regulates Human Breast Cancer Stem Cell Activity Via EGFR/HER2-Dependent and -Independent Pathway
Singh JK, Farnie G, Clarke RB, Bundred NJ. School of Cancer and Women’s Health, University of Manchester, Paterson Institute for Cancer Research, Manchester, United Kingdom; University Hospital of South Manchester, Wythenshawe Hospital, Manchester, United Kingdom.

P3-17-05  Beyond HER2 and Hormonal Agents: The Heat Shock Protein 90 Inhibitor Ganetespib as a Potential New Breast Cancer Therapy

P3-17-06  Final Results of a Controlled, Randomized 3-Arm Phase II Trial of EndoTAG™-1, a Cationic Liposomal Formulation of Paclitaxel Targeting Tumor Endothelial Cells, in Advanced Triple-Negative Breast Cancer (TNBC)
Awada A, Bondarenko IN, Tarasova O, Bonnetere J, Nowara E, Ferrero JM, Bakshi AV, Weidenthaler H, Wilke C, Piscart MJ. Institut Jules Bordet, Brussels, Belgium; Dnepropetrovsk State Medical Academy, Dnepropetrovsk, Ukraine; Academy of Medical Sciences of Ukraine, Kharkov, Ukraine; Centre Oscar Lambret, Lille, France; Instytut im. M.Skdowskiej-Curie, Gliwice, Poland; Centre Antoine Lacassagne, Nice, France; Kaushalya Medical Foundation, Thane, India; Medigene AG, Martinsried, Germany.

P3-17-07  EGCG, a Green Tea Antioxidant Suppresses Breast Tumor Angiogenesis and Growth Via Inhibiting the Activation of HIF-1α and NFκB, and VEGF Expression
Makey KI, Tucker KB, Chinchir E, Miele L, Pei I, Thomas EY, Gu J-W. University of Mississippi Medical Center, Jackson, MS.

P3-17-08  Macroautophagy Protects Breast Cancer MCF-7 Cells from TAM-Induced Apoptosis Via Mitogen-Activated Protein Kinase (MAPK) Pathway
Hou YF, Ma XY, Liu Z, Yu SJ, Shao ZM. Cancer Institute, Shanghai, China.

P3-17-09  Neutralizing the Prolactin Receptor with Therapeutic Antibody LFA102: A Novel Approach for the Treatment of Breast Cancer

P3-17-10  EpCAM as a Target for Chemical Antibodies in Metastatic Breast Cancer
Shigdar SL, Du W. Deakin University, Geelong, Victoria, Australia.

P3-17-11  Dovitinib (TKI258), a Dual Inhibitor of FGFR and VEGFR, Induces Tumor Growth Suppression in Xenograft Models of Primary Human Breast Cancer
Shi WM, Linnartz R, Versace R, Graus Porta D, Kay A, Dugan M, Novartis Oncology, East Hanover, NJ; Novartis Institutes for BioMedical Research, Basel, Switzerland.

P3-17-12  Regulation of tubulin detyrosination—a cancer cell specific antimicrotubule strategy for breast cancer treatment
Bleys SW, Sung Y-NS, Hall MD. Sahab ZI. Georgetown-Lombardi Comprehensive Cancer, Washington, DC.

P3-17-13  Romidepsin inhibits growth and metastasis and is synergistic with paclitaxel in pre-clinical models of inflammatory breast cancer
Robertson FM, Chu K, Mu Z, Boyle KM, Green TL, Moraes R, Zhang X, Alpaugh RR, B Photography A, Ye Z, Wright MC, Liu H, Luo AZ, Barsky SH, Heise C, Cristofanilli M. The University of Texas MD Anderson Cancer Center, Houston, TX; , Fox Chase Cancer Center, Philadelphia, PA; University of Nevada School of Medicine and Nevada Cancer Center, Reno and Las Vegas, NV, Celgene Corporation, San Francisco, CA.

Treatment – Therapeutic Strategies: Signal Transduction Inhibitors

P3-18-01  cMET Inhibitor and the Inhibition of Growth of Breast Cancer Cells in Bone Marrow Matrix Environment
Ye L, Mazon MD, Bramble P, Jiang WG. Cardiﬁ University School of Medicine, Cardiff, Wales, United Kingdom; Astra-Zeneca Pharmaceuticals, Surr, United Kingdom.

P3-18-02  A Combination of Pathway-Targeted Inhibitor with DNA-Repair Inhibitor: Preclinical Efficacy of Zsamtima and Olaparib in Triple Negative Subset of Breast Cancer
Dey N, Wu H, Sun Y, De P, Leyland-Jones B. Emory University, Atlanta, GA.
P3-18-03  In Vitro Potency of mTOR Kinase (TOR1/TOR2) Inhibitor, INK128 in ER+ and HER2 Overexpressing Breast Cancer Cells
De P, Sun Y, Dey N, Leyland-Jones B. Emory University, Atlanta, GA

P3-18-04  Pathway Guided Selection of Targeted Inhibitors for Breast Cancer Treatment

P3-18-05  Triple-Negative Breast Cancer: Stem Cells, Cancer and New Treatment Strategy
Yin S, Xu L, Reddy KB. Wayne State University School of Medicine, Detroit, MI

Engel J, Sospelt I, Honig A, Hahne JC, Teifel M. Medical University of Würzburg, Würzburg, Germany; Attema Zentaris GmbH, Frankfurt, Germany.

P3-18-07  Multiplex RTK Inhibitor Screening Utilizing a Plate-Based Immunoassay with Near-Infrared Detection
Finkel DJ, James AE, Felix RA, Wegner GI. R&D Systems Inc., Minneapolis, MN; Tecnos Bioscience, Bristol, United Kingdom.

5:15 pm–7:00 pm POSTER DISCUSSION V: HER2

Ballroom A

Viewing 5:15 pm
Discussion 5:30 pm
Discussant: Michael F. Press, MD, PhD
USC/ Norris Comprehensive Cancer Center
Los Angeles, CA

PD05-01  Trans-CHER-Lob: A Biomarker Analysis of the Randomized Phase II Study of Neoadjuvant Chemotherapy Plus Trastuzumab, Lapatinib or Combined Trastuzumab and Lapatinib in HER2 Positive Operable Breast Cancer
Guameri V, Frassoldati A, Faciara G, Maiorana A, Bettelli S, Bottini A, Cagossi K, Bisagni G, Ravaoli A, Amadori D, Musolino A, Cavanna L, Orlando L, Giardina G, Piacentini F, Bagnalata M, Conte P. Modena University Hospital, Modena, Italy; Medical Oncology, Ferrara University Hospital; Modena University Hospital; Istituti Ospitalieri, Cremona; Ramazzini Hospital, Carpi; Arcispedale Santa Maria Nuova, Reggio Emilia; Ospedale Infermi, Rimini; Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori, Meldola (FC); Parma University Hospital; Hospital of Piacenza; Ospedale di Circolo e Fondazione Macchi, Varese; Perrino Hospital, Brindisi; GlaxoSmithKline, Verona.

PD05-02  Effect of HER2/Topoisomerase II alpha (TOP2A) Gene Status on Protein Expression and Chromosome 17 (CEP17) Polysomy on the Outcome of Breast Cancer Patients Treated with Anthracycline-Containing Dose-Dense Sequential Adjuvant Chemotherapy with or without Paclitaxel - A Pooled Analysis of Two Hellenic Cooperative Oncology Group (HeCOG) Phase III Trials

PD05-03  Impact of Quantitative Measurement of HER2, HER3, HER4, EGFR, ER and PTEN Protein Expression on Benefit to Adjuvant Trastuzumab in Early-Stage HER2+ Breast Cancer Patients in NCTCG N9831
Perez EA, Ballman KV, Reinholz MM, Dueck AC, Cheng H, Jenkins RB, McCullough AE, Chen B, Davidson NE, Martino S, Kaufman PA, Kutteh LA, Sledge GW, Geiger XJ, Ingle JN, Tenner KS, Harris LN, Gralow JR, Rimm DL. Mayo Clinic, Jacksonville, FL; Mayo Clinic, Rochester, MN; Mayo Clinic, Scottsdale, AZ; University of Pittsburgh Cancer Institute, Pittsburgh, PA; Angeles Clinic and Research Institute, Santa Monica, CA, Dartmouth Hitchcock Medical Center, Lebanon, NH, Oncology Associates of Cedar Rapids, Cedar Rapids, IA, Indiana University Medical Center Cancer Pavilion, Indianapolis, IN; Yale University, New Haven, CT; Seattle Cancer Care Alliance, Seattle, WA.

PD05-04  Quantitative Measurement of Antigen Degradation in NCTCG N9831 Tissue Microarrays
Cheng H, Rimm DL, Reinholz MM, Lingle WL, Ballman KV, Dueck AC, Chen B, McCullough AE, Jenkins RB, Perez EA. Yale University School of Medicine, New Haven, CT; Mayo Clinic, Rochester, MN; Mayo Clinic, Scottsdale, AZ; Mayo Clinic, Jacksonville, FL.

PD05-05  Meta Analysis of Discordant HER2 Status in Matched Primary and Metastatic Breast Cancer
Richter S, Zee A. Princess Margaret Hospital; University of Western Ontario.

PD05-06  Determination of HER2 Status with Analysis of Plasma DNA by Digital PCR in Patients with Metastatic Breast Cancer
Greaser MK, Sevensliewen H, Smith E, Ashworth A, Turner NC, Institute of Cancer Research, London, United Kingdom; Royal Marsden Hospital, London, United Kingdom.

PD05-07  Prospective Validation and Characterization of HER2 Positive Circulating Tumor Cells in Patients with HER2 Negative Metastatic Breast Cancer

5:15 pm–7:00 pm POSTER DISCUSSION VI: COST EFFECTIVENESS/UTILIZATION

Ballroom B

Viewing 5:15 pm
Discussion 5:30 pm
Discussant: Thomas J. Smith, MD, FACP
Johns Hopkins
Baltimore, MD

PD06-01  Molecular Classification with 21 Gene Assay (OncoType Dx) in 196,967 ER Positive Patients Shows High Frequency of Low Recurrence Score (LRS) in Both Node Positive (N+) and Negative (N-) Breast Cancer (BrCa) Cohorts. Cost and Guideline Implications

PD06-02  Cost-Effectiveness Evaluation of the Oncotype DX® Breast Cancer Assay in Clinical Practice in the UK
Holt SDH, Bennett H, Bertelli G, Valentine WJ, Phillips CJ. Prince Philip Hospital, Llanelli, United Kingdom; Cardiff Research Consortium, Cardiff, United Kingdom; Singleton Hospital, Swansea, United Kingdom; Ossian Health Economics and Communications, Basel, Switzerland; Swansea University, Swansea, United Kingdom.

PD06-03  Cost Effectiveness Analysis of BRCA1/2 Genetic Testing
Li Q, Holland M, Huston A, Noyes K. University of Rochester School of Medicine, Rochester, NY.
OT2-01-03 Eribulin in Women with Locally Advanced Breast Cancer Who Do Not Achieve Pathologic Complete Response (pCR) Following Neoadjuvant Chemotherapy: A Sarah Cannon Research Institute Phase II Trial
Yardley DA, Peacock NW, Hainsworth JD, Burris III HA. Sarah Cannon Research Institute, Nashville, TN. Tenesse Oncology, PLLC, Nashville, TN.

OT2-01-04 Cardiac Safety of Anthracycline-Containing Adjuvant Chemotherapy of Early Breast Cancer: OSCAR/ABC Ongoing, Observational, Multicentric Study
Ricevuto E, Cociolone V, Zilli M, Scognamiglio MT, Pistilli B, Di Menna G, Mancini M, Carnita K, Adinolfi MI, Ferrandina MG, Piccotti A, Recchia F, Latini L, Ficorella C, Iacobelli S. Endocrine Therapy

OT2-02-01 The SOLE Trial: International Breast Cancer Study Group (IBCSG 35-07) and Breast International Group (BIG 1-07) Study of Letrozole Extension
Colleoni M. SOLE Collaborative Group and International Breast Cancer Study Group.

OT2-03-01 Incidence of Mastalgia as a Presenting Complaint in Iranian Population with Regard to Age, BMI, Education, Residency (City or Rural), State of Marriage and Compare with Western Countries
Razavi S. Private Breast Clinic, Esfahan, Islamic Republic of Iran.

OT2-03-02 Prospective Neo-Adjuvant Registry Trial Linking MammaPrint, Subtyping and Treatment Response: Neoadjuvant Breast Registry - Symphony Trial (NBRST)
Whitworth P, Betsch P, Gentleman M, Akbari S. Nashville Breast Center, Nashville, TN; Dallas Surgical Group, Dallas, TX; Breast Care Specialists, Allentown, PA; Virginia Hospital Center, Arlington, VA.

OT2-03-03 Spectroscopic Feature of Breast Cancer

OT2-03-04 A Trial Model for the Future in the Search for Personalised Medicine - The UK POETIC and EPHOS-B Perioperative Trials Experience
Bliss JM, Robison LE, Webster-Smith MF, Emson MA, Kilburn LS, Smith IE, Robertson J, Dowsett M, Bundred NJ, Cameron DA, Vidya H, Horgan K, Evans AA, Kokan JS, Pinhel I, A'Hern R, on Behalf of the POETIC & EPHOS-B Trialists. Institute of Cancer Research, Sutton, London, United Kingdom; Royal Marsden Hospital, London, United Kingdom; Nottingham University Hospitals, Nottingham, United Kingdom; Royal Marsden Hospital and Breakthrough Breast Centre, London, United Kingdom; Wythenshawe Hospital, Manchester, United Kingdom; Western General Hospital, Edinburgh, United Kingdom; Stafford Hospital, Stafford, United Kingdom; Leeds General Infirmary, Leeds, United Kingdom; Poole Hospital, Poole, United Kingdom; Macclesfield District General Hospital, Macclesfield, United Kingdom.

OT2-03-05 Evaluation of the Prevalence and Prognostic Significance of VEGF 165s in Breast Cancer Patients Compared to Healthy Women

Chemotherapy

OT2-01-01 International Breast Cancer Study Group (IBCSG) Trial 22-00: Low-Dose Cytotoxics as Maintenance “Anti-Angiogenesis Treatment” Following Adjuvant Induction Chemotherapy for Patients with ER-Negative and PgR-Negative Breast Cancer
Colleoni M. International Breast Cancer Study Group.

OT2-01-02 First-Line Bevacizumab in Combination with Capecitabine or Paclitaxel for HER2-Negative Locally Recurrent or Metastatic Breast Cancer (LR/MBC): A Randomized Phase III Trial
Besl,ia Brodowicz, Greil, Inbar MJ, Kahain, Kaufman, Lang, Steger, Stemmer, Zielinski, Zierbale, The CECOG TURANDOT Trialists: Institute of Oncology, Sarajevo, Bosnia and Herzegovina; Medical University of Vienna, Vienna, Austria; University Hospital Salzburg, Salzburg, Austria; Tel Aviv Sourasky Medical Centre, Tel Aviv, Israel; University of Szeged, Szeged, Hungary; Sheba Medical Center, Tel Hashomer, Israel; National Institute of Oncology, Budapest, Hungary; Rabin Medical Center, Petah Tikva, Israel; Riga Eastern Clinical University Hospital, Riga, Latvia.
OT2-03-06  ACRIN 6698 MR Imaging Biomarkers for Assessment of Breast Cancer Response to Neoadjuvant Chemotherapy: A Sub-Study of the I-SPY 2 TRIAL (Investigation of Serial Studies To Predict Your Therapeutic Response with Imaging And molEcular Analysis)

Hylton NM, Partridge SC, Rosen M, Kim E, L’Heureux DZ, Esserman L, University of California at San Francisco, San Francisco, CA; University of Washington, Seattle, WA; Hospital of the University of Pennsylvania, Philadelphia, PA; Brown University, Providence, RI; American College of Radiology Imaging Network, Philadelphia, PA.

OT2-03-07  Withdrawn

Prevention

OT2-04-01  A Randomized Phase II Trial of Vitamin D vs Placebo in Premenopausal Women: CALGB 70806

Wood MC, Kingsley F, Ambaye AB, Yee L, Jung S-H, Marshall JR, Paskett E, University of Vermont, Burlington, VT; Ohio State University, Roswell Park Cancer Institute; Duke University.

OT2-04-02  Metformin for Breast Cancer Prevention: A Pilot Study

Ledgerwood NM, Djedja-Fourmer H, Patterson R, Hasteil F, Andre MP, Cadmus L, Blair S, University of California, San Diego, CA.

OT2-04-03  Uptake of a Randomized Breast Cancer Prevention Trial Comparing Letrozole to Placebo in BRC1/2 Mutations Carriers: The FNCLCC ONCO-03/LIBER Trial

Pujal P, Lasset C, Berthet P, Dugast C, Delagelle S, Fricker JP, Chabbert Buffet N, Lemonnier J, Rocca L, Mjolmen S, Baudry K, Martin AL, University Hospital CHU Amiens de Villeneuve, Montpellier, France; Centre Léon Bérard, Lyon and Université de Lyon 1; CNRS; UMR 5558, Villeurbanne, France; Centre Francois Baclesse, Caen, France; Institut Gustave Roussy, Villejuif, Centre Paul Strauss, Strasbourg, AP HP Hôpital Tenon; Fédération Nationale Française des Centres de Lutte Contre le Cancer.

Imaging

OT2-05-01  An Open-Label Positron Emission Tomography Study To Investigate and Quantify Brain and Tumor Penetration of Carbon-11-Labeled Lapatinib in Patients with HER2-Overexpressing Advanced or Metastatic Breast Cancer

OT2-05-02  ACRIN 6691 Monitoring and Predicting Breast Cancer Neoadjuvant Chemotherapy Response Using Diffuse Optical Spectroscopic Imaging (DOSI)

Trombregh BJ, L’Heureux DZ, Mankoff DA, Zhang Z, Cerussi A, Mehta R, Carpenter PM, Butler JA, Hylton NM, Kaufman P, Pogue BW, Paulsen K, Yodh AG, Boas DA, Isakoff S, University of California, Irvine, CA; American College of Radiology Imaging Network, Philadelphia, PA; University of Washington, Seattle, WA; Brown University, Providence, RI; University of California at San Francisco, San Francisco, CA; Dartmouth University, Lebanon, NH; University of Pennsylvania, Philadelphia, PA; Massachusetts General Hospital, Charlestown, MA; Massachusetts General Hospital, Boston, MA.

OT2-05-03  ACRIN 6688 Phase II Study of Fluorine-18 3'-Deoxy-3'-Fluorothymidine (FLT) in Invasive Breast Cancer

Jollès P, Kontakouglu L, Bear HE, Iwado MO, Kurzziel K, Shankar L, Mankoff DA, Duan F, L’Heureux DZ, Virginia Commonwealth University, Richmond, VA; Mount Sinai School of Medicine, New York, NY; National Cancer Institute, Bethesda, MD; University of Washington, Seattle, WA; Brown University, Providence, RI; American College of Radiology Imaging Network, Philadelphia, PA.

OT2-05-04  ACRIN PA 4006: Comparison of Full-Field Digital Mammography with Digital Breast Tomosynthesis Image Acquisition in Relation to Screening Call-Back Rate

Conant EF, Maidment A, Copt D, Olson CB, Heckel ML, Gatsonis C, Hospital of the University of Pennsylvania, Philadelphia, PA; Albert Einstein Medical Center, Philadelphia, PA; American College of Radiology Imaging Network, Philadelphia, PA; Brown University, Providence, RI.

OT2-05-05  Phase II/II Study of Adoptive T Cell Therapy Following In Vivo Priming with a HER2 Peptide-Based Vaccine in Patients with Stage IV Breast Cancer

Parker SL, Higgins DM, Childs JS, Dang Y, Guthrie KA, Disis ML, Salazar LG, Covelar A, University of Washington, Seattle, WA; Fred Hutchinson Cancer Research Center, Seattle, WA.

OT2-05-06  ACOSOG Z11101/ACRIN 6694: Effect of Preoperative Breast MRI on Surgical Outcomes, Costs and Quality of Life of Women with Breast Cancer

Bedrossian J, Suman VJ, Yao K, Shih Y-CT, Yen TWF, Comstock C, Newsstead G, Birdwell R, Kim E, L’Heureux DZ, Gatsonis C, MD Anderson Cancer Center, Houston, TX; Mayo Clinic, Rochester, MN; University of Chicago, Evanston, IL; University of Chicago, Chicago, IL; Medical College of Wisconsin, Milwaukee, WI; Memorial Sloan-Kettering Cancer Center, New York City, NY; Harvard Medical School, Boston, MA; Brown University, Providence, RI; American College of Radiology Imaging Network, Philadelphia, PA.

Radiotherapy

OT2-06-01  A Phase III Randomized Multicentric French Study To Evaluate the Impact of a Localized 16-Gy Boost after Conservative Surgery and a 50-Gy Whole-Breast Irradiation in Breast Ductal Carcinoma In Situ (The BONBIS Trial)

Azria O, Cowen D, De La Lande B, Bourger C, Latorzeff I, Leblanc-Ofroy M, Douadi-Gaci Z, Pradier O, Peignaux K, Levy C, Ellis S, Lecouillard I, Racadot S, Bontemps P, Berinyock P, La Garde N, Laharie-Mineur H, Cretin J, Marchal C, Serin D, Lemanski C, CRLC Val d’Aurelle, Montpellier, France; AP-HM, Marseille, France; Centre Rene Huguenin, Saint Cloud, France; IGR, Villejuif, France; Groupe ONCOCRAD, Toulouse, France; Centre Rene Gauducheau, Nantes, France; Centre Catherine de Sienne, Nantes, France; CHU Brest, Brest, France; CRLC G-F, Clermont, Tours, France; CRLC Francois Baclesse, Caen, France; Centre Catalan d’Oncologie, Perpignan, France; CRLC Eugene Marquis, Rennes, France; Centre Leon Berard, Lyon, France; CHU Besancon, Besancon, France; Centre Henri Becquerel, Rouen, France; Institut Bergonie, Bordeaux, France; Clinique Tivoli, Bordeaux, France; Clinique Valdegouer, Nimes, France; Centre Alexis Vautrin, Vandoeuvre les Nancy, France; Institut Sainte Catherine, Avignon, France.

OT2-06-02  A Randomized Phase III Study of Conventional Whole Breast Irradiation (WBI) vs Partial Breast Irradiation (PBI) for Women with Stage 0, 1, or 2 Breast Cancer: NSABP B-39/RTOG 0413

Julian TB, Costantino JP, Vicini FA, White JR, Cecchini RS, Winter KA, Arthur DW, Kuske R, Rabinovitch R, Parida DS, Mamouns EP, Curran Jr WJ, Wolmark N, National Surgical Adjuvant Breast & Bowel Project (NSABP), Pittsburgh, PA; Allegheny General Hospital, Pittsburgh, PA; NSABP Biostatistical Center, Pittsburgh, PA; University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA; Beaumont Health System, Royal Oak, MI; Radiation Therapy Oncology Group (RTOG), Philadelphia, PA; Medical College of Wisconsin, Milwaukee, WI; Virginia Commonwealth University, Richmond, VA; Arizona Breast Cancer Specialists, Scottsdale, AZ; University of Colorado Denver, Aurora, CO; Aultman Health Foundation, Canton, OH; Emory University, Atlanta, GA.
Side-effect Control

OT2-07-01 Pasireotide Long Acting Release (LAR) in Breast Cancer Patients To Prevent Lymphocytosis after Mastectomy and Axillary Node Dissection: A Randomized, Multicenter, Phase II Study

OT2-07-02 SWOG S0927: A Randomized Double Blind Placebo-Controlled Trial of -3-Fatty Acid for the Control of Aromatase Inhibitor (AI)-Induced Musculoskeletal Pain in Women with Early Stage Breast Cancer
Hershman DL, Unger JM, Crow KD, Monpourn CR, Minasian LM, Hansen L, Lew DL, Kabelke K, Wade JL, Meyskens FL. Columbia University, New York, NY; SWOG, Seattle, WA; National Cancer Institute, Bethesda, MD; Legacy Good Samaritan Hosp & MC, Portland, OR; SWOG, San Antonio, TX; Cancer Care Specialists of Illinois, Decatur, IL; University of California, Irvine, Orange County, CA.

7:30 pm–9:30 pm
OPEN SATellite EVENT
Marriott Rivercenter, Grand Ballroom
Targeting breast Cancer Molecular Phenotypes: A Dialogue Between Community and Academic Oncologists
WEBSITE: http://primeoncology.org/sanantoniosymposium2011

FRIDAY, DECEMBER 9, 2011

6:45 am–5:15 pm
REGISTRATION
Bridge Hall

7:00 am–9:00 am
POSTER SESSION 4 & CONTINENTAL BREAKFAST
Exhibit Halls A-B

Tumor Cell Biology: Endocrine Therapy and Resistance

P4-01-01 Preclinical and Clinical Studies of Estrogen Deprivation Support the PDGF/Abl Pathway as a Novel Therapeutic Target for Overcoming Resistance

P4-01-02 Endocrine Resistance: Mechanism, Tumorogenic Capacities, and New Therapeutic Strategies
Morrison GD, Fu X, thimakin S, rimawi MF, wicha MS, Osborne CK, Schirf R. Baylor College of Medicine, Houston, TX; University of Michigan, Ann Arbor, MI.

P4-01-03 Establishment and Characterization of an Endocrine Resistance Model In Vitro and In Vivo by Inducible PTEN Knockdown
Fu X, Shea M, Biswal NC, Mitchell T, Giuliano M, Healy NA, Meerbrey KL, Joshi A, Westbrook T, Hilsenbeck SG, Osborne CK, Schirf R. Baylor College of Medicine, Houston, TX; National University of Ireland, Galway, Ireland.

P4-01-04 Effects of CYP2D6 Phenotype and Drug Adherence on Tamoxifen Metabolite Levels

P4-01-05 The Multikinase Inhibitor Sorafenib Can Overcome Antiestrogen Resistance in Patients with Progressive Metastatic Estrogen Receptor (ER) Positive Breast Cancer

P4-01-06 Global Characterization of the SRC-1 Transcriptome Identifies Disintegrin C as an ER-Independent Mediator of Endocrine Resistant Breast Cancer
Bolger JC, McCartan DP, McIlroy M, Byrne C, Fagan A, Xu J, O’Gara P, Hill ADK, Young LS. Royal College of Surgeons in Ireland, Dublin, Ireland; University College Dublin, Dublin, Ireland; Dan L. Duncan Cancer Center, Baylor College of Medicine, Houston, TX.

P4-01-07 Combining Hedgehog Inhibitor, GDC-0449 with Tamoxifen Overcomes Tamoxifen-Resistance in In-Vitro and In-Vivo Studies of Estrogen-Receptor Positive Breast Cancer
Majumder S, Lu Y, Teng K-y, Kaffenberger T, Zhang X, Nuovo G, love RR, Ramsawamy B. The Ohio State University, Columbus, OH; International Breast Cancer Research Foundation, Madison, WI.

P4-01-08 The Role of Ser991 PELP1 Phosphorylation in Therapy Resistance and Metastasis of Breast Cancer
Sareddy GR, Nair BC, Krishnan SR, Konugunta VK, Vakalambudi RK. UTHSCSA, San Antonio, TX.

P4-01-09 Reduced CYBA Expression Leads to the Development of Fulvestrant Resistance in a Breast Cancer Cell Line
Skerri BJO, Ramsahoye BH. The University of Edinburgh, Edinburgh, United Kingdom.

P4-01-10 The Role of the Steroid Receptor Coactivator SRC1 and Its Functional Partner HOXC11 in the Development of Endocrine Resistant Breast Cancer
Walsh CA, McCartan D, Hill ADK, Young LS. Royal College of Surgeons in Ireland, Dublin, Ireland.

P4-01-11 Autocrine Human Growth Hormone (hgh) Reduces the Sensitivity of Breast Cancer Cells to Treatment with Tamoxifen and Fulvestrant
Perry JK, Chen H, Bougen NM, Liu D-X, Lobie PE. University of Auckland, Auckland, New Zealand; National University of Singapore, Singapore.

P4-01-12 The Unfolded Protein Response (UPR) and Pro-Survival Autophagy Contributes to Antiestrogen Resistance in Breast Cancer
Clarke R, shajahan AN, Cook KL, Hickman FE, Facey CO. Georgetown University, Lombardi Comprehensive Cancer Center, Washington, DC.

P4-01-13 Biology of Aggressiveness and Tamoxifen Resistance in Hormone Receptor-Positive Very Young Age Breast Cancer
Han W, Ro J, Jung S. Seoul National University Hospital, Seoul, Korea; National Cancer Center, Goyang, Kyunggi, Korea.

P4-01-14 Fulvestrant Regulates Epidermal Growth Factor (EGF) Ligands and Induces EGF Receptor Activation in MCF-7 Breast Cancer Cells
Zhang X, Diaz MR, Yee D. University of Minnesota, Minneapolis, MN.

P4-01-15 Alteration of Y-box Binding Protein-1 Expression Modifies the Response to Endocrine Therapy in Estrogen Receptor Positive Breast Cancer
Ikeda T, Kamijo S, Isumi H, Kohno K, Ito K-i. shirushi University School of Medicine, Matsumoto, Nagano, Japan; University of Occupational & Environmental Health, Kitakyo, Fukuoka, Japan.

P4-01-16 The Influence of CYP2D6 Genetic Polymorphisms on Variability of Tamoxifen Metabolism in the Lebanese Breast Cancer Population
P4-01-17  TIMP-1 Over-Expression Confers Resistance of MCF-7 Breast Cancer Cells to Fulvestrant
Bjerre CA, Vinther L, Belling K, Schroih Rasmussen A-S, Li J, Lin X, Han Z, Wang J, Bolund L, Jensen V, Nielsen BS, Soekilde R, Gupta R, Lademann U, Brunner N, Stenvang J. Faculty of Life Sciences, University of Copenhagen, Copenhagen, Denmark; Technical University of Denmark, Lyngby, Denmark; Aarhus University, Aarhus, Denmark; BGI-Shenzhen, Shenzhen, China; Eotop AS, Vedbeak, Denmark.

P4-01-18  AP-1 Blockade Potentiates the Anti-Tumor Effect of Endocrine Treatment and Reverts the Resistant Phenotype in Hormone Receptor-Positive Breast Cancer
Malorni L, Giuliano M, Migliaccio I, Wang T, Creighton CJ, Lupien M, Hilsenbeck SG, Healy N, Mazumdar A, Trivedi MV, Jeselsohn R, He HH, Fu X, Gutierrez C, Brown M, Brown PH, Osborne CK, Schiff R. Baylor College of Medicine, Houston, TX; Hospital of Prato, Prato, Italy; The University of Texas M.D. Anderson Cancer Center, Houston, TX; Dana-Farber Cancer Institute and Harvard Medical School, Boston, MA; Dana-Farber Cancer Institute, Boston, MA; Beth Israel Deaconess Medical Center, Boston, MA; Dartmouth Medical School, Lebanon, NH; UH College of Pharmacy, Houston, TX.

P4-01-19  SRC-1 Expression Is a Prognostic Factor of Breast Cancer-Specific and Disease-Free Survival in Inflammatory Breast Cancer

P4-01-20  Specific Anti-Proliferative Profile of Endoxifen for MCF-7 Cell Compared to 4-OH Tamoxifen
Saji S, Hirose M, Hayashi S-i, Kuroi K. Saitama Medical University, IMC, Saitama, Japan; Tokyo Metropolitan Komagome Hospital, Tokyo, Japan; Tohoku University Graduate School of Medicine, Sendai, Japan; Kyoto University, Graduate School of Medicine, Kyoto, Japan.

P4-01-21  An Estrogen-Inducible Transcription Factor FOXP1 Promotes Estrogen-Dependent Cell Proliferation of Breast Cancer Cells and Is Associated with 5-Year Disease-Free Survival in Patients with Tamoxifen-Treated Breast Cancer
Shigekawa T, Ichij N, Ikeda K, Hone-Inoue K, Shimizu C, Saji S, Aogi K, Tsuchida H, Osaki A, Sasaki J, Inoue S. Tokyo Metropolitan Cancer and Infectious Disease Center, Komagome Hospital; Research Center for Genomic Medicine, Saitama Medical University; International Medical Center, Saitama Medical University; National Cancer Center Hospital; National Shikoku Cancer Center; Graduate School of Medicine, The University of Tokyo.

P4-01-22  Cyclin D1 and Its Prognostic Value in Planning of Endocrine Therapy for Women of Postmenopausal Age with Breast Cancer
Skvortsov V, Manikhas A, Manikhas G, Oganessian A, Raskin G. City Cancer Therapy for Women of postmenopausal age with breast Cancer and is associated with 5-year Disease-Free Survival in patients with tamoxifen-treated breast Cancer; Faculty of Life Sciences, University, Columbus, OH.

Tumor Cell Biology: Hormonal Factors and Receptors

P4-02-01  Bis(2-Ethylhexyl) Phthalate: A Potential Endocrine Disruptor Induces Letrozole Insensitivity and Induction of Aromatase Activity in Breast Cancer Cells
Nair HB, Bhaskaran SS, Krishnegowda NK, Tekmal RR, Vandenberg JL. Texas Biomedical Research Institute, San Antonio, TX; University of Texas Health Science Center, San Antonio, TX.

P4-02-02  The Natural Fetal Estrogen Estetrol (E4), Causes Anti-Estrogenic Effects in Women with Endocrine-Responsive Positive Early Breast Cancer
Singer CF, Natter C, Steurer S, Radas M, Moinfar F, Appels NRCA, Visser M, Kubista E, Bennink C. Medical University of Vienna, Wien; Medical University of Graz, Wien; Pantaerheie Bioscience.

Tumor Cell Biology: Animal Models

P4-03-01 Stat5 regulates the PI3-Kinase/Akt1 pathway during Mammary Gland Development and Promotes Neoplastic Transformation in a Mouse Model for Cowden Syndrome
Schmidt JW, Sakamoto K, Creamer BA, Levine G, Wagner K-U. University of Nebraska Medical Center, Omaha, NE; Ohio State University, Columbus, OH.

P4-03-02  Biological Functions of Estrogen Receptor-beta and Its Variants in Breast Cancer

P4-03-04  Androgen Receptor (AR) Expression in a Cohort of Patients (pts) with Triple Negative Breast Cancer (TNBC)

P4-03-05  The Regulation of Artemin Signalling by IGF-1 in Mammary Carcinoma Cells
Yip C, Liu D, Lobie PE, Perry JK. University of Auckland, Auckland, New Zealand; National University of Singapore, Singapore.

P4-03-06  Progesterone Receptor Expression Predicts Poor Outcome in Estrogen Receptor Positive, Lymph Node Negative Breast Cancer - A Population Based Study
Purdie CA, Quinlan P, Jordan LB, Ashfield A, Baker L, Dewar JA, Thompson AM. Ninewells Hospital & Medical School, Dundee, United Kingdom; University of Dundee, Dundee, United Kingdom.

P4-03-07  Influence of the Progesterone Receptor on the Prognosis of Breast Cancer in Interaction with Other Prognostic Factors

P4-03-08  Obesity-Induced Aromatase Expression in the Breast Microenvironment Promotes Estrogen Receptor Activity and Circulating Estradiol Levels
Bowers LW, Brenner AJ, Li R, Tekmal RR, deGraffenried LA. The University of Texas at Austin, Austin, TX; The University of Texas Health Science Center at San Antonio, San Antonio, TX.

P4-03-09  Estrogen-Related Receptor a mediates Insulin-Like Growth Factor-I Dependent Migration in Breast Cancer Cells
Fettig-Anderson LM, Oh AS, Yee D. University of Minnesota, Minneapolis, MN.

P4-03-10  The Relationship between Estrogen Receptor Gene Polymorphism and Mammographic Density in Postmenopausal Women
Baldisserotto FDG, Elias S, Silva IDCG, Nazario ACP. Universidade Federal de Sao Paulo - UNIFESP-EPMS, Sao Paulo, SP, Brazil.

P4-03-11  Insulin-Like Growth Factor I Promotes Estrogen Receptor Positive Breast Cancer Cell Proliferation, in Part, through CYPIA1 Signaling
Rodriguez M, Becker M, Yee D, Potter D. University of Minnesota, Minneapolis, MN.

P4-03-12  Plasma Estradiol Levels and Degree of Estrogen Receptor Positivity by Image Analysis in a Large Cohort of Breast Cancer Cases: Results from the Nurses’ Health Study
Collins LC, Frielin GW, Ahern TP, Hu R, Hankinson SE, Tamimi RM. Beth Israel Deaconess Medical Center, Boston; Harvard Medical School, Boston; Channing Laboratory, Brigham and Women’s Hospital, Boston; Harvard School of Public Health, Boston.

Cancer Res; 71(24 Suppl.) December 15, 2011
52s Cancer Research
P4-03-02  High Fat Diet-Induced Postmenopausal Obesity Promotes Tumor Angiogenesis and Breast Cancer Progression in Age-Relevant Ovariectomized Mice  
Gu J-W, Young E, Patterson SG, Makey KL, Huang M, Tucker KB, Chinch E, Miele L. University of Mississippi Medical Center, Jackson, MS.

P4-03-03  Therapeutic Sensitivities of Mouse Models of Human Breast Cancer  

P4-03-04  Identification of Molecular Targets for Cancer-Initiating Cells Using a Triple-Negative Breast Cancer Mouse Model  
Kai I, Iwamoto T, Pusztai L, Hortobagyi GN, Saya H, Ueno NT. The University of Texas MD Anderson Cancer Center, Houston, TX; Institute for Advanced Medical Research, Shinjuku-ku, Tokyo, Japan.

P4-03-05  Development of an Inducible Estrogen Receptor Co-Activator PELP1 Mammary Tumor Model  
Cortez VA, Newaldo D, Chodosh LA, Tekmal RR, Vadlamudi RK. The University of Texas Health Science Center at San Antonio, San Antonio, TX; University of Pennsylvania School of Medicine, Pennsylvania, PA.

P4-03-06  Development and Comparative Characterization of Metastasis in Newly Developed Pre-Clinical Models of Inflammatory Breast Cancer  
Chu K, Mu Z, Alpaugh KR, Fernandez S, Freiter EM, Wu H, Zook MB, Barsky SH, Cristofanilli M, Robertson FM. The University of Texas MD Anderson Cancer Center, Houston, TX; Fox Chase Cancer Center, Philadelphia, PA; University of Nevada School of Medicine, Reno, NV; Nevada Cancer Institute, Las Vegas, NV.

Tumor Cell Biology: Mammary Development and Differentiation

P4-04-01  Identification of a Unique Mammary Cell Type Expressing Mesenchymal Markers, but Capable of Multilineage Epithelial Differentiation  
Landua JD, Lewis MT. Baylor College of Medicine, Houston, TX.

P4-04-02  Smoothened Function as a G-Protein Coupled Receptor in Mammary Epithelial Cells  
Villanueva H, Vishal AP, Bimbauer L, Plummer NW, Lewis MT. Baylor College of Medicine, Houston, TX; National Institute of Environmental Health Sciences, Research Triangle Park, NC.

Tumor Cell Biology: Metabolism and Breast Cancer

P4-05-01  Rab25 Alters Cellular Energetics and Growth Signaling during Breast Oncogenesis  
Mitra S, Cheng KW, Dennison JB, Mills GB. MD Anderson Cancer Center, Houston, TX.

P4-05-02  Early Developmental Exposures to a High Carbohydrate/High Fat Diet Affect Glucose Metabolism and Mammary Cancer Susceptibility  
Berton TR, Lambertz I, Tian J, Johanning G, Conti C, Fuchs-Young R. UT MD Anderson Cancer Center, Smithville, TX; UT MD Anderson Cancer Center, Bastroop, TX.

P4-05-03  Mechanism Underlying Metabolic Heterogeneity in Breast Cancer Subtypes  
Molina JR, Dennison JB, Zhang F, Mills GB. MD Anderson Cancer Center, Houston, TX.

P4-05-04  Arachidonic Acid-Induced Elevated Expression of 5-Lipoxygenase Is Linked to Metastatic Migration of Breast Cancer Cells  

P4-05-05  Imaging Mass Spectrometry Based Lipid Metabolites Analysis for Breast Cancer  
Ide Y, Nishio T, Hosokawa Y, Matsunuma R, Koizumi K, Ogura H, Shiya N, Setou M. Hamamatsu University School of Medicine, Hamamatsu, Japan.

P4-05-06  Systemic Cholesterol promotes Breast Tumor Aggressiveness  
Santos CR, Almeida JM, Dias S. Portuguese Institute of Oncology, Lisbon, Lisbon, Portugal.

P4-05-07  Insulin-like growth factor 1 induces a rewiring of the aerobic glycolysis pathway in breast cancer  
Pinto DM, Murphy JP, Chisholm KA, Drucker D. National Research Council of Canada, Halifax, Nova Scotia, Canada; Harvard University, Boston, Massachusetts, United States; Queen Elizabeth II Health Sciences Centre, Halifax, Nova Scotia, Canada.

P4-05-08  Metabolomic Profiling of Breast Cancer Delineates Clinical and Race-Specific Subtypes and Associated Bioprocesses  
Putluri N, Dorsey T, Golffmann L, Nanda S, Putluri V, Wallace T, Mathi E, Zhang X, Tenunuma A, Michalidis G, Lewis M, Schirr R, Amb S, Seekumar A. Baylor College of Medicine, Houston, TX; National Cancer Institute, Bethesda, Maryland; University of Michigan, Ann Arbor, MI.

Tumor Cell Biology: Micrometastases

P4-06-01  Withdrawn

P4-06-02  Microscopic Disease in Blood and Bone Marrow Predicts Survival in Early Stage Breast Cancer  
Lucci A, Krishnamurthy S, Lodhi A, Bhattacharyya A, Hall C, Anderson A, Beddosian I, Singh B, Kuerer H. University of Texas MD Anderson Cancer Center, Houston, TX.

P4-06-03  Multiplex Gene Expression of Disseminated Tumor Cells in the Bone Marrow of Breast Cancer Patients Identifies Novel Therapeutic Targets  
Aft R, Mudalagiriyappa C, Pillai S, Fleming T, Watson M. Washington University, St. Louis, MO.

P4-06-04  Detection of HER2 Gene Amplification in Circulating Tumor Cells and Disseminated Tumor Cells by Fluorescence In Situ Hybridization Using OncoCee™  
Krishnamurthy S, Bischoff FZ, Mayer JA, Wong K, Pham T, Kuerer HM, Lodhi AK, Bhattacharyya A, Hall C, Lucci A. University of Texas M.D. Anderson Cancer Center, Houston, TX; Biocept Laboratories, San Diego, CA.

P4-06-05  Prognostic Impact of Disseminated and Circulating Tumor Cells in Patients Treated for Locally Advanced Breast Cancer  
Mathiesen RR, Neslund JM, Renolten A, Lakkevik E, Anjer G, Ostenstad B, Lundgren S, Riiberberg T, Mjaaland I, Ovalheim G, Lønning PE, Naume B. Oslo University Hospital The Radium Hospital, Oslo, Norway; Oslo University Hospital, Oslo, Norway; University of Bergen, Bergen, Norway; Haukeland University Hospital, Bergen, Norway; St. Olavs University Hospital, Trondheim, Norway; Norwegian University of Science and Technology, Trondheim, Norway; University Hospital of Northern Norway and Institute of Clinical Medicine, University of Tromsø, Tromsø, Norway; Stavanger University Hospital, Stavanger, Norway; Oslo University Hospital, The Radium Hospital, Oslo, Norway; University of Oslo, Oslo, Norway.

P4-06-06  Morphological Categories of ICC-Detected CK+ Cells in Bone Marrow Have Different Prognostic Impact in Breast Cancer  
Borgen E, Symnestsved M, Schirmer CB, Schlichting E, Nesland JM, Naume B. The Radium Hospital, Oslo University Hospital, Oslo, Norway; The Radium Hospital, Oslo University Hospital, Oslo, Norway; Ullevål Hospital, Oslo University Hospital, Oslo, Norway; University of Oslo, Oslo, Norway.

www.aacrjournals.org
Detection and Diagnosis – Pathology: Circulating Tumor Cells

Circulating Tumor Cells, Disease Recurrence and Survival in Newly Diagnosed Breast Cancer
Franken B, de Groot MR, Tenstappen LWWM, Mastboom WJB, Van der Palen J, Tibbe AGJ. Medisch Spectrum Twente, Enschede, Overijssel, Netherlands; University of Twente, Enschede, Overijssel, Netherlands.

Detection, Enrichment, Characterization and Propagation of Circulating Tumor Cells from Patients with Advanced Metastatic Breast Cancer
Mihalicou C, Lian J, Bertos N, Omeroglu A, Sebag M, DiBattista J, Li J, Chughtai N, Park M, Kremer R, Royal Victoria Hospital/McGill University, Montreal, QC, Canada; McGill University, Montreal, QC, Canada.

Identification of Triple-Negative Primary Breast Cancer Xenograft Models with High Numbers of Circulating and Disseminated Tumor Cells
Giuliano M, Christy PJ, Zhang X, Mao S, Contreras A, Lewis MT, Rimawi MF, Osborne CK, Schiff R, Trivedi MV. Baylor College of Medicine, Houston, TX; UH College of Pharmacy, Houston, TX.

Nomogram Including Circulating Tumor Cells (CTC) Count before and during Chemotherapy for Individual Survival Prediction of Metastatic Breast Cancer Patients
Bidard F-C, Hajage D, Bachelot T, Delaloge S, Brain E, Campone M, Wolp-Diniz R, Dieras V, Mathiot C, Asselain B, Pierga J-Y. Institut Curie, Paris, France; Centre Leon Berard, Lyon, France; Institut Gustave Roussy, Villejuif, France; Institut de Cancérologie de l’Ouest, Nantes, France.

Comparison of PIK3CA Hot Spot Mutations in the Primary Tumor or Metastases with PIK3CA Mutations or PIK3CA Over-Expression in Circulating Tumor Cells of Metastatic Breast Cancer Patients under Sequential Palliative Therapy
Aktas B, Kasimir-Bauer S, Kasper S, Derks C, Kimmig R, Schuler M, Tewes M. West German Cancer Center, University Hospital Essen, Germany; University of Duisburg-Essen, Essen, Germany.

Correlation of Two Analytical Methods for Circulating Tumor Cells in Peripheral Blood of Patients with Primary Breast Cancer
Jaeger BAS, Rack B, Jueckstock J, Salmen J, Oettmann U, Lorenz R, Rezaiz M, Beck T, Schneeweß A, Zwingers T, Beckmann MW, Friese K, Janni W. Klinikum der Ludwig-Maximilians-Universität - Campus Innenstadt, Munich, Germany; Heinrich Heine-Universität, Duesseldorf, Germany; Gemeinschaftspraxis Lorenz-Hecker-Wesche, Braunschweig, Germany; Lusenkrankenhaus, Duesseldorf, Germany; RoMed Klinikum Rosenheim, Rosenheim, Germany; University Hospital Heidelberg, Heidelberg, Germany; Estimate, Augsburg, Germany; Frauenklinik der Universitaet Erlangen, Erlangen, Germany.

Circulating Tumor Cells Predict Survival in Non-Metastatic Breast Cancer
Lucci A, Krishnamurthy S, Bhattacharyya A, Lodhi A, Hall C, Singh B, Anderson A, Bedrosian I, Kuerer H. University of Texas MD Anderson Cancer Center, Houston, TX.

Subsets and Molecular Signatures of Circulating Tumor Cells in Breast Cancer Brain Metastasis
Marchetti D, Zhang L, Wetzel M, Zaidi T, Ridgway M, Schoeber W, He W, Groves MD, Katz RL. Baylor College of Medicine, Houston, TX; MD Anderson Cancer Center, Houston, TX.

Automated Quantitative Assessment of HER2 Expression of Circulating Tumor Cells (CTC) in Metastatic Breast Cancer (IC 2006-04 Study)
Bidard F-C, Ligthart ST, Decraene C, Bachelot T, Delaloge S, Brain E, Campone M, Pierga J-Y, Tenstappen LWWM. Institut Curie, Paris, France; University of Twente, Enschede, Netherlands; Centre Leon Berard, Lyon, France; Institut Gustave Roussy, Villejuif, France; Institut de Cancérologie de l’Ouest, Nantes, France.

Circulating Tumor Cells in Newly Diagnosed Inflammatory Breast Cancer
Mego M, Giordano A, De Giorgi U, Hsu L,ucci A, Dawood S, Woodward WA, Ueno NT, Valero V, Andreoupolou E, Hortobagyi GN, Reuben JM, Cristofanilli M. Comenius University, School of Medicine, Bratislava, Slovakia (Slovak Republic); UT MD Anderson Cancer Center, Houston, TX; Fox Chase Cancer Center, Philadelphia.

Circulating Tumor Cells after Neoadjuvant Therapy Predict Outcome in Stage I to Ill Breast Cancer
Gainer S, Krishnamurthy S, Bhattacharyya A, Lodhi A, Hall C, Kuerer H, Bedrosian I, Anderson A, Singh B,ucci A. The University of Texas MD Anderson Cancer Center, Houston, TX.

Identification of p53 Mutation in Whole Genome DNA from Single Circulating Tumor Cells (CTCs) and Primary Breast Cancers (BC) from Patients (pts) with Metastatic Breast Cancer (MBC)

Prognostic Impact of Circulating Tumor Cells Assessed with the Cell Search Assay and Adna Test Breast in Metastatic Breast Cancer Patients - The DETECT Study
Mueller V, Riehensperger S, Rack B, Wolfgang J, Paschinger PA, Solomayer E, Aktas B, Kasimir-Bauer S, Mury D, Pental K, Fehrm T. University Medical Center Hamburg-Eppendorf, LMU Munich; University Medical Center Dusseldorf; Hospital Erlangen, Friedrich-Alexander University Erlangen Nuremberg, Erlangen; University Medical Center Hamburg-Saar; University Medical Center Essen; University Medical Center Tubingen, All Authors on Behalf of the DETECT Study Group.

Circulating Tumor Cells (CTCs) Detection and HER2 Profiling by CellSearch® in Non-Metastatic Breast Cancer: An International Ring Study To Assess Inter-Reader Variability
Ignatiadis M, Pierga J-Y, Campion M, Fehrm T, Payne R, Rack B, Pavlidis D, Riehensperger S, Rothe F, Besi S, Auma C, Sandri MT, Borgen E, Kraan J, Tenstappen LWWM, Picart M, Sotiriou C, Michalis, S, Pantel K. Institut Jules Bordet, Brussels, Belgium; Institut Curie, Paris, France; Mayo Clinic, Rochester, Universitäts-Frauenklinik, Tubingen, Germany; Hamersmith Hospital, Imperial College, London, United Kingdom; Ludwig-Maximilians-Universitat, Munchen, Germany; University of Crete, Crete, Greece; University Medical Center Hamburg-Eppendorf, Hamburg, Germany; Hospital of Prato, Prato, Italy; Vall d’Hebron, Barcelona, Spain; European Institute of Oncology, Milan, Italy; Oslo University Hospital, Oslo, Norway; Erasmus Medical Center, Rotterdam, Netherlands; University of Twente, Twente, Netherlands.

Insulin-Like Growth Factor Receptor I (IGFIR) Expression in Circulating Tumor Cells (CTCs) of Patients with Early and Metastatic Breast Cancer
Spiliotis M, Markanomolakis H, Kokotsaki M, Kallergi G, Pavlidis D, Georgoulis V, Agelaki S. School of Medicine, University of Crete, Heraklion, Crete, Greece; University General Hospital of Heraklion, Heraklion, Crete, Greece.

Development of Circulating Tumor Cell-Endocrine Therapy Index in Metastatic Breast Cancer Patients

Isolation of Highly Pure Circulating Tumor Cells (CTCs) from Metastatic Breast Cancer (MBC) Patients for Gene Expression Analysis
P4-07-18  Prospective Assessment of Circulating Tumor Cells and Serum Markers for PFS Prediction in Metastatic Breast Cancer
Bidard F-C, Hajage D, Bachelot T, Delaloge S, Brain E, Campone M, Cottu P, Beuzeboc P, Mathiot C, Perga J-Y. Institut Curie, Paris, France; Centre Léon Bérard, Lyon, France; Institut Gustave Roussy, Villejuif, France; Centre René Gauduchau, Nantes, France.

P4-07-19  Bone Marrow Involvement is Associated with High Numbers of Circulating Tumor Cells in Peripheral Blood of Metastatic Breast Cancer Patients
Grisanti S, Consolfi F, Almici C, Bertagna F, Versardi R, Ungari M, Amoroso V, Pedersini V, Rassali I, Montani E, Simoncini EL. Spedale Civili di Brescia, Brescia, Italy; University of Brescia, Brescia, Italy.

P4-07-20  Apoptosis in Circulating Tumor Cells (CTCs) of Early and Metastatic Breast Cancer Patients
Kallergi G, Konstantinidis G, Papadaki M, Agelaki S, Movroudis D, Stournaras C, Georgoulas V. School of Medicine, University of Crete, Heraklion, Crete, Greece; University General Hospital of Heraklion, Heraklion, Crete, Greece.

P4-07-21  A Comparison of Two Methods for the Detection of Circulating Tumor Cells (CTCs) in Patients (pts) with Early and Metastatic Breast Cancer (BC): RT-PCR for Cytokeratin (CK) -19 mRNA Versus the CellSearch System
Politaki E, Agelaki S, Apostolaki S, Perraki M, Hatzidaki D, Lianidou ES, Movroudis D, Georgoulas V. University General Hospital of Heraklion, Heraklion, Crete, Greece; University of Athens, Athens, Greece.

Detection and Diagnosis – Pathology: Circulating Markers

P4-08-01  Predictive Value of HER2 Serum Levels in Patients Treated with Lapatinib or Trastuzumab - A Translational Project in the Neoadjuvant “Geparquinto” Trial
Witzel ID, Loibl S, von Minckwitz G, Abdallah A, Kühn T, Overkamp F, Fehm T, Schrader I, Ueler C, Kohls A, Strumborg S, zu Eulenburg C, Untch M, Müller V. University Medical Center Hamburg-Eppendorf, Hamburg, Germany; German Breast Group, Neu-Isernburg, Germany; Helios Klinikum Berlin Buch, Berlin, Germany; University Medical Center Tubingen, Tubingen, Germany; Hospital Gelsenkirchen, Gelsenkirchen, Germany; Hospital Esslingen, Esslingen, Germany; Oncologianova, Recklinghausen, Germany; Gynäko-Onkologische Praxis Hannover, Hannover, Germany; Gynäkologische Gemeinschaftspraxis, Hildesheim, Germany; Ev. Krankenhaus, Ludwigsfelde-Teltow, Germany; Frauenklinik Rheinfelden, Rheinfelden, Germany.

P4-08-02  Estradiol (E2) Mediated Secretion of Vascular Endothelial Growth Factor (VEGF) and Stimulation of T-Regulatory Cells (T-Regs): Their Role for the Worse Prognosis of Breast Cancer (BC) in Premenopause
Recchia F, Candeloro G, Desideri G, Necozione S, Recchia COC, Rea S. Civilian Hospital, Avezzano, AQ, Italy; University, L’Aquila, AQ, Italy.

P4-08-03  Serum Autoantibodies to Breast Cancer Associated Antigens Reflect Tumor Biology: An Opportunity for Early Detection & Prevention?
Eiermann W, Jackson L, Murray A, Chapman CJ, Peek LJ, Widschwendter P, Allen J, Graham H, Robertson J-F. Fauenklinik vom Rheinfelden, Rheinfelden, Germany; Frauenklinik Rheinfelden, Ludwigsfelde-Teltow, Germany; Frauenklinik Rheinfelden, Hildesheim, Germany; Ev. Krankenhaus, Ludwigsfelde-Teltow, Germany; Hospital Gelsenkirchen, Gelsenkirchen, Germany; Oncologianova, Recklinghausen, Germany; Gynäko-Onkologische Praxis Hannover, Hannover, Germany; Gynäkologische Gemeinschaftspraxis, Hildesheim, Germany; Ev. Krankenhaus, Ludwigsfelde-Teltow, Germany; Frauenklinik Rheinfelden, Rheinfelden, Germany.

P4-08-04  Preoperative Thrombin Pathway Activation Identifies Node Positive Patients in Early Breast Cancer
Shaker H, Kirwan C, Landberg G, Bundjor NJ. University Hospital of South Manchester, Manchester, United Kingdom; Paterson Institute for Cancer Research, Manchester, United Kingdom.

P4-08-05  Diagnostic Significance of Exosomal miRNAs in the Plasma of Breast Cancer Patients
Kwong A, Ng EKO, Leung CPH, Chan V, Li R, Wong CLP, Ma ESK. The University of Hong Kong,Pokfulam, Hong Kong, Hong Kong Sanatorium & Hospital, Hong Kong.

P4-09-01  Identification of Poor Prognosis T1T2N0 Luminal ERBB2-ve Breast Carcinomas

P4-09-02  G Protein-Coupled Estrogen Receptor 1 Positively Correlates with Estrogen Receptor α Expression and Increased Distant Disease-Free Survival of Breast Cancer Patients

P4-09-03  Clinical Significance of HER2+ and Triple-Negative Status in Patients with Tumor Size ≤ 1 cm and Node Negative Breast Cancer
Shao T, Boobil SK, Boache-Adjie K, Klein P. Beth Israel Medical Center, Continuum Cancer Centers of New York, New York, NY.

P4-09-04  Do Decreased CEP17 Signals Indicate the Presence of “Monosomy” in Breast Cancer? A Study of HER2 Gene Status and HER2 Immunohistochemistry
Tse CH, Hwang HC, Goldstein LC, Kandali SP, Duisterhoef SM, Kussick SL, Gown AM. PhenoPath Laboratories, Seattle, WA.

P4-09-05  CA15-3 Adds Prognostic Information in “Luminal” Type Breast Cancer - A Single Center Experience Evaluating 700 Patients with a Median Follow-Up of 5 Years
Thomssen C, Kettelhardt EJ, Vetter M, Steer S, Ruiter T, Holzhausen H-J, Strauß H-G, Görgle R, GYN/OB, Halle (Saale), Germany; Inst. of Pathology, Halle (Saale), Germany.

P4-09-06  The Prognostic Value of Tumour-Stroma Ratio in Triple Negative Breast Cancer
Moorman AM, Vink R, Heijmans HJ, van der Palen J, Kouwenhoven EA. Hospital Group Twente, Almelo, Netherlands; Pathology Laboratory East Netherlands, Enschede, Netherlands; Medical Spectrum Twente, Enschede, Netherlands; Hospital Group Twente, Hengelo, Netherlands.

P4-09-07  Breast Cancer Outcome by Combined Immunohistochemical ER/PR/HER2 Receptor Phenotype

P4-09-08  Secretary Leukocyte Protease Inhibitor as a Differential Diagnostic Biomarker of Tumor Emboli in Inflammatory Breast Cancer

P4-09-09  Expression of c-MET and Phospho-c-MET in Breast Cancers by Subtype and Its Impact on Survival Outcomes

P4-09-10  Assessment of Circulating Immune Parameters in Patients with Metastatic Breast Cancer Improves Survival Prediction
P4-09-11 Kinesin Family Member 2C (KIF2C) Is a New Surrogate Prognostic Marker in Breast Cancer (BC)
Abdel-Fatah TMA, Green AR, Lemetre C, Moseley P, Chan S, Ellis IO, Balls G. Nottingham University City Hospital NHS Trust, Nottingham, United Kingdom; Nottingham University, Nottingham, United Kingdom; Nottingham Trent University, Nottingham, United Kingdom.

P4-09-12 Clinical Validation of Immunohistochemical Signature Predictive of Patients’ 8 Year Outcome in Node Negative Breast Carcinomas
Charpin C, Tavassoli F, Giusiano S, Secq V, Villaret J, Garcia S, Lavaut M-N, Bonnier P, Birnbaum D, Iovanna J. INSERM U624 - Hospital Nord, Marseille, France; Yale University School of Medicine, New Haven; INSERM UMR 891, Marseille, France.

P4-09-13 External Validation of Adjuvant! Online Breast Cancer Prognosis Tool. Improvement Is Still Needed

P4-09-14 Differential Expression of the Akt1 Isoform in Mammary Ductal Carcinoma
Sanders AJ, Mansel RE, Jiang WG. Cardiff University School of Medicine, Cardiff, United Kingdom.

P4-09-15 Clinical and Pathological Predictors of Outcome among Patients with Triple Negative Breast Cancer
Pearlstone DB, Gray M, Garofalo RM, Trapani M, Nyirenda T, Hazelwood VA. Hackensack University Medical Center, Hackensack, NJ; Stevens Institute of Technology, Hoboken, NJ; John Theurer Cancer Center, Hackensack, NJ.

P4-09-16 Factors Affecting the Development of Axillary Lymph Node Metastases in T1A-T1B Breast Carcinomas
Khair TA, Boolbol SK, Boachi-Adjei K, Klein P. Beth Israel Medical Center, Continuum Cancer Centers of New York, New York, NY.

P4-09-17 Leptin and Adiponectin Expression in Breast Cancer
Jeong Y-J, Jeong H-Y, Bong J-G, Park S-H, Choi H-K. School of Medicine, Catholic University of Daegu, Daegu, Korea; College of Pharmacy, Kyung Hee University, Seoul, Korea.

P4-09-18 Australian Decision Impact Study: The Impact of Oncotype DX Recurrence Score (RS) on Adjuvant Treatment Decisions in Hormone Receptor Positive (HR+), Node Negative (NO) and Node Positive (N+) Early Stage Breast Cancer (ESBC) in the Multidisciplinary Clinic (MDC)
de Boer RH, Baker C, Speakman D, Mann B. Royal Melbourne Hospital, Melbourne, Victoria, Australia; Austin Hospital, Melbourne, Victoria, Australia; Peter MacCallum Cancer Institute, Melbourne, Victoria, Australia; Royal Melbourne and Royal Women’s Hospital, Melbourne, Victoria, Australia.

P4-09-19 PCNA+ Tumor Associated Macrophages Are Associated with M1 and M2 Gene Expression, and Confer Poor Prognosis in the Absence of Anti-Tumor Immune Environment

P4-09-20 Expression Profile of Interleukin 17B and the Receptor IL-17BR in Clinical Breast Cancer
Sanders AJ, Mansel RE, Mason MD, Jiang WG. Cardiff University School of Medicine, Cardiff, United Kingdom.

P4-09-21 A Novel Prognostic Marker for Triple-Negative Breast Cancers
Wallon UM, Sabol JL, Zsemba-Palko V, Carp NZ, Ciocca RM, Wojciechowski BS, Prendergast GC. Lankenau Institute for Medical Research, Wynnewood, PA; Lankenau Medical Center, Wynnewood, PA.

P4-09-22 Multicenter Quality Assurance Profile Review of Lobular Breast Carcinomas Versus the 21 Gene Recurrence Score: Assessment of Clinical Relevance
Dabbs DJ, Hicks D, Tubb R, Bhatta R, Bruksky A. University of Pittsburgh Medical Center, Pittsburgh, PA; University of Rochester Medical Center, Rochester, NY; Cleveland Clinic, Cleveland, OH.

P4-09-23 Monitoring Autophosphorylation of Mammalian Target of Rapamycin (mTOR) for Histoprognostic Grading of Invasive Breast Cancer: Impact on the Reclassification of Patients with Grade 2 Tumors Using the Nottingham Grading System
Sauri-Nadal T, Del Barco S, Vazquez-Martin A, Oliveras-Ferreros C, Cuff S, Martin-Castillo B, Lopez-Bonet E, Menendez JA. Catalun Institute of Oncology, Girona, Catalonia, Spain; Dr. Josep Trueta University Hospital, Girona, Catalonia, Spain.

P4-09-24 Correlation of Aurora Family Member Expression with Clinical Breast Cancer Prognosis
Annakesavan A, Sanders AJ, Harding KG. School of Medicine, Cardiff University, Cardiff, Wales, United Kingdom.

P4-09-25 Impact of Body Mass Index (BMI) for Clinical Outcomes in Japanese Breast Cancer Patients

P4-09-26 Prognostic Significance of Tissue Inhibitor of Metalloproteinase-1 (TIMP-1) in Breast Cancer
Dechaphunkul A, Phukaooul M, Kanjianapradit K, Graham K, Ghosh S, Santos C, Mackey JR. Cross Cancer Institute, University of Alberta, Edmonton, AB, Canada; Faculty of Medicine, Prince of Songkla University, Hat Yai, Songkhla, Thailand.

P4-09-27 Can We Predict the Benefit of the 70-Gene Signature in the Choice of Adjuvant Systemic Treatment for ER Positive, HER2 Negative Tumors in Daily Practice? A Single Institution Experience

P4-09-28 Comparison of Oncotype DX (ODX) and Mammastrat (MS) Risk Estimations and Correlations with Histologic Tumor Features in Low Grade, ER-Positive Invasive Breast Carcinoma (BC)
Acs G, Kilik J, Loftus L, Laronga C. Moffitt Cancer Center, Tampa, FL; Women’s Pathology Consultants, Ruffolo Hooper & Associates, Tampa, FL.

P4-09-29 A Nomogram To Predict Prognosis in Node-Negative Breast Carcinoma

P4-09-30 Relationship between DNA Ploidy, Biomarker Expression and Molecular Subtypes of Invasive Breast Cancer
Sarode VR, Rahardja D, Morrison DH, Peng Y, Rao R, Euhus D. University of Texas Southwestern Medical Center, Dallas, TX.

P4-09-31 Withdrawn

P4-09-32 Withdrawn

P4-09-33 The Prognostic Significance of Metaplastic Carcinoma of the Breast - A Comprehensive Comparison Study with Common Breast Cancers
Lai H-W, Kuo S-J, Chen D-R, Chen S-T. Changhua Christian Hospital, Changhua, Taiwan.
P4-09-34 Luminal Infiltrating Lobular Carcinoma of the Breast: Clinical and Prognostic Features

P4-09-35 Co-Expression of Ki-67 Is Critical for Outcome of Cyclooxygenase-2 Positive Breast Cancer

P4-10-01 Tumor Markers Predicting Recurrence Type after a Primary Ductal Carcinoma In Situ
Zhou W, Johansson C, Jeström K, Ringberg A, Blomqvist C, Amini R-M, Fälldiskog M-L, Wärnberg F. Uppsala University Hospital, Uppsala, Sweden; Malmö University Hospital, Malmö, Sweden; Lund University, Lund, Sweden; Helsinki University Central Hospital, Helsinki, Finland; Uppsala University, Uppsala, Sweden.

P4-10-02 A Meta-Analysis of the Association of Blood Levels of Vitamin-D and the Risk of Breast Cancer
Amir E, Carlsson L, Seruga B, Ocanà A, Goodwin P. Princess Margaret Hospital, Toronto, Canada; Institute of Oncology Ljubljana, Ljubljana, Slovenia; Albacete University Hospital, Albacete, Spain; Mount Sinai Hospital, Toronto, Canada.

P4-10-03 Association between BMI, Physical Activity and Breast Cancer Histologic Types
Nyante SJ, Dallal CM, Gierach GL, Sherman ME, Park Y, Hollenbeck AR, Brinton LA. National Cancer Institute, Rockville, MD; AARP, Washington, DC.

P4-10-04 Automated Breast Cancer Risk Assessment: Identifying High Risk Women in the Primary Care Setting
Ozanne E, Omer Z, Carlson K. University of California, San Francisco; Massachusetts General Hospital.

P4-10-05 Improved Breast Cancer Risk Assessment in Biopsied Women Using the Polyfactorial Model Oncovue®
Jupe ER, Pugh TW, Knowlton NS, DeFreese DC. InterGenetics LLC, Chotaw, OK.

P4-10-06 Evaluation of BRCAPro Risk Assessment Model in Patients with Ductal Carcinoma In Situ
Muse KI, Elsayegh N, Gutierrez-Barrera AM, Kuerer H, Valero V, Litton JK, Hortobagyi GN, Arun BK. UT MD Anderson Cancer Center, Houston, TX.

P4-10-07 Clinico-Pathologic Features of Breast Cancer Patients with Primary Metastatic Disease Versus Localized Disease: A Multicenter Study
Barinoff J, Hils R, Bender A, Gross J, Kurz C, Tauchert S, Mann E, Schwidde I, Ipsen B, Sawitzki K, Heitz F, Harper P, Traut A, du Bois M, A. Kliniken Essen Mitte, Essen, Germany; Dr.-Horst-Schmidt-Klinik, Wiesbaden, Germany; Asklepios Klinik, Lich, Germany; Sanikt Gertrauden-Krankenhaus, Berlin-Wilmersdorf, Germany; Klinikum Esslingen, Esslingen am Neckar, Germany; Cantinklinik St. Theresa, Saarbrücken, Germany; Universitätsklinikum Gießen und Marburg, Germany; Klinikum Frankfurt Höchst, Frankfurt am Main, Germany; Evangelisches Krankenhaus Wesel, Wesel, Germany.

P4-10-08 Risk Factor Profiles of Women with DCIS and Invasive Ductal Breast Cancers

P4-10-09 Hormone Replacement Therapy: A Benign Breast Disease’s Risk?

P4-10-10 Breast Cancer Risk Factors among Asian Versus Caucasian Women with BRCA1/2 Mutations
de Bruin MA, Kwong A, Goldstein BA, Lipson JA, Ikeda DM, McPherson LA, Sharma B, Kardashian A, Schackmann EA, Kingham KE, Mills MA, West DW, Ford JM, Kuiran AW. Stanford University School of Medicine, Stanford, CA; University of Hong Kong Li Ka Shing Faculty of Medicine, Hong Kong, China.

P4-10-11 Genetic and Environmental Predictors, Endogenous Hormones and Growth Factors and Risk of Estrogen Receptor-Positive Breast Cancer in Japanese Women
Yoshimoto N, Nishiyama T, Toyama T, Takahashi S, Shinaki N, Sugira H, Endo Y, Iwasa M, Fuji Y, Yamashita H. Nagoya City University Graduate School of Medical Sciences, Nagoya, Aichi, Japan.

P4-11-01 Bilateral Oophorectomy Is Associated with a Higher Prevalence of Arthritis and Lower Bone Mineral Density in Women 40 Years and Older
McCarthy AM, Visvanathan K. Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD.

P4-11-02 Insulin-Like Growth Factor-1 (IGF-1), Insulin-Like Growth Factor Binding Protein-3 (IGFBP-3) and Lobule Type among Women in the Nurses’ Health Study II (NHS II)
Collins LC, Rice MS, Shen D, Connolly JL, Schnitt SJ, Tamimi RM. Beth Israel Deaconess Medical Center and Harvard Medical School; Brigham and Women’s Hospital and Harvard School of Public Health, Boston.

P4-11-03 Prognosis of Pregnancy-Associated Breast Cancer: A Meta-Analysis Involving 39,415 Patients
Azim, Jr HA, Santoro L, Russell-Edu W, Pentheroudakis G, Pavlidis N, Peccatoni FA. Institut Jules Bordet, Brussels, Belgium; European Institute of Oncology, Milan, Italy; University of Ioannina, Ioannina, Greece.

P4-11-04 Risk of Primary (PBC) and Contralateral Breast Cancer (CBC) after Ovarian Cancer (OC) in BRCA1 and BRCA2 Mutation Carriers: Implications for Surveillance and Risk Reducing Mastectomy

P4-11-05 Association between Bisphosphonate Use in Metastatic Breast Cancer (MBC) and Overall Survival
Mathew A, Mathew IE, Rozenszvig MQ, Bruyse AM. University of Pittsburgh Medical Center; University of Pittsburgh Cancer Institute; Magee-Womens Hospital.

P4-11-06 Uptake of Selective Estrogen Receptor Modulators and Other Breast Cancer Prevention Strategies among High-Risk Women Seen in a Breast Center
P4-11-07 Feasibility and Acceptability of Offering Breast Cancer Risk Estimation in the Context of the UK National Health Service Breast Cancer Screening Programme: A New Paradigm for Cancer Prevention

P4-11-08 Changes in the Distribution of Loco-Regional and Distant Breast Cancer Recurrences over the Last 20 Years: Implications for Patient Care and Future Research
Bouganim N, Clemons M, Amir E. The Ottawa Hospital Cancer Center, Ottawa, ON, Canada; Princess Margaret Hospital, Toronto, ON, Canada.

P4-11-09 Polymorphisms Related to Steroid Hormone Concentrations in Nipple Aspirate Fluid (NAF)

P4-11-10 Perceptions, Knowledge and Satisfaction with Contralateral Prophylactic Mastectomy among Young Women with Breast Cancer
Tracy MS, Meyer ME, Sepucha K, Gelber S, Hirshfield-Bartek J, Troyan S, Morrow M, Schapira L, Come S, Winer E, Partridge AH, Dana- Farber Cancer Institute, Boston, MA; Massachusetts General Hospital, Boston, MA; Memorial Sloan-Kettering Cancer Center, New York, NY; Beth Israel Deaconess Medical Center, Boston, MA.

P4-11-11 Thyroid Disease Is Associated with Breast Cancer: A Meta-Analysis
Hardefeldt PJ, Elick KD, Edirinne M. The University of Sydney, Sydney, NSW, Australia; Nepean Hospital, Pennth, NSW, Australia.

P4-11-12 Molecular Phenotype of Breast Cancers in a Large Cohort of Young Women According to Time Interval Since Pregnancy
Collins LC, Gelber S, Marothi JD, Cole KR, Kereakoglow S, Ruddy KE, Brachtel EF, Schapira L, Come SE, Borges VF, Schedin PJ, Warner E, Winer E, Partridge A. Beth Israel Deaconess Medical Center, Boston; Harvard Medical School, Boston; Dana Farber Cancer Institute, Boston; Dartmouth-Hitchcock Medical Center, Lebanon, Hanover, NH; Brigham and Women’s Hospital, Boston; Massachusetts General Hospital, Boston; University of Colorado Cancer Center, Colorado; Sunnybrook Odette Cancer Centre, Toronto.

P4-11-13 Influence of Two Years of Exemestane on Bone Mineral Density in Postmenopausal Women at Increased Risk of Developing Breast Cancer: a Companion Study to the NCIC CTG MAP.3 Trial
Goss PE, Richardson H, Ingle JN, Chlebowski RT, Fabian CJ, Garber JE, Sarto GE, Hiltz A, Tu D, Cheung AM. Massachusetts General Hospital Cancer Center, Boston, MA; Queen’s University, Kingston, ON, Canada; Mayo Clinic, Rochester, MN; Los Angeles Biomedical Research Institute, Torrance, CA; University of Kansas Medical Center, Westwood, KS; Dana Farber Cancer Institute, Boston, MA; Center for Women’s Health and Health Research, Madison, WI; General Hospital, Toronto, ON, Canada.

P4-11-14 Number Needed To Treat (NNT) as a Measure of Incremental Drug Benefit: Denosumab vs. Zoledronic Acid for the Prevention of Skeletal Related Events (SREs) in Advanced Breast Cancer
Dranitsaris G, Kaura S. Augmentum Pharma Consulting, Toronto, Canada; Novartis Pharmaceuticals, NJ.

P4-11-15 Increased Propensity of Triple Negative Breast Cancer (TNBC) in Premenopausal Patients after Exogenous Hormonal Intake (EHI)

P4-11-16 Withdrawn

P4-11-17 Noninferiority (NI) Phase III Trials in Advanced Breast Cancer (ABC) over 12 Years
Saad ED, Milindo MS. Dendrix Research, Sao Paulo, Brazil.

P4-11-18 Mammographic Surveillance in Atypical Hyperplasia of the Breast and Subsequent Development of Cancer. A Need for Long Term Follow Up
Korron R, Sridharan U, Mitchell G, Holcombe C. Royal Liverpool and Broadgreen University Hospital Trust, Liverpool, Merseyside, United Kingdom.

Yong M, Christiansen CF, Gammelager H, Svane C, Chia V, Atchison C, Fryzek J. Ameera Inc. Thousand Oaks, CA; Aarhus University Hospital, Aarhus, Denmark; Exponent, Alexandria, VA.

P4-11-20 Observational Study of Body Weight Changes and Metabolic Syndrome in Breast Cancer Patients Receiving Adjuvant Therapy: Characteristics of Dietary Pattern in Korean Breast Cancer Patients

P4-11-21 A Retrospective Analysis of Women at Increased Lifetime Risk for Breast Cancer: Referral Patterns to Subspecialty Providers, Recommendations and Outcomes

P4-11-22 Familial History of Cancer among Breast Cancer Women under 36 yr. in Rio De Janeiro, Brazil
Koifman S, Ortega GPJ, Koifman RJ. National School of Public Health, Oswaldo Cruz Foundation (FIOCRUZ), Rio de Janeiro, RJ, Brazil.

P4-11-23 Lifelong exposure to isoflavones results in a reduced responsivity of the mammary gland towards estradiol
Diel P, Vollmer G, Hertrampf M, Moller FJ, Scholtens D, Molzberger A. German Sports University, Cologne, Germany; Technical University Dresden, Dresden, Germany; Max Rubner-Institut, Karlsruhe, Germany.

Psychosocial, Quality of Life, and Educational Aspects: Survivorship Research

P4-12-01 The Breast-Activity and Healthy Eating after Diagnosis (B-AHEAD) Study - A Randomised Comparison of Weight Control Programmes during Adjuvant Treatment
Harvie M, Pegington M, Bundre N, Campbell A, Wolstenholme J, Adams J, Speed S, Morris J, Howell A. University Hospital of South Manchester, Manchester, United Kingdom; University of Dundee, United Kingdom; University of Oxford, United Kingdom; University of Manchester, United Kingdom; University Hospital of South Manchester, United Kingdom.

P4-12-02 The Association of Anastrozole Adherence and Cognitive Function in Breast Cancer
Sereika SM, Dunbar-Jacob JM, Ryan CM, Adam B, Bender CM. University of Pittsburgh, Pittsburgh, PA; University of Pittsburgh Medical Center, Pittsburgh, PA.
P4-12-03 Post-Diagnosis Weight Gain in Breast Cancer Survivors: When Should We Intervene? Brayshaw PT, Cleveland RJ, Stevens J, Rosamond W, Abrahamson PE, Teitelbaum SL, Neugut AI, Gammon MD. University of North Carolina at Chapel Hill, Chapel Hill, NC, Mount Sinai School of Medicine, New York, NY; Columbia University, New York, NY.

P4-12-04 Withdrawn

P4-12-05 Impact of the Lifestyle Intervention Study in Adjunct Treatment of Early Breast Cancer (LISA) Weight Loss Intervention upon Physical Activity Ligibel JA, Segal R, Pond G, D’Amico M-J, Pichardt KJ, Levine M, Goodwin PJ, Dana-Farber Cancer Institute, Boston, MA; University of Ottawa, Ottawa, ON, McMaster University, Hamilton, ON, University of Toronto, Toronto, ON.

P4-12-06 Risk Factors for Relative Weight Gain >10% in Breast Cancer Survivors: Findings from the SU VI.MAX Cohort Zelek L, Czernichow S, Galan P, Hercberg S. Assistance Publique Hôpitaux de Paris, CHU Avicenne, Bobigny, France; INSERM U1125 INRA/CNAM/Université Paris 13, Bobigny, France.

P4-12-07 Outcomes of a Behavioral Weight Control Intervention among Rural Breast Cancer Survivors Befort CA, Klemp JR, Austin HL, Krigel S, Sullivan DK, Schmitz KH, Perri MG, Fabian CJ. University of Kansas Medical Center, University of Pennsylvania; University of Florida.

P4-12-08 Five Year Preliminary Outcomes of a Prospective Surveillance Model To Reduce Upper Extremity Morbidity Related to Breast Cancer Treatment Stout NL, Pfalter L, Levy E, McGarvey C, Gerber L, Springer B, Soballe P. National Naval Medical Center, University of Michigan-Flint; National Institutes of Health; CLM Consulting. George Mason University; Office of the Surgeon General; Naval Hospital San Diego.

P4-12-09 Withdrawn

P4-12-10 A Prospective Study of Physical Activity Patterns and Changes in Breast Cancer Patients during Active Breast Cancer Treatment Kim I-R, Choi E-K, Nam S-J, Lee J, Lee S-K, Yang J, Noh DY, Han W, Cho J. Samsung Comprehensive Cancer Center, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea; Surgery-Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea; Konkuk University Medical Center, Konkuk University School of Medicine, Seoul, Korea; Seoul National University Hospital, Seoul National University School of Medicine, Seoul, Korea; Johns Hopkins Bloomberg School of Public Health, Baltimore; Behavior and Society, Johns Hopkins Bloomberg School of Public Health, Baltimore.

P4-12-11 Myelodysplastic Syndrome Post Primary Breast Cancer Treatment: Cases from a Community Cancer Center: 1990-2010 Kaplan HG, Malmgren JA, Atwood MK. Swedish Cancer Institute, Seattle, WA; HealthStat Consulting, Inc., Seattle, WA.

P4-12-12 Patient-, Illness-, and/or Treatment-Related Baseline Predictors of Nonadherence to Oral Hormonal Therapy Wickersham KE, Sereika SM, Bender CM. University of Pittsburgh, Pittsburgh, PA.

P4-12-14 Pilot Study Utilizing Fluorine-18 Fluorodeoxyglucose (F-18 FDG) Positron Emission Tomography-Computed Tomography Scan (PET-CT Scan) To Investigate Brain Metabolic Changes during Treatment in Women with Breast Cancer Virani S, Lagos R, Hobbs G, Marano G, Nagaiah G, Abraham J. West Virginia University, Morgantown, WV.

P4-12-15 Cancer Survivor Care: An Evaluation of a Group Visit Model of Care for Breast Cancer Survivors at Duke Cancer Center Trotter KJ, Schneider S. Duke University Medical Center, Durham, NC; Duke University, Durham, NC.

P4-13-01 Pain Severity and Analgesic Use Associated with Skeletal-Related Events in Patients with Advanced Breast Cancer and Bone Metastases Fallowfield L, Cleeland CS, Body J-J, Stopeck A, von Moos R, Patrick DL, Clemens M, Tonkin K, Masuda N, Lipton A, De Boer R, Salvagni S, Toselio Olivera C, Ying W, Braun A, Cong Z. Cancer Research UK, University of Sussex, Brighton, United Kingdom; University of Texas, M.D. Anderson Cancer Center, Houston, TX; CHU Brugmann, Université Libre de Bruxelles, Brussels, Belgium; University of Arizona, Arizona Cancer Center, Tucson, AZ; Kantonsspital Graubünden, Chur, Switzerland; University of Washington, Seattle, WA; The Ottawa Hospital Cancer Centre, Ottawa, ON, Canada; Cross Cancer Institute, Edmonton, AB, Canada, Osaka National Hospital, Osaka, Japan; Penn State Milton S. Hershey Medical Center, Hershey, PA; Royal Melbourne Hospital, Melbourne, Australia; Azienda Ospedaliera di Parma, Parma, Italy; Instituto Brasileiro de Controle do Cancer-IBCC, São Paulo, Brazil; Amgen Inc., Thousand Oaks, CA.

P4-13-02 Hospice Utilization and End of Life Care in Metastatic Breast Cancer Patients at a Comprehensive Cancer Center O’Connor TL, Ngamphaiboon N, Morris J, Callinan NK, Milch RA, Kerr CH, Watroba N, Edge SB. Roswell Park Cancer Institute, Buffalo, NY; The Buffalo Center for Hospice and Palliative Care, Cheektowaga, NY.

P4-13-03 Retrospective Analysis of Palonosetron Compared with Older 5-HT3 Receptor Antagonists (Ondansetron, Dolasetron, and Granisetron) in Preventing Anthracycline-Induced Nausea and Vomiting in Breast Cancer Patients from Four Phase 3 Trials Rugo HS, Schwartzberg L, Morow GR, Barbour SY, Ballinari G, Thorn MD, Cox D. UCSF Helen Diller Family Comprehensive Cancer Center, West Clinic; University of Rochester, School of Medicine and Dentistry; Duke University Medical Center, Helsinn Healthcare SA; Statistical Resources Inc; Eisai, Inc.

P4-13-04 Psychosocial, Quality of Life, and Educational Aspects: Palliation and Pain Management

P4-14-01 Weight-Adjusted Change of Unilateral Arm Volumes for Quantification of Lymphedema after Bilateral Breast Surgery Miller CI, Specht MC, Ancukiewicz M, Skolny MN. O‘Toole J, Taghian AG. Massachusetts General Hospital, Boston, MA.

P4-14-02 Risk Factors for Early Lymphoedema Do not Predict Late Development of Lymphoedema Kilbreath SL, Beith J, Refshauge KM, Lee M-J, Ward LC. University of Sydney, Sydney, NSW, Australia; Royal Prince Alfred Hospital, Camperdown, NSW, Australia; University of Queensland, St Lucia, QLD, Australia.

P4-14-03 Support Groups in Breast Cancer: An Evidence Based Assessment of 1606 Patients with Concerning Topics for Support Group Discussion and Presentation Gralla RJ, Morse KD, Rittenberg CN, Petersen JA, Rosen LM, Lesser M. Hofstra North Shore - LIJ School of Medicine, New York, NY; Nexeura, Seattle, WA; Feinstein Institute for Medical Research, Manhasset, NY.

Chemotherapy-Induced Alopecia, Body Image and Psychological Distress in Women with Breast Cancer: A Prospective Study
Choi E-K, Kim I-R, Nam S-I, Lee J, Yang J, Lee S-K, Noh D-Y, Han W, Cho J. Samsung Comprehensive Cancer Center, Samsung Medical Center, Sungkyunkwan University School of Medicine; Johns Hopkins Bloomberg School of Public Health; Samsung Medical Center, Sungkyunkwan University School of Medicine; Konkuk University Medical Center, Konkuk University School of Medicine; Seoul National University Hospital, Seoul National University School of Medicine.

Psycosocial, Quality of Life, and Educational Aspects: Psychological Aspects

High Prevalence of Prospective Memory (PM) Impairment in Early Breast Cancer (EBC) Survivors within 1 Year of Adjuvant Chemotherapy Completion: Novel Findings Concerning Post Chemotherapy Cognitive Effects
Paquet L, Verma S, Collins B, Song X, Wheatley-Price P, Hopkins S, Segal R, Dent S, Mirkys D, Goel R, Young V, Clemons M, Keller O, Chinneck A, Young R, Bedard M. Carleton University, Ottawa, ON, Canada; The Ottawa Hospital Cancer Center, Ottawa, ON, Canada; The Ottawa Hospital, Ottawa, ON, Canada.

Clinical and Epidemiological Correlates of Elevated Distress Thermometer Scores in Breast Cancer Patients
Powers K, Pappas L, Buchmann L, Anderson L, Gauchay L, Rich A, Agarwali J. University of Utah, Salt Lake City, UT; Huntsman Cancer Institute, Salt Lake City, UT.

Patient-Provider Communication and Patient Informational Needs for Breast Reconstruction Post-Mastectomy: Results from a National Survey

Proteomic Analysis of Patient Plasma Identifies Parathyroid Hormone Related Protein (PTHrP12-48) as a Potential Biomarker of Breast Cancer Bone Metastasis
Hasham CL, Byrum SD, Leitell K, Suhail AM, Lipion A, Suva LJ, Winthrop P. Rockefeller Cancer Institute, University of Arkansas for Medical Sciences, Little Rock, AR; Penn State Hershey Cancer Institute, Penn State Hershey Medical Center, Hershey, PA; Lebanon VA Medical Center, Lebanon, PA.

Problems with Identifying Bone Metastasis-Specific Genes without Considering Biological Differences between ER-Positive and ER-Negative Breast Cancers
Hayashi N, Iwamoto T, Qiu Y, Nikura N, Sanatpia L, Nakamura S, Hortobagyi GN, Pusztai L, Symmans F, Leno NT. The University of Texas MD Anderson Cancer Center, Houston, TX; Hospital of Prato, Prato, Italy; Instituto Toscano Tumori, Prato, Italy; Showa University School of Medicine, Tokyo, Japan.

Proof of the Anti-Tumour Effect of Zoledronic Acid (ZA) in Naive Bone-Only Metastatic and Locally Advanced Breast Cancer: Results from the Biological Window Therapy
Foroni C, Andreis D, Maldotti M, Cappelletti MR, Generali DG. Istituti Ospitalieri di Cremona, Cremona, Italy.

An Open-Label, Phase IIa, Non-Randomized Study of Radium-223 in Breast Cancer Patients with Bone Dominant Disease No Longer Considered Suitable for Endocrine Therapy
Coleman R, Flamen P, Naume B, Jerusalem G, Garcia C, Piccart M, O’Bryan-Tear CG, Aknes A-K. Weston Park Hospital, Sheffield, United Kingdom; Institut Jules Bordet, Brussels, Belgium; Oslo University Hospital, Oslo, Norway; CHU Sart Tilman, B3S, Liege, Belgium; Algeta ASA, Oslo, Norway; Bayer Healthcare Pharmaceuticals, Montville, NJ.

A Randomized Phase 2 Study of a Loading Dose of Ibandronate in Patients with Bone Metastases from Breast Cancer
Ritchie DM, Bray C, Canney P. Beatson West of Scotland Cancer Centre, Glasgow, United Kingdom.

Expression Patterns of Receptor Activator of Nuclear Factor-κB (RANK) and Src in a Series of Primary Breast Tumors (BT) and Bone Metastases (BM) in Patients (pts) with Metastatic Breast Cancer (MBC)
Gucalp A, Comen E, Redana S, Evangelista L, Giri DD, Zhang XH, Patil S, Akram M, Norton L, Hudes CA, Forner MN. Memorial Sloan-Kettering Cancer Center, New York, NY; Sloan-Kettering Institute, New York, NY; Piemontese per l’Oncologia - Institute for Cancer Research and Treatment, Candiolo, Italy; Istituto Oncologico Veneto (IOV - IRCCS), Padua, Italy.

Breast Cancer Bone Metastasis Prevalence and Survival Outcomes: A Quantitative Review of the Literature

Pilot Randomized Trial of De-escalated (q12 Weekly) Versus Standard (q3-4 Weekly) Intravenous Bisphosphonates in Women with Low-Risk Bone Metastases from Breast Cancer
Amir E, Freedman O, Carlsson L, Usman T, Lee E, Dranitsaris G, Clemons M. Princess Margaret Hospital and The University of Toronto, Canada; The Ottawa Hospital Cancer Centre and The University of Ottawa, Canada.

Health Resource Utilization (HRU) Associated with Skeletal-Related Events (SREs) in Advanced Breast Cancer Patients with Bone Metastases: Results from a Prospective Multinational Observational Study
Lutfner D, Lorusso V, Duren I, Hechmati G, Garzon-Rodriguez C, Ashcroft J, Bahl A, Ghelani P, Wei R, Thomas E, Hoefele H. Universitatsmedizin Berlin, Berlin, Germany; Oncology Institute ASL, Leeece, Italy; Centro Integral Oncologico Clara Campal (CIOC), Madrid, Spain; Amgen (Europe) GmbH, Zug, Switzerland; Instituto Catalán Oncología ICO-IDIBELL, Barcelona, Spain; Pinderfields General Hospital, Wakefield, United Kingdom; University Hospitals Bristol, Bristol, United Kingdom; Ovatech Solutions, London, United Kingdom; Amgen Inc., So. Francisco, CA; Forschungszentrum Ruhr, Witten, Germany.

Trastuzumab Does Not Increase the Incidence of Central Nervous System (CNS) Relapses in HER2-Positive Early Breast Cancer: The HERA Trial Experience

Whole-Brain Radiation Therapy Plus Concomitant Temozolomide for the Treatment of Brain Metastases from Breast Cancer: A Randomized Prospective Multicenter Phase II Study

Incidence Rate of Asymptomatic Brain Metastases in Patients with HER2+ Metastatic Breast Cancer Screened for EGFR111438/CEREBEL Study
Pivot X, Hackmann J, Manikhas A, Moore Y, Parikh R, Krohri D, Joshi A, Aktan G, Coleman R. University Hospital of Besancon; Marien-Hospital, St Petersburg City Clinical Oncology Dispensary; GlaxoSmithKline, Collegeville, PA; GlaxoSmithKline, Uxbridge, United Kingdom; Weston Park Hospital.
Treatment – Types and Sites of Breast Cancer: Inflammatory Breast Cancer

P4-20-01 Multicentric Phase II PACS 09/Beverly1 Trial: First Efficacy and Safety Results of Neoadjuvant Chemotherapy Combined with Bevacizumab in HER2-Negative Patients with Non-Metastatic Inflammatory Breast Cancer
Viens P, Petit T, Dalenc F, Pienga JY, Delcoeur T, Romieu G, Bonneterre J, Ferrero J-M, Kerbrat P, Mouret-Reynier M-A, Bachelot T, Soulie P, Leebourrs F, Fymard J-C, Deblock M, Lortholary A, Hardy-Bessard A-C, Boher J-M, Asselain B, Charafe-Jauffret E, Lemonsin J, Martin A-L, Andre F. Institut Paoli Calmettes, Marseille, France; Centre Paul Strauss, Strasbourg, France; Institut Claudius Regaud, Toulouse, France; Institut Curie, Paris, France; Centre François Baclesse, Caen, France; Centre Val d’Aurelle, Montpellier, France; Centre Oscar Lambret, Lille, France; Centre Antoine Lacassagne, Nice, France; Centre Eugène Marquis, Rennes, France; Centre Jean Perrin, Clermont-Ferrand, France; Centre Leon Berard, Lyon, France; Centre Paul Papan, Angers, France; Institut Curie, Saint Cloud, France; Institut Jean Godinot, Reims, France; Centre Alexis Vautrin, Nancy, France; Centre Catherine de Sienne, Nantes, France; Clinique Armoiricaine, Saint Brieuc, France; B&d Oncancer, Paris, France; Institut Gustave Roussy, Villejuif, France.

P4-20-02 Inflammatory Breast Cancer (IBC) in the National Comprehensive Cancer Network (NCCN): The Disease, the Recurrence Pattern and the Outcome
Lubbe W, Li T, Hughes M, Ottesen R, Cristofanilli M, Weeks J, Wong Y-N. Fox Chase Cancer Center, Philadelphia, PA; Dana-Farber Cancer Institute, Boston, MA; City of Hope Cancer Center, Duarte, CA.

P4-20-03 T-Cell Cytokine Production Related to Progression of Breast Cancer Patients
Cohen EN, Gao H, Lee B-N, Giordano A, Tin S, Anfossi S, Parker CA, Cristofanilli M, Valero V, Alvarez RH, Hortobagyi GN, Woodward WA, Ueno NT, Reuben JM. The University of Texas MD Anderson Cancer Center, Houston, TX; Fox Chase Cancer Center, Philadelphia, PA; The University of Texas Graduate School of Biomedical Sciences at Houston, Houston, TX.

P4-20-04 Cytokine Synthesis by Activated Dendritic Cells in Relation to Disease Progression in Inflammatory Breast Cancer (IBC)
Gao H, Cohen EN, Lee B-N, Giordano A, Tin S, Anfossi S, Parker CA, Cristofanilli M, Valero V, Alvarez RH, Hortobagyi GN, Woodward WA, Ueno NT, Reuben JM. The University of Texas MD Anderson Cancer Center, Houston, TX; Fox Chase Cancer Center, Philadelphia, PA.

P4-20-05 Inflammatory Breast Cancer: Comparison of Epidemiology, Biology, and Prognosis between Japan and the United States, a Hospital-Based Study
Yamauchi H, Natori A, Hayashi N, Soejima K, Takahashi O, Fukui T, Nakamura S, Cristofanilli M, Ueno N. St. Luke’s International Hospital, Chuo-ku, Tokyo, Japan; Showa University, Shinagawa-ku, Tokyo, Japan; Fox Chase Cancer Center, Philadelphia, PA; The University of Texas MD Anderson Cancer Center, Houston, TX.

7:00 am–9:00 am
POSTER DISCUSSION VII: WHAT’S NEW IN CHEMOTHERAPY TRIALS?
Ballroom A

Viewing 7:00 am
Discussion 7:45 am

Discussant: Clifford Hudis, MD
Memorial Sloan-Kettering Cancer Center
New York, NY

PD07-01 Sequential Treatment with Epirubicin/Cyclophosphamide, Followed by Docetaxel vs. FEC120 in the Adjuvant Treatment of Breast Cancer Patients with Extensive Lymph Node Involvement: Final Survival Analysis of the German ADEBAR Phase III Study
Janni WJ, Harbeck N, Sommer H, Rack B, Salmen J, Augustin D, Simon W, Jueckstock J, Wischum N, Arkeke K, Melcher C, Friese K, Kechle M. Heinrich-Heine-University, Dusseldorf, Germany; University Cologne, Cologne, Germany; Ludwig-Maximilians-University, Munich, Germany; Mammazentrum Ostbayern, Deggendorf, Germany; Robert-Bosch-Krankenhaus, Stuttgart, Germany; Zentalklinikum, Augsburg, Germany; Technische Universität, Munich, Germany.

PD07-02 Docetaxel Is Superior to Paclitaxel Given Every Three Weeks in Post Operative Patients with Node-Positive Breast Cancer: Results of the Final Analyses of the NSAS-BC (National Surgical Adjuvant Breast Study of Cancer) 02 Trial from Japan
Watanabe T, Kuranami M, Inoue K, Masuda N, Aogi K, Iwata H, Mukai H, Uemura Y, Ohashi Y. Hamamatsu Oncology Center, Hamamatsu, Japan; Kitasato University Hospital, Sagamihara, Japan; Saitama Cancer Center, Inachou-омuro, Japan; NHO Osaka National Hospital, Osaka, Japan; Shikoku Cancer Center, Matsuyama, Japan; Kyushu Cancer Center, Fukuoka, Japan; Aichi Cancer Center, Nagoya, Japan; National Cancer Center, Kashiwa, Japan; University of Tokyo, Tokyo, Japan.

PD07-03 Phase II Trial of Adjuvant TC (Docetaxel/Cyclophosphamide) Plus Trastuzumab (HER TC) in HER2-Positive Early Stage Breast Cancer Patients
Jones S, Collea R, Paul D, Oratz R, Sedlacek S, Favret AM, Gore, Jr II, Lindquist DL, Holmes FA, Allison MAK, Steinberg MS, Stokoe C, Portillo RM, Crockett M, Wang Y, Asmar L, Robert N, O’Shaughnessy J. US Oncology, The Woodlands, TX; Baylor Sammons Cancer Center, Dallas, TX; New York Oncology Hematology, Albany, NY; Rocky Mountain Cancer Center, Denver, CO; Physician, New York, NY; Virginia Cancer Specialists, PC, Fairfax, VA; Birmingham Hematology and Oncology, Birmingham, AL; Arizona Oncology Associates, Sedona, AZ; Texas Oncology, Houston, TX; Comprehensive Cancer Center, Henderson, NV; Virginia Oncology Associates, Virginia Beach, VA; Texas Oncology, Plano, TX; Texas Oncology, El Paso, TX.

PD07-04 Lapatinib vs Trastuzumab in Combination with Standard EC-D Chemotherapy in the Neoadjuvant Treatment of HER2+ Patients. Results from the GECAM 2006-14 Phase II Randomized Trial
Alba E, Albanell J, de la Haba J, Barnadas A, Calvo L, Sanchez P, Ramos M, Rojo F, Burgués O, Porrás I, Tibau A, CArrasco E, Cámara MC, Lluch A. Hospital Virgen de la Victoria, Malaga, Spain; Hospital del Mar, Barcelona, Spain; Hospital Universitario Reina Sofia, Córdoba, Spain; Hospital Santa Creu i Sant Pau, Barcelona, Spain; Complejo Hospitalario Universitario de A Coruña, A Coruña, Spain; Hospital General de Jaén, Jaén, Spain; Centro Oncológico de Gaúlica, A Coruña, Spain; Fundación Jiménez Díaz, Madrid, Spain; Hospital Clínico Universitario de Valencia, Valencia, Spain; GECAM (Spanish Breast Cancer Research Group), San Sebastián de los Reyes, Madrid, Spain.
PD07-05 Local Recurrence Risk in 6377 Patients with Early Breast Cancer Receiving Neoadjuvant Anthracycline-Taxane +/- Trastuzumab Containing Chemotherapy

PD07-06 Adjuvant Chemotherapy with or without Darbepoetin alpha in Node-Positive Breast Cancer: Survival and Quality of Life Analysis from the Prospective Randomized WSG ARA Plus Trial
Nitz U, Gluz O, Oberhoff C, Reimer T, Schumacher C, Hackmann J, Warm M, Ulher C, Runde V, Kuemmel S, Zuna I, Harbeck N. West German Study Group, Moenchengladbach, Germany; Bethesda Hospital, Moenchengladbach, Germany; Bethesda Hospital, Wuppertal, Germany; University Hospital Essen, Essen, Germany; Catholical Hospital Essen North, Essen, Germany; University Hospital Suedstadt, Rostock, Germany; St. Elisabeth Hospital, Cologne, Germany; Menen-Hospital Witten, Witten, Germany; University Hospital Cologne, Cologne, Germany; Krankenhaus Koeln-Holweide, Cologne, Germany; Gynecological Practice, Hildesheim, Germany; Wilhelm-Anton-Hospital Goeh, Goeh, Germany; Hospital Essen-Mitte, Essen, Germany.

PD07-07 Combination of Paclitaxel and Bevacizumab without or with Capecitabine as First-Line Treatment of HER2-Negative Locally Recurrent or Metastatic Breast Cancer (LR/MBC): First Results from a Randomized, Multicenter, Open-Label, Phase II Study of the Dutch Breast Cancer Trials’ Group (BOOG)
Lam SW, de Groot SM, Honkopes AH, Jager A, ten Tije AJ, Bos MMEM, Linn SC, van den Bosch J, Nortier JW, Braun JJ, de Graaf H, Portielje JEA, Los M, Gooyer DD, van Tinteren H, Boven E. PD07-08 The Effect on Surgical Complications of Bevacizumab Added to Neoadjuvant Chemotherapy: NSABP Protocol B-40
Bret HD, Tang G, Rastogi P, Geyer CE, André R, Atkins JN, Baez-Diaz L, Brufsky AM, Mehta RS, Fehrenbacher L, Pajon ER, Senecal FM, Gaur R, Mangolese RG, Adams PT, Gross HM, Costantino JP, Swan SM, Mamounas EP. Wolmark N. National Surgical Adjuvant Breast and Bowel Project (NSABP), Virginia Commonwealth University, Massey Cancer Center, University of Pittsburgh Graduate School of Public Health; University of Pittsburgh Cancer Institute School of Medicine; Allegheny General Hospital; Centre Hospitalier de l’Université de Montréal; Southeast Cancer Control Consortium CCOP, San Juan MBCCOP; University of Pittsburgh/Magee Women’s Hospital, University of California at Irvine, School of Medicine, Chao Family Comprehensive Cancer Center, Kaiser Permanente, Northern California; CCOP, Colorado Cancer Research Program; CCOP, North-West Medical Specialties; Kansas City Clinical Oncology Program; Jewish General Hospital, McGill University; Genesys Regional Medical Center, Dayton CCOP, Washington Cancer Institute, Washington Hospital Center; Aultman Health Foundation.

PD08-01 JNK2 Regulates Mammary Lineage Differentiation in Tumors and Normal Glands through Notch1 and p53
Cantrell MA, Ebelt ND, Van Den Berg CL. University of Texas at Austin, Austin, TX.

PD08-02 Targeting BCL-2 Expressing Breast Tumors with BH3-Mimetics - A New Class of Drugs in Breast Cancer?
Lindeman GJ, Oakes SR, Vailliant F, Lim E, Lee L, Breslin K, Feleppa F, Deb S, Ritchie ME, Takano E, Ward T, Fox SB, Generali D, Smyth GK, Strasser A, Huang DCS, Visvader JE. The Walter and Eliza Hall Institute of Medical Research, Parkville, VIC, Australia; The Royal Melbourne Hospital, Parkville, VIC, Australia; The University of Melbourne, Parkville, VIC, Australia; Peter MacCallum Cancer Centre, East Melbourne, VIC, Australia; Ospitaleri di Cremona, Cremona, Italy.

PD08-03 Inhibition of MEK/ERK- and JNK-Dependent Expression of Interleukin-6 and Interleukin-8 Targets Basal-Like Breast Cancer Stem Cells
Balko JM, Cook RS, Kuba MG, Miller TW, Bhola NE, Sanders ME, Meszoely IM, Dowsett M, Gomez H, Arteaga CL. Vanderbilt University, Nashville, TN; Royal Marsden Hospital, United Kingdom; Instituto Nacional de Enfermedades Neoplásicas, Lima, Peru.

PD08-04 Inhibition of the TGFβ/TGFβR2 Pathway Prevents Enrichment of Drug-Resistant Breast Cancer Stem Cells by Anti-Cancer Chemotherapy
Bhola N, Arteaga C. Vanderbilt University Medical Center, Nashville, TN.

PD08-05 Stat3 Signaling in Human Breast Cancer Stem Cells
Wei W, Zhang M, Tweardy D, Rosen J, Lewis M. Baylor College of Medicine.

PD08-06 ERK2 Promotes Stem Cell-Like Characteristics in Triple-Negative Breast Cancer
Bartholomeusz C, Saso H, Dadabin A, Kazuharu K, Hortobagyi GN. The University of Texas MD Anderson Cancer Center, Houston, TX.
PD08-07  Wound-Healing Drainage Fluids Promote Triple Negative Breast Cancer Progression

PD08-08  Preclinical Efficacy of the Combination of Met and Src Family Kinase Inhibitors in Triple-Negative Breast Cancer
Gartner EM, Kim EHH, Choi L, Boerner J. Karmanos Cancer Center at Wayne State University, Detroit, MI.

PD08-09  PTPN12 Gene Expression Signature in Triple Negative Breast Cancer Cohort
Ghazalpour A, Bender RP, McGinnis MJ, Ashfaq R. Caris Life Sciences, Phoenix, AZ.

PD08-10  High Frequency of Triple Negative Mammary Carcinomas in the Dog as Model of Human Breast Cancer

PD08-11  Targeting Porcupine, a Critical Node for Wnt Signalling in Cancer

9:00 am–9:30 am  PLENARY LECTURE 3
Exhibit Hall D

Advances in Axillary Surgery: Sentinel Nodes and Beyond
Barbara L. Smith, MD, PhD
Massachusetts General Hospital
Boston, MA

9:30 am–11:30 am  GENERAL SESSION 5
Exhibit Hall D
Moderator: Muthaffar Rimawi, MD
Baylor College of Medicine
Houston, TX

9:30  SS-1. Neoadjuvant pertuzumab and trastuzumab: Biomarker analyses of a 4-arm randomized phase II study (NeoSphere) in patients with HER2-positive breast cancer
Gianni L, Bianchini G, Kiermaier A, Bianchi G, Im Y-H, Pienkowski T, Roman L, Liu M-C, Tseng L-M, Ratnayake J, Szaa T, Ross GA, Valagusa P. Oncologia Medica, San Raffaele Cancer Center, Milan, Italy; Roche, Basel, Switzerland; Oncologia Medica 1, Fondazione IRCCS Instituto Nazionale Tumori, Milan, Italy; Samsung Medical Center, Seoul, Korea; Centrum Onkologii, Warsaw, Poland; Leningrad Regional Oncology Dispensary, St Petersburg, Russian Federation; Koo Foundation Sun Yat-Sen Cancer Center, Taipei, Taiwan; Taipei-Veterans General Hospital, National Yang-Ming University, Taipei, Taiwan; Roche Products Limited, Welwyn, United Kingdom; Genentech, South San Francisco, CA; Fondazione Michelangelo, Milan, Italy.

9:45  SS-2. PAM50 HER2-enriched subtype enriches for tumor response to neoadjuvant anthracyclines/taxane and trastuzumab/taxane containing regimens in HER2-positive breast cancer
Cheang MCU, Prat A, Fan C, Perou CM. Lineberger Comprehensive Cancer Center, Chapel Hill, NC.

10:00  SS-3. Basement membrane localized tumor cells are protected from PARP-1 targeted therapy in vivo
Zoeller JJ, Bronson RT, Gilmer TM, Selfers LM, Lu Y, Mills GB, Brugge JS. Harvard Medical School, Boston, MA; GlaxoSmithKline, Research Triangle Park, NC; UT MD Anderson Cancer Center, Houston, TX.

10:15  SS-4. pCR as a surrogate in HER2-positive patients treated with trastuzumab

10:30  SS-5. A phase III, randomized, double-blind, placebo-controlled registration trial to evaluate the efficacy and safety of pertuzumab + trastuzumab + docetaxel vs. placebo + trastuzumab + docetaxel in patients with previously untreated HER2-positive metastatic breast cancer (CLEOPATRA)
Baselga J, Kim S-B, Im S-A, Hegg R, Im Y-H, Roman L, Pedrini JL, Cortés J, Knott A, Clark E, Ross GA, Swain SM. Massachusetts General Hospital Cancer Center, Boston, MA; Asan Medical Center, University of Ulsan, College of Medicine, Seoul, Korea; Seoul National University College of Medicine, Seoul, Korea; Hospital Pêrola Byington, São Paulo, Brazil; Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea; Lengrad Regional Oncology Dispensary, St. Petersburg, Russian Federation; CPMEC-Mastology Unit of Consejoacion Hospital, Porto Alegre, Brazil; Vall d’Hebron University Hospital, Barcelone, Spain; Roche Products Limited, Welwyn, United Kingdom; Washington Cancer Institute, Washington Hospital Center, Washington, DC.

10:45  SS-6. Neoadjuvant pertuzumab and trastuzumab concurrent or sequential with an anthracycline-containing or concurrent with an anthracycline-free standard regimen: A randomized phase II study (TRYPHAENA)
Schneeweiss A, Chia S, Hickish T, Harvey V, Enull A, Hegg R, Tausch C, Seo J-H, Tsai Y-F, Ackrill A, Ross G, Cortés J. National Center for Tumor Diseases, University Hospital, Heidelberg, Germany; British Columbia Cancer Agency - Vancouver Centre, University of British Columbia, Vancouver, Canada, Royal Bournemouth Hospital, Bournemouth University, Bournemouth, United Kingdom; Auckland City Hospital, Auckland, New Zealand; Cancer Institute "I. Chitucita", Cluj-Napoca, Romania; Hospital Pêrola Byington, São Paulo, Brazil; Breast-Center, Zürich, Switzerland; Korea University Guro Hospital, Guro, Korea; Taipei Veterans General Hospital, Taiwan, Taiwan; Roche Products Limited, Welwyn, United Kingdom; Vall d’Hebron University Hospital, Barcelone, Spain.

11:00  SS-7. A phase 2, randomized, open-label, study of neratinib (HKI-272) vs lapatinib plus capecitabine for 2nd/3rd-line treatment of HER2+ locally advanced or metastatic breast cancer
Martin M, Bonnetterre J, Geyer, Jr CE, Ito Y, Ro J, Lang I, Kim S-B, Germa C, Vermette J, Vo Van ML, Wang K, Wang K, Awada A. Hospital Universitario Gregorio Marañon, Madrid, Spain; Centre Oscar Lambret, Lille, France; Allegheny Cancer Center, Pittsburgh, PA; The Cancer Institute Hospital of JFCR, Tokyo, Japan; National Cancer Center, Goyang, Korea; National Institute of Oncology, Budapest, Hungary; Asan Medical Center, Seoul, Korea; Pfizer Global Research and Development, Paris, France; Pfizer Inc, Collegeville, PA; Bristol Meyers Squibb, Princeton, NJ; Jules Bordet Institute, Brussels, Belgium.

11:15  Discussion
C. Kent Osborne, Baylor College of Medicine, Houston, TX.
11:30 am–12:00 pm

AACR OUTSTANDING INVESTIGATOR AWARD FOR BREAST CANCER RESEARCH, FUNDING BY SUSAN G. KOMEN FOR THE CURE*
Exhibit Hall D
Alteration and Inhibition of PTEN in Breast Cancer
Ramon E. Parsons, MD, PhD
Columbia University
New York, NY

12:00 pm–1:35 pm
LUNCH

12:15 pm–1:15 pm
PRODUCT THEATRE
Exhibit Hall C – Exhibit Area
Abrazane
Sponsored by Celgene Corporation

12:30 pm–1:35 pm
CASE DISCUSSION 2
Ballroom A
Moderator: Mothaffar Rimawi, MD
Baylor College of Medicine
Houston, TX
Panelists:
Kimberly Blackwell, MD
Duke University
Durham, NC
Jennifer Bellon, MD
Dana-Farber Cancer Institute
Boston, MA
Ismail Jatoi, MD
UT Health Science Center
San Antonio, TX
Martine Piccart, MD, PhD
Institut Jules Bordet
Brussels, BELGIUM
Vernal Branch
Virginia Breast Cancer Foundation
Richmond VA

12:30 pm–1:35 pm
BASIC SCIENCE FORUM
Ballroom B
Tumor Microenvironment
Moderator: Rong Li, PhD
UT Health Science Center San Antonio
San Antonio, TX
Extrinsic and Intrinsic Force Regulation of Breast Cancer Progression and Treatment
Valerie M. Weaver, PhD
University of California San Francisco
San Francisco, CA
COX-2 dependent collagen fibrillogenesis drives metastasis in the postpartum involuting mammary gland

3:15  **56-1.** Menopause-specific and health-related qualities of life among post-menopausal women taking exemestane for prevention of breast cancer: Results from the NCIC CTG MAP.3 placebo-controlled randomized controlled trial
Maursell E, Richardson H, Ingle JN, Ales-Martinez JE, Chlebowski RT, Fabian CJ, Sarto GE, Garber JE, Pujoel P, Hiltz A, Tu D, Goss PE. Université Laval, Quebec City, QC, Canada; Queen’s University, Kingston, ON, Canada; Mayo Clinic, Rochester, MN; Hospital Ntra Sra Sonsoles, Avila, Spain; Los Angeles Biomedical Research Institute, Torrance, CA; University of Kansas Medical Center, Westwood, KS; Center for Women’s Health and Health Research, Madison, WI; Dana Farber Cancer Institute, Boston, MA; CHU-Hopital Arnaud de Villeneuve, Montpellier, France; Massachusetts General Hospital Cancer Center, Boston, MA.

3:30  **56-2.** Patient-reported predictors of early treatment discontinuation: NCIC JMA.27/E1203 quality of life study of postmenopausal women with primary breast cancer randomized to exemestane or anastrozole
Wagner LL, Zhao F, Chapman J-AW, Cella D, Shepherd LE, Sleight GW, Goss PE. Northwestern University Feinberg School of Medicine, Chicago, IL; Dana-Farber Cancer Institute, Boston, MA; NCIC Clinical Trials Group, Queen’s University, Kingston, ON, Canada; Indiana University Simon Cancer Center, Indianapolis, IN; Massachusetts General Hospital, Boston, MA.

3:45  **Discussion**
Patricia A. Ganz, MD
UCLA Jonsson Comprehensive Cancer Center
Los Angeles, CA

4:00  **56-3.** Influence of hospital factors, physician factors and type of health insurance on receipt of immediate postmastectomy reconstruction in young women with breast cancer
Hershman DL, Neugut AI, Richards CA, Kalinsky K, Charles AS, Wright JD. Columbia University, New York, NY; Mailman School of Public Health, New York, NY.

4:15  **56-4.** Protein kinase mutation patterns in human breast cancer

4:30  **56-5.** Obesity drives epithelial-to-mesenchymal transition and tumor progression in a novel claudin-low mammary cancer model
Dunlap SM, Chiao LJ, Nurieua L, Usary J, Perou CM, Varticovski L, Hurston SD. University of Texas, Austin, TX; University of North Carolina, Chapel Hill, NC; National Cancer Institute, Bethesda, MD; University of Texas M.D. Anderson Cancer Center, Smithville, TX.

4:45  **56-6.** Expression of key estrogen-regulated genes differ substantially across the menstrual cycle in ER+ breast tumours
Haynes BP, Viale B, A-Hemi R, Smith IE, Dowsett M, Galimberti V, Rotmensz N, Gibe1li B. Royal Marsden Hospital, London, United Kingdom; Institute of Cancer Research, Sutton, Surrey, United Kingdom; European Institute of Oncology, Milan, Italy.

5:00 pm–7:00 pm
**POSTER SESSION 5 & RECEPTION**
Exhibit Halls A-B

**Tumor Cell Biology: Biomarkers**

**PS-01-01 Identification, Validation and Assessment of Transcriptional Relevance of a PDGFR-Activation Signature in (Inflammatory) Breast Cancer**
Van Laere SJ, Van Golen KL, Joglekar M, Ueno NT, Finetti P, Van Dam PA, Viens P, Bimbbaum D, Bertucci F, Vermeulen PB, Dirix LY. Oncology Center - GH Sint-Augustinus, Wilrijk, Belgium; University of Delaware, Newark, DE; The University of Texas MD Anderson Cancer Center, Houston, TX; Institut Paoli-Calmettes (IPC), Marseille, France; World IBC Consortium; Contributed Equally.

**PS-01-02 Wnt5a Is a Prognostic Biomarker in Estrogen Receptor-Positive Premenopausal Breast Cancer**
Sand-Jensen JT, Ehrenstrom R, Andersson T, Ryden L. Clinical Sciences, Skåne University Hospital, Lund, University, Malmö, Sweden; Laboratory Medicine, Skåne University Hospital, Lund University, Malmö, Sweden.

**PS-01-03 Correlation between Aromatase Expression in Metastatic and Primary Breast Cancer**
Ribeiro JM, Luis IV, Correia L, Casimiro S, Fernandes A, Quintela A, Mestan J, Ramos M, Costa L. Hospital de Santa Maria, Lisbon, Portugal; University of Lisbon, Lisbon; Hospital de Santa Maria, Lisbon; Novartis Pharma.

**PS-01-04 FOXP3 Positive Regulatory T Lymphocytes and Epithelial FOXP3 Expression in Synchronous Normal, Ductal Carcinoma In Situ and Invasive Cancer of the Breast**

**PS-01-05 Activating Mutations in PIK3CA or AKT1 in the I-SPY 1 Trial (CALGB 150007/150012; ACRIN 6657)**
Boudreau A, You C, Petrolli L, Stemke-Hale K, Mills GB, Gray J, Wolf DM, van’t Veer LJ, The I-SPY 1 TRIAL Investigators, Esserman LJ, University of California, San Francisco; University of Texas MD Anderson Cancer Center; Oregon Health & Science University.

**PS-01-06 Gene Copy Number and Expression of TYMP and TMS Are Predictive of Outcome in Breast Cancer Patients Treated with Capecitabine**
Audet RM, Changyu S, Duchnowska R, Adamowicz K, Zok J, Rogowski W, Litwinuk M, Desbska S, Jawonska M, Foszczyńska-Klocla M, Kulma-Kreft M, Zabkowska K, Jassem J, Edgerton S, Yang Nielsen K, Thor A, Chang J, Miller K, Sledge GW. Yale University of Research, Montreal, QC, Canada; Medical University of Gdańska, Gdańska, Poland; Indiana University School of Medicine, Indianapolis, IN; Melvin and Ben Simon Cancer Center, Indianapolis; Emory University, Atlanta, GA; UC Denver School of Medicine, Aurora, CO; DAKO, Glostrup, Denmark; The Methodist Hospital Research Institute, Houston, TX; Military Institute of Medicine, Warsaw, Regional Oncology Center, Olsztyn; Poznan University of Medical Sciences; Regional Cancer Center, Lodz, MD; District Hospital, Wrocław, MD; West Pomeranian Oncology Center, Szczecin; Gdynia Oncology Center.

**PS-01-07 Identification of SORBS2 as a Candidate Marker To Predict Metastatic Relapse in Breast Cancer**

**PS-01-08 Immunocytchemistry Staining of Estrogen Receptor in Circulating Tumor Cells as Compared to Primary Tumor**
Mayer JA, Pham T, Wong KL, Birscholf FZ. Biocent Inc, San Diego, CA.

**PS-01-09 Differences in Serum Estradiol and Prolactin Concentrations in Women Who Yield Nipple Aspiration Fluid and Those Who Do Not**
Khan SA, Fought AJ, Scholten DM, McGathey C, Hintz RE, Chatterton RT. Northwestern University, Feinberg School of Medicine, Chicago, IL.

**PS-01-10 A Potential New Marker for, and Facilitator of, Hormone Independence**
Monaco ME, Wu X, Lee P. NYU School of Medicine, New York, NY; VA NY Harbor Healthcare System, New York, NY.

**PS-01-11 Small Node-Negative (T1b-C0) Invasive Hormone Receptor (HR)-Positive Breast Cancers: Is There a Population Which Might Have Benefit from Adjuvant Chemotherapy?**
Cancer Res; 71(24 Suppl.) December 15, 2011

PS-05-03 The Effect of Breastfeeding on Molecular Characteristics of Invasive Breast Cancer
Ellsworth RE, Valente AL, Kane JL, Shriver CD, Henry M. Jackson Foundation, Windber, PA; Windber Research Institute, Windber, PA; Walter Reed Army Medical Center, Washington, DC.

PS-05-04 Tamoxifen-Induced Apoptosis Is Compromised by Bisphenol-A and Methylparaben Exposure
Goodson III WH, Luciani MG, Sayed A, Jaffe J, Moore II DH, Dairkee SH. California Pacific Medical Center Research Institute, San Francisco, CA; Kimmel Cancer Center, San Francisco, CA; California Pacific Medical Center, San Francisco, CA; University of California, San Francisco, CA.

PS-05-05 Human Papilloma Virus Identification in Intraductal Papilloma and Breast Cancer Using Broad-Spectrum Primers
Balić FL, Bender O, Coskun F, Duzgun AP, Saylam B, Yuney E, Rota S, Fidan I, Feldman S, Soran A. Numune Training and Research Hospital, Ankara, Turkey; Okmeydani Training and Research Hospital, Istanbul, Turkey; Gazi University School of Medicine, Turkey; Columbia University College of Physicians and Surgeons, New York; University of Pittsburgh, Magee-Womens Hospital, Pittsburgh.

PS-05-06 Dysregulation in the Transport of Iron and Haem Is Implicated in the Aetiopathogenesis of Breast Cancer
Roe T, Hoar F, Tslepis C. University of Birmingham, Birmingham, United Kingdom; City Hospital, Birmingham, United Kingdom.

PS-05-07 The Msp1 Polymorphism of Cytochrome P-450 CYP1A1 in Asymptomatic Women with Breast Cysts
Fensile R, Nazario A, Facina G. Federal University of Sao Paulo, Sao Paulo, SP, Brazil.

Tumor Cell Biology: Drug Resistance

PS-06-01 Gene Expression Analysis of Resistance to Bevacizumab in a VEGF-Reinforced Xenograft Model of ER-Positive Breast Cancer
Golken-Polar Y, Toroni RA, Goswami C, Sanders KL, Mehta R, Sinmalle U, Tansaa B, Chen C, Li I, Ivan M, Badve S, Sledge GW. Indiana University School of Medicine, Indianapolis, IN; University of Medicine and Pharmac, La Jolla, CA.

PS-06-02 Response and Acquired Resistance of BRCA1-Deficient Triplet-Negative Breast Cancer Xenografts to Alkylators or PARP Inhibitors

PS-06-03 Gene Expression Associated with Breast Cancer Primary and Secondary Resistance to Neoadjuvant Chemotherapy
Fujita FK, Katayama MLH, Brentani H, Carraro DM, Abeu APS, Barros Filho MC, Oliveira CT, Caldeira JRF, Góes JCS, Brentani MM, Folgueira MAX. Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil; Faculdade de Medicina da USP, Sao Paulo, Brazil; Hospital do Cancer A.C. Camargo, Sao Paulo, Brazil; Instituto Brasileiro de Controle do Cancer, Sao Paulo, Brazil; Hospital do Cancer A.C. Camargo, Sao Paulo, Brazil; Hospital Amaral Carvalho, Jau, Sao Paulo, Brazil.

PS-06-04 Mechanisms of Acquired Resistance to Insulin-Like Growth Factor 1 Receptor Inhibitor in MCF-7 Breast Cancer Cell Line
Ekyalongo RC, Mukohara T, Kataoka Y, Kyota N, Fujiwara Y, Minami H. Kobe University Graduate School of Medicine, Kobe, Japan; Kobe University Hospital Cancer Center, Kobe, Japan.

PS-06-05 Withdrawn

PS-06-06 The RNA Binding Protein FUS Is a Potential Marker for Breast Cancer Progression and Therapy Response
Brooke GN, Bevan CL, Rudraraju B, Palmieri C. Imperial College London, London, United Kingdom.

Tumor Cell Biology: Breast Cancer Xenografts

PS-06-08 Mesenchymal Stem Cells and Carcinoma-Associated Fibroblasts Sensitize Breast Cancer Cells in 3D Cultures to Kinase Inhibitors
Dittmer J, Dittmer A, Oerlecke J, Leyh B, Martens JMV, Thomssen C. Clinic for Gynecology University Halle, Germany; Erasmus Medical Center.

PS-06-09 Acquired Sensitivity to TRAIL Mediated Apoptosis in Lapatinib Resistant SKBR3 Cells
Eustace AJ, Browne BC, McDermott M, Gallagher C, Watson W, Crown J, O’Donovan N. Dublin City University, Dublin, Ireland; University College Dublin, Dublin, Ireland; St. Vincents University Hospital, Dublin, Ireland.

PS-06-10 Leptin Signaling Impacts Notch and Wnt Crosstalk in Breast Cancer
McGlothen TZ, Gillaume C, Colbert L, Blaylock-Hogans D. Morehouse School of Medicine, Atlanta, GA; Spelman College, Atlanta, GA.

PS-06-11 Quercetin-3-Methyl Ether Inhibits Lapatinib-Sensitive and Lapatinib-Resistant Breast Cancer Cell Growth by Inducing G2/M Arrest and Apoptosis
Bode AM, Li J, Zhu F, Normanno NE, Ericson ME, Lubeet GA. University of Minnesota, Austin, MN; INT-Fondazione Pascale, Naples, Italy; University of Minnesota, Minneapolis, MN; National Cancer Institute, Rockville, MD.

Tumor Cell Biology: Breast Cancer Xenografts

PS-07-01 Novel Alternative Splice Variants of HER2 in Invasive Breast Cancer
Assam EE, Rhodes A, Ladomery M, Harries L, Sohal M. University of the West of England, Bristol, Gloucestershire, United Kingdom; Royal Devon and Exeter NHS Foundation Trust Hospital, Exeter, Devon, United Kingdom; United Hospitals Bristol Foundation Trust, Bristol, Gloucestershire, United Kingdom.

PS-07-02 Could the Combination of COX-2 Inhibitor and Calcitriol Be a New Chemopreventive Approach To Decrease the Incidence of Breast Cancer?

PS-07-03 Modulation of Autophagic Activity by Extracellular pH
Xu T, Su H, Ganapathy S, Yuan Z-M. University of Texas Health Science Center at San Antonio, San Antonio, TX.

PS-07-04 Is α-L-Fucose Overexpressed on Cells of Aggressive Human Breast Cancers?
Listinsky JJ, Siegal GP, Listinsky CM. University of Alabama at Birmingham, Birmingham, AL; Case Western Reserve University, Cleveland, OH.

PS-07-05 Hypoxic Mammary Epithelial Cells in Three-Dimensional Culture Develop a Cancer-Like Phenotype
Vaapil M, Helcynska K, Pählinan S, Jögi A. Lund University, Sweden.

PS-07-06 Effect of Angiotensin-(1-7) and Angiotensin II on T47D Breast Cancer Cells in the Proliferation and cAMP Production
Correa-Noronha SSAA, Noronha SMR, Alercim C, Shimuta SI, Nakae CR, Gebrim LH, Nazario ACP, Silva IDCG. UNIFESP, Sao Paulo, SP, Brazil.

PS-07-07 Follistatin Suppresses In Vitro Growth of Breast Cancer Cells and Its Reduced Expression in Breast Cancer Associated with Poor Differentiation and Prognosis
Ye L, Mansel RE, Jiang WG. Cardiff University School of Medicine, Cardiff, United Kingdom.

Cancer Res; 71(24 Suppl.) December 15, 2011

68s Cancer Research
PS-07-08  Pomegranate extract targets miRNA-27a and miRNA-155 in the reduction of inflammation and cell growth in ER+ breast cancer in vitro and vivo  
Mertens-Talcott SU, Banerjee N, Safe S, Talcott S. Texas A&M University, College Station, Texas; Texas A&M Health Science Center, College Station, Texas.

Detection and Diagnosis – Imaging and Screening: Breast Imaging – Mammography

PS-08-01  Quantitative Analysis of Strain Ratio of Microcalcification Lesions with Surgical Specimen Mammography  
Hung S-H, Chen R-C, Wu Y-T, Chen T, Lin C-H. Taipei City Hospital, Taiwan; National Yang- Ming University, Taiwan.

PS-08-02  Mammographic Breast Texture Predicts Benign Biopsy Results and Composition  

PS-08-03  How Reader’s Training, Software, and Image Formats Impact Percent Dense Area Measures  
Fan B, Duever F, Wu F, Kertikowske K, Vachon C, Shepherd JA. University of California San Francisco, San Francisco, CA; Mayo Clinic College of Medicine, Rochester, MN.

PS-08-04  Mammographic Microcalcifications and Breast Cancer Tumorigenesis: A Radiologic-Pathologic Analysis  

PS-08-05    Withdrawn

PS-08-06  Comparison of Mammographic Density between Ductal Carcinoma In Situ and Benign Breast Disease  

Detection and Diagnosis – Imaging and Screening: Screening

PS-09-01  Breast Cancer Annual Screening Program Núcleo Mama Porto Alegre (NMPOA): Imaging Results after Seven Years  

PS-09-02  Reducing Excess Biopsies: Improving Screening through Risk Stratification and New Thresholds for Intervention  
Kim DN, Kim J-H, Flowers CJ, Elias S, Moore DH, Esserman LJ. Athena Breast Health Network, San Francisco, CA; Moffitt Cancer Center, Tampa, FL; University Medical Center Utrecht, Utrecht, Netherlands; University of California, San Francisco, CA.

PS-09-03  Health Literacy Affects Use of Screening Mammography in an Underinsured Population  
Komenaka IK, Nodora J, Hsu C-H, Machado L, Klemens AE, Zenuk R, Bouton ME, Martinez ME, Weiss BD. Maricopa Medical Center, Phoenix, AZ; University of Arizona, Tucson, AZ.

PS-09-04  Predictors of Malignancy and Surgical Outcomes Following Indeterminate Core Needle Biopsy in the British Breast Screening Programme  
Gillespie HS, Lowry K, Somerville J, McIntosh SA. University of Aberdeen, Foresterhill, Aberdeen, Aberdeenshire, Scotland, United Kingdom; Belfast City Hospital, Belfast, County Down, United Kingdom.

PS-09-05  Non-Palpable Lesions Findings in a Breast Cancer Opportunistic Screening in South Brazil  

PS-09-06  Breast cancer detection through metabolic fingerprint in blood  

Detection and Diagnosis: Imaging and Screening: Radiology – Tumor Monitoring

PS-10-01  Metabolic Pharmacodynamic Effect Evidenced by 18FDG-PET as a Tool for Early Prediction of Iniparib Efficacy in Metastatic Triple Negative Breast Cancer (TNBC): A Proof of Concept Study  
Kerrou K, Gligorov J. Eastern Paris University Hospitals, APHP Tenon, Paris, France; Eastern Paris University Hospitals, APHP Tenon - APREC, Paris, France.

PS-10-02  Relevance of Magnetic Resonance Imaging To Predict Disease-Free Survival after Neoadjuvant Chemotherapy of Breast Cancer  
Loo CE, Vrancken Peeters M-JTFD, Wesseling J, Gilhuys KG. NKI-AVL (Netherlands Cancer Institute - Antoni van Leeuwenhoek Hospital), Amsterdam, Netherlands; University Medical Centre Utrecht, Utrecht, Netherlands; NKI-AVL, Amsterdam, Netherlands.

Detection and Diagnosis – Pathology: Diagnostic Pathology

PS-11-01  The Accuracy of Preoperative Ultrasonography Guided Vacuum-Assisted Breast Biopsy in Determining Histological Type, ER Status, PgR Status, HER2 Status and Ki67 Level in Invasive Breast Cancer  

PS-11-02  Prediction of Results of MammaPrint’s 70 Gene Signatures by Conventional Histopathological and Biological Approaches in Patients with Breast Cancer  

PS-11-03  Real-Time Imaging of Human Breast Tissue with Reflectance Confocal Microscopy: Correlation with Routine Pathology  
Fogarty SP, Shiffert MT, Berezowski K, Hartmann D, Cabrera MC, Sidaway MK, Furth PA, Liu MC. Georgetown University, Washington, DC.

PS-11-04    Withdrawn

PS-11-05  Measurement of Neoadjuvant Chemotherapy Tumor Response in Locally Advanced Breast Cancer by Three Methodologies. Correlation with Overall Survival  
Garcia-Saenz JA, Romero A, Lopez Garcia-Asenjo JA, Roman JM, Moreno A, Fuentes M, Furto V, Pelayo A, Diaz-Rubio E, Caldes T, Martin M. Hospital Clinico San Carlos, Madrid, Spain; Hospital Principe de Asturias, Alcala de Henares, Madrid, Spain; Hospital Gregorio Maranon, Madrid, Spain.

PS-11-06  Immunohistochemistry Discordance between Primary and Recurrent Tumors in Breast Cancer. Analysis of Potential Influence of Technique Bias by Comparing Test-Results under Two Different Conditions  

PS-11-07  Receptor Concordance in Triple-Negative Breast Cancer (TNBC) Recurrences  
Killian ME, De Los Santos JF, Foreno-Torres A, Krontiras H. University of Alabama at Birmingham, Birmingham, AL.
PS-11-08  High Concordance of 5 HER2 In Situ Hybridization Methods with Abbott FISH  
Boers JE, Netjes C, Meeuwissen HC, Prinsen C, Bart J, van der Logt EMJ, Schuuring E, Isala Klinieken, Zwolle, Netherlands; University Medical Center, Groningen, Netherlands.

PS-11-09  High Concordance for Microarray Based Determination of ER, PR and HER2 Receptor Status and Local IHC/FISH Assessment Worldwide in 749 Patients  
Wesseling J, Cusumano G, Tintemari C, Sapino A, Zanconati F, Fukutake-Holzlik N, Nguyen B, Deck K, Querzoli P, Penn T, Giardina C, Seitz G, Guinebretiere J, Barone J, Watanabe T. Netherlands Cancer Institute, Amsterdam, Netherlands; CHC, Liege, Belgium; Instituto Clinico Humanitas, IRCCS, Rozzano, Italy; Universita di Torino, Torino, Italy; Universita di Trieste, Trieste, Italy; Medisch Spectrum Twente, Enschede, Netherlands; Locg Beach Memorial Health Care, Loch Beach, CA; Saddleback Memorial Medical Center, Laguna Hills, CA; Instituto di Patologia, Universita di Ferrara, Ferrara, Italy; Centro di Riferimento Oncologico, Aviano, Italy; Instituto di Anatomia Patologica, Universita degli Studi di Bari, Bari, Italy; Klinikum Bamberg, Bamberg, Germany; Centre Rene Huguenin, Saint-Cloud, France; Comprehensive Breast Care and Sharp Memorial Hospital, San Diego, CA; Hamamatsu Oncology Center, Hamamatsu, Japan.

PS-11-10  Reproducibility and Robustness of the FDA Approved INFORM HER2 Dual ISH DNA Probe Cocktail Assay  

PS-11-11  Automated Quantification Methods Improve the Accuracy of PR as an Independent Prognostic Factor in Tamoxifen Treated Breast Cancer Patients  
Klimowicz AC, Komaga EN, Yau A, Pohorelic BK, Petillo SK, Konno M, Magliocco AM. Tom Baker Cancer Centre, Calgary, AB, Canada; University of Calgary, Calgary, AB, Canada.

PS-11-12  Correlation of Ki67 Expression between Initial Biopsy and Surgical Specimen in Untreated Breast Cancer Patients: Does Menstrual Cycle Matter?  

PS-11-13  Rates of Upgrade to Malignancy for 271 Cases of Atypical Columnar Cell Hyperplasia Diagnosed by Breast Core Biopsy  
Peres A, Barranger E, Becette V, Boudinet A, Guinebretiere J-M, Chere P. Lariboisiere Hospital, Paris, France; Institut Curie, Saint-Cloud, France.

PS-11-14  Flat Epithelial Atypia of the Breast: A Single Institution Experience  

PS-11-15  Should HER-2 Score 0/1+ Breast Cancer Cases Be Retested by In-Situ Hybridisation? Results of a Multicenter Retesting Study  
Reiner-Concin AM, Lack S, Regina-Toni P, Kronberger C, Jasarevic Z, Bogner S. Danube Hospital, Vienna, Austria; General Hospital Graz West, Graz, Austria; Medical University Graz, Graz, Austria; LHU Salzburg, Salzburg, Austria; LHK Feldkirch, Feldkirch, Austria; LKH Linz, Linz, Austria.

PS-11-16  CD44 and CD24 Expression in Ductal Invasive Breast Carcinomas, Classified by Molecular Subtypes and Its Association with Prognostic Factors  
Bernardi MA, Logullo AF, Pasini F, Nonogaki S, Soares FA, Maciel MD, Brentani MM. Hospital AC Camargo, Sao Paulo, Brazil; Universidade Federal de Sao Paulo, Sao Paulo, Brazil; Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil; Hospital A.C. Camargo, Sao Paulo, Brazil.

PS-11-17  Evaluating Tumor Heterogeneity in Immunohistochemistry Stained Breast Cancer Tissue  
Portis SJ, Landis N, Eberhard DA, Schmehel SC, Young D, Lange H. Flagship Biosciences, Flagstaff, AZ; University of North Carolina, Chapel Hill, NC; University of Minnesota, Minneapolis, MN.

Detection and Diagnosis – Pathology: Detection and Diagnosis – Other  
PS-12-01  Aromatase Inhibitor Specific Metastasis Is Driven by the Steroid Receptor Coactivator SRC-1  
Thiesen SM, McBayan J, Byrne C, Hughes E, Coccigia S, Hill AD, Young LS. Royal College of Surgeons in Ireland, Dublin 2, Ireland.

PS-12-02  Vacuum Assisted Biopsies of Ductal Carcinoma In Situ and Concordance with Post-Operative Histology: Implications for the Low Risk DCIS Trial  
Soumian S, Down SK, Roked F, Chaudhri S, Francis A. Queen Elizabeth Hospital, University Hospitals Birmingham, Birmingham, England, United Kingdom.

PS-12-03  An Innovative Quantification Method for Tamoxifen and Three Metabolites in Formalin-Fixed Paraffin-Embedded Tissues by Liquid Chromatography and Tandem Mass Spectrometry  
Magliocco AM, Ng ES, Kangaroo B, Konno M, Paterson A. Tom Baker Cancer Centre, Calgary, AB, Canada; University of Calgary, Calgary, AB, Canada.

PS-12-04  Genetic Linkage between Acquired and Primary Lymphedema Evaluated through Whole Exome Sequencing and NIR Fluorescence Lymphatic Imaging  
Sevick-Muraca EM, Gonzalez-Garay ML, Fife CE, Guilliod R, Hall O, Marshall MV, Rasmussen JC, Aldrich MB, Darne C, Zhu B, Tan I-C, Caskey CT. University of Texas Health Science Center, Houston, TX; Memorial Hermann Hospital, Houston, TX.

PS-12-05  (In-)Efficiencies in the Preoperative Imaging Evaluation of the Medicare Breast Cancer Patient  

PS-12-06  Gastrointestinal metastasis of invasive lobular breast carcinoma: Brazilian Cancer Institute review from March 2004 to April 2009  

PS-12-07  Physicians’ call to use mammary ductoscopy in patients without spontaneous nipple discharge  
Xu Z, Dou T-H, Wu S, Xing H, Song C, Dou C. Norman Bethune Medical School, LiU University, Changchun, Jilin Province, China; Dehui County Hospital, Dehui, Jilin Province, China; Indiana University, Indianapolis, IN; Georgia University System/Georgia Gwinnett College, Lawrenceville, GA.

Prognosis/Response Predictions: Response Predictions – II  
PS-13-01  Survival Outcome with Bevacizumab: Activation of the Phosphatidylinositol-3 Kinase (PI3K) Pathway Due to PI3KCA Mutations or PTEN Loss Makes a Difference  

PS-13-02  Prediction of Dasatinib Sensitivity of Breast Cancer Based on a Novel Tyrosine Kinase-Activity Profiling Assay  
Kawai M, Tonkoshi Y, Notoya M, Gohda K, Ueno NT, Ishihara H. Sysmex Corporation, Kobe, Hyogo, Japan; The University of Texas MD Anderson Cancer Center, Houston, TX.
Discordance of Estrogen Receptor and HER-2/neu Status Can Be Seen between First and Subsequently Biopsied Metastatic Lesions in Breast Cancer
Lower EE, Kennedy D. Oncology Hematology Care, Cincinnati, OH.

PTEN and Tau-Protein Expression: Predictive Value of Poor Response to Trastuzumab Plus Paclitaxel in Patients with HER2-Positive Breast Cancer
Koo DH, Ahn J-H, Youn DH, Kim S-B, Lee HJ, Kong KY, Son BH, Ahn SH, Jung KH. Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea.

Can the Ki67 Proliferation Index Predict the Oncotype DX Recurrence Score in Lymph Node Negative, ER Positive Breast Cancer?
Prendergast A, Martin K, Doolan P, Clarke C, Clynes M, Eddy D, McDermott E, Crawn J, Kennedy S. Dublin City University, Dublin, Ireland; Conway Institute of Biomolecular and Biomedical Research, University College Dublin, Dublin, Ireland; St. Vincent’s University Hospital, Dublin, Ireland.

The Role of Topoisomerase IIα in Predicting Sensitivity to Anthracyclines in Breast Cancer Patients: A Meta-Analysis of Published Literatures
Lu L, Du Y, Zou Q, Yin W, Zhou L, Di G, Shen Z, Shao Z. Shanghai Cancer Center, Fudan University, Shanghai, China; Shanghai Medical College, Fudan University, Shanghai, China.

Drug-Metabolizing Enzyme Polymorphisms and Clinical Outcome of Anthracycline-Based Chemotherapy in Chinese Han Breast Cancer Patients
Tang J, Zhao J, Wu J, Ji M, Zhong S. Jiangsu Cancer Hospital, Nanjing, Jiangsu, China.

Proteomic Identification of Predictive Biomarkers of Resistance to Neoadjuvant Chemotherapy in Luminal Breast Cancer: A Possible Role for 14-3-3 and BID?
Hodgkinson VC, EL-Fadl D, Agarwal V, Garimella V, Drew PJ, Lind MJ, Cawkwell L. University of Hull, Hull, United Kingdom; Castle Hill Hospital, Hull, United Kingdom; Hull York Medical School, Hull, United Kingdom.

Reduction in PET Uptake-Value Is an Early Predictor for Response to Neoadjuvant Therapy Including Anthracycline and Taxane in Stage II-IIIA Breast

Multigene Signature Assays in Patients with Early-Stage Breast Cancer (ESBC) Receiving Neoadjuvant Chemotherapy: An NCI-Funded Systematic Review and Evidence Summary of Predictive Performance
Lyman GH, Cukalova E, Pieperwierski MS, Huang M, Barry W, Ginski G, Abemethy A, Marcom PK, Ready N, Kuderer NM. Duke University School of Medicine, Durham, NC; Duke University, Durham, NC.

A Study of the Usefulness of Tumor Markers CA 15-3 and TPS in Monitoring of Different Subgroups of Metastatic Breast Cancer

Borderline Estrogen and Progestosterone Receptor Expression and Efficacy of Anti-Estrogen Therapy Analyzed by Subpopulation Treatment Effect Pattern Plot Analysis
Luch S-W, Ramsey B, Park B, Keen A. Oregon Health and Science University, Portland, OR; Portland Veterans Administration Medical Center, Portland, OR.
PS-13-20  TOP2A Amplification Have Associated with Response to Anthracycline-Based Preoperative Chemotherapy in Primary Breast Cancer
Wang J, Xu B, Yuan P, Zhang P, Li Q, Ma F, Zhao L. Cancer Hospital, Chinese Academy of Medical Science, Beijing, China.

PS-13-21  Japanese Patients with Discordance in Estrogen Receptor between Primary Breast Cancer and Recurrent Tumor Have a Poorer Outcome

PS-13-22  Gene Expression Profiles Predict Pathological Complete Response to Standard Neoadjuvant Fluorouracil, Doxorubicin, and Cyclophosphamide and Paclitaxel with or without Trastuzumab in Early Breast Cancer
Tamura K. National Cancer Center Hospital, Tokyo, Japan.

PS-13-23  Individualized Treatment Strategies for HER2-Negative Breast Cancer Subtypes
Ishikawa T, Shimizu D, Yamada A, Sasaki T, Monita S, Tanabe M, Kawachi K, Nozawa A, Chishima T, Kimura M, Ichikawa Y, Endo I. Yokohama City University Medical Center, Yokohama, Kanagawa, Japan; Yokohama City University, Yokohama, Kanagawa, Japan.

PS-13-24  A Predictive Model of Early Systemic Disease Relapse after Standard Adjuvant Therapy for Breast Cancer

Prognosis/Response Predictions: Prognostic and Predictive Factors – Other

PS-14-01  Differences in Efficacy by Assessment Method: NCIC CTG Adjuvant Breast Cancer Trials MA.5, MA.12, MA.14, MA.21, MA.27 Meta-Analysis
Dong B, Chapman J-AW, Yerushalmi R, Goss PE, Pollak MN, Burnell MJ, Bramwell VH, Levine MN, Pritchard KI, Whelan T, Ingle JN, Parulekar W, Shepherd LE, Gelmon KA. NCIC Clinical Trials Group, Queen’s University, Kingston, ON, Canada; Vancouver Cancer Centre - BCNA; Vancouver, BC, Canada; Harvard Medical School, Boston, MA; McGill University, Montreal, QC, Canada; Atlantic Health Sciences Corporation, Saint John, NB, Canada; Alberta Cancer Board, Calgary, AB, Canada; McMaster University, Hamilton, ON, Canada; University of Toronto, Toronto, ON, Canada; Mayo Clinic, Rochester, MN.

PS-14-02  Clinico-pathological and Prognostic Difference of Screen Detected Breast Cancer Compared with Symptomatic Breast Cancer

PS-14-03  Genomic Comparison of Paired Primary Breast Carcinomas and Macrometastatic Lymph Node Metastases Using Quantitative RT-PCR by Oncotype DX® Assessment of the Recurrence Score and Quantitative Single Genes

PS-14-04  RANK Expression in Primary Tumor Tissue at the Time of Diagnosis Correlates with Risk of Subsequent Bone Metastases in the I-SPY 1 Trial (CALGB 150007/150012; ACRIN 6657)
Li J, Moore D, Yao C, Campbell M. Park J-I-SPY-1 TRIAL Investigator, Rugo HS. University of California, San Francisco, CA; Cancer and Developmental Therapeutics Program, Buck Institute for Age Research, Novato, CA.

PS-14-05  Anti-Müllerian Hormone (AMH) Levels in Premenopausal Breast Cancer Patients Treated with Adjuvant Chemotherapy - A Translational Research Project of the SUCCESS Study
Neugebauer J-K, Rack BK, Kupka M, Dinkel C, Schneeweiss A, Schrader I, Tesch H, Rezai M, Söling U, Friese K, Beckmann MW, Janin W, Müller V. Ludwig-Maximilians-Universität, Munich, Germany; University Hospital Heidelberg, Heidelberg, Germany; Henriette-Stiftung Hannover, Hannover, Germany; Facharzpraxis für Onkologie, Frankfurt, Germany; Lüsenkranzenhaus Düссeldorfer, Düссeldorfer, Germany; Gemeinschaftspraxis Sieh&Söling, Kassel, Germany; University Hospital Erlangen, Erlangen, Germany; Heinrich-Heine-Universität, Düссeldorfer, Germany; University Medical Center, Hamburg-Eppendorf, Germany.

PS-14-06  Interaction between Stoma and Tumor Characteristics as a New Prognostic and Predictive Marker in Breast Carcinomas

PS-14-07  Withdrawn

PS-14-08  Impact of Progesterone Receptor Semiquantitative Immunohistochemical Result on Oncotype DX® Recurrence Score: A Quality Assurance Study of 1078 Cases
Bhargava R, Dabbs DJ. Magee-Womens Hospital of UPMC, Pittsburgh, PA.

PS-14-09  Withdrawn

PS-14-10  Ethnic Differences in the Association between Tumor Size and Lymph Node Status among Breast Cancer Patients in South East Asia
Saxena N, Verkooyen HM, Bhoo Pathy N, Siew EL, Iau P, Lee SC, Yip CH, Hartman M. National University of Singapore, Singapore; Singapore; University Medical Center Utrecht, Utrecht, Netherlands; Julius Center University of Malaya, Kuala Lumpur, Malaysia; National Cancer Institute, National University Health Systems, Singapore, Singapore; Faculty of Medicine, University of Malaya Medical Center, Kuala Lumpur, Malaysia.

PS-14-11  Elevated Serum Ferritin Predicts Reduced Progression-Free and Overall Survival in Trastuzumab-Treated Metastatic Breast Cancer
Alkhatteeb AA, Connor J, Leitzel K, Ali S, Campbell-Baird C, Evans M, Koelster W, Fuchs E-M, Lipton A. The Pennsylvania State University Hershey Medical Center, Hershey, PA; Lebanon VA Medical Center, Lebanon, PA; Medical University of Vienna, Vienna, Austria.

PS-14-12  Bayesian Belief Network Mortality Analysis of a Breast Cancer Registry Data Set
Eberhardt JS, Hyslop T, Hu H, Rui H. DecisionQ Corporation, Washington, DC; Thomas Jefferson University, Philadelphia, PA; Windber Research Institute, Windber, PA.

PS-14-13  Favorable Prognosis in Patients with T1a,b Node-Negative Triple Negative Breast Cancers Treated with Multimodality Therapy
Ho AY, Gupta G, Perez CA, King TA, Pati SM, Rogers KH, Brogi E, Morrow M, Huds C, Traina T, McCormick B, Powell SN, Robson ME. Memorial Sloan Kettering Cancer Center, New York, NY.

PS-14-14  The Presence of a Fibrotic Focus Adds Significant Prognostic Information to the Prognostic 76-Gene Relapse Score in Lymph Node Negative Breast Cancer
Van den Eynden GG, Van Laere SJ, Smid AJ, Fooekens JA, Vermeulen PB, Dirix L.Y. Augustinus Hospital, Antwerp, Belgium; Erasmus Medical Center Rotterdam, Rotterdam, Netherlands.
PS-14-15 Prognostic Impact of Chemotherapy-Induced Amenorrhea (CIA) in Premenopausal Breast Cancer: A Meta-Analysis of Published Literatures  
Lu J, Zhou Q, Yin W. Fudan University Shanghai Cancer Center, Shanghai, China.

PS-14-16 Molecular Classification in Primary Breast Cancer and Corresponding Lymph Node Metastasis Show Impaired Prognostic Profile in the Metastatic Node  

PS-14-17 Stage IV at Presentation - Are HER2 Positive Tumors Overrepresented?

PS-18-01 No Effect of Adjuvant Chemotherapy in Postmenopausal Patients with Invasive Lobular (Mixed) Breast Cancer
Truini W, Voogd A, Vreugdenhil G, Van der Heiden-van der Loo M, Sieuling S, Roumen R. Maxima Medical Centre, Veldhoven, Netherlands; Maastricht University, Maastricht, Netherlands; Comprehensive Cancer Centre, Utrecht, Netherlands; Comprehensive Cancer Centre, Enschede, Netherlands.

A Population Level Assessment of Emergency Room Visits and Hospitalizations for Women Undergoing Adjuvant Chemotherapy for Early Breast Cancer
Enright KA, Trudeau M, Yun L, Grunfeld E, Krzyzanowska M. Peel Regional Cancer Centre, Credit Valley Hospital, Mississauga, ON, Canada; Sunnybrook Odette Cancer Centre, Toronto, ON, Canada; Institute for Clinical Evaluative Science, Toronto, ON, Canada; University of Toronto, Toronto, ON, Canada; Cancer Care Ontario, Toronto, ON, Canada; Princess Margaret Hospital, Toronto, ON, Canada.
December 6-10, 2011  
Program Schedule

PS-18-03  First Interim Toxicity Analysis of the Randomized Phase III WSG Plan B Trial Comparing 4xE C-4xD doc Versus 6xTC in Breast Cancer Patients with HER2 Negative Breast Cancer (BC)
Nitz U, Gluz O, Krepe H, Liedtke B, Aktas B, Herschens S, Pollmanns A, Krabisch P, Zuna L, Shvak S, Thomssen C, Harbeck N, West German Study Group, Moenchengladbach, Germany; Breast Centre Niederer Ben/Bethesda Hospital, Moenchengladbach, Germany; Bethesda Hospital, Wuppertal, Germany; Medizinische Hochschule, Hannover, Germany; Evangelical Hospital, Bergisch Gladbach, Germany; University Hospital, Essen, Germany; Johanniter Hospital, Stendal, Germany; Evangelical Hospital, Oberhausen, Germany; City Hospital Chemnitz, Chemnitz, Germany; Genomic Health Inc, Redwood City, CA; University Hospital Halle/Saale, Halle/Saale, Germany; University Hospital Cologne, Cologne, Germany.

PS-18-04  Safety Profile of Ixabepilone as Adjuvant Treatment for Poor Prognosis Early Breast Cancer: First Results of theunicancer-PACS 08 Trial
Cammone M, Spielmann M, Wildiers H, Cottu P, Kerbrat P, Levy C, Mayer F, Bachelot T, Winston T, Eymard J-C, Uwer L, Machels J-P, Verhoeven D, Jaubert F, Facchin T, Orfeuvre H, Canon J-L, Asselin B, Roca L, Lacroix Tiki M, Martin AL, Roche H, Centre René Gauducheur, Nantes, France; Institut Gustave Roussy, Villejuif, France; Catholique Universit, Leuven, Belgium; Institut Curie, Paris, France; Centre Éugène Marquis, Rennes, France; Centre François Baclesse, Caen, France; Centre Georges-François Leclerc, Dijon, France; Centre Léon Bérard, Lyon, France; Mayo Clinic Florida, Jacksonville; Institut Jean Godinot, Reims, France; Centre Alexis Vautrin, Nancy, France; UCL Cliniques Universitaires Saint-Luc, Bruxelles, Belgium; AZ Klin A Oncology, Brasschaat, Belgium; Clinique Tivoli, Bordeaux, France; Polyclinique de Courlancy, Reims, France; Centre Hospitalier de Fleyriat, Bourg en Bresse, France; Grand Hopital de Charleroi, Charleroi, Belgium; Centre Val d’Aurelle, Montpellier, France; Institut Claudius Regaud, Toulouse, France; R&D Unicancer, Paris, France.

PS-18-05  Incidence of Febrile Neutropenia in Patients Treated with Docetaxel and Cyclophosphamide (TC) for Adjuvant Breast Cancer

PS-18-06  Taxanes and Cyclophosphamide Are Equally Effective in Breast Cancer: A Meta-Analysis of Ten Phase III Trials in Early and Advanced Disease
Vriens BE, Lobbezoo DJ, Voogd AC, Veenk J, Tjan-Heijnen VC. Maastricht University Medical Centre, Maastricht, Netherlands; Maxima Medical Centre, Eindhoven, Netherlands.

PS-18-07  Presence of Disseminated Tumor Cells after Adjuvant Chemotherapy in Breast Cancer and Disseminated Tumor Cells Monitoring during Secondary Adjuvant Treatment
Synnestvedt M, Borgen E, Wist E, Wiedswang G, Weyde K, Risberg T, Kersten C, Nygaard I, Vindi L, Schirmer CB, Nesland JM, Naume B. Oslo University Hospital, The Radium Hospital, Oslo, Norway; Oslo University Hospital, Ullevål, Oslo, Norway; Hospital Imlandet, Gjøvik, Norway; University Hospital Northern Norway, Tromsø, Norway; Sørlandet Hospital Kristiansand, Kristiansand, Norway; Stavanger University Hospital, Stavanger, Norway; Ålesund Hospital, Ålesund, Norway; Stavanger University Hospital, Stavanger, Norway; Roche, France; Institut Gustave Roussy, Villejuif, France.

PS-18-08  A Comparative Effectiveness Analysis of Trastuzumab Persistence between Two Adjuvant Breast Cancer Treatment Regimens among US Health Plan Enrollees

PS-18-09  The Incidence of Febrile Neutropenia in the First Course of Adjuvant Chemotherapy with Docetaxel/Cyclophosphamide with or without Pegfilgrastim
Jones S, Paul D, Sledacter S, Vukelja S, Wilks LT, Stokoe C, Osborne CR, Kerekow L, McIntyre K, Holmes FA, Guerra LG, Zhan F, Asmar L, O’Shaugnessy J, Blum JL. US Oncology, The Woodlands, TX; Baylor-Sammons Cancer Center, Baylor University, Dallas, TX; Rocky Mountain Cancer Center, Denver, CO; Texas Oncology-Tyler, Tyler, TX; Cancer Care Center of South Texas, San Antonio, TX; Texas Oncology, Plano, TX; Breast Cancer Center of North Texas, Bedford, TX; Texas Oncology-Dallas Presbyterian Hospital, Dallas, TX; Texas Oncology-Houston Memorial City, Houston, TX.

PS-18-10  Utilisation of Primary and Secondary G-CSF Prophylaxis Enables Optimal Dose Delivery of Standard Adjuvant Chemotherapy in Early Breast Cancer: Results of 1653 Patients from a Single Institution
Chan A, McGreggor S. Mount Hospital, Perth, WA, Australia.

PS-18-11  Incidence of Chemotherapy Dose Reductions and Dose Delays, and Reduced Chemotherapy Dose Intensity in Early Stage Breast Cancer
Weycker D, Edelberg J, Kartashov A, Barron R, Lyman G. Policy Analysis Inc. (PAI), Brookline, MA; Amgen Inc., Thousand Oaks, CA; Duke University, Durham, NC.

PS-18-12  Perception, Practice and Toxicity of Adjuvant Treatment of HER2+ Breast Cancer in Wisconsin
Rocque GB, Onitilo AA, Engel JM, Pettite EN, Boshoven AM, Zhang S, Kim K, Rishi S, Waack B, Winsinski KB, Tevaarwerk AJ, Burkard ME. University of Wisconsin Carbone Cancer Center, Madison, WI. The Marshfield Clinic, Weston, WI; University of Wisconsin School of Medicine and Public Health, Madison, WI.

PS-18-13  Adjuvant Chemotherapy with Vinorelbine+5FU or Capecitabine in Poor Responders to Neoadjuvant EC-Docetaxel Chemotherapy (NAC) for Locally Advanced Breast Cancers

Treatment – Chemotherapy: Chemotherapy in Advanced Disease

Campone M, Dobrovoloskaya N, Tjulandin S, Chen S-C, Fourie S, Mefti M, Konstantinova M, Lefresne F, Meheust N, Jassem J. Institut de Cancérologie de l’Ouest/René Gauducheur, Saint Herblain, Nantes Cedex, France; Cancer Research Center of Roentgenomarology, Moscow, Russian Federation; Russian Oncological Research Center, Moscow, Russian Federation; Chang-Gung Memorial Hospital, Taipei, Taiwan; Wilmed Park Oncology, Klerkdoor, South Africa; Centre René Huguenin, Saint-Cloud, France; Moscow Regional Oncology Dispensary, Moscow, Russian Federation; University Hospital, Essen, Germany; Johanniter Hospital, Hamburg, Germany; Evangelical Hospital, Bergisch Gladbach, Germany; Betheslada University, Wuppertal, Germany; Medizinische Hochschule, Hannover, Germany; Evangelical Hospital, Bergisch Gladbach, Germany; University Hospital, Essen, Germany; Johanniter Hospital, Stendal, Germany; Evangelical Hospital, Oberhausen, Germany; City Hospital Chemnitz, Chemnitz, Germany; Genomic Health Inc, Redwood City, CA; University Hospital Halle/Saale, Halle/Saale, Germany; University Hospital Cologne, Cologne, Germany.

www.aacrjournals.org
Comparison of the Incidence of Peripheral Neuropathy with Eribulin Mesylate Versus Ixabepilone in Metastatic Breast Cancer Patients: A Randomized Phase II Study

Vahdat L, Gopalakrishna P, Garcia AA, Vogel C, Pellegrino C, Lindquist, Jannotti N. Weill Cornell Medical College, New York, NY; Eisai, Inc., Woodcliff Lake, NJ; University of Southern California Keck School of Medicine, Los Angeles, CA; Sylvestre Comprehensive Cancer Center, University of Miami, Miller School of Medicine, Deerfield Beach, FL; Montefiore Medical Center, New York, NY; Hematology-OncoLOGY-Associates of the Treasure Coast, Port Saint Lucie, FL; US Oncology, Sedona, AZ.

Albumin-Bound Paclitaxel (ab-pac) Versus Docetaxel for First-Line Treatment of Metastatic Breast Cancer (MBC): Overall Survival and Safety Analysis of a Randomized Phase II Trial

Gradishar WJ, Krasnojon D, Cheporov S, Makhson AN, Manikhas GM, Clawson A, Bhat P. Northwestern University, Chicago, IL; Leningrad Regional Oncology Center, Russian Federation; Yaroslav Regional Clinical Oncology Hospital, Yaroslavl, Russian Federation, City Oncology Hospital, Moscow, Russian Federation; St. Petersburg Oncology Center, St. Petersburg, Russian Federation; Celgene Corporation, Summit, NJ.

Results of a Randomized Phase II Study Demonstrate Benefit of Platinum-Based Regimen in the First-Line Treatment of Triple Negative Breast Cancer (TNBC)

Fan Y, Xu BH, Yuan P, Wang JY, Ma F, Ding XY, Zhang P, Li Q, Cai RG. Cancer Institute & Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China.

Age-Related Changes in the Pharmacokinetics (pk), Response, and Toxicity of Weekly nab-Paclitaxel in Patients with Metastatic Breast Cancer (MBC)

Highly Effective of Gemcitabine and Cisplatin (gp) as First-Line Combination therapy in patients with Triple-Negative Breast Cancer: Final Report of a Phase II Trial

The Effects of ABC2 and SLCO1B3 Single Nucleotide Polymorphisms on Docetaxel-Induced Leukopenia in Breast Cancer Patients

Chen J, Wu LJ, Shen P, Yu LF, Huang S. The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, Zhejiang, China.

Comparison of Individual Patient Data from Capecitabine Monotherapy Clinical Trials in Anthracycline-/Taxane-Pretreated Locally Advanced or Metastatic Breast Cancer (LA/MBC)

Blum JL, Barrios CH, Feldman N, Verma S, McKenna E, Lee S, Scotto N, Gralow J. Baylor Sammons Cancer Center, Texas Oncology, US Oncology, Dallas, TX; PUCRS School of Medicine, Porto Alegre, Brazil; Olive View-UCLA Medical Center, Sylmar, CA; Sunnybrook Odette Cancer Centre, University of Toronto, Toronto, ON, Canada; Hoffmann-La Roche Inc., San Francisco, CA; Hoffmann-La Roche Ltd, Basel, Switzerland; University of Washington, Seattle, WA.

Phase II Trial of Ixabepilone Plus Carboplatin in Patients with Metastatic Breast Cancer: The ECLIPSE Study

Osborne C, Challagulla JD, Fanning SR, Eisenhors CF, Holmes FA, Monaghan G, Neubaurer MA, Rabe AC, Raja V, Robbins GJ, Taboada C, Vukelja SJ, Wilks ST, Wang Y, Brown J-A, Asmar L, O'Shaughnessy J. US Oncology, The Woodlands, TX; Baylor-Sammons Cancer Center, Dallas, TX; Texas Oncology, Witchita Falls, KS; Cancer Centers of The Carolinas, Greenville, SC; Cancer Centers of North Carolina, Raleigh, NC; Texas Oncology-Houston Memorial City, Houston, TX; Kansas City Cancer Center, Kansas City, MO; Kansas City Cancer Center-Southwest, Overland Park, KS; Kansas City Cancer Center, Kansas City, KS; Florida Cancer Institute-New Hope, New Port Richey, FL; Texas Oncology-Methodist Charlton Cancer Center, Dallas, TX; Texas Oncology-Tyler, Tyler, TX; Cancer Centers of South Texas, San Antonio, TX.

Correlation of Response of Weekly Paclitaxel and Paraplatin as First Line Treatment of Metastatic Breast Cancer with p53 Status

El-Sadda W, Magdy M, Abdel-Halim I, Abdel-Wahab A. Mansoura University Hospital, Mansoura, Egypt.

Tesetaxel, an Oral Taxane, as First-Line Therapy for Women with Metastatic Breast Cancer

Schwartzberg L, Rubin P, Patnaik A, Itri L, Olson AL, Seidman AD. The West Clinic, Memphis, TN; The Moses H. Cone Regional Cancer Center, Greensboro, NC; START Center - South Texas Accelerated Research Therapeutics, San Antonio, TX; Genta Incorporated, Berkeley Heights, NJ; Memorial Sloan-Kettering Cancer Center, New York, NY.

Integration of Capecitabine Monotherapy with Capecitabine Combination Therapy in Metastatic Breast Cancer Patients: First Report on Safety and Efficacy of Single Agent Capecitabine Maintenance Study

A Randomized Phase II Trial of First-Line Metastatic Breast Cancer (MBC) Patients: Sub-Set Analysis of Albumin-Bound Paclitaxel (ab-pac) Given Weekly at 150 mg/m2

Gradishar WJ, Krasnojon D, Cheporov S, Makhson AN, Manikhas GM, Clawson A, Bhat P. Northwestern University Feinberg School of Medicine, Chicago, IL; Leningrad Regional Oncology Center, Russian Federation; Yaroslav Regional Clinical Oncology Hospital, Yaroslavl, Russian Federation; City Oncology Hospital, Moscow, Russia; City Oncology Hospital, St. Petersburg, Russian Federation; Yaroslavl Regional Clinical Oncology Hospital, Yaroslavl, Russian Federation; City Oncology Hospital, Russian Federation; St. Petersburg Oncology Center, St. Petersburg, Russian Federation; Celgene Corporation, Summit, NJ.

Platinum-Based Chemotherapy in Triple-Negative Breast Cancer

Villarreal-Garza C, Bouganim N, Khalaf D, Clemons M, Kassam F, Enright K, Verma S, Myers J, Dent R. Sunnybrook Odette Cancer Centre, Toronto, ON, Canada; The Ottawa Hospital Cancer Centre, Ottawa, ON, Canada; Princess Margaret Hospital, Toronto, ON, Canada; Credit Valley Hospital, Mississauga, ON, Canada.

Treatment – Chemotherapy: Toxicities and Management

Patient Valuation of Reduced Risk of Side Effects during Treatment for Metastatic Breast Cancer

Lalla D, McLaughlin T, Brummer M, Bramley T, Bare A, Carlton R, Genentech Inc., S San Francisco, CA; Xcenda, Palm Harbor, FL.

N-Terminal Pro-Brain B-Type Natriuretic Peptide (nt-pro-BNP) before and during Treatment with Trastuzumab Allows Early Detection of Cardiotoxicity in Breast Cancer Patients

Blancas I, Camillo J, Legérin M, Delgado M, Jurado JM, Zarcos I, Villaescusa A, Gómez FJ, Moreno E, García-Puche JL. Hospital Clínico San Cecilio, Granada, Spain; University of Granada, Granada, Spain.
Personalizing Supportive Care: A Clinical Prediction Model for Neutropenic Complications in Patients with Early-Stage Breast Cancer (ESBC) Receiving Intermediate Risk Chemotherapy
Kudeerer NM, Culakova E, Poniewierski MS, Crawford J, Dale D, Lyman GH. Duke University, Durham, NC; University of Washington, Seattle, WA.

Is Primary Prophylaxis with G-CSF Indicated for Adjuvant TC or FEC-D Chemotherapy? A Systematic Review and Meta-Analyses
Younis T, Rayson D, Thompson K. Dalhousie University at the Queen Elizabeth II Health Sciences Centre, Halifax, NS, Canada.

Peripheral Blood Transcriptomics and Doxorubicin Cardiotoxicity
Todorova VK, Beggs ML, Dhakal IB, Hennings LJ, Mahkoul I, Klimger VS. University of Arkansas for Medical Sciences, Little Rock, AR.

Survival in Women with Breast Cancer Who Used or Did Not Use Scalp Cooling in the Neoadjuvant/Adjuvant Setting
Lemieux J, Perron L, Provencher L, Brisson J, Amireault C, Blanchette C, Maussell E. Centre de Recherche FRQS du CHA Universitaire de Québec, Quebec City, QC, Canada; Hôpital du Saint-Sacrement, Quebec City, QC, Canada; Université Laval, Quebec City, QC, Canada; Institut National de Santé Publique, Quebec City, QC, Canada; Université de Montréal, Montreal, QC, Canada.

Estimation of Febrile Neutropenia in Women Receiving Docetaxel Plus Cyclophosphamide as Adjuvant Therapy for Early Stage Breast Cancer: A Retrospective Analysis

Multicenter Results of Scalp Cooling To Prevent Chemotherapy-Induced Alopecia in 1500 Breast Cancer Patients
van den Hurk C, Peeboom M, Komen M, Nortier H, Breed W. Comprehensive Cancer Centre South (IKZ), Eindhoven, Netherlands; Medical Centre Alkmaar, Alkmaar, Netherlands; Leiden University Medical Centre, Leiden, Netherlands.

Treatment – Trial Resources etc.: Tissue and Data Banks

A Renewable Tissue Resource of Phenotypically Stable Human Breast Cancer Xenografts for Preclinical Studies
Zhang X, Dobrolecki LE, Lai Q, Landis MD, Wong H, Tsimelzon A, Claerhout S, Contreras A, Gutierrez C, Huang J, Wu M-F, Pavlick AC, Froehlich AM, Hilsenbeck SG, Mills GB, Wiechmann L, Petrovic I, Rimawi MF, Schiff R, Chang JC, Lewis MT. Baylor College of Medicine, Houston, TX; The University of Texas MD Anderson Cancer Center, Houston, TX.

The Susan G. Komen for the Cure® Tissue Bank at the IU Simon Cancer Center: The Source for Normal Breast Tissue and Biospecimens
Clare SE, Mathieson T, Henry JE, Zhang H, Way ES, Ridley KE, Badve S, Herbert B-S, Rufenbarger CA, Storniolo AMV. Indiana University School of Medicine, Indianapolis, IN.

The Breast Cancer Campaign Tissue Bank
Jones L, Chelala C, Ellis E, Ekbote J, Green A, Hanby A, Jordan L, Purdie C, Quinlan P, Speirs V. Barts Cancer Institute, London, United Kingdom; University of Nottingham, Nottingham, United Kingdom; University of Leeds, Leeds, United Kingdom; University of Dundee, Dundee, United Kingdom.

Patient Attitudes towards Undergoing Additional Breast Biopsy for Research Purposes
Nairn FM, Ballinger R, McLaughlan R, Hadjiminas DJ, Hogben K, Palmieri C, Cleetor SJ. Royal Free Hospital, Royal Free Hampstead NHS Trust, London, United Kingdom; Brighton and Sussex Medical School, Brighton, United Kingdom; Charing Cross Hospital, Imperial NHS Healthcare Trust, London, United Kingdom.

Feasibility and Patient Safety of Serial Biopsies (bx) in Metastatic HER2-Positive Breast Cancer (BC) To Evaluate Alterations in Molecular Biomarkers (BM): Preliminary Results of SHERSig (Study of HER2 Signature in Metastatic Breast Cancer) a Prospective Phase II Study
Chan A, Chan S, Price D, Bergh J, Uch J, Redfern A, Chirgwin J, Librindo E, Dhadda A, Lopez-Vega J, Lindman B, Bith L, Barn-Hay S, Kiemier A, Herbst F, Ellis I. Mount Medical Centre, Perth, Australia; Nottingham City Hospital, Nottingham, United Kingdom; Karolinska Institutet and University Hospital, Stockholm, Sweden; Hospital Clinico Universitario de Valencia, Valencia, Spain; Royal Perth Hospital, Perth, Australia; Eastern Health Melbourne, Australia; Scarborough Hospital, Scarborough, United Kingdom; Hospital Universitario Marques de Valdecilla, Santander, Spain; Uppsala University Hospital, Uppsala, Sweden; Royal Prince Alfred Hospital, Camperdown, Australia; Royal North Shore Hospital, St Leonards, Australia; F Hoffmann-La Roche Ltd, Basel, Switzerland; Nottingham University Hospitals, Nottingham, United Kingdom.

The Impact of Primary Tumor Resection on the Survival of Patients with Stage IV Breast Cancer According to Molecular Subtype
Ahn SK, Moon H-G, Kim JS, You Jm, Shin Hc, Han W, Noh D-y. Seoul National University Hospital.

Clinicopathological Features of Young Patients Age <35 Years with Breast Cancer in Japan
Katoaka A, Tokunaga E, Masuda N, Shien T, Ohno S, Kinoshita T, Shimizu C. Breast Surgery Clinic, Minato-ku, Tokyo, Japan; Kyushu University Hospital, Fukuoka, Japan; National Hospital Organization Osaka National Hospital, Osaka City, Osaka, Japan; Okayama University Hospital, Okayama City, Okayama, Japan; National Hospital Organization Kyushu Cancer Center, Fukuoka City, Fukuoka, Japan; National Cancer Center Hospital, Chuo-ku, Tokyo, Japan; The Japanese Breast Cancer Society (JBCS) Study Group on Breast Cancer in Young Women.

Breast Cancer in Elderly Treatment Algorithm - A New Approach To Optimize the Management of Breast Cancer in Older Patients
Tahir M, Pretorius R, Robinson T, Walker R, Stottter A. University Hospitals of Leicester NHS Trust, Leicester, United Kingdom.

Gonadotrophin-Releasing Hormone Analogues for Ovarian Function Preservation in Women with Premenopausal Breast Cancer Undergoing Adjuvant Chemotherapy: A Systematic Review and Meta-Analysis
Cruz MRS, Motta E, Silva EMK, Atallah AHN. Hospital Sao Jose, Sao Paulo, Brazil; Universidade Federal de Sao Paulo, Sao Paulo, Brazil.

Withdrawn

Monitoring of Quality Indicators Should lead to Quality Improvement: A Practical Guide for Clinical Trials

Treatment Strategy of Locally Advanced Breast Cancer in Sub Group (T3N1M0, T4bN1M0) in Developing Countries
Gupta AK, Kaushal M. Mahatma Gandhi Memorial Medical College and Maharaja Yashwantrao Hospital, Indore, Madhya Pradesh, India.
PS-23-08  Minimally invasive treatment of elderly breast cancer patients using preferential radiofrequency ablation
Schasbiger K-LJ, Lofgren L, Leifland K, Thomsen K, Wiksell H. Karolinska Institutet, Stockholm, Sweden; Capio St Gorans Hospital, Stockholm, Sweden; Unilabs AB, Capio St Gorans Hospital, Stockholm, Sweden.

5:00 pm–7:00 pm
POSTER DISCUSSION IX: PI3K/MTOR
Ballroom A
Viewing 5:00 pm
Discussion 5:30 pm
Discussant: Ana-Maria Gonzalez-Angulo, MD, MSC
UT MD Anderson Cancer Center
Houston, TX

PD09-01 Target-Based Therapeutic Matching in Early-Phase Clinical Trials in Patients with Advanced Breast Cancer and PI3CA Mutations
Janku F, Moulder SL, Wheler JJ, Stepanek V, Falchuck GS, Naing A, Hong DS, Fu S, Piha-Paul SA, Luthra R, Tsmbriendou AM, Kurzrock R. The University of Texas MD Anderson Cancer Center, Houston, TX.

PD09-02 Withdrawn

PD09-03 Phase I/II Study of BMK120 in Combination with Trastuzumab in Patients with HER2 Overexpressing Metastatic Breast Cancer Resistant to Trastuzumab-Containing Therapy
Saura C, Bendell J, Jerusalem G, Graña-Suárez B, Su S, Su Q, De Buck S, Devisse C, Bosch A, Urtucuchoea A, Beck JT, DiTomaso E, Rouyze N, Stemberg DW, Massacesi C, Hirawat S, Dinx L, Baselga J. Hospital Vall d’Hebron, Barcelona, Spain; Sarah Cannon Research Institute, Nashville, TN; C.H.U. Sant-Tilman, Liege, Belgium; Novartis Pharmaceuticals, Horsham Park, NJ; Novartis Pharma AG, Basel, Switzerland; Hospital Clinico Universitario de Valencia, Valencia, Spain; Catalan Institute of Oncology, Barcelona, Spain; Highlands Oncology Group, Fayetteville, AZ; Novartis Institutes for BioMedical Research, Cambridge, MA; Novartis Oncology, Paris, France; Oncologisch Centrum AZ-St. Augustinus Oncology, Wilrijk, Belgium; Massachusetts General Hospital, Boston, MA.

PD09-04 A Phase Ib, Open-Label, Dose-Escalation Study of the Safety and Pharmacology of the PI3-Kinase Inhibitor GDC-0941 in Combination with Paclitaxel and Bexacizumab in Patients with Locally Recurrent or Metastatic Breast Cancer
Scholfski P, De Benedictis E, Gendreau S, Gennai L, Krop IE, Levy G, Ware J, Wildiers H, Winer EP. Catholic University, Leuven, Belgium; Istituto Nazionale dei Tumori, Milan, Italy; Gencentech Inc., South San Francisco, CA; Dana-Farber Cancer Institute, Boston, MA.

PD09-05 SU2C Phase Ib Study of pan-PI3K Inhibitor BMK120 Plus Aromatase Inhibitor Letrozole in ER+/HER2- Metastatic Breast Cancer (MBC)
Mayer IA, Ballo JM, Kuba MG, Sanders ME, Yap J, Li Y, Winer E, Arteaga CL. Vanderbilt-Ingram Cancer Center, Nashville, TN; Dana Farber Cancer Institute, Boston, MA; MD Anderson Cancer Center, Houston, TX.

PD09-06 Phase II Trial of RAD001 (Everolimus), an mTOR Inhibitor, with Weekly Cisplax and Paclitaxel in Patients with HER2-Negative Metastatic Breast Cancer (MBC)
Mayer IA, Means-Powell J, Abramson VG, Shyr Y, Baliok JM, Kuba MG, Ghavri HM, Schlabach L, Arteaga CL, Pietenpol JA. Vanderbilt-Ingram Cancer Center, Nashville, TN; Vanderbilt-Ingram Cancer Center Affiliated Network (VICIAN).

PD09-08 Combined Inhibition of mTORC1 with Temsirolimus and HER2 with Neratinib: A Phase II/I Study in Patients with Metastatic HER2-Amplified or Triple-Negative Breast Cancer

5:00 pm–7:00 pm
POSTER DISCUSSION X: TUMOR SUPPRESSORS/DNA REPAIR
Ballroom B
Viewing 5:00 pm
Discussion 5:30 pm
Discussant: Nicholas Turner, MD
Royal Marsden Hospital
London, UNITED KINGDOM

PD10-01 Prevalence of Dysfunctional Fanconi Anemia (FA) DNA Repair Pathway in Breast Cancer
Ramswamy B, Strividya V, Mullins D, Carothers S, Young G, Wernui D, Zhao W, Lustberg M, Leon M, Wleslowski R, Layman R, Mrozek E, Shapiro CV, Villalona-Calero M. The Ohio State University, Columbus, OH.

PD10-02 Sporadic Breast Cancers Show Defects in the BRCA1-BRCA2 Pathway of Homologous Recombination in All Biomarker-Defined Sub-Types of Breast Cancer
Powell SN, Mutter RW, Deliste R, Bindra R, King T, Giri D, Park J. Memorial Sloan-Kettering Cancer Center, New York, NY.

PD10-03 Withdrawn

PD10-04 Exploration of the Relationship between Loss of PTEN and BRCA1 Expression in Triple Negative Breast Carcinoma

PD10-05 Identification of Novel BRCA1 Transcriptional Targets That Promote the Survival of BRCA1-Mutated Estrogen Receptor-a Negative (ER-a) Breast Tumours
Lamers E, Haddock P, Cochrane DJ, Gorski JJ, Blayney J, McDeray FA, Mullan JM, Mullan PB, Couch FJ, Kennedy RD, Harkin PD, Quinn JE. Queen’s University of Belfast, Belfast, Antrim, United Kingdom; Almac Ltd., Craigavon, United Kingdom; Mayo Clinic College of Medicine, Rochester, MN.

PD10-06 Loss of the Retinoblastoma Tumor Suppressor (RB) in Triple Negative Breast Cancer Is Associated with a Favorable Prognosis

PD10-07 microRNA Profiles of Breast Tumors Identifies the mir 17-92 Cluster as a Group of Potentially Essential Oncomirs in Triple-Negative Breast Cancer
Son BH, Birkbak NJ, Tian R, Iglehart D, Wang ZC, Richardson AL. Dana-Farber Cancer Institute, Boston, MA; Asian Medical Center, Seoul, Korea; Technical University of Denmark, Lyngby, Denmark; Brigham and Women’s Hospital, Harvard Medical School, Boston, MA.

5:00 pm–7:00 pm
POSTER SESSION ONGOING TRIALS 3
Exhibit Hall B

New Agents
OT3-01-01 Randomized Phase II Study of Fulvestrant Versus Fulvestrant Plus Bortezomib in Postmenopausal Women with Estrogen Receptor (ER) Positive, Aromatase-Inhibitor (AI) Resistant Metastatic Breast Cancer (MBC): New York Cancer Consortium Trial P8457
Adelson KD, Raptis G, Sparano J, Germain D. Mount Sinai School of Medicine, New York, NY; Albert Einstein Cancer Center, Bronx, NY.
OT3-01-02
Imatinib Mesylate in Combination with Vinorelbine for Patients with Metastatic Breast Cancer - An Ongoing Phase I/II Clinical Trial

OT3-01-03
Pre-Surgical Evaluation of the AKT Inhibitor MK-2206 in Patients with Operable Invasive Breast Cancer: New York Cancer Consortium Trial PI840
Kalinsky K, Sparano JA, Kim M, Crew KD, Maurer MA, Tabak B, Feldman SM, Hishiboshi H, Wiechmann LS, Adelson KB, Hershman DL. Columbia University Medical Center, New York, NY; Albert Einstein College of Medicine, New York, NY; Mount Sinai School of Medicine, New York, NY.

OT3-01-04
TANIA: A Randomized Phase III Trial Evaluating Continued and Reintroduced Bevacizumab (BEV) in Patients Previously Treated with 1st-Line BEV for Locally Recurrent/Metastatic Breast Cancer (LR/mBC)
von Minckwitz G, Cortés J, Gilgrov J, Marschner NW, Puglisi F, Vedoljak E, Duenne A-A, Zielinski C. German Breast Group, LBFG Forschungs GmbH, Neu-Iseburg, Germany; Vall d'Hebron University Hospital, Barcelona, Spain; APHP Tenon-APREC, Paris, France; Outpatient Cancer Center, Freiburg, Germany; University Hospital of Udine, Udine, Italy; Centre of Oncology, Split, Croatia; F. Hoffmann-La Roche Ltd, Basel, Switzerland; Medical University of Vienna, Vienna, Austria.

OT3-01-05
PARP Inhibition after Preoperative Chemotherapy in Patients with Triple-Negative Breast Cancer (TNBC) or Known BRCA 1/2 Mutations: Hoosier Oncology Group BRE09-146
Miller KD, Perkins SM, Badve SS, Sledge GW, Schneider BP. Indiana University Melvin and Bren Simon Cancer Center.

OT3-01-06
A Phase 2 Study Investigating the Safety, Efficacy and Surrogate Biomarkers of Response of 5-Azaditidine (5-AZA) and Entinostat (MS-275) in Patients with Advanced Breast Cancer
Connolly RM, Jankowitz RC, Andreopoulou E, Alfred JB, Jeter SC, Zorzi J, Adam BM, Espinosa-Delgado I, Baylin SB, Zahnov CA, Ahuja N, Davidson NE, Stearns V. Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD; University of Pittsburgh Cancer Institute, Pittsburgh, PA; Albert Einstein College of Medicine, Montefiore Medical Center, New York, NY; Mayo Clinic, Rochester, MN; National Cancer Institute, Bethesda, MD.

OT3-01-07
The BEACON Study (BrEAsT Cancer Outcomes with NKTTR-102): A Phase 3 Open-Label, Randomized, Multicenter Study of NKTTR-102 Versus Treatment of Physician's Choice (TPC) in Patients (pts) with Locally Recurrent or Metastatic Breast Cancer (MBC) Previously Treated with an Anthracycline, a Taxane, and Capecitabine (ATC)
Avada A, Leung ACF, Zhao C, Hannah AL, Perez EA. Universite Libre de Bruxelles, Brussels, Belgium; Nektar Therapeutics, San Francisco, CA; Mayo Clinic, Jacksonville, FL.

OT3-01-08
Phase II Study of 5-1 Combined with Cisplatin in the First-Line Treatment of Triple Negative Breast Cancer
Fan Y, Xu Bt. Cancer Hospital & Institute,Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China.

OT3-01-09
Phase 3 Trial Comparing Capecitabine in Combination with Sorafenib or Placebo for Treatment of Locally Advanced or Metastatic HER2-Negative Breast Cancer (RESILIENCE)
Baselga J, Schwartzberg LS, Petrenicci O, Shan M, Gradishar WJ. Massachusetts General Hospital Cancer Center; West Clinic; Bayer HealthCare Pharmaceuticals; Feinberg School of Medicine, Northwestern University.

OT3-01-11
A Randomized, Phase II Multicenter, Double-Blind, Placebo-Controlled Trial Evaluating MetMab and/or Bevacizumab in Combination with Weekly Paclitaxel in Patients with Metastatic Triple-Negative Breast Cancer
Daniel BR, Campone M, Dieras V, Envin T, Yu W, Paton VE, Xia Q, Peterson A. Chattanooga Oncology Hematology Associates - SCHR, Chattanooga, TN; Centre Rene Gauducheau, Nantes-Saint Herblain, France; Institute Curie, Paris, France; Florida Cancer Specialists, Englewood, FL; Genentech Inc, South San Francisco, CA.

OT3-01-12
Withdrawn

OT3-01-13
Phase One Trial of Combined Temsirolimus, Erlotinib, and Crizotinib in Advanced Solid Tumors

OT3-01-14
N0937: Phase II Trial of Brostallicin and Cisplatin in Patients with Metastatic Triple Positive Breast Cancer
Moreno-Aspitia A, Rowland KM, Liu H, Hillman DW, Stella PJ, Perez EA, Mayo Clinic, Jacksonville, FL; Mayo Clinic, Rochester, MN; Carle Cancer Center, Urbana, IL; St Joseph Mercy Cancer Center, Ypsilanti, MI.

OT3-01-15
Phase III Trial Evaluating the Addition of Bevacizumab to Endocrine Therapy as First-Line Treatment for Advanced Breast Cancer: The LEA Study
De la Haba-Rodriguez JR, von Minckwitz G, Martin M, Morales S, Crespo C, Guerrero A, Anton-Torres A, Gil M, Muñoz M, Carrasco E, Rodríguez-Martin C, Porras I, Akbas T, Schooneg E, Tio J, Mehta K, Loibl S, on Behalf of GEICAM and GBG. University Reina Sofia Hospital, Córdoba, Spain; German Breast Group, Neu-Isenberg, Germany; Universital Gregorio Marañon, Spain; Hospital Aramu de Vilanova de Llerda, Spain; Hospital Universitario Ramón y Cajal, Spain; Instituto Valenciano de Oncologia, Spain; Miguel Servet University Hospital, Spain; Institut Catala d'Oncologia, Spain; Provincial Hospital University Clinic, Barcelona, Spain; GEICAM Headquarters, Madrid, Spain; University Hospital, Essen, Germany; Praxis Dr Schooneg, Berlin, Germany; Universitätsklinikum Muener, Germany.

OT3-01-16
A Phase 2 Study of Ridaforolimus (RIDA) and Daltuzumab (DALO) in Estrusgon Receptor Positive (ER+) Breast Cancer
Lu BD, Blum JL, Cortes J, Rugo HS, Swanton C, Eaton L, Song Y, Zhang T, Ebbinghaus SW, Baselga J. **Treatment of Metastatic Breast Cancer – Breast Cancer as a Chronic Disease: Triple Negative Breast Cancer.**  
Stearns V. Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD

Carcinomas of the breast that do not express the estrogen or progesterone receptors (ER/PR) and are not associated with overexpression or amplification of HER2/new have been designated triple negative breast cancer. These tumors represent approximately 15-20% of all breast cancers, but are more prevalent in younger women, in African Americans, and in BRCA1 mutation carriers. Molecular profiling data suggest that many of triple negative tumors, but not all, are basal-like. The basal-like tumors are more likely to be resistant to standard therapies resulting in disease recurrence and poor prognosis. It is likely that triple negative breast cancer will be further sub classified to several additional distinct subtypes. Regardless of additional sub classification of the entity, the only treatment currently available for women with triple negative breast cancer is chemotherapy-based. In this symposium, I will review current molecular classification, prognosis and predictive markers, treatment options, emerging approaches, and clinical trials.

ES2-2  
**Mouse Models of Basal-Like Breast Cancer.**  
Jonkers J. Netherlands Cancer Institute, Amsterdam, Netherlands

Mouse models of human cancer provide powerful in vivo tools to study the mechanisms underlying drug response and acquired resistance. Once these processes are understood in sufficient detail it may be possible to design (combination) therapies that not only cause complete remissions but also eliminate remnant cells that might elicit recurrent disease. Women carrying germline mutations in BRCA1 are strongly predisposed to developing basal-like breast cancers, which frequently contain TP53 mutations. To study the role of BRCA1 loss-of-function in development of basal-like breast cancer, we and others have established human tumor xenograft models for basal-like-breast cancer as well as genetically engineered mouse models (GEMMs) for BRCA1-mutated basal-like breast cancer based on tissue-specific deletion of p53 and Brca1 [1]. The mammary tumors that arise in these mouse models show strong similarity to basal-like breast cancer with respect to expression of basal cell markers, high tumor grade, and lack of expression of hormone receptors and HER2 [2]. In addition, the BRCA1-mutated basal-like tumors in our mouse models are characterized by a high degree of genomic instability and hypersensitivity to DNA-damaging agents due to loss of homology-directed double-strand break (DSB) repair [3].

We have successfully used the xenograft models and GEMMs of BRCA1-deficient basal-like breast cancer for preclinical evaluation of therapy response and elucidation of mechanisms of acquired drug resistance. BRCA1-deficient mammary tumors are highly sensitive to PARP inhibitors and platinum drugs, but none of these drugs is capable of causing tumor eradication and all tumors grow back after drug treatment. Using functional genetic screens and mouse genetics, we found that therapy response and resistance is affected by several factors, including drug efflux transporter activity [3,4], type of BRCA1 founder mutation and 53BP1 status [5]. The lack of tumor eradication prompted us to look for additional drugs targeting BRCA1-deficient tumors. Using a cell-based screening approach, we found that bifunctional alkylators such as nimustine may cause durable complete remission of BRCA1-deficient mouse mammary tumors [6], suggesting that BRCA1-mutated hereditary breast cancers and BRCA-like sporadic tumors may be eradicated by dose-intensive treatment with bifunctional alkylators. In support of this notion, patients with breast cancers that display a BRCA1-like profile of genomic aberrations show a high complete remission rate and long progression-free survival after treatment with high-dose alkylating chemotherapy [7].

ES2-3  
**Patient-Derived Xenograft Models for Preclinical Breast Cancer Research: Not Just “Basal” Anymore.**  
Lewis MT. Baylor College of Medicine, Houston, TX

Translational breast cancer research is hampered by difficulties in obtaining and studying primary human breast tissue, and by the lack of in vivo preclinical models that reflect the range of patient tumor biology accurately. In an effort to overcome these limitations, several groups have recently succeeded in propagating patient-derived breast cancer xenografts representing multiple breast cancer subtypes, including estrogen and progesterone receptor positive, and HER2 positive tumors. In our laboratory, we have developed a diverse set of human breast tumors grown as xenografts in the mammary fat pad of SCID/Beige and NOD/SCID/IL2γ-receptor null (NSG) mice, two relatively new immunocompromised mouse models, under various transplant conditions. In all cases, xenograft lines were established directly from breast cancer patient samples, without intervening culture in vitro, using the epithelium-free mammary fat pad as the transplantation site. Of the conditions tested, xenograft take rate was highest in the presence of a low-dose estradiol pellet without exogenous human fibroblasts. Thirty five stably transplantable xenograft lines representing 27 patients were established, using pre-treatment, mid-treatment, and/or post-treatment samples. Most patients yielding xenografts were “triple-negative” (ER-PR-HER2-) (n=21). However, we were able to establish lines from three ER-PR-HER2+ patients, one ER-PR+HER2-, one ER-PR+HER2-, and one “triple-positive” (ER-PR+HER2+) patients. Serially passaged xenografts show phenotypic consistency with the tumor of origin at the histopathology level, and remarkable stability across multiple transplant generations at both the genomic, transcriptomic, and proteomic levels. Of 27 lines evaluated fully, thirteen xenografts showed metastasis to the mouse lung. These models, in conjunction with others like them, thus serve as renewable, quality-controlled tissue resources, and are proving useful for preclinical evaluation of experimental therapeutics.

ES3-3  
**Adjuvant Therapy in Patients with a Borderline HER-2 Status.**  
Odamian C, Migliaccio I, Santarpia L, Di Leo A. Hospital of Prato, Istituto Toscano Tumori, Prato, Italy

Adjuvant trastuzumab is indicated in individuals with early breast cancer which has HER2 gene amplification and/or HER2 protein overexpression. In the pivotal phase III adjuvant trials which tested the addition of trastuzumab to chemotherapy, positive HER2 status was defined as strong and complete cell membrane staining by immunohistochemistry (IHC) of >10% of invasive tumor cells or gene
amplification determined by fluorescence in-situ hybridisation (FISH) ratio of HER2 gene copy number to chromosome 17 centromeres (CEP17) of >2.0. The decision to use trastuzumab is based on a binary categorization of HER2 as positive or negative. As such, the definition of HER2 positivity is critical, as it dictates who will or will not receive potentially efficacious treatment. The challenge in creating guidelines for anti-HER2 treatment is that an HER2 result is described as positive or negative, but HER2 exists as a continuum of gene copy number and protein expression. 

A source of uncertainty in the management of patients is the discordance between the diagnostic thresholds for HER2 adopted in the adjuvant trastuzumab trials and those specified in the subsequently published American Society of Clinical Oncology and the College of American Pathologists (ASCO-CAP) guidelines. According to ASCO-CAP, HER2 positivity is defined by uniform intense and complete membrane staining by IHC in ≥30% of cells or HER2/CEP17 FISH ratio≥2.2. The definition is stricter than thresholds applied in the adjuvant trials, identifying a narrower population as HER2 positive. 

A further source of uncertainty is discordance between IHC and FISH. There is generally high concordance between the two methods, as increased HER2 protein is generally attributable to HER2 amplification. Discordant results may occur if one assay is correct and the other is incorrect, due to pre-analytic, analytic, and/or post-analytic error. True discordance may be attributable to intra-tumoral heterogeneity or polysomy chromosome 17. Within a tumor, HER2 amplification and/or overexpression may be detected in discrete focal HER2 amplified clones (FHAC) or in individual cells diffusely scattered on a dominant background of HER2 negative/equivocal expression. FHAC have been reported in association with discordance between IHC and FISH. Cells with polysomy chromosome 17 have extra copies of the HER2 gene. In such cases, tumors may be IHC positive although the HER2:CEP17 FISH ratio is not elevated. Notably, available data are inconsistent and uncertainty remains as to whether polysomy 17 without HER2 amplification is associated with protein overexpression. During this session, clinical situations with borderline HER2-status will be presented and discussed. Biological heterogeneity within the same tumor, polysomy chromosome 17, and moderate HER2 positivity may contribute to determination of an uncertain HER2 status, making unclear the benefit of adjuvant trastuzumab in these cases. Clinical considerations highlighting pros/cons of adjuvant trastuzumab in these cases, as well as updated biological information and clinical perspectives, will be presented.

ES5-1
Breast Cancer Trials in Developing Countries – Opportunities and Challenges.
Gupta S, Badwe RA, Mittra I, Nag S, Dawood S, Munshi A. Tata Memorial Hospital, Mumbai, Maharashtra, India; Jehangir Hospital, Pune, India; Dubai Hospital, Dubai, United Arab Emirates

Breast cancer (BC) incidence is low, but increasing in the urban areas of many developing countries (DC) because of adoption of western lifestyle, including reproductive and fertility patterns. Because of large populations in DC, the absolute number of BC patients is high. Distinctive features of BC in DC include younger median age (population pyramid effect), advanced stage at presentation, absence of screen detected cancers, higher fraction of triple negative and lower fraction of hormone responsive tumors and higher mortality/incidence ratio. Several common themes emerge when considering the design/implementation of BC trials in DC:

1. Many DC have established population-based cancer registration process with good quality data on BC incidence. However data on patterns of care and long term outcome is sparse. This affects the accuracy of baseline assumptions while designing BC trials.
2. There is lack of unique identification numbers for citizens with linked national health/death registers in DC that creates difficulties in follow-up. Ensuring adequate follow-up in BC trials requires special efforts in DC.
3. There is deficient cooperative group trials culture in most DC with consequent inefficient recruitment, retention and follow-up in clinical trials, despite large absolute numbers of BC patients. Investment in creating such a culture is likely to be very productive in the long term.
4. Healthcare community, civil society and governments in DC are insufficiently sensitized to the importance of clinical trials as drivers of improvement in health delivery, in addition to providing solutions for topical problems in BC. Sustained effort in this area is likely to result in better acceptance of clinical trials.
5. There are cultural differences with western countries (paternalistic healthcare systems with passive acceptance of healthcare by consumers) that makes informed consent (IC) process difficult. The complexity of IC documents prepared by western researchers in collaborative projects, coupled with the desire for literal translation into local languages, makes the IC process daunting, even for experienced researchers.
6. Regulatory and ethical oversight of BC trials in DC is variable, ranging from sophisticated to rudimentary. Several tertiary care academic centers have well organized institutional review boards that ensure proper conduct of BC trials. Approval of international collaborative projects, especially those that involve transfer of biological material for translational science, is difficult in many countries.
7. Since BC patients in DC receive fewer lines of therapy as a routine standard, there are opportunities to research new interventions in less heavily treated patients.
8. There is opportunity to research technology that has not yet been widely adopted in DC (such as sentinel lymph node technique versus other forms of reduced axillary surgery, newer radiation delivery techniques) in randomized trials.
9. Testing neoadjuvant therapies in large tumors is very feasible in DC because of large numbers.

There are other research opportunities in DC that can be themes of collaborative research with developed countries. Simplicity of design and ease of implementation will facilitate such collaborations. These will be discussed in the final presentation.

ES5-3
Novel Approaches to Breast Cancer Management in Low-Income Countries.
Kerr DJ. Africa-Oxford Cancer Consortium

There is clear evidence that the global burden of cancer is increasingly affecting low and middle – income countries, effectively those nations who have least health infrastructure to deal with complex diseases like cancer. A new approach to cancer therapy is required that combines efficacy, reduced side effects, cost-effectiveness with a delivery mechanism that does not rely on access to distant and expensive regional cancer centres. To this end we propose to develop a combination oral chemotherapy formulation which is likely to offer a clinically useful advantage to patients suffering from breast cancer For almost half a century, systemic therapy of cancer
has been dominated by the use of cytotoxic chemotherapeutics. Most of these drugs are DNA damaging agents or microtubule inhibitors that are designed to inhibit or kill rapidly dividing cells, often administered in single doses or short courses of therapy at the highest doses possible, with prolonged breaks (generally of 2–3 weeks in duration) between successive cycles of therapy. A reappraisal of the optimal way of administering chemotherapy is underway. Instead of using short bursts of toxic chemotherapy interspersed with long breaks to allow recovery from the harmful side effects, there is now a shift in thinking towards the view that more chronic and decelerated schedules of drug administration using much smaller individual doses than the MTD may be more effective — not only in terms of reducing certain toxicities, but perhaps also improving anti-tumour efficacy with an additional anti-endothelial cell effect, so-called ‘metronomic’ chemotherapy. We propose development of a flat dose, combination, oral chemotherapy formulation which will contain the following classes of antineoplastic agents, which have been shown to have activity in breast cancer. Fluoropyrimidines eg Capecitabine; Alkylating Agents eg Cyclophosphamide; Antiemetics eg Metoclopramide; administered continuously at doses inducing Grade 1 toxicity.

The drug doses will be carefully selected to provide moderately effective cancer control with reduced toxicity profiles. The clinical development pathway will be conducted in India and Sub-Saharan Africa with a view to providing a managed package of care which will allow delivery of the MetroPill to women with breast cancer in rural and minor urban settings rather than the regional cancer centres. We will train a cohort of district general hospital doctors/nurses to monitor and deliver the MetroPill, supported by a teaching package app and mobile phone technology to provide symptom support for patients. A phase 1 feasibility and pharmacokinetic study will be performed in 20–30 patients followed by single arm Phase 2 studies (n=40 patients) in breast cancer patients, which will report response rates, progression free survival and quality of life as a prelude to phase 3 trials. We believe that this is the sort of lateral approach we must consider if we are to take elements of cancer therapy to those regions which lie beyond the shadow of conventional cancer centres.

ES6-1

**Oncofertility: Translation in Multiple Dimensions.**

Woodruff TK. Northwestern University

Breast cancer is a disease associated with aging. In the US, the median age of breast cancer diagnosis and death is 61 years and 68 years, respectively. The number of older adults in the US is rising, and the number of individuals age 65 and older is expected to double by the year 2030. This demographic shift will lead to an increase in the number of individuals diagnosed with breast cancer. It is estimated that from 2010 to 2030 there will be a 57% growth in the number of new cases of breast cancer in patients age 65 and older.1 A challenge in caring for older adults with breast cancer is that they have been historically underrepresented in clinical trials that set the standard for breast cancer care.2 However, a growing body of evidence-based literature can be utilized to inform and optimize the care of the older adults with breast cancer. This presentation will focus on the treatment of early stage breast cancer in older adults, including the risks and benefits of local and systemic therapies, as well as survivorship issues. Recently reported phase III studies have led to advances in the treatment of older adults with breast cancer. A phase III randomized study evaluated the role of radiation therapy following lumpectomy in patients age 70 and older with stage I hormone receptor (HR) positive breast cancer who received treatment with tamoxifen. Receipt of radiation therapy was associated with a decrease in the risk of locoregional recurrence; however, there was no difference in overall survival. The study results underscore the importance of competing comorbidity as a cause of death in older adults with early stage breast cancer.3 The role of axillary lymph node dissection was evaluated in a randomized study of women over age 60 with node-negative, HR positive breast cancer who received treatment with tamoxifen. Patients were randomized to breast surgery and axillary dissection, or breast surgery alone. There was no difference between disease-free and overall survival in the 2 study arms.4 A phase III randomized study evaluated the efficacy of standard adjuvant IV chemotherapy (doxorubicin and cyclophosphamide [AC] or cyclophosphamide, methotrexate, and 5-fluorouracil [CMF]) versus oral chemotherapy (capecitabine) in patients age 65 and older with stage I-III breast cancer. Those patients who received standard chemotherapy showed improvement in progression-free and overall survival compared with patients who received capecitabine. This study demonstrates that IV polychemotherapy regimens remain the standard of care for older adults who are prescribed adjuvant chemotherapy.5 These phase III studies advance our understanding in the care of older adults with breast cancer. Furthermore, they demonstrate the feasibility and importance of accruing older adults to phase III trials, which will improve our evidence-based care of this growing population.

Breast Reconstruction with Implants and Post-Mastectomy Irradiation: Algorithm and Outcomes.
Cordeiro PG. Memorial Sloan-Kettering Cancer Center, New York, NY
Breast reconstruction in the face of radiotherapy proposes a unique set of challenges to the plastic surgeon and often alters the algorithm of the reconstruction. The impact of radiation changes on the alloplastic breast reconstruction is unpredictable. The author will review current approaches to reconstruction of the patient if they are to undergo post-mastectomy radiation. The algorithm for reconstruction and outcomes after radiation will be presented.

ES8-3
Measuring Outcomes in Breast Reconstruction: The Patient Perspective.
Pusic A. Memorial Sloan-Kettering Cancer Center, New York, NY
In breast reconstruction, understanding patients’ perceptions of surgical results is of primary importance. As new reconstructive techniques continue to advance, surgeons and patients require high quality information on key outcomes such as patient satisfaction and quality of life. The need for meaningful data is further accentuated by concerns over healthcare expenditures and the increasing involvement of patients in their own surgical decision-making. Patient-reported outcome (PRO) measures are questionnaires specifically designed to quantify aspects of outcome such as patient satisfaction and health-related quality of life. When developed and validated according to internationally recognized standards, PRO measures can provide reliable and valid assessment of patient outcomes. Traditionally, PRO measures were used in clinical research alone; however, advances in psychometric methods have now facilitated the development of a new generation of PRO measures that are also useful in clinical care. This presentation will provide an overview of PRO research in breast reconstruction. The BREAST-Q, a new PRO measure for breast surgery patients, will be highlighted. Physicians will gain the necessary critical appraisal skills to interpret and apply evidence from PRO studies in their own clinical practice. Approaches to routine use of PRO measures in clinical care will also be described.

DL1-1
Adaptive Resistance to Targeted Therapies.
Brugge JS, Muranen T, Zoeller J, Worster D, Iwanicki M, Selfors L, Mills G. Harvard Medical School, Boston, MA; MD Anderson Cancer Center, Houston, TX
While therapies that target specific molecular alterations in human tumors are showing significant efficacy in the clinic, drug resistance remains a major obstacle. Studies from our laboratory and others have provided evidence that PI3K- and HER2- targeted therapies induce a program of molecular responses to drug treatment that significantly contributes to drug resistance. Interestingly, we have found that resistance in vitro and in mouse models is significantly enriched in cells attached to basement membrane. This resistance correlates with specific upregulation of the adaptive response in the matrix-attached cells. Importantly, inhibition of key components of the adaptive response, like BCL-2, abrogates the drug-induced adaptive resistance. We propose a model in which matrix-protection from targeted therapies allows survival of a subpopulation of tumor cells associated with matrix/basement membrane which expand and lead to more stable drug resistance.

PL1-1
How To Use Endocrine Therapy for Breast Cancer: Beyond the Basics.
Winer EP. Dana-Farber Cancer Institute
Over two thirds of all breast cancers are hormone receptor positive. The majority of these tumors have some degree of sensitivity to endocrine treatments. The approach to endocrine therapy has become more complex over the past decade, and there are more treatment choices than before. Not only are there choices about which endocrine therapy to use, but also important decisions about how long to continue treatment and how to sequence agents. It has become clear that the benefits and risks of endocrine therapy vary both from tumor to tumor and from person to person. The landscape will soon become even more complicated as targeted therapies are combined with endocrine therapy to prevent or reverse drug resistance. This lecture will focus on a number of key issues: 1) Can we improve upon a 5 year course of tamoxifen in premenopausal women? 2) Given the high risk of late recurrence in many patients with hormone receptor positive disease, which patients will benefit from extended adjuvant therapy and what should this therapy be? 3) Is the use of an aromatase inhibitor alone in postmenopausal women sufficient therapy for all breast cancer patients and how should we select individuals who should be considered for other approaches? 4) In 2011, are there patients with hormone receptor positive disease who should not receive adjuvant endocrine therapy? 5) What approaches can be used to circumvent resistance to hormonal therapy, and how quickly will they be incorporated into clinical practice? The talk will address the dilemmas that are most vexing for clinicians and have immediate relevance for clinical practice.

BS1-1
Stem Cells, Cancer, and Cancer Stem Cells.
Wahl GM. Salk Institute for Biological Studies
Significant advances in breast cancer prevention and treatment have come from strategies based on knowledge of mammary cell biology and the unique molecular fingerprints of individual tumors. The work I will present concerns the contribution of stem-like cells we and others have found in many breast cancers. It has been proposed that such cells may mediate cancer initiation, perpetuation, and
generation of tumor heterogeneity, drug resistance and metastasis. The problem of “intratumoral heterogeneity” is very important to understand, for it provides a plausible mechanism of resistance to targeted therapies and can contribute to metastasis, two critical problems to solve to increase survival and improve cure rates of breast cancer patients.

Cancer has been called a caricature of embryogenesis. However, we are not aware of studies to determine whether mammary stem cells arise during mammogenesis, or whether they are only found in the adult. If such cells do arise during development, do they exhibit similarities to the stem-like cells detected in breast cancers? We explored these questions by isolating stem cells from mice, and then studying archival tumor microarrays and human cell lines. We dissected each stage of mouse mammogenesis and determined that fetal mammary stem cells (fMaSC) are not measurable by transplantation analyses early in development. However, they increase in abundance dramatically in late development, at the time when the rudiment invades through the mesenchyme into the adjacent fat pad. The cell surface properties of these cells enabled us to purify them extensively, and determine the genes they express, as well as those expressed in the stroma with which they associate. We found that the fMaSCs have many similarities to aggressive breast cancers, including an impressive enrichment for the MaSC gene expression program in basal-like breast cancers. Interestingly, the associated fetal stromal (fSTR) cells have similarities to what have been termed “Cancer Stem Cells”, and we found the fSTR signature enriched in the rather rare Claudin-low and metaplastic breast cancers. We have also identified growth regulatory pathways that may provide therapeutic targets for breast cancers exhibiting an fMaSC-like gene expression signature.

Our studies establish significant links between the molecular pathways present in both the stem cell containing and the stromal associated compartments of the embryo. How stem-like cells arise in breast cancer, however, still remains an open question. An intriguing possibility is suggested by our observation that breast cancers encoding mutant p53 genes are also highly enriched for stem-like gene expression signatures. We propose that just as p53 deficiency increases the frequency of somatic cell reprogramming, p53 deficiency in breast cancer may enable cancer cells to revert to an embryonic stem-cell state that offers advantages for cancer cell survival, proliferation, and ability to invade adjacent tissue.

BS1-2
Stem and Progenitor Cells and the Origins of Breast Cancer Heterogeneity.
Smalley MJ, Molyneux G, Melchor L. The Institute of Cancer Research, London, United Kingdom

Breast cancer heterogeneity results from different genetic lesions occurring in different stem or progenitor cells of origin. We previously demonstrated that deletion of the Brca1 tumour suppressor in basal stem cells or luminal estrogen receptor negative progenitors in the mouse mammary epithelium resulted in very different tumour phenotypes. Remarkably, the progenitor origin tumours most closely resembled human BRCA1 tumours. Having examined what occurs when the same genetic lesion is made is different cells of origin, we are now examining the results of making different lesions in the same cell. We have knocked out different combinations of Brca2, Pten and p53 in the luminal progenitors and carried out a comparative analysis of the resulting tumours. Confirming the hypothesis that tumour heterogeneity is dependent on both genetic lesion and cell of origin, widely differing tumour phenotypes were generated. Remarkably, one gene combination generated tumours in which the same cells expressed both basal and luminal cell lineage terminal differentiation markers. These results have important implications for our understanding of the origins of tumour cellular heterogeneity.

Breast Cancer and the Environment: A Life Course Approach – Report Release from an IOM Committee
Hertz-Picciotto I. University of California, Davis

In response to a request from Susan G. Komen for the Cure®, an Institute of Medicine (IOM) committee was convened to review and assess the strength of the science base regarding the relationship between breast cancer and the environment. As part of their charge, the committee members reviewed the evidentiary standards for identifying and measuring cancer risk factors and the methodological challenges involved in conducting research on breast cancer and the environment. They also considered the potential interaction between genetic and environmental risk factors. The committee’s report notes evidence-based actions that women could take to reduce their risk of breast cancer and offers recommendations for future research on breast cancer and the environment. The results of this IOM committee’s work will be presented.

BS2-2
Nuclear Receptor Coactivators: Physiology and Disease.
O’Malley BW. Baylor College of Medicine, Houston, TX

Nuclear receptors control gene expression by recruiting transcriptional coactivators (or corepressors). The coactivators are ‘master regulators’ that activate genes to control physiologies such as reproduction, growth and metabolism. Consequently, they are major players in the development of many inherited and acquired endocrine-related pathologies such as fertility/endometriosis, cancers, and disorders of carbohydrate, lipid and protein metabolism. The coactivator proteins provide important insights to polygenic diseases and represent a new class of drug targets for therapeutic interventions.
MS1-1
Imaging Cancer Invasion In Vivo: Mechanisms and Implications for Therapy.
Friedl P. Radboud University Nijmegen

The tumor microenvironment contributes to cancer invasion, growth and survival and thereby impacts tumor responses to therapy. Using infrared-excited multiphoton microscopy in orthotopic fibrosarcoma and melanoma xenografts, we here identify a novel radio- and chemoresistance niche consisting of invading tumor cell strands consisting of several hundred connected cells located within collagen-rich stroma nearby blood and lymph vessels. Despite normoxia, perivascular invasion strands were resistant to high-dose hypofractionated irradiation which otherwise was sufficient to induce regression of the tumor main mass. This invasion-associated chemo- and radioresistance was sensitive to the simultaneous inhibition of β1 and β3 integrins by RNA interference or combined anti-β1/αV integrin antibody treatment leading to proliferation arrest, anoikis induction and subtotal to complete regression of both tumor lesion and invasion strands. Thus, collective invasion is an important invasion mode in solid tumors into a microenvironmentally privileged perivascular survival niche which conveys radioresistance by integrin-dependent signals.

MS1-2
Tumor Entrained Neutrophils Inhibit Seeding in the Pre-Metastatic Lung.
Granot Z, Heneke E, Comen EA, King TA, Norton L, Benezra R. Memorial Sloan-Kettering Cancer Center

Primary tumors have been shown to prepare distal organs for later colonization of metastatic cells by stimulating organ-specific infiltration of bone marrow derived cells. We have recently demonstrated that neutrophils are mobilized by the primary tumor and accumulate in the lung prior to the arrival of metastatic cells in mouse models of breast cancer. Tumor-engraded neutrophils (TENs) inhibit metastatic seeding in the lungs by generating H2O2 and tumor secreeted CCL2 is both required and sufficient for optimal anti-metastatic entrainment of G-CSF-mobilized neutrophils. TENs are present in the peripheral blood of breast cancer patients prior to surgical resection but not in healthy individuals. Thus, while tumor-secreted factors contribute to tumor progression at the primary site, they concomitantly induce a neutrophil-mediated inhibitory process at the metastatic site.

MS1-3
Tumor Heterogeneity and Metastasis.
Ellis MJ, Perou C, Carey L, Mardis E. Washington University School of Medicine, St Louis, MO; UNC, Chapel Hill, NC

Massively parallel sequencing using Next Gen sequencing approaches have opened a new window into our understanding of the molecular architecture of breast cancer. A significant advantage of these technologies are that they are digital in nature because the measurement technology begins with single DNA molecules attached to a substrate. As a result, not only do these technologies provide an efficient means to identify somatic mutations, information is also provided on the frequency with which any given mutation is observed within the population of DNA molecules in the sample under analysis. The first and most striking feature of Next Gen analysis of breast cancer is the large numbers of somatic mutations that have been identified. Genome wide, thousands of mutations can be present in a single tumor. While this finding generates immense complexity from the perspective of defining biological drivers versus passengers, it does open up a new opportunity to study variations in mutation frequency. In a perfectly monoclonal tumor with a diploid genome and no contaminating normal cell DNA the mutation frequencies generated by digital sequencing will be 50% for a heterozygous mutation or 100% for homozygous mutations. Very few breast cancers subjected to whole genome sequencing exhibit this pattern, rather mutations occur with a wide variation of frequencies from the detection limit, around 5%, through to 100%. Furthermore mutation frequency clustering often occurs, a phenomenon best explained by the presence of a repertoire of mutations present in a founder clone that are present in all tumors, combined with additional less common mutations that represent a subdominant or minority population of cells that have arisen through additional clonal outgrowth.

In a multi-clonal model one of the most critical questions is “which clone determines the prognosis?”. One way to begin to answer this question is to sequence tumors before and after therapy and to compare primary tumors versus metastases. In our initial experience of a patient with a basal-like breast cancer in which a whole cancer genome was generated from her primary, her subsequent brain metastasis and a mouse xenograft generated from the breast primary, there was clear evidence of a shift in mutation frequency primary to metastasis, suggesting the brain metastasis arose from a minor sub-clone. The mutational profile of the xenograft more closely resembled the metastasis rather than the primary, suggesting the grafting process captured the metastatic clone (1).

In this invited lecture we will present an extension of our sequencing experiences with further human progenitor-mouse xenograft comparisons, comparisons between human primaries and paired metastases and also examples of ER+ breast cancer genomes obtained before and after neoadjuvant endocrine therapy. In all these experiments multiclonoality appears to be the rule rather than the exception. The clinical and biological implications of these findings will be discussed.

MS2-1
Early Life Exposures and Breast Cancer Risk: Preeclampsia and Puberty.
Forman MR. UT MD Anderson Cancer Center

Women diagnosed with preeclampsia (PE) in pregnancy have a 12-72% reduced risk of breast cancer compared to women with a normotensive pregnancy while her daughter from the index pregnancy also has a lower breast cancer risk than normotensive (NT) daughters. Why is this so? The preeclamptic (PE) pregnancy is highly androgenic with low levels of estrogens and insulin-like growth factor -1 levels. We followed a cohort of offspring of preeclamptic pregnancies, comparisons between human primaries and paired metastases and also examples of ER+ breast cancer genomes obtained before and after neoadjuvant endocrine therapy. In all these experiments multiclonoality appears to be the rule rather than the exception. The clinical and biological implications of these findings will be discussed.

and that age of greatest weight gain in infancy is associated with the odds of age at onset of puberty. Our findings and those of others in early life exposures and breast cancer risk provide clues to tailoring the effect of early exposures by maternal morbidity in pregnancy.

**Environmental Exposures, Epigenetics, and Epidemiology: Influence of Environmental Factors on Pubertal Maturation and Breast Cancer Etiology.**

*Huiatt RA. University of California, San Francisco, San Francisco, CA*

Although much of breast cancer etiology can be explained on the basis of reproductive and family histories, there remains concern among both the public and scientific communities about the possible role of environmental factors. Several well-established observations suggest a role of external environmental factors including the 5-fold international differences in incidence rates and the rapid inter-generational increases in incidence with migration from low to high incidence countries. Although epidemiologic studies in adult populations have generally failed to discover a strong role for environmental factors in breast cancer etiology, emerging data suggests that relevant exposures may have effects in early life during so-called “windows of susceptibility” and be missed by attempted measurement in adulthood. Exposures to ionizing radiation and to diethylstilbestrol during pubertal development and in utero, respectively, are two examples. Recently, more attention has been directed to other environmental exposures, especially endocrine disrupting chemicals (EDCs) during early development and the pubertal period in particular. Many EDCs can now be measured in biospecimens from young prepubertal girls and in pregnant women, and animal studies suggest that some of these may cause changes in reproductive systems.

Early menarche is a well-established risk factor for breast cancer and increases risk approximately 2-fold compared to later menarche. The average age at menarche has also dramatically decreased in developed countries over the last 100 years, likely as the result of environmental factors including diet. However, the relevant exposures and their mode and timing of action are not well understood. An on-going epidemiologic cohort study of 1239 pre-pubertal girls from diverse race/ethnic and socioeconomic backgrounds has documented still earlier ages of pubertal onset and is offering insights into the potential role of EDCs and other chemicals, diet, physical activity, psychosocial and genetic factors on pubertal onset, the age of menarche and other markers of early development. This research on early environmental exposures in humans is proving both exciting and challenging and requires consideration of the complex nature of breast cancer etiology.

**MS2-3**

**Breast Cancer and the Environment: Developmental Reprogramming of Cancer Susceptibility by Early Life Environmental Exposures.**

*Walker CL. Texas A&M Institute for Biosciences and Technology, Houston, TX*

In the last two decades it has become appreciated that adverse environmental exposures early in life can have a profound impact on susceptibility to adult diseases such as obesity, cardiovascular disease, diabetes, metabolic syndrome and cancer. The “developmental origins of health and disease” or DOHaD hypothesis, posits that environmental exposures during key periods of tissue development and organogenesis can “reprogram” the cell’s epigenome in a way that increases susceptibility to disease later in life. It is now clear that even brief environmental exposures can reprogram developing tissues and profoundly increase risk of developing cancer in adulthood decades after the exposures occurred. This developmental reprogramming has been best appreciated in the context of early life exposures to environmental agents such as xenoestrogens that mimic steroid hormones, with such exposures dramatically increasing susceptibility to hormone-dependent tumors of the breast and reproductive tract later in life. Recent advances in the field of environmental epigenomics have provided data that epigenetic alterations in both DNA methylation and histone methyl marks are induced during developmental reprogramming. In some tissues, xenoestrogens induce these epigenetic alterations via activation of non-genomic signaling, providing a direct link between xenoestrogen exposure and disruption of the cell’s epigenetic machinery. For example, xenoestrogen-induced activation of non-genomic PI3K/AKT signaling has been shown to target the histone methyltransferase EZH2, modulating the activity of this epigenetic “writer” and disrupting the proper “installation” of epigenetic histone methyl marks during development. Understanding the nature of the epigenetic reprogramming induced by early life exposures to xenoestrogens (and other environmental agents) has important implications for our understanding of breast cancer susceptibility across the life-course and for identifying effective strategies to prevent this disease.

**PL2-1**

**Macrophages as Novel Targets for Therapy in Breast Cancer.**

*Coussens LM. University of California San Francisco*

While BC has not historically been linked to underlying inflammation or infection, it exhibits tumor-associated inflammation marked by infiltration of innate and adaptive immune cells into developing tumors. In BC, macrophages are one of the most abundant innate immune cells present. BC-associated macrophages are regulated in part by colony stimulating factor 1 (CSF1), a key cytokine involved in monocyte/macrophage maturation, recruitment and activation, and its cognate receptor CSF1R. Macrophage presence in BC correlates with increased CSF1, increased vascular density, and worse clinical outcome. We reported that CD4+ T cells promote invasion and metastasis of mammary adenocarcinomas by directly regulating macrophage phenotype that in turn fosters invasive tumor growth, presence of circulating tumor cells and pulmonary metastasis. This preclinical data implied that women with BC heavily infiltrated by macrophages would have a worse clinical outcome as compared to tumors not heavily infiltrated with macrophages. We evaluated survival outcomes in 698 women with invasive BC treated with surgery alone and found that recurrence-free survival could be stratified based upon macrophage and T cell infiltration. Thus, we investigated CSF1 and CSF1R antagonists, in combination with standard-of-care chemotherapy (CTX) in mouse models of mammary carcinogenesis. We found that when macrophage infiltration in mammary adenocarcinomas was blocked, paclitaxel (PTX) chemosensitivity was increased, accompanied by development of productive anti-tumor immune responses and CD8+ cytotoxic T cell (CTL) infiltration. The combined effects of these changes were reduced primary tumor growth, 85% reduction in metastases and increased survival. In collaboration with clinical colleagues, we are currently evaluating the clinical benefit of macrophage modulation in preclinical models of BC to facilitate biomarker identification, and inform clinical trials of CTX in combination with macrophage-antagonists. Based on our preliminary data, we hypothesize that components of macrophage responses in BC can be identified to serve as biomarkers for risk stratification. And, that these components can be
effectively targeted for therapeutic intervention, resulting in reduced late-stage BC development and metastasis when combined with CTX. LMC acknowledges generous support from the NIH/NCI (R01CA130980, R01CA13256, R01CA140943, R01CA15531), the Department of Defense (W81XWH-09-1-0342, W81XWH-10-BCRP-EOHS-EXP) and the Susan G Komen Foundation (KG111084).

**BS3-1**

Extrinsic and Intrinsic Force Regulation of Breast Cancer Progression and Treatment.

**Weaver VM. University of California San Francisco, San Francisco, CA**

Breast tissue development and homeostasis are tightly regulated by mechanical cues. Alterations in tensional homeostasis characterize breast cancer. The challenge is to clarify how chemical and mechanical cues collaborate to regulate breast tissue function and to determine when and how these forces regulate breast cancer behavior. The Weaver group has been studying how cells in the breast sense and transduce mechanical cues to regulate their behavior and how altered mechanical force compromises breast tissue homeostasis to drive cancer (Dufort et al., Nature Mol Biol Rev 2011). Our work focuses on clarifying the role of force in normal breast behavior and in breast cancer initiation, transformation, metastasis and treatment response. We showed that extracellular matrix (ECM) stiffness, which is tightly controlled through matrix concentration, topology and posttranslational modifications, is a critical isometric force that modulates mammary gland morphogenesis and tumorigenesis. We demonstrated that the ECM associated with the mammary epithelium progressively stiffens as the tissue transforms and that breast cancer subtype is characterized by increasing ECM stiffness. Thus, normal human breast tissue is quite soft, the ECM associated with fibroproliferative lesions is twice as stiff, ER/PR+ve invasive breast cancers are 4 fold stiffer and triple negative breast lesions are the stiffest (6-10 times stiffer). We showed that a stiffened ECM modifies breast tissue behavior by promoting the assembly of integrin focal adhesions which potentiate growth factor receptor signaling and induce cytoskeletal remodeling and actomyosin contractility (Paszek et al., Cancer Cell 2005; Paszek et al., PLOS Computational 2009). We determined that ECM stiffness also potentiates the tumor promoting effect of oncogenes such as Ras, EGFR and ErbB2 by increasing the activity of ERK, wnt and PI3 kinase and inducing tissue fibrosis. Inducing ECM stiffening prevents breast tissue fibrosis and tumor progression and metastasis (Levental et al., CELL 2009). Importantly, the tissue response to force also depends upon the cellular mechanoresponsive machinery and we determined that oncogenic transformation and elevated chemokine and cytokine signaling induces aberrant force sensing and elevated breast tumor tension. Most notably we demonstrated that oncogenic signaling through Ras signaling to ERK induces ECM remodeling and stiffening which are required to stimulate wnt thereby driving tumor cell invasion to induce an epithelial to mesenchymal like transition that potentiates breast tumor aggression and metastasis. More recently we found that ECM stiffness dictates the efficacy of treatment response - with high ECM stiffness potentiating chemo, immune and radiation-induced tumor regression and apoptosis. The clinical relevance of these findings are now being investigated with collaborators at UCSF and Duke. **BS3-2**

Mammary Stroma as an NSAID Target; Implications for Pregnancy-Associated Breast Cancer.

**Schedin P, Lyons TR, O’Brien J, Callihan E, Russell T, Martinson H, Tan A-C, Hansen K, Keely PJ, Borges V. University of Colorado Denver Anschutz Medical Campus, Aurora, CO; University of Wisconsin, Madison, WI**

Utilizing a young women’s breast cancer cohort from the University of Colorado Cancer Center, we show that women diagnosed as late as five-to ten years postpartum have worse prognosis than nulliparous women or women diagnosed during pregnancy, and represent ~50% of all young women’s breast cancer patients. We propose that breast invasion following pregnancy accounts for this poor prognosis. Characterization of invasion identifies tissue remodeling programs that share similarities with microenvironments known to promote metastasis. Using SHG imaging, we find fibrillar collagen bundles with radially-aligned fibers similar to those observed in invasive tumors deposited in the involuting gland. By immunohistochemistry and FACS we find macrophages with an M2-polarization-like profile similar to tumor-associated macrophages at abundant levels during invasion. In three independent mouse models for post-partum breast cancer, we isolate postpartum mammary gland invasion as a driving force for cancer progression. Mammary tumors arising in the mouse involuting microenvironment express COX-2 and isolated tumor cells are motile and invasive in a collagen-1/COX-2 dependent manner. Targeting invasion-macrophages as likely mediators of tumor promotion was accomplished using a previously described mouse transgenic model. Macrophage depletion during involution had catastrophic effects on normal mammary gland involution. Conversely, inhibition of COX-2 with celecoxib, aspirin or ibuprofen did not interfere with postpartum lobular regression. COX-2 inhibition did decrease tumor growth, local tumor cell dispersion and lung metastasis. NSAID treatment also suppressed collagen and tenascin-C deposition in the involuting microenvironment, suggesting that modulation of extracellular matrix proteins may be a novel mechanism by which NSAIDs exhibit chemopreventive activity. Our studies indicate two distinct roles for COX-2 in the postpartum setting. COX-2 activity within the tumor cell is required for invasiveness and COX-2 activity in the host promotes collagen fibrillogenesis. Several correlative observations implicate the collagen/COX-2 pathway in postpartum breast cancer in women: involuting breast tissue has increased collagen with radially aligned fibers, analysis of 11 publicly available microarray data sets shows high COL1A and COX-2 independently correlate with decreased relapse free-survival in young breast cancer patients, and COX-2 protein is observed in DCIS lesions in postpartum cases at higher levels than nulliparous cases. In summary, our studies suggest further research into COX-2 inhibitor use might provide a novel strategy to improve the prognosis of young women should they be diagnosed with postpartum breast cancer. The question of whether an NSAID based intervention study could be aimed at recently pregnant women at high risk for breast cancer also remains to be determined, but is an extremely desirable objective given that the ~ 6 million pregnancies in the US per year. Inhibition of HIF-1 activity by genetic or pharmacologic strategies dramatically inhibits the metastasis of breast cancer cells to the lungs in orthotopic mouse models (2, 3). HIF-1 also plays critical roles in breast cancer metastasis. HIF-1 transactivation and reprograms glucose metabolism in cancer cells (1). Pyruvate kinase M2 (PKM2) coactivator function, reduces glucose uptake and lactate production, and PKM2 hydroxylation on proline-403/408. PHD3 knockdown inhibits PKM2 binding to HIF-1 subunit and promotes transactivation of HIF-1 target genes by enhancing HIF-1 binding and p300 recruitment to hypoxia response elements, whereas PKM1 fails to regulate HIF-1 activity. Interaction of PKM2 with prolyl hydroxylase 3 (PHD3) enhances PKM2 binding to HIF-1α and PKM2 coactivator function. Mass spectrometry and anti-hydroxyproline antibody assays demonstrate PKM2 hydroxylation on proline-403/408. PHD3 knockdown inhibits PKM2 coactivator function, reduces glucose uptake and lactate production, and increases O2 consumption in cancer cells. Thus, PKM2 participates in a positive feedback loop that promotes HIF-1 transactivation and reprograms glucose metabolism in cancer cells (1). HIF-1 also plays critical roles in breast cancer metastasis. HIF-1 controls metastatic niche formation by activating transcription of genes encoding lysyl oxidase (LOX) and LOX-like proteins 2 and 4, which remodel collagen in the lungs, thereby recruiting bone marrow-derived cells that establish a microenvironment suitable for colonization by breast cancer cells (2). HIF-1 also promotes the extravasation of circulating breast cancer cells in the lungs by activating transcription of the genes encoding L1CAM, which encodes a cell adhesion molecule that promotes the interaction of breast cancer cells with vascular endothelial cells (ECs), and angiopoietin-like 4, which encodes a secreted factor that inhibits EC-EC interaction (3). Inhibition of HIF-1 activity by genetic or pharmacologic strategies dramatically inhibits the metastasis of breast cancer cells to the lungs in orthotopic mouse models (2, 3).

**HIF-1, Metabolism, and Breast Cancer Metastasis.**

Luo W, Zhang H, Wong CC-L, Gilkes DM, Hu H, Semenza GL. The Johns Hopkins University School of Medicine, Baltimore, MD; University of Science and Technology of China, Hefei, Anhui, China

Increased glucose uptake and metabolism is a universal characteristic of advanced solid cancers. There are two well-established mechanisms underlying the reprogramming of tumor metabolism. First, intratumoral hypoxia induces the activity of the transcriptional activator hypoxia-inducible factor 1 (HIF-1) by inhibiting the O2-dependent prolyl and asparaginyl hydroxylases that inhibit HIF-1α stability and transactivation, respectively. Second, genetic alterations increase the activity of HIF-1, thereby increasing the expression of glucose transporters (GLUT1, GLUT3), glycolytic enzymes (ALDOA, ENO1, HK2, LDHA, PKM2), pH regulators (CAR9, NHE1, MCT4), and proteins that inhibit mitochondrial metabolism (BNIP3, PDK1). Metabolites, such as the glycolytic end-product lactate, also induce HIF-1 activity, thereby providing a signal to further increase glycolytic metabolism. Recently, we have identified a novel feed-forward mechanism by which glycolytic enzyme expression leads to increased HIF-1 transcriptional activity. Pyruvate kinase isoforms PKM1 and PKM2 are alternatively spliced products of the PKM2 gene. PKM2, but not PKM1, alters glucose metabolism in cancer cells and contributes to tumorigenesis by mechanisms that are not explained by its known biochemical activity. We show that PKM2 gene transcription is activated by HIF-1. PKM2 interacts directly with the HIF-1α subunit and promotes transactivation of HIF-1 target genes by enhancing HIF-1 binding and p300 recruitment to hypoxia response elements, whereas PKM1 fails to regulate HIF-1 activity. Interaction of PKM2 with prolyl hydroxylase 3 (PHD3) enhances PKM2 binding to HIF-1α and PKM2 coactivator function. Mass spectrometry and anti-hydroxyproline antibody assays demonstrate PKM2 hydroxylation on proline-403/408. PHD3 knockdown inhibits PKM2 coactivator function, reduces glucose uptake and lactate production, and increases O2 consumption in cancer cells. Thus, PKM2 participates in a positive feedback loop that promotes HIF-1 transactivation and reprograms glucose metabolism in cancer cells (1). HIF-1 also plays critical roles in breast cancer metastasis. HIF-1 controls metastatic niche formation by activating transcription of genes encoding lysyl oxidase (LOX) and LOX-like proteins 2 and 4, which remodel collagen in the lungs, thereby recruiting bone marrow-derived cells that establish a microenvironment suitable for colonization by breast cancer cells (2). HIF-1 also promotes the extravasation of circulating breast cancer cells in the lungs by activating transcription of the genes encoding L1CAM, which encodes a cell adhesion molecule that promotes the interaction of breast cancer cells with vascular endothelial cells (ECs), and angiopoietin-like 4, which encodes a secreted factor that inhibits EC-EC interaction (3). Inhibition of HIF-1 activity by genetic or pharmacologic strategies dramatically inhibits the metastasis of breast cancer cells to the lungs in orthotopic mouse models (2, 3).

**MS3-3**

**Energy Metabolism in Breast Cancer: Translational Science Insights Relevant to Effects of Diet, Exercise, and Metformin on Risk and Prognosis.**

Pollak M. McGill University and Jewish General Hospital

Energy metabolism is relevant to breast cancer at both the cellular and whole organism levels. Whole organism energy balance determines body mass, which has been associated with variations in both breast cancer risk and prognosis. Experimentally, breast carcinogenesis is facilitated by excess caloric intake and inhibited by caloric restriction. The simplistic notion that excess food intake provides additional energy to breast epithelial cells at risk for transformation or to breast cancers, leading to aggressive behavior, is not supported by experimental data. Rather, variations in energy balance have important influences on the hormonal and cytokine environment of the patient, and these influence carcinogenesis and tumor behaviour. Experimental models provide evidence that one such mediating hormone is insulin. Most breast cancers have insulin receptors. When mice with breast cancer are experimentally manipulated to have insulin deficiency (type I) diabetes, tumor growth rate is slowed (despite hyperglycemia). Conversely, when mice are provided with a “junk food” diet, insulin levels rise, tumor insulin receptor activation increases, and tumors grow more quickly. However, when breast cancers evolve to have activating mutations in signalling networks downstream of insulin receptors, they become more aggressive and unresponsive to variations in energy intake and insulin no longer influences their behavior.

There is retrospective pharmacoepidemiologic evidence for a substantial (~50%) reduction in breast cancer risk in type II (hyperinsulinemic) diabetic patients prescribed metformin. This has contributed to current interest in the hypothesis that metformin has uses in cancer prevention or treatment. Metformin acts to reduce cellular ATP production by inhibiting mitochondrial respiratory complex I. This results in activation of AMPK. In liver, this results in reduced gluconeogenesis, which reduces the hyperglycemia and hyperinsulinemia of type II diabetes. This systemic effect may reduce proliferation of the subset of neoplasms that are growth stimulated by insulin, but does not operate in the absence of baseline hyperinsulinemia. Other mechanisms of metformin action involve direct effects on at-risk or transformed cells. These mechanisms require adequate levels of the drug in the relevant cells, but metformin doses used in diabetes treatment may not achieve optimum concentrations in cancers, particularly those that lack the active transport molecules responsible for cellular metformin uptake. Overall, laboratory studies suggest that any benefits of metformin will not be homogeneous among a population of at-risk women in a prevention context, nor among breast cancer patients in a treatment context. The validation of candidate predictive biomarkers for metformin benefit, together with more detailed pharmokinetic data, may allow for optimized clinical trial design. Further research is also required to clarify if metformin should best be evaluated as a single agent or in combinations. Thus, metformin and derivatives can be regarded as lead compounds for optimization, and this line of research may lead to novel metabolic approaches to breast cancer prevention and treatment.
MS4-1
The Neoadjuvant Setting, HER2-Driven and Triple Negative Breast Cancer.
Carey LA. University of North Carolina

The benefits of neoadjuvant therapy include: tumor cytoreduction, minimizing surgical resection volume, conversion to breast conservation, and the opportunity to test new drugs and regimens because response in the breast is a surrogate for long-term survival. Off-trial, neoadjuvant regimens should mimic adjuvant regimens in drug, dose, and schedule; "tailored" approaches or treatment to best response have not been adequately studied. In HER2+ and triple negative (ER-, PR-, and HER2-negative, TNBC) BrCa, the backbone of neoadjuvant treatment is chemotherapy, with HER2-targeting added to the former. In hormone receptor-positive, HER2-negative BrCa, randomized clinical trials suggest similar efficacy of endocrine therapy and chemotherapy in response, however pathologic complete response (pCR) is rare.

HER2-targeting with the anti-HER2 antibody trastuzumab (H) added to chemotherapy for HER2+ BrCa augments pCR, with 1 year of H completed adjuvantly. Off-trial options include AC-doxetaxel (D) + H, AC-paclitaxel (T) + H, and D + carboplatin + H (DCH). It is likely that small, node-negative HER2+ BrCa are overtreated by these regimens; a challenge is to develop less chemotherapy-intensive regimens for the lower-risk setting. Several studies have examined other HER2-targeted drugs. In NeoALTO, HER2+ patients received either TH, T + HER1/HER2 inhibitor lapatinib (TL), or the combination TTHL. pCR was lower (and toxicity higher) in TL; THL had the highest pCR rate (47%). GeparQuinto compared EC-DH to EC-DL and also found lower pCR rate and higher toxicity in the L-containing arm. NeoSPHERE examined the anti-HER2 heterodimerization domain antibody pertuzumab (P), pCR rates were higher with combination DHP (46%) vs. DH (29%) and DP (24%). The all-biologic HP arm had a 17% pCR rate. In TBCRC006, HL alone resulted in a 28% pCR rate. These studies support combination HER2-targeting-based regimens in adjuvant trials.

TNBC lacks the known targetable molecules, ER, PR, or HER2, leaving chemotherapy the mainstay of treatment. Early TNBC is sensitive to conventional agents, and possesses one of the highest pCR rates to neoadjuvant anthracycline/taxane-based chemotherapy. The use of DNA-damaging drugs in TNBC is based on the association of Basal-like BrCa with BRCA1 germline mutations. Neoadjuvant studies are small and heterogeneous but supportive of a high pCR rate (>70%) to platinum in known carriers, however studies of sporadic TNBC are less clear. CALGB 40603, an ongoing randomized phase II study of taxane with or without carboplatin and with and without the anti-VEGF antibody bevacicuzumab (B), will provide direct evidence. Although lacking known targeted therapy, subset analysis of the HER2-negative component of GeparQuinto suggested that TNBC had higher pCR rates with EC-D + B (45%) compared with chemotherapy alone (36%). The biology and identification of novel targets in TNBC as well as optimization of the chemotherapy remain subjects of intense study.

Neoadjuvant therapy is an excellent approach for patients with clinical stage II-III in whom the nature of systemic therapy is clear. It also provides a rich laboratory for drugs, regimens, and the identification of predictive markers and subtype biology in a timely and efficient manner.

MS4-2
Preoperative Endocrine Therapy: New Approaches.
Smith I. The Royal Marsden Hospital, London, United Kingdom

Modern neoadjuvant endocrine therapy trials comparing aromatase inhibitors (AIs) with tamoxifen have shown that neoadjuvant AIs can downstage cancers and avoid mastectomy in around 50% of post menopausal women with large ER positive tumours, and are superior to tamoxifen in this respect.

The future potential of preoperative endocrine therapy is in the use of molecular biomarkers after starting treatment to predict outcome. This approach was pioneered in the IMPACT trial which showed that the reduction in tumour proliferation as measured by the biomarker Ki67 comparing neoadjuvant anastrozole v tamoxifen v. the combination. was significantly greater for anastrozole than for the other 2 arms, predicting the same long-term outcome benefit in the equivalent adjuvant ATAC trial. The change in Ki67 with treatment could be used to predict potential benefit with other novel endocrine therapy approaches. Recently a similar neoadjuvant trial comparing anastrozole v letrozole v exemestane has shown no significant difference in Ki67 suppression between arms, predicting no long-term difference in clinical outcome with these agents.

Around 15% of patients with good initial tumour Ki67 suppression after 2 weeks of preoperative endocrine therapy show recovery of Ki67 by 12 weeks, providing early biomarker evidence of treatment resistance. Clinical outcome in these patients appears correspondingly worse. This provides an opportunity for biomarker led studies of agents targeting both innate and acquired resistance to endocrine therapy, defined by 2 week and 12 week Ki67 levels,. One such preoperative endocrine therapy trial with Ki67 as primary endpoint has already been carried out: patients were started on 2 weeks of preoperative anastrozole and then randomised to the addition or not of the tyrosine kinase inhibitor, gefitinib (IRESSA). This novel pre-operative endocrine therapy approach also allows the study of changes in other biomarkers and in gene expression as a means of elucidating underlying mechanisms of resistance.

Finally the clinical potential of Ki67 after 2 weeks preoperative AI treatment is further demonstrated by the observation that higher 2 week values of Ki67 after treatment in the IMPACT trial predicted for a significantly worse recurrence-free survival. This raises the intriguing possibility that patients with ER positive breast cancer, including small cancers, could be treated with 2 weeks pre-operative endocrine therapy before surgery and Ki67 levels at surgery be used to predict long-term outcome for the individual patient and in particular to identify those patients with a good prognosis who would not require chemotherapy. This hypothesis is being tested in the UK POETIC (Peri-Operative Endocrine Therapy for Individualised Care) trial which has so far accrued around 2,000 patients out of an overall target of 4,000. A similar approach in which Ki67, pathologic stage and ER at the end of a course of neoadjuvant endocrine therapy are combined to produce a Preoperative Endocrine Prognostic Index (PEPI) is being used to identify patients with such a low risk of relapse that adjuvant chemotherapy may not be necessary.

MS4-3
Radiation for Patients Treated with Neoadjuvant Chemotherapy.
Buchholz TA. UT MD Anderson Cancer Center

The increased use of neoadjuvant systemic therapy for patients with stage II or stage III breast cancer has raised a number of important questions concerning local-regional treatments, particularly within the field of radiation oncology. Historically, the indications for radiation use after mastectomy and treatment of regional lymph node fields were
Axillary node status is one of the strongest prognostic factors in breast cancer patients. The presence of tumor in axillary nodes, and number of positive nodes, predicts risk of metastatic disease and long term survival. In the past, axillary dissection provided both accurate evaluation of nodal status and excellent local control. However, complications of axillary dissection, including lymphedema, pain, and impaired arm function, have led to keen interest in alternatives to axillary dissection for local control and assessment of prognosis.

Sentinel node biopsy provides a low-morbidity alternative to axillary dissection for patients with clinically negative nodes. It was recognized that breast lymphatics converge in the axilla, delivering fluid, travelling tumor cells and dye particles to a small number of “sentinel” nodes. Sentinel node biopsy techniques take advantage of this lymphatic anatomy using dye injection intraoperatively to permit identification and removal of only the most important axillary nodes – those most likely to contain metastases. A negative sentinel node provides accurate staging and reliably predicts a low axillary recurrence rate, eliminating the need for dissection. Sentinel node mapping also allows study of the relationship between the size of a nodal metastasis and impact on prognosis. Sentinel node mapping techniques, morbidity, and data on the reliability of sentinel node biopsy will be reviewed.

40-50% of patients with a positive sentinel node will have additional positive axillary nodes, indicating a need for additional axillary treatment for local control. Completion axillary dissection was initially used for local control and prognostic assessment in patients with a positive sentinel node. Recently, the ACOSSG Z0011 trial showed that patients with 1 or 2 positive sentinel nodes who receive standard whole breast irradiation without further axillary surgery have equivalent local control as patients having completion axillary dissection. Axillary recurrence rates in the Z0011 trial were <1% at 6.3 years follow-up in both the radiation alone and dissection arms. Changing axillary management algorithms resulting from these data will be discussed. Sentinel node biopsy can now replace axillary dissection for patients with negative nodes undergoing either lumpectomy or mastectomy. Sentinel node biopsy can also replace dissection for lumpectomy patients with 1-2 positive sentinel nodes where data on the precise number of additional positive axillary nodes is not needed for treatment decisions. At present, axillary dissection is still recommended for patients with palpable axillary nodes, 3 or more positive sentinel nodes, gross extranodal tumor, and positive sentinel nodes after neoadjuvant therapy, or for positive nodes in patients undergoing mastectomy. Trials of radiation instead of dissection in such patients are likely.

Management of the axilla will evolve further as options for assessment of tumor and host factors increase. Gene expression profiling may prove more important than primary tumor size and node status for predicting prognosis and guiding therapy – an approach already used in estrogen receptor positive tumors. Future options for incorporating axillary node status with tumor and host factors in breast cancer management will be considered.

Advances in Axillary Surgery: Sentinel Nodes and beyond.

**Smith BL. Massachusetts General Hospital**

Sentinel node biopsy provides a low-morbidity alternative to axillary dissection for patients with clinically negative nodes. It was recognized that breast lymphatics converge in the axilla, delivering fluid, travelling tumor cells and dye particles to a small number of “sentinel” nodes. Sentinel node biopsy techniques take advantage of this lymphatic anatomy using dye injection intraoperatively to permit identification and removal of only the most important axillary nodes – those most likely to contain metastases. A negative sentinel node provides accurate staging and reliably predicts a low axillary recurrence rate, eliminating the need for dissection. Sentinel node mapping also allows study of the relationship between the size of a nodal metastasis and impact on prognosis. Sentinel node mapping techniques, morbidity, and data on the reliability of sentinel node biopsy will be reviewed.

40-50% of patients with a positive sentinel node will have additional positive axillary nodes, indicating a need for additional axillary treatment for local control. Completion axillary dissection was initially used for local control and prognostic assessment in patients with a positive sentinel node. Recently, the ACOSSG Z0011 trial showed that patients with 1 or 2 positive sentinel nodes who receive standard whole breast irradiation without further axillary surgery have equivalent local control as patients having completion axillary dissection. Axillary recurrence rates in the Z0011 trial were <1% at 6.3 years follow-up in both the radiation alone and dissection arms. Changing axillary management algorithms resulting from these data will be discussed. Sentinel node biopsy can now replace axillary dissection for patients with negative nodes undergoing either lumpectomy or mastectomy. Sentinel node biopsy can also replace dissection for lumpectomy patients with 1-2 positive sentinel nodes where data on the precise number of additional positive axillary nodes is not needed for treatment decisions. At present, axillary dissection is still recommended for patients with palpable axillary nodes, 3 or more positive sentinel nodes, gross extranodal tumor, and positive sentinel nodes after neoadjuvant therapy, or for positive nodes in patients undergoing mastectomy. Trials of radiation instead of dissection in such patients are likely.

Management of the axilla will evolve further as options for assessment of tumor and host factors increase. Gene expression profiling may prove more important than primary tumor size and node status for predicting prognosis and guiding therapy – an approach already used in estrogen receptor positive tumors. Future options for incorporating axillary node status with tumor and host factors in breast cancer management will be considered.

An important goal, that of characterizing the breadth and complexity of mutations in breast cancer, is being approached by The Cancer Genome Atlas in its next-generation sequencing and analysis of the exome and whole genome content of breast cancer samples. At present, we have produced, analyzed, and validated mutations by exome capture of matched tumor and normal genomic DNA across all breast cancer subtypes, using over 500 samples as our primary discovery set. The resulting information has been further analyzed by integration with other data types being generated in the project, including RNA-seq, methylation and SNP array data.
SR2-3
Integrative Genomic Analyses of Breast Cancer from The Cancer Genome Atlas (TCGA).
Creighton C. Baylor College of Medicine

Cancer is a disease characterized by genetic aberrations, which lead to widespread deregulation of cell signaling and gene transcription. Over ten years ago, gene transcription profiling of human cancers was found to distinguish distinct intrinsic molecular subtypes of the disease (luminal A/B, HER2, basal, normal-like). TCGA is a large-scale collaborative effort which seeks to comprehensively catalogue the molecular aberrations in various cancers, including breast cancer, at levels of somatic mutation, copy alteration, DNA promoter methylation, protein signaling, and gene and miRNA transcription. Having all of these molecular data on the same set of ~500 human breast tumors, allows us to construct a more complete molecular portrait of the intrinsic subtypes, along with their candidate molecular drivers. Among other things, integrative analysis of the p53 and PI3K pathways in breast cancer reveal differences in pathway alteration and pathway activity among the subtypes.

SR2-5
The DNA Copy Number Landscapes and Genomic Architecture; Relevance for Progression and Outcome.
Børresen-Dale A-L. Norwegian Radium Hospital, Oslo University Hospital, Oslo, Norway; Faculty of Medicine, University of Oslo, Oslo, Norway

Patterns of genomic aberrations have been defined that underlie specific expression subgroups of breast cancer (BC) that may infer paths of tumor progression and shed light on mechanisms involved. Classifications built on levels of genomic distortion have been shown to have prognostic value. We recently developed two platform-independent algorithms to explore genomic architectural distortion using aCGH data to measure whole-arm gains and losses [whole arm aberration index (WAAI)] and complex rearrangements [complex arm aberration index (CAAI)]. By applying CAAI and WAAI to data from 595 BC patients, we were able to separate the cases into eight subgroups with different distributions of genomic distortion. Within each subgroup data from expression analyses, sequencing and ploidy indicated that progression occurs along separate paths into more complex genotypes. Histological grade had prognostic impact only in the luminal-related groups, whereas the complexity identified by CAAI had an overall independent prognostic power. The DNA Copy Number Landscapes and Genomic Architecture; Relevance for Progression and Outcome.

SR2-6
Genome Data for the Masses: Presentation of TCGA and IGC Breast Tumor Data.
Haussler D. Howard Hughes Medical Institute

Large-scale cancer genomics projects will sequence tens of thousands of tumors in the next few years, along with matched normal tissue samples. Among these are the Cancer Genome Atlas (TCGA), Therapeutically Applicable Research to Generate Effective Treatments (TARGET), and the International Cancer Genomics Consortium (IGC). TCGA alone plans to analyze 500 clinically characterized samples from each of 20 different cancer types, detecting frequently mutated genes, common copy number variants, rearrangements, altered gene expression, and methylation changes. These data will provide an exceptional resource for identifying new diagnostic targets and predictors of response.

As a data analysis center and the primary sequence database for TCGA, we have built on technology developed for the UCSC Genome Browser to develop a cancer genome analysis pipeline and a cancer genomics browser (genome-cancer.ucsc.edu). These interpret cancer genomics data to aid in the identification of new targets. We reconstruct changes in tumor genomes and their expressed transcripts from tumor sequencing data (DNA, RNA, methylation) and use an approach based on factor graphs, called PARADIGM, to map multiple data types into a single coherent pathway model that includes thousands of genes and interactions for higher-level interpretation. By transforming raw genomic data to pathway activity levels, PARADIGM provides a comprehensible window into the data that can be coupled to predictors of response to improve accuracy. This paves the way to form hypotheses that clinical investigators can test in cell-line models and later explore in clinical trials.

Today's concurrent cancer genomic projects provide an exceptional opportunity to study the molecular nature of cancer on an enormous scale never before possible. A cancer genomics data repository that hosts multiple large projects and makes them accessible through a general cancer genomics browser (with effective data access control) will leverage each study and enable cross-tumor cancer research.

Mehta RS, Barlow WE, Albain KS, Vandenbarg T, Dakhil SR, Tirumali NR, Lew DL, Hayes DF, Gralow JR, Livingston RB, Hortobagyi GN. University of California at Irvine, Chao Family CCC, Orange, CA; SWOG, Seattle, WA; Loyola University Chicago Stritch School of Medicine, Maywood, IL; London Regional Cancer Program, London, ON, Canada; Wichita CCOP, Wichita, KS; NW Permanente, Portland, OR; University of Michigan, Michigan; Seattle Cancer Care Alliance, Seattle, WA; Arizona Cancer Center, Tucson, AZ; University of Texas/MD Anderson Cancer Center, Houston, TX

Background: Anastrozole inhibits the aromatase enzyme-induced estrogen synthesis, and fulvestrant down-regulates estrogen receptors in hormone receptor-positive breast cancer. We hypothesized that the simultaneous disruption of the ligand-receptor axis with concurrent use of these agents may be potentially additive or synergistic in first-line therapy of hormone receptor-positive metastatic breast cancer in postmenopausal women.

Materials and Methods: A total of 707 patients were randomized to either 1 mg anastrozole P.O. daily (Arm 1) or to the combination of anastrozole and fulvestrant (Arm 2). Fulvestrant was given as an intramuscular injection as follows: loading dose of 500 mg on day 0, followed by 250 mg on days 14, 28 and 250 mg maintenance monthly thereafter. The primary endpoint was progression-free survival (PFS), with a power of 90% and one-sided alpha of 0.025 to detect an expected median PFS of 10 months in Arm 1 versus 13 months in Arm 2. Randomization was stratified by adjuvant tamoxifen use with a median age of 60 years in the fulvestrant arm (40%) and 50% in the anastrozole arm. Patients were encouraged to crossover to fulvestrant after progression on the anastrozole alone arm (40% did), if they were not candidates for immediate chemotherapy. Analysis of survival was by 2-sided stratified log-rank tests and Cox regression using intent-to-treat. Two interim analyses were performed with the final analysis using a 2-sided p-value of 0.04.

Results: There were 548 events (287 and 261 by arms, respectively) among 694 eligible patients (345 and 349, respectively). Overall, median PFS was 13.5 months for anastrozole and 15.0 months for the combination of fulvestrant and anastrozole (log-rank p = 0.0145; HR = 0.81 (95% CI 0.68-0.96)). In a subset analysis of tamoxifen-naive women (60%, n = 414), median PFS was 12.6 months and 17.0 months for Arms 1 and 2, respectively (log-rank p = 0.0069; HR = 0.74 (95% CI 0.60-0.92)), and 14.1 months and 13.5 months for Arms 1 and 2, respectively, in the 40% of tamoxifen-pretreated women (log-rank p = 0.56; HR = 0.93 (95% CI 0.71-1.20)). A trend for improved overall survival (OS) in the combination arm was seen (median OS was 42 and 48.6 months based on 152 and 137 deaths respectively, log-rank p = 0.094; HR = 0.82 (95% CI 0.65-1.03)). On the combination arm, there were 694 deaths related to the treatment: due to pulmonary embolism (2) or cerebrovascular ischemia (1); one Grade 4 thrombosis/embolism and one Grade 4 neutropenia and lymphopenia were reported. On the anastrozole arm, four patients experienced Grade 4 toxicities: thrombosis/embolism, arthralgia, thrombocytopenia, and dyspnea. In general, Grade 3 or higher toxicity was rare (12.7% vs. 14.5% for Arms 1 and 2, respectively) and did not differ significantly.

Discussion: The combination of anastrozole and fulvestrant was associated with improved PFS compared to anastrozole alone as well as a trend in OS despite substantial crossover, thus offering a new standard in the first-line treatment of hormone receptor-positive breast cancer in postmenopausal women, specifically in tamoxifen-naive patients. ClinicalTrials.gov:NCT00075764. Funding: NIH/NCI CA32102, CA38926 and AstraZeneca.

S1-2
Long-Term Follow-Up in ABCSG-12: Significantly Improved Overall Survival with Adjuvant Zoledronic Acid in Premenopausal Patients with Endocrine-Receptor–Positive Early Breast Cancer.
Gnant M, Milneritsch B, Luschin-Ehengreuth G, Stoeger H, Dubsky P, Jakess R, Singer C, Eidtmann H, Feil C, Eiermann W, Marth C, Greil R. Medical University of Vienna, Vienna, Austria; Paracelsus Medical University Salzburg, Salzburg, Austria; Medical University of Graz, Graz, Austria; University of Schleswig-Holstein, Kiel, Germany; Austrian Breast and Colorectal Cancer Study Group, Vienna, Austria; Red Cross Women’s Hospital, Munich, Germany; Medical University of Innsbruck, Innsbruck, Austria

Background: We have previously reported significantly improved disease-free survival (DFS) in premenopausal patients with endocrine-responsive early breast cancer receiving adjuvant zoledronic acid (ZOL) in ABCSG-12 (Gnant M, et al. NEJM. 2009;360:679-91). Other trials, such as ZO-FAST and the premenopausal (>5 yr) subset analysis of AZURE, have demonstrated similar anticancer effects with ZOL. Now with >6 yr of follow-up in ABCSG-12, we report an overall survival (OS) benefit and preplanned subgroup analyses that more precisely define interactions between the ZOL benefit and patient/tumor characteristics.

Methods: Premenopausal women with endocrine-receptor–positive early stage breast cancer (N = 1,803) were randomized to ovarian function suppression with goserelin (3.6 mg q28d) and tamoxifen (TAM; 20 mg/d) or anastrozole (ANA; 1 mg/d) ± ZOL (4 mg q6mo) for 3 yr. Endpoints included DFS and OS, both analyzed using log-rank test and Cox models.

Results: At median follow-up of 76 mo, patients receiving ZOL had a significant 27% reduction in the risk of DFS events (HR = 0.73; Cox P = .022) and a significant 41% reduction in the risk of death (HR = 0.59; Cox P = .027) vs no ZOL. Multivariate analyses showed a strong interaction between ZOL and patient age, but did not show any interactions between ZOL and ANA/TAM or any classic tumor parameter (eg, T, N, grade, ER). Among patients > 40 yr of age (n = 1,390) with presumed complete ovarian blockade, ZOL significantly reduced the risk of DFS events by 34% (HR = 0.66; Cox P = .014) and the risk of death by 49% (HR = 0.51; Cox P = .020); however, there were no significant DFS or OS benefits in patients <40 yr of age. Currently, all patients have completed 3 yr of ZOL and are in the follow-up phase with no reported cases of osteonecrosis of the jaw or renal failure. Additional analyses at a median follow-up of approximately 84 mo are planned for late 2011 and will be presented, providing additional insights into disease recurrence patterns with and without ZOL.

Conclusions: Long-term follow-up of ABCSG-12 (76 months) confirms and extends previous results seen at 48 mo and 62 mo follow-up, and suggests that anticancer benefits of adjuvant ZOL result in highly significant DFS and OS benefits mainly in patients with a low-estrogen environment (ie, ovarian suppression and age >40 yr). These results are consistent with the significant DFS and OS improvements seen in the postmenopausal (>5 yr) cohort of the AZURE trial, and suggest that both estrogen deprivation and reduction of bone-turnover–derived growth factors in the bone marrow microenvironment are needed for sufficient suppression of dormant micrometastases. Taken together with the previously demonstrated bone-protective effects of ZOL, these DFS and OS benefits strongly
suggest that adding ZOL to adjuvant endocrine therapy should be considered for premenopausal women with endocrine-receptor–positive early breast cancer.

S1-3
Long-Term Survival Outcomes among Postmenopausal Women with Hormone Receptor-Positive Early Breast Cancer Receiving Adjuvant Letrozole and Zoledronic Acid: 5-Year Follow-Up of ZO-FAST.

de Boer R, Bunded N, Eidmann H, Neven P, von Minckwitz G, Martin N, Modi A, Coleman R. Royal Melbourne Hospital, Victoria, Australia; University Hospital of South Manchester NHS Foundation Trust, Manchester, United Kingdom; University Frauenklinik, Kiel, Germany; UZ Gasthuisberg, Leuven, Belgium; German Breast Group, Frankfurt, Germany; Novartis Oncology, East Hanover, NJ; University of Sheffield, Sheffield, United Kingdom

Introduction: Recent clinical trials suggest potential anticancer activity for bisphosphonates combined with adjuvant endocrine therapy in patients with hormone receptor-positive (HR+) early breast cancer (EBC). Data from the interim analysis of AZURE suggest that the benefits of adding zoledronic acid (ZOL) may be greatest in patients with low estrogen levels (Coleman RE, et al. SABCS 2010). In ZO-FAST, we have previously demonstrated that adding ZOL to adjuvant therapy significantly improved bone mineral density (BMD) and prolonged disease-free survival (DFS) vs delayed ZOL (de Boer R, et al. SABCS 2010). We report here the effect of time since menopause at breast cancer diagnosis (ie, baseline menopausal status) on DFS benefits with ZOL.

Methods: Postmenopausal women with HR+ EBC receiving letrozole (LET; 2.5 mg qd × 5 yr) with a BMD T-score ≥-2 (N=1065) were randomized to ZOL (4 mg q6mo): immediate (IMZOL) or delayed (DZOL); initiated for postbaseline T-score <-2 or nontraumatic/asymptomatic fracture). Patients were followed for disease recurrence and overall survival (OS) for 5 years. Patients were eligible for the study if they had established menopause at the time of diagnosis, or if they became menopausal because of chemotheraphy or ovarian suppression (ie, recently postmenopausal). The effect of baseline menopausal status on DFS was examined in Cox regression analyses. Results: At 60 months’ follow-up in the overall population (N=1065), IMZOL significantly reduced the risk of a DFS event by 34% vs DZOL (hazard ratio [HR]=0.66; 95% confidence interval [CI], 0.44-0.97; P=0.034). In exploratory analyses of women who were postmenopausal for >5 years or >60 years old at study entry (n=670), IMZOL improved DFS (HR=0.63; 95% CI, 0.39-1.01; P=0.052) and significantly prolonged OS (HR=0.50; 95% CI, 0.27-0.92; P=0.022) vs DZOL. Additional subgroup analyses including patterns of breast cancer recurrence will be presented. During 5 years of treatment, osteonecrosis of the jaw (ONJ) was reported in 4/669 patients (0.6%) who received ZOL, and there was no increase in renal adverse events (AEs) in the ZOL-treated patients. Overall, AEs were consistent with the known safety profiles of both study drugs.

Conclusions: Long-term follow-up in ZO-FAST confirms the overall survival benefits of adding ZOL (4 mg q6mo) to adjuvant LET therapy for EBC. However, subset analyses suggest that women with established postmenopausal status may benefit from ZOL therapy more than others. These results are consistent with observations in the AZURE trial, and support potentially greater ZOL benefits in a low-estrogen environment. Additional studies are needed to fully define the patient populations most likely to benefit from adjuvant ZOL in this setting.

S1-4
Retrospective Analysis of Study EGF30008 by Mass-Spectrometry Based Serum Assay (VeriStrat®).

Roder J, Roder H, Hunsucker S, Grigorieva J, Ellis C, Florance A, Gagnon R, O’Rourke L, Johnston S, Biodesix Inc., Aurora, CO; GlaxoSmithKline, Collegeville, PA; Royal Marsden Hospital, London, United Kingdom

Background: In EGF30008 the addition of lapatinib (La) to first-line treatment with letrozole (Le) significantly improved progression-free survival (PFS) in patients (pts) with hormone receptor positive (HR+), HER2 positive (HER2+) metastatic breast cancer (hazard ratio (HR) = 0.71; P=0.019), but not in HR+, HER2 negative (HER2-) pts. This study assessed the ability of VeriStrat (VS), a mass-spectrometry blood-based pretreatment assay correlating with clinical outcome from EGFR-TKI therapy, to stratify pt outcome in EGF30008. The VS assay assigns VS Good (Good), VS Poor (Poor), or Indeterminate labels to a serum sample based on a specific 8-peak signature in the mass-spectra (Taguchi F et al., JNCI 2007).

Methods: Blinded to clinical data, pretreatment serum was analyzed using standard VS procedure. Statistical analyses were performed using Mantel-Haenszel and Cox proportional hazards methods; correlations were evaluated using Fisher’s exact and χ² tests.

Results: Of the 1286 pts randomized (HER2+=219; HER2-=952; HER2 unknown=115), 1163 pts had serum available; a VS label was assigned to 1046 pts (961 Good; 80 Poor; 5 Indeterminate); 117 were not evaluable (hemolyzed). In the overall population there was no significant difference in PFS between Good and Poor groups within the Le+La arm (p=0.53). In contrast, PFS of the Good group was longer than that of the Poor group within the Le only arm (HR=0.36, p<0.001) and comparable with that of Good pts within the Le+La arm (median PFS 10.8 mo vs 11.0 mo). An interaction test showed significantly different HRs for PFS in Good vs Poor between treatment arms (p=0.002).

In the HER2+ population both Good (n=169) and Poor (n=13) groups received significant PFS benefit from addition of La to Le: in Good HR=0.71, p=0.046, medians 3.0 mo (Le) vs 8.0 mo (Le+La); in Poor HR=0.17, p=0.02, medians 2.3 mo (Le) vs 8.6 mo (Le+La). In the HER2- population median PFS for the Poor group (n=58) increased from 3.1 to 11.0 mo (HR=0.57, p=0.068) with addition of La to Le, whereas the Good group (n=702) received no significant benefit, median 13.6 mo on Le and 13.8 mo on Le+La (PFS HR=0.85, p=0.09).

In multivariate analysis VS remained independently significant and predictive of differential treatment effect in the overall population. No significant correlation of VS classification with HER2 status (p=0.35) or prior adjuvant hormonal therapy (p=0.33) was found. VeriStrat was also not significantly correlated with baseline HER2 ECD levels (low <15 ng/ml vs. high ≥15 ng/ml, p=0.23, or ER expression (H-score:lower quartile:<160 vs. rest), p=0.18.

Conclusions: In the overall population VeriStrat predicted PFS in Le alone but not in the Le+La combination, with a significant differential treatment effect. VeriStrat identified a subset of pts with inferior PFS on Le therapy. Adding La to Le improved outcome in HER2+ pts, and interestingly suggested an improvement in the VS Poor subset of HER2- pts. HER2- VS Good pts do not gain benefit with the addition of La. No correlation between VS and investigated predictors of benefit from the addition of La to Le in HER2- pts was observed. If these results can be validated in a prospective study, the addition of La to Le may be a potential treatment option for HER2- HR+ VS poor pts.
**S1-5**

Modulation of Cancer and Stem Cell Biomarkers by the Notch Inhibitor MK-0752 Added to Endocrine Therapy for Early Stage ER+ Breast Cancer.

Albain KS, Czerlanius C, Zlobin A, Covington KR, Rajan P, Godellas C, Bova D, Lo SS, Robinson P, Sarker S, Gaynor ER, Cooper R, Aranha G, Czaplicki K, Busby B, Rizzo P, Demuth T, Stiff P, Fuqua SAW, Miele L. Loyola University Chicago Cardinal Bernardin Cancer Center; Maywood, IL.; Baylor Breast Center, Houston, TX; Merck Oncology, North Wales, PA; University of Mississippi Cancer Institute, Jackson, MS

**Background:** New strategies to enhance endocrine therapy (ET) efficacy and/or overcome resistance by targeting key survival pathways are needed. Preclinical data indicate that unwanted effects of ET include reactivation of the Notch pathway, critical for breast tumor initiating (stem) cells. Notch inhibition with gamma secretase inhibitors (GSI) enhances tamoxifen (tam) efficacy in xenografts, but impact of GSI+ET in human breast cancer (BC) is unknown. Our objective was to add short exposure of the GSI MK-0752 to ongoing tam or letrozole (let) in the presurgical window to assess feasibility, safety and biomarker/pathway impact in a 20-patient (pt) pilot study (ClinTrials.gov NCT00756717). We previously evaluated several biomarkers in the first cohort, which showed promise with Notch and proliferation inhibition. We present new results adding the final cohort, plus additional biomarkers and microarray analyses.

**Methods:** Pts with early stage ER+ BC received 25 days (d) of ET. MK-0752 was added d15 (350 mg PO 3d on, 4d off, 3d on) with definitive surgery d25. Core biopsies were done at baseline, d14 and d25, with qRT-PCR for Notch-related and other genes critical to stem cell renewal/proliferation. Gene expression levels after GSI (d25) vs ET alone (d14) were analyzed and d25 changes in all pts combined for each gene were compared. Microarray expression estimates and modeling were performed using dChip and Red-R, generating gene-wise comparisons using Limma. Probes were defined as significantly regulated by paired t tests if p ≤ 0.001 for the comparisons of baseline to tam/let and tam/let to tam/let+GSI. Data were exploratory so all probe data were included in the modeling, and no corrections for multiple comparisons were used. Differentially expressed genes were submitted to DAVID for pathway analysis.

**Results:** Of 22 pts accrued, 20 (11 tam, 9 let) were evaluable, meeting accrual goals (2 withdrew before MK-0752); 19 completed therapy to date. Toxicity was minimal. Significant (p<.05) changes in mRNA levels after GSI+ET vs ET in 17 pts (3 in progress) were down-regulation of Notch4 in 13; Ki67, 13; Notch1, 12; RUNX1 (stem cell transcription factor), 13; ADAM19 (disintegrin/metalloproteinase), 12; MMP7 (Wnt target), 11; CCND1 (cyclin D1), 10; and up-regulation of NOXA (pro-apoptotic BH3-only gene), 13. Microarray analyses (10 completed, remainder underway) defined as significantly regulated by paired t tests if p ≤ 0.001 for the comparisons of baseline to tam/let and tam/let to tam/let+GSI. Data were exploratory so all probe data were included in the modeling, and no corrections for multiple comparisons were used. Differentially expressed genes were submitted to DAVID for pathway analysis.

**Conclusions:** Short exposure of MK-0752 added to ET was feasible, well tolerated, and resulted in significant biomarker response in all tumors. MK-0752 favorably modulated proliferation, apoptosis, stem cell and metastasis-related targets, and impacted critical cancer pathways. This suggests potential roles for MK-0752 in optimizing endocrine therapy and overcoming endocrine resistance.

---

**S1-6**

Characterization of Breast Cancer Distant Metastasis Based on Outcome over Time Using a Gene Expression Profiling Approach and Identification of Pathway Activities of Late Relapse.

**Background**

Previous reports have described the use of microarrays to assess the molecular classification of human breast cancers and defined new subgroups based on gene expression that are relevant to patient management through their ability to predict metastatic relapse and survival relapse. However, different mechanisms may be associated with the development of early and late distant metastases. With the hypothesis that tumors may lead to early or distant metastases based on their intrinsic biological initial features, we aimed at defining molecular profiles for several subgroups of patients based on their outcome over time.

**Material and methods**

Breast primary tumors were selected from retrospective series of patients with frozen material available. These series include patients of all ages, LN- and LN+; Estrogen or Progesteron-receptor positive, Her2-negative, no adjuvant treatment, with a follow-up of more than 10 years (y) for the control group or distant metastatic relapse as first event (DM) for the study group (n=144). Patients tumors were classified in 4 groups: no relapse at 10 y (M0), DM before 3 y (M0-3, n=30), DM between 3 and 7 y (M3-7), DM after 7 y (M7+). Samples were collected in 2 different institutions (NKI series for identifying the signature and IGR series for validation).

Gene expression analysis of breast tumor samples was performed using custom-made Agilent 44K high-density microarrays and hybridized against the MammaPrint® reference pool (MRP). Tumors were also assessed for their MammaPrint® status, wound-healing signature status and their intrinsic subtypes based on the Blueprint® signature. Moreover, we identified the pathway-level activities of the patient groups using PARADIGM.

**Results and Discussion**

For the NKI series, A subset of 144 samples was included based on the selection criteria: 57 M0, 31 M0-3, 25 M3-7, 31 M7+. None of the 3 previously mentioned signatures correctly identified M0 vs. M7+ patients. In order to identify a predictive signature of late relapse (after 7y) we considered M0 and M7+ MammaPrint-Low Risk patients and we split them in a training (n=41) and in a test (n=23) sets. A 73-gene signature was able to classify M7+ patients with 75% of sensitivity and 66% of specificity on the test set. DM after 7yr showed significant activation of pathway related to inflammatory response and angiogenesis. Detailed results and validation results on the independent IGR series will be presented at the meeting.
S1-7
Molecular Tumor Characteristics Influence Adjuvant Endocrine Treatment Outcome.
Bianchini G, Pusztai L, Iwamoto T, Kelly CM, Zambetti M, Fasolo A, Del Conte G, Santarpia L, Symmans WF, Gianni L. San Raffaele Cancer Center, Milan, Italy; University of Texas, MD Anderson Cancer Center, Houston; Mater Misericordiae University Hospital, Dublin, Ireland; Hospital of Prato and Istituto Toscana Tumori, Prato, Italy.

Background
Used upfront or after 2 to 3 years (yrs) of tamoxifen (TAM) or as extended treatment after 5 yrs of TAM, aromatase inhibitors (AIs) are associated with less recurrences than with 5 yrs of TAM. However, up front AIs were not superior to TAM→AI sequence in node negative (N-) tumors (TEAM study, SABCS 2009; BIG1-98 trial, NEJM 2009). The observation is consistent with the hypothesis that early relapses may be more frequently due to intrinsic endocrine resistance irrespective of the use of TAM or AIs whereas late relapses depend on acquired resistance.

Methods
Affymetrix HGU133A-based gene expression profiles from two adjuvant datasets (n=556) of patients treated with 5 yrs TAM were evaluated and included 285 N-, 247 N+ and 24 Nx estrogen receptor-positive cases. A proliferation score based on the expression of 12 mitotic kinases (MKS) (Bianchini, Cancer Res 2010) and a 4-gene estrogen-related score (ERS) adopted from the Oncotype DX Recurrence Score were assessed. Median cut-off points were used for both biomarkers. Pattern of relapse according to marker status were evaluated in three distinct time cohorts (0-2.5 yrs, 2.5-5 yrs, 5-10 yrs). Outcome was assessed according to distant relapse rates.

Results
A violation of the proportional hazards assumption was found for both scores indicating time-dependent effects. The table shows distant relapse rates according to biomarker group within each time cohort.

Among low proliferation tumors (lowMKS), the highERS group had low and steadily increasing recurrence rates, while the lowERS group showed a higher risk of relapse that increased continuously over the time. Among the highly proliferative tumors (highMKS), the high endocrine-sensitive group (highERS) had a lower risk of relapse within the 0-2.5 yrs compared to lowERS cancers. The difference is not persisting at the longer follow up of 2.5-5 yrs, and at 5-10 yrs the highERS group has higher risk of relapse. The pattern of relapse was similar for N- and N+ cancers. However, in the 0-2.5 yrs interval all recurrences occurred in the highMKS/lowERS among N- cancers, while only 57% of recurrences did occur in N+ cases in the same biomarkers group (p=0.012).

Discussion
Highly proliferative, high endocrine-sensitive (highERS) cancers are at the greatest risk of late relapse and extended endocrine therapy beyond 5 yrs may be useful. Low proliferation, low ERS cancers also remain at substantial risk for late recurrences. Between 0 to 2.5 yrs all recurrences in N- tumors and close to 60% in N+ were in high proliferative/low endocrine-sensitive tumors. This difference could explain the beneficial trend for up-front AIs vs. sequential TAM→AIs in the N+, but not in N- subgroups of the TEAM and BIG1-98 trials. It also is consistent with the hypothesis that the highly proliferative low ERS group includes tumors intrinsically resistant to both AIs and TAM. Risk stratification by these two simple metrics may improve the readout of future adjuvant clinical trials with endocrine drugs, and may influence their design.

S1-8
Molecular Signaling Distinguishes Early ER Positive Breast Cancer Recurrences Despite Adjuvant Tamoxifen.

Background: Unlike recurrences with other therapies, ER+ breast cancers (BC) can recur ≥10 yrs after an apparent successful period of adjuvant endocrine therapy. The molecular basis for this pattern of resistance is unresolved. We addressed the hypothesis that early recurrences during tamoxifen (TAM) treatment exhibit different biological characteristics than those that recur years later by assessing for variation in their respective transcriptionomes.

Methods: Appropriate tumors were identified from a set (BC030280) of snap-frozen tumor biopsies collected in Edinburgh from subjects with stage I-III BC before starting TAM (no chemotherapy); all had ≥10 yrs follow-up. Using rigorous standard operating procedures, high quality total RNA was extracted from samples with ≥50% malignant epithelium and arrayed on Affymetrix U133 Plus 2.0 GeneChips. Raw data were normalized using PLIER and analyzed with an adapted validated training and internal cross-validation workflow to avoid gene selection bias. A published dataset (Loi) was used for independent classifier validation that best fit our criteria for sample size, treatment (TAM only), data quality, and recurrence distribution. Early (E) vs late (L) recurrences were defined as distant relapse ≤3 vs ≥10 yrs from diagnosis. To explore putative mechanistic associations driving the transcriptome differences, a novel computational procedure was developed to integrate gene expression data with protein-protein interaction (PPI) data and create a statistical network model of the signaling. Metropolis sampling, a Markov Chain Monte Carlo method that can be implemented as a modified random walk procedure, identified ER network topology represented by the genes (nodes) and their predicted interconnections (edges).

Results: A support vector machine with recursive feature elimination was used for the binary classification tasks on the BC030280 dataset. The optimized classifier for E vs L recurrence was independently validated on the Loi dataset with high levels of accuracy, specificity, and sensitivity.

Classifier validation is supported by the respective survival curves (not shown). Gene set enrichment analysis reveals the top PPIs are primarily related to apoptosis (23/50; p=2.9e-13) and proliferation (14/50; p=6.8e-5). Substantial overlap of the network features and topology was seen between datasets. Specifically, increased relative expression of ESR1, ESR2, EGFR, BCL2, and AR was seen in L vs E recurrent tumors, and increased expression of CALM1, CALM2, SRC, CDK1, and MAPK1 was seen in E vs L recurrent tumors. Several hubs (nodes with ≥5 edges) independently predicted for recurrence in additional public datasets of ER+ BC.

Discussion: Our work provides clear evidence that robust molecular differences exist between ER+ BC that recur early vs. much later despite adjuvant TAM. Exploiting these differences will improve...
our understanding of involved signaling pathways, allow for the reliable prediction of early treatment failure, and guide use of novel therapeutics specifically directed at preventing E vs L recurrences on endocrine therapy.

S2-1
Partial Breast Brachytherapy Is Associated with Inferior Effectiveness and Increased Toxicity Compared with Whole Breast Irradiation in Older Patients.

Smith GL, Xu Y, Buchholz TA, Giordano SH, Smith BD. University of Texas M.D. Anderson Cancer Center, Houston, TX

Background: Accelerated partial breast brachytherapy (APBI-brachy) is an increasingly popular radiation treatment for older patients diagnosed with early stage breast cancer. Despite growing utilization, there is a lack of population-based cohort studies as well as randomized phase III data to compare its effectiveness and toxicity profile with standard whole breast irradiation (WBI). The purpose of this study was to provide the first nationally comprehensive comparison of effectiveness and toxicity outcomes in older Medicare patients treated with APBI-brachy versus WBI.

Methods: Medicare billing claims identified beneficiaries age ≥66 with incident invasive breast cancers diagnosed between 2000 and 2007 and treated with conservative surgery followed by APBI-brachy alone versus WBI. Cumulative incidence of subsequent mastectomy (a validated surrogate for local failure) was compared between the two treatment groups using the log-rank test. Adjusted risk of subsequent mastectomy was determined using a multivariate Cox proportional hazards model including demographic, socioeconomic, and clinical covariates. Risks of acute complications (hospitalization or infection within 120 days of radiation), were compared using the chi-square test. Adjusted odds of acute complications were determined using multivariate logistic models including covariates. Cumulative incidences of long-term toxicities (rib fracture, fat necrosis, breast pain, and pneumonitis) were compared using the log-rank test.

Results: In 130,535 women, use of APBI-brachy increased over time from <1% of patients treated in 2000 to 13% of patients in 2007 (P<0.001 for trend). Patients treated with APBI-brachy were less likely to have axillary lymph node involvement or to have received chemotherapy, and were more likely to be older, White, and have comorbid illness. At 5 years, the cumulative incidence of subsequent mastectomy was significantly higher in patients treated with APBI-brachy (4.0% in APBI-brachy vs. 2.2% in WBI, P<0.001). On multivariate analysis, there was a two-fold increased risk for subsequent mastectomy in patients treated with APBI-brachy (HR= 2.14; 95% CI 1.83-2.52, P<0.001). APBI-brachy was also associated with more acute complications, including a higher risk of hospitalization (9.6% vs. 5.7%; P<0.001) (Adjusted OR= 1.71; 1.58-1.86); and infection (8.1% vs. 4.5%; P<0.001) (Adjusted OR= 1.85; 1.69-2.02; P<0.001). APBI-brachy was also associated with higher 5-year cumulative incidence of rib fracture (4.2% vs. 3.6% in WBI), fat necrosis (9.1% vs. 3.7%), and breast pain (14.9% vs. 11.7%) (P<0.001 for all comparisons), but a lower incidence of pneumonitis (0.1% vs. 0.8%, P<0.001).

Discussion: APBI-brachy was associated with inferior effectiveness as well as increased acute and late toxicities compared with WBI in this cohort of older breast cancer patients. These data underscore the importance of awaiting mature results of randomized trials designed to prospectively compare these treatments before employing widespread adoption of APBI-brachy as an alternative to WBI in select patients.

S2-2
Luminal A Subtype Predicts Radiation Response in Patients with T1N0 Breast Cancer Enrolled in a Randomized Trial of Tamoxifen with or without Breast Radiation.

Fyles A, McCready D, Pintilie M, Shi W, Done S, Miller N, Olivotto I, Weir L, Liu F-F. Princess Margaret Hospital, Toronto, Canada; British Columbia Cancer Agency, Vancouver, Canada

Objectives
To determine the predictive effect of molecular subtyping using the six biomarker immunohistochemical panel in predicting ipsilateral breast relapse (IBR) in women age 50 and older with T1 and T2 node negative breast cancer in a randomized trial of tamoxifen (Tam) +/- whole breast radiation (WBRT).

Methods
Between December 1992 and June 2000, 769 women were randomized to WBRT and Tamoxifen (Tam, n=386) 20 mg daily for 5 years or Tam alone (n=383). Median age was 68 years, 639 (83%) had pT1 tumors. Intrinsic molecular subtype was determined using semi-quantitative analysis of ER, PR, Ki-67, HER2, EGFR and cytokeratin (CK) 5/6 on tissue microarrays constructed from tumor blocks from 172 of 345 available tumors. Patients were classified into the following categories: luminal A, luminal B, luminal-HER2, HER2 enriched, basal-like, or triple-negative phenotype-nonbasal. Median follow-up was 10 years.

Results
IBR at 10 years was 13.8% with Tam compared to 5.0% with Tam/ WBRT (p<0.0001). Tumour size (HR 1.54, p=0.001), ER positive (HR 0.35, p=0.006), age (HR 0.96, p=0.014), and treatment with Tam/WBRT (HR 0.28, p=0.0001) were significant factors for IBR. Luminal A tumors (ER or PR positive, HER2 negative, Ki-67<14%, n=95) had the lowest rate of IBR, 6.9% at 10 years with Tam alone and 4.5% with Tam/WBRT, p=0.4. In women aged 60 and over with Luminal A subtype IBR was 5.4% with Tam alone and 6% with Tam/ WBRT (n=74, p=0.8). Luminal B (ER or PR positive, HER2 negative, Ki67>14%, n=53) had an IBR of 23.8% with Tam alone and 0% with Tam/WBRT, p=0.012). Luminal HER2 (ER or PR positive, HER2 positive, n=10) and HER2-enriched (ER and PR negative, HER2 positive, n=14) demonstrated the highest risk of IBR.

Conclusions
Six marker IHC subtype appears to be predictive for radiation response in women over 50 with T1/2 node-negative breast cancer. Luminal A subtype demonstrated a low risk of breast relapse with Tam alone, particularly in women age 60 and older. These results require validation in additional specimens and clinical trials, but this subgroup represents a significant proportion of women (74/172 or 43%), who may be spared the inconvenience and side effects of breast radiation. In contrast, breast RT is beneficial in women with higher risk subtypes (Luminal B, HER2 enriched, basal). Limitations of this analysis include the relatively small numbers of patients and the low event rate in smaller subgroups.
S2-3
NSABP Protocol B-34: A Clinical Trial Comparing Adjuvant Clodronate vs. Placebo in Early Stage Breast Cancer Patients Receiving Systemic Chemotherapy and/or Tamoxifen or No Therapy – Final Analysis.

Paterson AHG, Anderson SJ, Lembersky BC, Feenbacher L, Falkson CI, King KM, Weir LM, Brufy AM, Dakhil S, Lad T, Baer-Diaz L, Gralow JR, Robidoux A, Perez EA, Zheng P, Geyer CE, Swain SM, Costantino JP, Mamounas EP, Wolmark N. National Surgical Adjuvant Breast and Bowel Project (NSABP); Tom Baker Cancer Centre; University of Pittsburgh Graduate School of Public Health; University of Pittsburgh Cancer Institute School of Medicine; Kaiser Permanente, Northern California; University of Alabama at Birmingham/ECOG; Cross Cancer Institute; British Columbia Cancer Agency: University of Pittsburg/Magee Women’s Hospital; Cancer Center of Kansas; Stroger Hospital Cook County MBCCOP; San Juan MBCCOP; University of Washington/SWOG; Centre Hospitalier de l’Université de Montréal; Mayo Clinic Jacksonville/NCCTG; Allegheny General Hospital; Washington Cancer Institute, Washington Hospital Center; Aultman Health Foundation

Bisphosphonates reduce the incidence of skeletal-related events (fractures, pain, hypercalcemia) in patients (pts) with bone metastases from breast cancer. By inhibiting osteoclast function and subsequent bone turnover they may inhibit the growth of bone (and other) metastases. Their role in preventing or delaying the development of bone (or other) metastases in pts with early breast cancer is uncertain.

Three previous trials of oral clodronate have given mixed results. The largest trial (placebo-controlled) and a smaller open-label trial suggested that oral clodronate benefitted pts with improved bone metastases-free survival (BMFS) and overall survival (OS), but a third open-label study showed no benefit with an apparent detrimental effect on survival. Studies of IV zoledronate in open-label trials in early breast cancer have also shown mixed results: the AZURE trial in pts with node positive breast cancer showed no benefit in disease-free survival (DFS) or OS with a possible effect in pts aged over 60. The ABCSG-12 trial in GnRH (plus tamoxifen or anastrozole) treated women with early breast cancer showed a small DFS benefit for those receiving IV zoledronate but no BMFS or OS benefit.

Methods: B-34 is a prospective, randomized, double-blind, phase III clinical trial in pts with stage 1, 2 or 3 breast cancer assessing oral clodronate 1600mg daily for 3 years compared to placebo given alone or in addition to adjuvant chemo- or hormone therapy. Stratification is by age (<50, >50), number of positive nodes (0, 1-3, >3) and ER/PR status. The primary end-point is DFS. Secondary endpoints are the incidence of skeletal metastases, OS, relapse-free survival, incidence of non-skeletal metastases, and incidence of skeletal morbid events.

Results: 3323 patients were accrued – 1662 in Group A and 1661 in Group B. As of March 31, 2011, 54 pts were declared ineligible: 23 in Group A and 31 in Group B. The average time on study is 101.3 months. Patient characteristics were evenly distributed throughout both groups. Approximately 75% of pts in each group had negative axillary lymph nodes and some 78% in each group were ER and/or PR positive. About 64% of pts were age 50 or over. Oral clodronate was generally tolerable, toxicities observed being mainly due to the concomitant systemic chemotherapy. One pt in Group A had a 1 mm area of osteonecrosis on the palatal tarsus. Compliance, as expected with trials of oral medications, has been a problem. 1910 pts completed 3 years of therapy. Event rates were slower than anticipated. This final analysis assesses a total of 598 events in the two arms.

Conclusions: This trial is the largest placebo-controlled study of an oral bisphosphonate in patients with early breast cancer and will provide further information on the role of bisphosphonates in breast cancer management. Supported by NSABP by NCI U10CA12027, -37377, 69651, 69974; and Bayer Schering Pharma Oy; for ECOG by U10CA021115; for NCCTG by U10CA25224; for SWOG by U10CA38926.

S2-4
GAIN (German Adjuvant Intergroup Node Positive) Study: A Phase-III Multicenter Trial To Compare Dose Dense, Dose Intense ETC (iddETC) vs. EC-TX and Ibandronate vs. Observation in Patients with Node-Positive Primary Breast Cancer – 1st Interim EFFICACY Analysis.

Background: We previously showed that intense dose-dense (idd) epirubicin (E), paclitaxel (T), cyclophosphamide (C) results in a superior DFS and OS compared to conventionally dosed EC-T in pts with primary breast cancer (PBC) and ≥4 involved lymph nodes (LN) (Möbus et al JCO 2010). In the GAIN study, the intense dose-dense strategy has been further investigated as well as the adjuvant application of ibandronate (I). We here report on the planned interim efficacy analysis after 50% (N>401) of the required events have occurred.

Methods: A prospective, multi-center, controlled, non-blinded, randomized phase III trial investigating ETC (E: 150 mg/m², T: 225 mg/m², C: 2500–2000 mg/m², i.v. day 1; 15 cycles each: A1; or EC→TX (E: 112.5 mg/m² + C: 600 mg/m², i.v. day 1, q 4 weeks × 12 cycles; A2). Pts were further randomized in a 2:1 ratio to receive ibandronate: 50 mg/day p.o. for 2 years (B1) or observation (B2). Pts received a primary prophylaxis with either epeoitin (I) or darbinofos (D) and pegilaglumin (L). For recruitment of 1500 pts prophylactic ciprofloxacin was implemented and the dose of C was reduced to 2000 mg/m². Eligibility: Females ≥18 and <65 years, histologically confirmed LN positive uni- or bilateral PBC; adequate surgery, ≥1 pos.LN; ECOG ≤2; written informed consent.

Primary objective: compare DFS A1 vs. A2 and B1 vs. B2. Secondary objectives: OS, safety, incidence of secondary primaries, and EFS in subgroups of hormone sensitivity and number of pos. LN between arms; assessment of compliance; determine prognostic factors. 3000 pts with 801 events were needed to show an increase of 5-year DFS from 75% to 79% for pts receiving EC→TX and 728 events to show an increase of 5-year DFS from 75% to 79.5% for pts receiving l, assuming a drop-out rate of 5%, α=0.05 (two-sided) and 1-ß =80%.
An interim analysis for both primary objectives was planned after 50% of the expected events occurred. Safety results have been reported previously (Möbus et al. SABCS 2009).

**Results:** 3023 patients were randomized between 06/2004 and 08/2008. 1512 received ETC and 1511 EC→TX. 29pts never started therapy, 14 in ETC, 15 in EC→TX. Median follow-up is 38.7 months. Median age was 50 years; pN1 (37.7%), pN2 (35.4%); pN3 (26.7%); 77.4% had ductal invasive carcinoma, 46.6% were grade 3; 76.7% had hormone receptor-positive tumors, 22% were HER2-positive. 405 events have occurred by 12.05.2011. 380pts relapsed and 25pts died w/o relapse. The interim futility boundary for chemotherapy was not crossed. For the ibandronate question the futility boundary was reached. There was no difference in DFS and OS between the patients with and without ibandronate (DFS log-rank p=0.593; HR 1.059; 95%CI 0.861-1.301; OS log-rank p=0.801 HR 0.961; 95%CI 0.705-1.31).

**Conclusion:** The GAIN study demonstrated that adjuvant ibandronate does neither improve DFS nor OS in primary node positive breast cancer after treatment with dose-intensified chemotherapy.

**S2-5**

**An Anti-HER3 Antibody That Stabilizes the Inactive Conformation Inhibits Both HER2 and Ligand Driven Tumor Growth.**

Garner AP, Bialucha CU, Chen D, Elif W, Kunz C, Li S, Martic J, Saxena P, Sineschekova O, Sprague E, Ettenberg S. Novartis Institutes for Biomedical Research, Cambridge, MA; Morphosys AG, Munich, Germany; Sanofi-Aventis, Cambridge, MA

Background: HER3 (ErbB3) is a member of the ErbB family of receptor tyrosine kinases (RTK). In normal physiology, ligands (e.g. neuregulin) activate HER3 by promoting dimerization with other RTK's such as HER2 (ErbB2). Inappropriate HER2/HER3 dimerization as a result of HER2 over-expression in cancer results in HER3 mediated activation of the oncogenic PI3K pathway. The HER2-targeted antibody trastuzumab inefficiently inhibits HER2 mediated HER3 activation allowing persistent HER3 signaling that is speculated to limit clinical responses. Consequently, combination of a HER3-targeted agent with trastuzumab may be of clinical benefit. Furthermore, ectopic HER3 activation has recently been implicated in the relief of a feedback loop induced by PI3K inhibitors that may perhaps limit their efficacy in HER2 driven tumors. Since HER3 activation in HER2 driven cancers occurs in a ligand-independent manner, antibodies that primarily inhibit ligand-induced HER3 activation are largely inactive in HER2 driven xenograft models.

Results: H3F15, a high affinity (26pM) HER3-targeted fully human IgG1 antibody was selected from the Human Combinatorial Antibody Library (HuCAL) using phage display technology. In a broad range of HER2 amplified breast and gastric cell lines, H3F15 displayed potent inhibition (IC50 <1nM) of HER3/ AKT phosphorylation and proliferation. Interestingly, H3F15 also effectively inhibited neuregulin stimulated HER3 phosphorylation and downstream signaling in MCF7 cells indicating that H3F15 inhibits multiple modes of HER3 activation. Determining the H3F15/HER3 crystal structure revealed that H3F15 binds a novel conformational epitope that traps HER3 in the inactive conformation thus preventing its activation by either HER2 or neuregulin. In vivo testing of H3F15 using xenograft tumor models driven by either HER2 (BT474) or HER3 ligands (BxPC3) confirmed that single agent H3F15 (20mg/kg) significantly inhibited tumor growth (83% and 77% inhibition respectively). Furthermore, combinations of H3F15 with either trastuzumab or PI3K-targeted agents were synergistic in a panel of HER2 driven cell lines whilst the in vivo combination of H3F15 (20mg/kg) with trastuzumab (1mg/kg) was sufficient to induce tumor regression.

Discussion: H3F15 is a HER3-targeted antagonist IgG1 that stabilizes the inactive form of HER3. This novel mechanism of action enables H3F15 to uniquely inhibit both ligand-induced and HER2-mediated activation of HER3. Thus H3F15 is the first HER3 antibody to display single-agent efficacy in both HER2 and ligand driven xenograft models whilst also inducing tumor regressions in combination with trastuzumab. Based on preclinical data, combining H3F15 with either trastuzumab or PI3K-targeted agents fully inhibits the HER2/HER3 signaling pathway, which may lead to greater and more sustained clinical efficacy in HER2 driven cancers.

**S2-6**

**ErbB3 Expression Is Required for Maintenance of Normal and Transformed Luminal Breast Epithelial Cells.**

Cook RS, Balko JM, Rinehart C, Miller TW, Polyak K, Prat A, Perou CM, Arteaga CL. Vanderbilt University; UNC Lineberger Comprehensive Cancer Center; Dana Farber Cancer Institute

The ErbB receptor tyrosine kinase family regulates breast development and cancer. ErbB2/HER2 expression correlates with HER2-enriched breast cancers, while epidermal growth factor receptor (EGFR) expression often correlates with triple negative breast cancers. Less is known regarding ErbB3, which harbors only weak kinase activity, but strongly activates phosphatidylinositol-3 kinase (PI3K)/Akt signaling upon heterodimerization with EGFR or ErbB2. We report herein that ERBB3 mRNA expression strongly correlates with Luminal A/B breast cancers, which express lower levels of EGFR and ErbB2. Mammary-specific loss of ErbB3 in mice reduced Akt phosphorylation and caused cell death in the luminal epithelium. A decreased luminal population in ErbB3-deficient epithelium correlated with expansion of the mammary stem/progenitor fraction. In normal breast samples, ERBB3 mRNA expression was highest in mature/progenitor luminal populations, and lowest in the stem/basal population. Loss of ErbB3 shifted gene expression in mammary epithelial cells to resemble a mammary stem cell signature. The genes most greatly impacted by ErbB3 loss produced a signature that correlated with decreased overall survival in tamoxifen-treated patients. Knock-down of ErbB3 in human luminal breast cancer cells caused decreased cell growth under conditions of estrogen deprivation, decreased expression of the gene encoding aromatase, and impaired expression of estrogen receptor-induced genes, including those that encode progesterone receptor and TFF1. Treatment of MCF7 luminal breast cancer xenografts with AMG-888, a humanized monoclonal antibody directed against ErbB3, decreased tumor growth. Combination of AMG-888 with the estrogen receptor inhibitor fulvestrant caused MCF7 tumor regression. Taken together, these results suggest that ErbB3 is required to sustain normal and transformed luminal epithelial cells of the breast, and suggest that targeting ErbB3 may improve the clinical outcome of breast cancers treated with endocrine therapy.
S2-7
Mechanisms of Action and Biological Significance of HER2 Mutations in HER2-Overexpressing Breast Cancer.

Boulbes DR, Jin Q, Arold ST, Ladbury JE, Yu D, Esteva FJ. University of Texas - MD Anderson Cancer Center, Houston, TX

Background: Trastuzumab is the most successful HER2-directed therapy in patients with early-stage and advanced HER2 positive breast cancer. Although trastuzumab improves survival in the adjuvant setting, 15-20% of the patients develop metastasis. Lapatinib is currently the only tyrosine kinase inhibitor approved for the treatment of patients with metastatic breast cancer after trastuzumab progression. However, progression eventually occurs and the disease remains incurable for the majority of patients. Recently, somatic mutations in the HER2 kinase domain have been reported in lung adenocarcinomas which result in constitutive phosphorylation of HER2, EGFR and cellular substrates. Activation of these receptors and pathways in lung cancer was associated with tumor progression and trastuzumab resistance, but tumors remained sensitive to a tyrosine kinase inhibitor. Because there are many different types of breast cancer that respond differently to treatments, more approaches are needed to predict which patients will most likely respond to a given therapy.

Material and Methods: Using gene sequencing on 78 HER2 positive breast tumors, our laboratory identified 4 novel missense variants in the kinase domain of HER2. None of the patients whose tumors carried one of these mutations achieved objective response to trastuzumab. Mutants were created using directed mutagenesis, inserted in a lentiviral expression plasmid and stably expressed in different breast cancer or non-tumorigenic cell lines. An ATP-based assay was used for cell survival studies. Migration studies were performed using Boyden-chambers coated with Matrigel. Anchorage-independent colony formation was assessed in soft-agar. Signaling pathways and phosphorylation status were analyzed by Western blot. Localization results were obtained by immunofluorescence and confocal microscopy followed by deconvolution analysis.

Results: Two of the mutants were dramatically under-phosphorylated and presented an altered cellular localization revealed by immunofluorescence studies in both cell lines and patient surgical samples. Also, cells expressing HER2 mutants showed an increased ability to invade Matrigel and migrate and to form colonies in soft-agar, suggesting the induction of a more aggressive behavior. In particular, one of the mutations was strongly associated with resistance to lapatinib treatment in cell survival and soft-agar assays, and higher doses of lapatinib were necessary to inhibit the ERK and AKT pathways. Computational analysis revealed that the mechanism of lapatinib resistance could be explained by a sterical obstruction of the ATP-binding pocket of the protein kinase domain that would impede the binding of lapatinib.

Conclusion: HER2 mutations confer a more aggressive phenotype. A specific mutation directly interacts with Lapatinib binding to HER2 and predicts resistance to Lapatinib in HER2-overexpressing breast cancer cells. Further characterization of novel HER2 mutations may have a direct implication in the development of novel markers for early diagnostics, patient selection and characterization of more appropriate and personalized treatment.

S3-1
Update of International Breast Cancer Study Group Trial 23-01 To Compare Axillary Dissection Versus No Axillary Dissection in Patients with Clinically Node Negative Breast Cancer and Micrometastases in the Sentinel Node.

Introduction and Study Design
For patients (pts) with a metastatic sentinel node (SN), axillary dissection is standard treatment to achieve optimal locoregional control. However, for many pts the SN is the only positive node and for pts with minimal SN involvement, axillary dissection (AD) may be overtreatment. IBCSG Trial 23-01 was designed to determine whether AD is necessary in pts with minimal SN involvement (defined as one or more micrometastatic (<2 mm) SNs) and tumor ≤ 5 cm. Consenting eligible pts were first registered; those with the requisite SN involvement were randomized to AD (group A) vs. no further axillary surgery (group B). The primary endpoint was disease-free survival (DFS). Secondary endpoints included overall survival (OS) and systemic disease-free survival (SDFS). The trial started in April 2001 and closed in February 2010. The accrual target was 1,960 pts to provide 90% power to detect non-equivalence if 5-year DFS was 64% for group B and 70% in group A. At closure 6,681 pts had been registered, with 934 randomized from 27 centers. The primary reasons for early closure were that projected time to complete accrual was too long, and the aggregate event rate at 30 months median follow-up was much lower than anticipated.

Baseline Characteristics and Treatment
Mean patient age at entry was 54 years (range 26-81). More postmenopausal (56%) than premenopausal pts (44%) were randomized. Sixty-seven percent of pts had tumor <2 cm, while 7% had tumor ≥ 3 cm; 26% had grade 3 disease. Tumors were estrogen-receptor positive in 89% of pts, and progesterone-receptor positive in 75%. In the involved sentinel node(s), 67% of pts had ≤ 1.0 mm micrometastasis, 29% had 1.1-2.0 mm micrometastasis, 2% had metastasis >2.0 mm, and 2% were unknown. Most (96%) pts underwent lymphoscintigraphy, and 1 or 2 sentinel nodes were found in about 85%. A previous excision biopsy was performed in 16%. Conservative surgery was definitive treatment in 75%; the others received mastectomy. Adjuvant radiotherapy was performed in 89% of group A and 92% of group B.

Outcomes
On 25 May 2011, median follow was 49 months. There were 88 DFS events. Sites of first DFS event were breast cancer-related in 66 pts [local (8), contralateral breast (10), regional (6), and distant (42)], and non-breast cancer-related in 22 [second malignancies (17) and deaths without prior cancer event (5)]. Four-year DFS (+ standard error) was 91% (+1.4%). Four-year competing risk cumulative incidences were 7.3% (+1.0%) for breast cancer events and 2.0% (+0.5%) for non-breast cancer events. With 101 DFS events, the trial is estimated to have 90% power to detect non-equivalence if 5-year DFS is 87% for group B compared with 92% for group A.

Conclusion
In this trial, restricted to clinically N0 with microscopic SN involvement, breast cancer recurrence and relapse rates are very low at a median follow-up of 4 years. The first comparison of outcomes between the two arms will be presented after a median follow-up of 5 years, when number of DFS events is anticipated to exceed 100.
S3-2
Neoadjuvant Chemotherapy Adapted by Interim Response Improves Overall Survival of Primary Breast Cancer Patients – Results of the GeparTrio Trial.

Background:
The GeparTrio phase III trial investigated the concept of interim response-adapted neoadjuvant chemotherapy. Patients with an early response after 2 cycles chemotherapy were considered highly chemo-sensitive and randomized to additional 2 chemotherapy cycles compared to standard treatment. Patients with no early response were considered less chemo-sensitive and randomized to continue with a non-cross-resistant chemotherapy or with standard chemotherapy. Pathological complete response (pCR) rates were different between responders and non-responders but not between the randomized arms (von Minckwitz G, et al JNCI 2008+2008; Huober et al. BCRT 2010).

We report here on the results of the secondary endpoints: disease-free (DFS) and overall survival (OS).

Patients and Methods:
2072 patients with operable or locally advanced breast cancer were treated with 2 cycles TAC (docetaxel, doxorubicin cyclophosphamide) before interim response assessment. Responders were randomized to additional TACx4 (N=704) or TACx6 (N=686) and non-responders to TACx4 (N=321) or NXX4 (vinorelbine, capecitabine) (N=301). None of the HER2+ patients received Trastuzumab. Endocrine treatment was given postoperatively to ER+ and/or PgR+ patients. We observed 480 recurrences and 302 deaths during median 62 months of follow up.

Results:
Patients receiving the experimental treatments (TACx8 or TACx2-NXX4) showed a longer DFS (HR 0.71; 95%CI 0.60-0.86, p<0.001) and longer OS (HR 0.79; 95%CI 0.63-0.99, p=0.048) compared to patients receiving standard TACx6 treatment. Treatment effects on DFS were restricted to patients with luminal A (p=0.003), luminal B (HER2-) (p=0.006) and luminal B(HER2+) (p=0.04) tumors. Experimental treatments did not improve outcome in HER2+(non-luminal) (p=1.0) and triple-negative (p=0.5) tumors. Responders showed a significant longer DFS (HR 0.79; 95%CI 0.62-0.97, p=0.026) and a trend towards a longer OS (HR 0.76; 95%CI 0.57-1.01, p=0.061) if they were treated with TACx8 compared to TACx6. Non-responders showed a longer DFS (HR 0.6; 95%CI 0.43-0.82, p=0.001) but not OS (HR 0.85; 95%CI 0.57-1.27, p=0.4) when treated with TACx2-NXX4 compared to TACx6. Results according to phenotypes of responders and non-responders were comparable to the overall comparison. In general, patients with a pCR showed a better DFS if they had triple-negative (p<0.0001), HER2+(non-luminal) (p<0.0001) or luminal B(HER2-) (p=0.004), but not if they had luminal A (p=0.66) or luminal B (HER2+) (0.67) disease.

Conclusion:
Adapting neoadjuvant chemotherapy according to interim response leads to better DFS and OS and represents therefore a unique advantage over adjuvant treatment. The investigated strategies to improve standard chemotherapy were most effective in the luminal A and B phenotypes. These phenotypes are usually considered less chemo-sensitive and pCR is not a prognostic factor. This might explain why the observed survival advantages could not be predicted by pCR.

S3-3
Association of PTEN Loss and PIK3CA Mutations on Outcome in HER2+ Metastatic Breast Cancer Patients Treated with First-Line Lapatinib Plus Paclitaxel or Paclitaxel Alone.

Xu B, Guan Z-Z, Shen Z-Z, Tong Z-S, Jiang Z-F, Yang J-I, DeSilvio M, Leigh M, Ellis C. Cancer Hospital, CAMS & PUMC; Sun Yat-Sen Medical University Cancer Center; Shanghai Cancer Center, Fudan University; Tianjin Medical University Cancer Institute and Hospital; Hospital Affiliated to Military Medical Science; Beijing 301 PLA Hospital; GlaxoSmithKline

Background
Identifying molecular determinants underpinning response and resistance to anti-cancer therapies is essential to selecting optimal treatment for patients (pts). The PI3K pathway is frequently deregulated in cancer. In preclinical models deregulated PI3K has been shown to enhance the survival of breast cancer cells and confer resistance to chemotherapy and HER2-directed agents. This exploratory study evaluated the impact PIK3CA mutations and PTEN loss had on the efficacy of paclitaxel alone (P) and in combination with lapatinib (L+P) in HER2-positive metastatic breast cancer (MBC) pts enrolled in study EGF104535, results of which demonstrated that pts treated with the combination of L+P derived an absolute improvement in median overall survival (OS) of 7.3 months (median OS=27.8 months in L+P compared with 20.5 months in P).

Method
Baseline tissue from primary breast tumor or metastatic site was obtained in the form of formalin-fixed, paraffin-embedded material. Of the total study population (n=444), 389 pts had tissue available for biomarker analyses, 277 of whom provided written informed consent for optional tumor genetics (i.e., PIK3CA analysis). PTEN was evaluated on whole sections by immunohistochemistry (rabbit monoclonal antibody); pathology review and image analysis were performed, producing an ordinal score and optical density (OD). Qiagen/DxS assay was used in assessing PIK3CA mutation status. Logistic regression and Cox-proportional hazard models were used in analyses of biomarkers with efficacy endpoints.

Results
Evaluable results for PTEN and PIK3CA were available for 91% (354/389) and 62% (171/274) of pts, respectively. In the overall population, 24% (65/274) had tumors harboring PIK3CA mutations (ES42K, ES45K/D, H1047R); 13% (49/389) had absence of PTEN expression. Survival outcome appeared to be independent of PTEN expression (P>0.2). PIK3CA mutations were significantly associated with worse OS (HR=1.88; 95% CI=1.26, 2.80; P=0.002). DFS was significantly improved in pts treated with L+P compared with P in both PTEN strata (loss/expression; P<0.001). In pts stratified by PIK3CA status, treatment with L+P reduced the risk of progression compared with P in the wildtype strata (N=106; HR=0.43; 95% CI=0.28, 0.65; P<0.0001); in the mutation strata, PFS was not significantly reduced with the addition of L (N=65; HR=0.70; 95% CI=0.42, 1.17; P=0.179).
Conclusions
In this exploratory study, PTEN was not prognostic whereas PIK3CA mutations appear to be an adverse prognostic feature in HER2+/MBC. PTEN expression may not be predictive as both strata derived significant benefit with L+P treatment. PFS benefit from L+P was significant in pts with PIK3CA wildtype tumors whereas the PFS benefit was not significant in the PIK3CA mutation strata. Additional analyses are ongoing and will be presented.

S3-4
ER Downregulation with Fulvestrant in Combination with pan-PI3K Inhibitor BKM120 Synergizes Against ER+/PI3K-Mutant Breast Cancer Xenografts In Vivo.
Miller TW, Fox EM, Balko JM, Meszoely IM, Sanders ME, Kuba MG, Wagle N, Garraway LA, Maira S-M, Arteaga CL. Vanderbilt University, Nashville, TN; Dana-Farber Cancer Institute, Boston, MA; Novartis Inst for Biomedical Research, Basel, Switzerland
ER+ breast cancers typically respond to aromatase inhibitors (AIs), but a significant fraction exhibit de novo or acquired resistance. To discover mechanisms of resistance to AIs, we maintained four ER+, hormone-dependent human breast cancer cell lines in hormone-depleted conditions for several months until estrogen-independent populations emerged (termed long-term estrogen-deprived, LTED). A siRNA kinome screen identified 42 kinases that suppressed growth and/or proliferation in LTED cell lines, and ER downregulation with fulvestrant did not inhibit growth in these 42 kinases. Further, treatment with the PI3K/mTOR dual inhibitor BEZ235 or the pan-PI3K inhibitor BKM120 suppressed LTED cell growth, and prevented the emergence of hormone-independent cells. Activating mutations in PIK3CA, the gene encoding the p110α catalytic subunit of PI3K, are present in about 35% of ER+ breast cancers. We investigated whether PIK3CA mutations modify the tumor response to estrogen deprivation with letrozole in a pre-surgical clinical trial (NCT00651976). Twenty-one patients with stage I-II operable ER+/HER2- breast cancer were treated with letrozole for 10-21 days up to 24 h prior to surgery. Core tumor biopsies were obtained before treatment and at the time of surgical resection. Ki67 immunohistochemistry (IHC) was scored in pre- and post-letrozole specimens. The change in natural log of the Ki67 score between pre- and post-treatment samples was stratified by PIK3CA mutant vs. wildtype (WT) status. PIK3CA-mutant tumors exhibited a statistically lower reduction in Ki67 score compared to tumors with WT PIK3CA (p<0.05). These findings suggest that mutational activation of PI3K attenuates the response to estrogen deprivation.

In some LTED cell lines, downregulation of ER with fulvestrant or siRNA inhibited estrogen-independent growth, suggesting that the unliganded ER can maintain proliferation of cells adapted to estrogen deprivation. Prior work suggested that PI3K-ER crosstalk promotes resistance to estrogen deprivation. However, inhibition of PI3K/AKT/TORC1 signaling did not alter ER5167 phosphorylation in LTED cells, and ER downregulation with fulvestrant did not inhibit PI3K/AKT, suggesting that PI3K and ER modulate non-overlapping pathways in cells adapted to estrogen deprivation. Treatment with BKM120 synergized with fulvestrant to inhibit the growth of ER+/PI3K-mutant MCF-7 xenografts, while the combination induced near-complete tumor regression. IHC analysis showed increased cleaved caspase-3+ cells in BKM120-treated tumors and decreased Ki67+ cells in fulvestrant-treated tumors, implying that the combination induced tumor regression by both inhibition of tumor cell proliferation and induction of apoptosis. These data suggest that upon progression on an aromatase inhibitor, patients with ER+/PI3K-mutant breast cancer would benefit from a combination of an ER downregulator and a PI3K pathway inhibitor.

Next Generation Sequencing Reveals Co-Activating Events in the MAPK and PI3K/AKT Pathways in Metastatic Triple Negative Breast Cancers.
INTRODUCTION: The clinical application of next generation sequencing to comprehensively characterize groups of driving mutations in individual metastatic triple negative breast cancer (mTNBC) genomes has the potential to reveal therapeutically relevant pathway dependencies. Towards this end, we harvested tissue from 14 patients with mTNBC and are conducting deep whole genome and transcriptome sequencing for each case to identify mutations that can guide therapeutic targeting within available phase I/II clinical trials.
METHODS: Metastatic tumor tissue was harvested from 14 mTNBC patients, and 7 samples have undergone total genome and transcriptome sequencing with the others currently underway. We are utilizing the Life Technologies SOLID® system to sequence germline and tumor DNA to sufficient depth to identify somatic genome alterations including point mutations, indels, and structural events including translocations. Furthermore, RNA-seq is being performed on these tumors, along with a series of age- and ethnicity-matched normal breast controls to perform deep differential expression analysis, isoform expression analysis, and fusion transcript detection. Our team of genome scientists and clinical oncologists are evaluating the sequencing findings and are prioritizing the investigational therapeutic options for each patient.
RESULTS: Our whole genome and transcriptome sequencing study has revealed numerous known and novel mutations in mTNBC. However, all patients’ cancers analyzed to date had alterations that would activate the MAPK pathway, but through various mechanisms in different patients. These include BRAF amplification and overexpression, NF1 homozygous deletion, and consistent IQGAP3 overexpression. Furthermore, all patients’ cancers also harbor mutations that would activate the PI3K/AKT pathway including PTEN homozygous deletion or down-regulation, consistent INPP4B amplification/overexpression. However, we and others show ERBB4 down-regulation in breast tumors, we are the first to report unique somatic genomic events that significantly alter the ERBB4 locus leading to its loss in the majority (5/7) of our patients’ tumors. Importantly, we are beginning to use these insights to prioritize therapeutic targeting and have observed that one chemotherapy-refractory mTNBC patient, with a high-level BRAF amplification/overexpression along with down-regulation of PTEN and INPP4B, had a major response to combined mek plus akt inhibitors on a phase I study.
CONCLUSIONS: Comprehensive genomic and transcriptomic interrogation of mTNBCs has revealed events supporting co-activation of the MAPK and PI3K/AKT pathways in all the tumors.
albeit by different mutational mechanisms and supports potential effectiveness of combination therapy in the treatment of mTNBC. We plan to treat these patients with combined mek plus akt inhibitors on a new phase I study beginning in August 2011 to determine the effectiveness of co-inhibition of these pathways based on this frequent genomic context.

**Neoadjuvant Chemotherapy of Paclitaxel with or without Rad001: Results of the Non-Responder Part of the GEPAQUINTO Study (GBG 44).**

**Background:**

The oral signal transduction inhibitor everolimus (RAD001 = R), binds selectively to mTOR (mammalian target of rapamycin), an intracellular protein kinase implicated in the control of cellular proliferation of activated T-lymphocytes and neoplastic cells. Phase II data suggested that R can enhance the clinical efficacy of endocrine treatment in the metastatic and neoadjuvant setting. The GeparQuinto phase III study had 3 settings (HER2-positive: trastuzumab vs lapatinib; HER2-negative: +/- bevacizumab (Bev); HER2-negative non-responder: +/- R). Primary aim of the last setting was to improve pathological complete response (pCR) for patients with HER2-negative breast cancer not responding to 4x epirubicin/cyclophosphamide (EC) +/- Bev by adding R to weekly paclitaxel as neoadjuvant chemotherapy.

**Patients and Methods:**

Patients with untreated HER2-negative breast cancer were eligible if their tumors were stage cT3/4a-d; or estrogen (ER) and progesterone (PgR) receptor-negative; or ER/PgR-positive tumors with clinically N+ (for cT2) or pN+ (for cT1). Only patients without response (<50% tumor reduction) to 4x EC +/- Bev were eligible and were randomized to receive further paclitaxel (Pac: 80 mg/m² q1w x12) chemotherapy with or without R. Treatment with R started 21 to 35 days after the last application of EC with a dose escalation from 2.5 mg every 2nd day to 5 mg every day over 14 days and maintained at 5 mg/day for additional 10 weeks. Dose of R could be decreased days after the last application of EC with a dose escalation from 2.5 mg every 2nd day to 5 mg every day over 14 days and maintained at 5 mg/day for additional 10 weeks. Dose of R could be decreased to 2.5 mg/day in case of toxicity. Treatment with Pac started within 7-14 days after the start of R. pCR was defined as no invasive and no non-invasive tumor residuals in breast and nodes. We assumed a pCR rate of 5% for Pac based on the GeparDuo study and expected a pCR of 12.1% for Pac+R (odds ratio 2.62). A two-sided Pearson’s C with α=0.05 and β=0.20 calculated a sample size of 566 P. One interim futility analysis after 1/3 of patients completed therapy was planned. Randomization was stratified by participating center, ER/PgR status, extend of disease (T4 or N3 vs. T1-3 and N0-2) and pre-treatment with Bev or not.

**Results:**

Between 11/07 and 15/06/11 402 P were randomized to Pac (N=201) and Pac+R (N=201). Median age was 51.0 and 50.0 [-R / +R] years. Median clinical tumor size was 40 / 40 mm; 62% / 55% had cT2, 18% / 20% cT3, and 16.7% / 16.7% cT4a-d tumors; 88% / 89% had non-lobular; 35% / 33% grade 3; 55% / 57% node-positive; and 29% / 27% ER and PgR-negative (triple-negative) disease.

The futility interim analysis was performed in 02/10, futility boundary was not reached and the trial was continued. After the other 2 settings completed accrual in 06/10, recruitment to the 3rd setting dropped such that it appeared not possible to recruit the full number of patients. The trial will therefore close recruitment on June, 30th 2011 with an estimated statistical power of 65%. Results on histological response and surgical outcome will be reported.

**Conclusion:**

This will be the first report on efficacy data of neoadjuvant R + Pac for patients with early breast cancer. The results of the GeparQuinto study will have to be set into context with the results from the Bolero studies in metastatic disease.

**S3-7**

**Everolimus for Postmenopausal Women with Advanced Breast Cancer: Updated Results of the BOLERO-2 Phase III Trial.**

Hortobagyi GN, Piccart M, Rugo H, Burris H, Campone M, Noguchi S, Grant M, Pritchard KI, Vitiori L, Mukhopadhyay P, Sahmoud T, Lebwohl D, Baselga J. The University of Texas, MD Anderson Cancer Center, Houston, TX; Jules Bordet Institute (Institut Jules Bordet), Brussels, Belgium; University of California, San Francisco Helen Diller Family Comprehensive Cancer Center, UCSF, San Francisco, CA; Sarah Cannon Research Institute, Nashville, TN; Institut de Cancérologie du L’Ouest - René Gauducheau, Centre de Recherche en Cancérologie, Nantes Saint Herblain, France; Osaka University, Osaka, Japan; Comprehensive Cancer Center, Medical University of Vienna, Vienna, Austria; Sunnybrook Odette Cancer Centre and the University of Toronto, Toronto, Canada; Novartis Pharma AG, Basel, Switzerland; Novartis Pharmaceuticals Corporation, East Hanover, NJ; Massachusetts General Hospital Cancer Center and Harvard Medical School, Boston, MA

**Background:**

The mTOR pathway is constitutively activated in hormone-resistant advanced breast cancer (ABC). In phase II trials, everolimus (EVE) showed promising efficacy both as monotherapy and in combination with endocrine therapy in patients with estrogen receptor–positive (ER+) ABC. This double-blind, placebo-controlled, phase III study evaluated EVE plus exemestane (EXE) in patients with ER+ ABC refractory to letrozole or anastrozole.

**Patients and Methods:**

Eligible patients were randomized (2:1) to EXE (25 mg/day) with EVE (10 mg/day) or with matching placebo. The primary endpoint was progression-free survival (PFS). Secondary endpoints included overall survival, response rate, quality of life (QoL), and safety.

**Results:**

724 patients were randomized (485: EVE+EXE; 239: EXE). Baseline characteristics were well balanced; median age was 62 years, 56% had visceral involvement, and 84% had documented benefit from previous endocrine therapy, which included letrozole or anastrozole (100%), tamoxifen (48%), fulvestrant (16%), and chemotherapy for advanced disease (25%). This analysis is based on 457 events and median follow-up of 12.5 months. PFS by investigator assessment showed a hazard ratio (HR) of 0.44 (95% CI: 0.36-0.53) and a median duration of 7.4 (EVE+EXE) vs 3.2 months (EXE) (P<1 × 10^-9) and 12-month estimate of 31% vs 10%. PFS by central assessment showed an HR of 0.36 (95% CI: 0.28-0.45) and a median duration of 7.4 (EVE+EXE) vs 3.2 months (EXE) (P<1 × 10^-9) and 12-month estimate of 48% vs 18%. Response rates and clinical benefit rate were also higher for EVE+EXE (12.0% vs 1.3% and 50.5% vs 25.5%) vs EXE. A total of 138 patients died; 17.3% in the EVE+EXE arm and 22.6% in the EXE arm.

The most common grade 3/4 adverse events were stomatitis (8% vs 1%), anemia (7% vs 1%), hyperglycemia (5% vs 1%), dyspnea (4% vs 1%), and fatigue (4% vs 1%) for the EVE+EXE and EXE groups, respectively. Grade 3 pneumonitis was observed in patients receiving EVE (3% vs 0%). No difference in time to deterioration of QoL was
observed. EVE increased EXE steady-state C\text{max} and C\text{ss} levels by 45% and 64%, respectively, with no difference in estradiol levels. Serum markers of bone resorption and bone formation increased in the EXE arm and generally decreased in the EVE+EXE arm. **Conclusion:** The addition of EVE to EXE is associated with significant and sustained prolongation of PFS. Adverse events were higher in the combination arm but manageable by dose interruption and/or reduction and did not affect QoL. EVE in combination with an aromatase inhibitor is a promising therapeutic option for women with hormone receptor–positive advanced breast cancer.

**S4-1**

**Overdiagnosis in Breast Cancer Screening: Methodological Considerations of Current Estimates.**

Smith RA, Duffy SW. American Cancer Society, Atlanta, GA; Queen Mary University of London, London, United Kingdom

**Background**

A harm that has received considerable attention in breast cancer screening is overdiagnosis, i.e., the detection through screening of breast cancer that is non-progressive. Since there is no way to distinguish a truly non-progressive tumor from one that is progressive, overdiagnosis is a statistical phenomenon that is estimated as the difference between observed and expected incidence rates. However, there is no agreement on the true rate of overdiagnosis in breast cancer screening. Estimates vary widely, with the highest estimates reported in the scientific literature having received significant media attention under the premise that a significant fraction of newly diagnosed breast cancers are non-progressive and thus overtreated. We examined the range of overdiagnosis estimates in the context of factors that influence observed and expected breast cancer incidence rates over time.

**Methods**

Only studies that compared incidence rates of invasive breast cancer, or invasive breast cancer and ductal carcinoma in situ (DCIS), in a group invited or exposed to mammography compared with a group not invited or not exposed to mammography were included in our analysis. Studies were evaluated based on whether or not they adjusted for contemporaneous trends in the underlying incidence of disease, which may differ in different age groups, and age-specific effect on incidence rates due to lead time.

**Results**

We identified 17 studies (Table 1) that attempted to estimate overdiagnosis of breast cancer resulting from mammography screening. The main determinant of high estimated rates of overdiagnosis was a failure to adjust for lead time. The highest rate of overdiagnosis (33%) occurred in the one study that did not correct for either lead time or confounders. Studies that only partially corrected for lead time and confounding also had high estimates of overdiagnosis (mean = 30%), whereas studies that corrected for both lead time and confounders had the lowest estimate of overdiagnosis (mean = 5%).

**Conclusion**

The possibility that some breast cancers detected by mammography are indolent and not life threatening within the patient’s natural life is real. However, it is clear from our analysis that the wide range of estimates of overdiagnosis are due to whether or not studies have adjusted for factors in and outside of screening programs known to influence incidence rates over time. Our findings suggest that the true rate of overdiagnosis associated with breast cancer screening, to the extent that it exits at all, is small.

---

**S4-2**

**The Risk of Contralateral Breast Cancer in BRCA1/2 Carriers Compared to Non-BRCA1/2 Carriers in an Unselected Cohort.**

van den Broek AJ, Schmidt MK, Tollenaar RAEM, van ’t Veer LJ, van Leeuwen FE. Netherlands Cancer Institute, Amsterdam, Netherlands; Leiden University Medical Center; Leiden, Netherlands

**Background:** Women who survived their first breast cancer have a higher risk to develop a new primary tumor in the contralateral breast than the risk of women in the general population to develop a first breast cancer. Especially women who carry a germline mutation in either the BRCA1 or the BRCA2 gene face a high lifetime risk of developing a synchronous or metachronous bilateral breast cancer. It is important to provide precise risk estimates of contralateral breast cancer and identify factors which predict the risk of CBC in this group of high-risk women. To answer these questions, we looked at the effect of BRCA1/2-carriership and its interaction with other factors on the risk to develop a CBC in an unselected cohort of breast cancer patients.

**Materials and methods:** We collected clinico-pathological, treatment and follow-up data for 4856 patients with unilateral, invasive breast cancer, diagnosed under the age of 50, between 1970 and 2003, in ten different hospitals throughout The Netherlands. Germline DNA was isolated from formalin-fixed paraffin-embedded tissue and patients were tested for the most prevalent pathogenic BRCA1 and BRCA2 mutations in The Netherlands. DNA and clinical data were coded before the analyses. All second primary breast tumors in the contralateral breast diagnosed more than 3 months after the diagnosis of the first breast cancer were considered as events. Preliminary results from life-table analysis and Cox Proportional Hazard models adjusted for age at diagnosis are shown here. Further statistical analyses will include competing risk analysis.

**Results:** In 4856 patients genotyped for BRCA1/2 mutations, 206 (4.2%) carriers were identified. During a median follow-up of 9.8 years (range 0-38), 9% of the patients developed a CBC, resulting in a cumulative 15-year risk for CBC of 10.4% (95% CI = 9.25-11.7) for non-carriers and 35.4% (95% CI = 25.9-46.9) for carriers of a BRCA1 or BRCA2 mutation (HR = 4.04 (95% CI = 2.88-5.68)). Patients carrying a BRCA1/2 mutation who were diagnosed under the age of 40 with their first breast cancer experienced a cumulative 15-year risk for CBC of 52.4% (95% CI = 36.4-70.3) versus 21.3% (95% CI = 12.0-36.0) in those over the age of 40 (HR = 0.30 (95% CI = 0.14-0.65)). Furthermore, BRCA1/2 mutation carriers with a triple negative first tumor had a cumulative risk for CBC of 43.6% (95% CI = 25.1-67.7), in contrast, BRCA1/2 mutation carriers with a non-triple negative first tumor had a cumulative risk for CBC of 13.4% (95% CI = 4.21-38.4) (HR = 0.24 (95% CI = 0.07-0.86)). Age at diagnosis and triple negative status were not found to be predictors of the risk of CBC in non-carriers (HR = 0.81 (95% CI = 0.53-1.24) and HR = 1.49 (95% CI = 0.91-2.41) respectively).

**Discussion:** In this study we identified subgroups of patients with a high risk to develop a CBC after their first breast cancer. Guidelines about treatment decisions and screening for follow-up should take into account these high risk subgroups to provide even better information and counseling for BRCA1/2 mutation carriers.

On behalf of more than 20 involved authors of the BOSOM study from 10 different hospitals and institutions throughout The Netherlands.

Prospective Comparison of Risk Assessment Tools in Early Breast Cancer (Recurrence Score, uPA/PAI-1, Central Grade, and Luminal Subtypes): Final Correlation Analysis from the Phase III WSG-Plan B Trial.
Gluz O, Kreipe H, Degenhardt T, Kates R, Christgen M, Liedtke C, Shak S, Clements M, Markmann S, Ueber C, Augustin D, Thomssen C, Nitz U, Harbeck N. West German Study Group, Moenchengladbach, Germany; Medizinische Hochschule, Hannover, Germany; University of Muenster, Muenster, Germany; Genomic Health Inc, Redwood City; Klinikum Mutterhaus, Trier, Germany; Klinikum Suedstadt, Rostock, Germany; Gynecology Practice, Hildesheim, Germany; Klinikum Deggendorf, Deggendorf, Germany; University of Halle/ Saale, Halle/Saale, Germany; Bethesda Clinics, Moenchengladbach, Germany; University of Cologne, Cologne, Germany

Background: Both the Recurrence Score® (RS) multi-gene assay and invasion factors uPA/PAI-1 are recommended by guidelines (ASCO, AGO) for decision support regarding adjuvant chemotherapy (cht) in patients with early breast cancer (BC). In the EC-DOC trial, we previously suggested central grade 3 and high Ki-67 levels as independent predictive markers for enhanced benefit of taxane-based cht in intermediate risk BC. Here, we present the final WSG-Plan B trial correlation analysis of these risk assessment tools.

Methods: Plan B trial (evaluating anthracycline-free adjuvant cht, 6xTC, vs. 4xEC-4xDOC in HER2-negative BC; n=2,448 was randomized for chemotherapy). RS has been used as the selection criterion for cht vs. endocrine therapy alone in HR+ BC (if RS<11 in pN0 or pN1) since an amendment in August 2009. uPA/PAI-1 by ELISA is obtained as an optional risk factor. Evaluation of central grade and luminal B subtype (using 14% or 20% Ki-67 cut-offs) are performed by the independent trial pathologist in all HR+ tumors.

Results: From April 2009 to June 2011, 3037 patients have been recruited and 2290 randomized. The study will be completed by December 2011. Data on RS are available in 2361 patients with HR+ tumors: RS is distributed as follows: 0-11 (18%), 12-25 (61%), >25 (21%). In 257 patients with 0-3 involved LN, cht was omitted based on RS results (12.3% of patients after amendment).

The last interim analysis in February 2011, data on central grade are available in 1509 patients and Ki-67 in 592 patients. An only moderate positive correlation was observed between Ki-67 and RS (Spearman’s coefficient rs=0.336; p<0.001) as continuous variables and between RS and central grade (rs=0.498, p<0.001). High RS is predictive of high grade G3 (66% of RS>)(25% with high risk and 74% of RS=) high risk are G3), but 30-33% of tumors were assessed as G3 within S4-4
Clarioking the Risk of Breast Cancer in Women with Atypical Breast Lesions.
Coopey SB, Mazzola E, Buckley JM, Sharker J, Belli AK, Kim EMH, Polufriganoj F, Parmigiani G, Garber JE, Smith BL, Gadd MA, Specht MC, Guidi AJ, Roche CA, Hughes KS. Massachusetts General Hospital, Boston, MA; Dana-Farber Cancer Institute, Boston, MA; Newton-Wellesley Hospital, Newton, MA; Wayne State University, Detroit, MI

Background: Women diagnosed with atypical ductal hyperplasia (ADH), atypical lobular hyperplasia (ALH), lobular carcinoma in situ (LCIS), and borderline ADH/DCIS are at increased risk for breast cancer, but the precise degree of risk varies widely in the literature.

Information from prior studies is limited by grouping ADH and ALH together and by small cohort sizes.

Objectives: To identify women with a pathologic diagnosis of ADH, ALH, LCIS, and borderline ADH/DCIS using Natural Language Processing. To evaluate breast cancer risk based on atypia type.

Methods: Using Natural Language Processing, we reviewed all electronically available pathology reports from Massachusetts General Hospital, Brigham and Women’s Hospital, and Newton-Wellesley Hospital (members of Partners HealthCare System) from 1987-2010. We identified all women with a diagnosis of ADH, ALH, LCIS, and borderline ADH/DCIS with no prior or concurrent diagnosis of breast cancer. We determined the incidence of subsequent invasive and noninvasive breast cancer, the side of cancer diagnosis compared to original atypia side, and the time to cancer diagnosis for each atypia type.

Results: We reviewed 76,333 path reports in 42,950 unique individuals and identified 3049 women who were diagnosed with atypical breast lesions over this 14-year period; 1233 (40.4%) had ADH, 851 (27.9%) had ALH, 595 (19.5%) had LCIS, and 370 (12.1%) had borderline ADH/DCIS. The mean age for atypia diagnosis was 51 years (range: 18-93). At a mean follow-up of 66 months, cancer occurred in 7.0% of women with ADH, 11.3% of women with ALH, 11.1% of women with LCIS, and 8.4% of women with borderline ADH/DCIS. The median time to breast cancer diagnosis was 48 months with ADH, 50 months with ALH, 47 months with LCIS, and 60 months with borderline ADH/DCIS. Significantly more ipsilateral cancers developed than contralateral cancers for all types of atypia combined (p<0.027).

Table 1: Estimated 5 and 10-year breast cancer risks and laterality of cancer based on atypia type. The development of invasive versus noninvasive breast cancer was not significantly affected by atypia type. Subsequent cancers were DCIS in 121 patients (43.4%) and invasive in 158 patients (56.6%). Kaplan Meier curves for time to cancer diagnosis based on atypia type were created. The curves for ADH and borderline ADH/DCIS were similar and significantly different than the curves for ALH and LCIS (p<0.001). The estimated 5 and 10-year breast cancer risks for each atypia type are presented in Table 1.
Conclusion: A diagnosis of ADH, ALH, LCIS, or borderline ADH/DCIS increases a woman’s risk of invasive and noninvasive breast cancer in either breast. The breast cancer risk at 5 and 10 years is significantly higher in those with ALH or LCIS compared to those with ADH or borderline ADH/DCIS, but there is little difference in risk between ADH and borderline ADH/DCIS or between LCIS and ALH.

S4-5
Comparison of PAM50 Risk of Recurrence (ROR) Score with OncotypeDx and IHC4 for Predicting Residual Risk of RFS and Distant-(D)RFS after Endocrine Therapy: A TransATAC Study.

Methods: PAM50 analysis was conducted using NanoString technology on 125 ng RNA extracted from all 1026 samples from both N0 and N+ patients.

Background: OncotypeDx Recurrence Score (RS) is used to assess RR after endocrine therapy in primary ER+ breast cancer and is valid for both tamoxifen and anastrozole (Dowsett ref). IHC4 is a 4-panel set of IHC markers (ER, PgR, HER2, Ki67) that was shown to provide as much prognostic accuracy as RS in the translational arm of the ATAC trial (TransATAC) of anastrozole versus tamoxifen alone or combined and subsequently independently validated (Cuzick et al, JCO, 2011, in press). PAM50 is 50-gene test that has been optimised to separate intrinsic disease subtypes and is used to generate a ROR score. Good correlation has been shown between the ROR and RS but no large scale comparisons of their ability to predict clinical outcome have been conducted.

Methods: PAM50 analysis was conducted using NanoString technology on 125 ng RNA extracted from all 1026 samples from the TransATAC study that had at least 500ng RNA available. Nodal status was known on 986: N+, 271; N-neg 715. ROR scores were calculated and their relationship with RFS and DRFS assessed in both the N-neg and N+ categories. The prognostic value of ROR when added to standard clinical variables was assessed using the likelihood ratio chi-square. Finally, the relative accuracy of prognosis in this patient population using ROR, RS and IHC4 was evaluated by comparing the C-index for each test.

Results: Results are currently being derived and will be presented in full.

Discussion: This is the first large-scale clinical comparison of 2 prominent multi-gene predictors for use in FFPE material. The results will be instrumental in defining the preferred method for use in assessing residual risk of recurrence in patients treated with endocrine therapy.

S4-6
A Quantitative Multigene RT-PCR Assay for Predicting Recurrence Risk after Surgical Excision Alone without Irradiation for Ductal Carcinoma In Situ (DCIS): A Prospective Validation Study of the DCIS Score from ECOG E5194.

Methods: ECOG E5194 included 670 eligible patients with DCIS treated with surgical excision (≥ 3 mm negative margins) without irradiation, 228 of whom received tamoxifen. Patients had low or intermediate grade DCIS ≥ 2.5 cm, or high grade DCIS ≤ 1 cm. The Oncotype DX® assay was performed by quantitative RT-PCR using formalin fixed paraffin embedded tumor specimens from 327 patients (49% of the parent study). Recurrence Score® (RS) was calculated using the published algorithm. A new, prespecified DCIS Score™ was designed to predict recurrence using an optimized gene expression algorithm. The primary objective was to determine whether there was a significant association between the risk of an ipsilateral breast event (IBE) and the continuous DCIS Score in Cox models. 46 patients had an IBE (defined as ipsilateral local recurrence of DCIS [n=20] or invasive cancer [n=26]). Median follow-up was 8.8 years.

Results: The 10-year IBE rates were 15.4% for low/intermediate grade DCIS and 15.1% for high-grade DCIS (as determined by central pathology review), and for invasive IBE, 5.6% and 9.8%, respectively. Comparison between local and expert grading showed substantial disagreement. Continuous DCIS Score was significantly associated with IBE (HR 2.34 per 50 units; 95% CI 1.15, 4.59; p=0.02) when adjusted for tamoxifen use (prespecified primary analysis) and with invasive IBE (HR 3.73; CI 1.34, 9.82; p=0.01). DCIS Score was significantly associated with outcome when evaluated by the prespecified risk groups (see Table). Similar results were observed with and without adjustment for tamoxifen use or for negative margin width. Features associated with IBE in multivariate models included menopausal status (HR 0.49; 95% CI 0.27, 0.90; p=0.02), tumor size (HR 1.52 per 5 mm; 95% CI 1.11, 2.01; p=0.01) and continuous DCIS Score (HR 2.41; 95% CI 1.15, 4.89; p=0.02). The standard RS, which is calculated using thresholding of many genes unlike the DCIS Score, was not associated with IBE or invasive IBE (p > 0.6).

Conclusions: We have prospectively validated a multigene assay that quantifies recurrence risk and complements traditional clinical and pathologic factors in selected patients with DCIS treated with surgical excision without irradiation. The DCIS Score provides a new clinical tool for individualized selection of treatment for patients with DCIS.

Petrov Research Institute of Oncology, St Petersburg, Russian Federation

Background: H + taxane is an established and effective first-line treatment for HER2-positive LR/mBC. Preclinical data provide the rationale for combining BEV and H in HER2-positive LR/mBC but clinical data in this setting are limited to single-arm phase II studies. AVEREL is the first randomized trial of BEV in HER2-positive LR/mBC.

Methods: Eligible patients had measurable or evaluable HER2-positive LR/mBC (centrally confirmed IHC 3+ or FISH/CISH +), ECOG performance status 0/1, and had received no prior chemotherapy for advanced disease. Prior adjuvant H/taxanes were permitted unless disease had recurred ≤6/>12 months after the last dose, respectively. Patients with CNS metastases were excluded. Patients were stratified according to adjuvant H, prior (neo)adjuvant taxane (further stratified by time to relapse since last dose of [neo] adjuvant chemotherapy/no chemotherapy), hormone receptor status, and measurable disease, and were randomized to receive either H (8 mg/kg → 6 mg/kg q3w) + DOC (100 mg/m² q3w) or H + DOC + BEV (15 mg/kg q3w). H and BEV were given until disease progression; DOC was given for a planned minimum of 6 cycles unless progression or unacceptable toxicity mandated earlier discontinuation. The primary endpoint was progression-free survival (PFS). Additional endpoints included overall survival (OS), overall response rate (ORR; assessed by RECIST 1.0), duration of response, time to treatment failure, safety (NCI CTCAE v3.0 adverse events [AEs] and AEs of special interest for BEV), quality of life (FACT-B), and translational research. The primary analysis of PFS was prespecified after 310 investigator-assessed PFS events. The statistical design provided 90% power to detect a PFS hazard ratio (HR) of 0.69 (median PFS 11→16 months) with α=0.05.

Results: Between Sep 2006 and Feb 2010, 424 patients were enrolled from 60 centers; 421 received treatment. Baseline characteristics were generally well balanced in the H + DOC and H + DOC + BEV arms: median age 55 and 53 years, respectively; visceral metastases 71% and 77%; prior adjuvant H 12% and 13%; disease-free interval <12 months 43% in both arms; measurable disease 85% in both arms. Median follow-up was 26 months in both arms. Efficacy results are summarized in the table.

No new safety signals were observed. The following grade ≥3 AEs were more common in the BEV-containing arm than the H + DOC arm: congestive heart failure (5.1% vs 2.9%, respectively); febrile neutropenia (11.6% vs 8.7%); hypertension (11.6% vs 0.5%). Grade 5 AEs occurred in 1.4% of the H + DOC + BEV arm vs 1.9% of the H + DOC arm.

Conclusions: The addition of BEV to H + DOC improved PFS without reaching statistical significance according to investigator assessment (unstratified HR 0.82; 95% CI 0.65-1.02). The improvement as assessed by Independent Review Committee was statistically significant. Evaluation of biomarkers is ongoing to try to identify those patients who may benefit from first-line BEV-containing therapy for HER2-positive LR/mBC.

S5-1
Neoadjuvant Pertuzumab (P) and Trastuzumab (H): Biomarker Analyses of a 4-Arm Randomized Phase II Study (NeoSphere) in Patients (pts) with HER2-Positive Breast Cancer (BC).
Gianni L, Bianchini G, Kiermaier A, Bianchi G, Im Y-H, Pienkowski T, Roman L, Liu M-C, Tseung L-M, Ratnayeke J, Szado T, Ross GA, Valagussa P. Oncologia Medica, San Raffaele Cancer Center, Milan, Italy; Roche, Basel, Switzerland; Oncologia Medica I, Fondazione IRCCS Istituto Nazionale Tumori, Milan, Italy; Samsung Medical Center, Seoul, Korea; Centrum Onkologii, Warsaw, Poland; Leningrad Regional Oncology Dispansary, St Petersburg, Russian Federation; Koo Foundation Sun Yat-Sen Cancer Center, Taipei, Taiwan; Kapoor V, Veterans General Hospital, National Yang-Ming University, Taipei, Taiwan; Roche Products Limited, Welwyn, United Kingdom; Genentech, South San Francisco; Fondazione Michangelo, Milan, Italy

Background: NeoSphere showed that P with H and docetaxel (T) had a significantly higher pCR rate (45.8%) compared with TH
Materials and methods: Gene expression data on pre-treatment fresh-frozen tumor tissues were collected from a combined cohort of MDACC/I-SPY trial (GSE25055/65), and the XeNA trial (GSE22358). Patients from MDACC/I-SPY were treated with doxorubicin/cyclophosphamide (AC) or 5-fluorouracil/epirubicin or doxorubicin/C (FEC or FAC) sequentially with paclitaxel. All patients from XeNA received capicitabine/docetaxel (and trastuzumab if clinHer2+). Intrinsic subtypes were determined using PAM50. Chi-square test and multivariable logistic regression analysis were used to test significance of association between subtype and pathological complete response (pCR or residual cancer burden [RCB] 0/1) and residual disease (RD or RCB2/3) adjusted with pre-treatment tumor size. Kaplan Meier was used for distant relapse-free survival (DRFS) estimates.

Results: For the MDACC/I-SPY cohort (n=595), pCR rates for intrinsic subtypes were 3% (5/168) for LumA, 16% (14/90) for LumB, 33% (23/69) for HER2-E and 37% (76/208) for Basal-like. Tumors achieving RCB0/1 were significantly associated with better DRFS compared to those tumors with RCB 2/3, even within each intrinsic subtype. The 5-year DRFS for HER2-E with RCB0/1 and RCB2/3 was 100% and 31% (p=0.007), respectively. ClinHer2+ status was also significantly associated with pCR (34% vs. 19%, p=0.016). Strikingly, among the clinHer2+ tumors (n=47), 75% (12/16) of the responders were classified as HER2-E (Table 1A) and those tumors that were clinHer2+/HER2-E had 6 times odds to achieve pCR when compared to clinHer2+/non-HER2-E. In the XeNA trial (n=122), the HER2-E subtype was significantly associated with response, composing 85% (7/8) of the clinHer2+ who achieved a pCR. Finally, clinHer2+/HER2-E tumors were 34 times more likely to achieve pCR than clinHer2+/non-HER2-E tumors (Table 1B).

Conclusion: The sensitivity of clinHer2+ tumors to neoadjuvant anthracycline/taxane-based regimens, and trastuzumab-based chemotherapy is mainly contained within tumors of the HER2-E subtype. Given that this molecular subtype cannot simply be recapitulated using clinical ER and HER2 status, our results highlight the importance of identifying patients with HER2-E tumors as this appears to greatly enrich for responsiveness and treatment benefit.

S5-3
Basement Membrane Localized Tumor Cells Are Protected from HER2-Targeted Therapy In Vivo.

Zoeller JJ, Bronson RT, Gilmer TM, Selfors LM, Lu Y, Mills GB, Brugge JS. Harvard Medical School, Boston, MA; GlaxoSmithKline, Research Triangle Park, NC; UT MD Anderson Cancer Center, Houston, TX

Drug resistance compromises the efficacy of HER2-targeted therapy. Results from our laboratory, and previous reports from others, indicate that tumor cell attachment to basement membrane (BM) and other extracellular matrix (ECM) proteins may confer drug resistance. We have discovered a differential drug response between the outer, matrix-attached cells and inner matrix-deprived cells comprising...
3-dimensional (3D) tumor spheroids grown in reconstituted basement membrane (T. Muranen and J. Brugge, unpublished data). The outer matrix-attached cells are resistant to multiple drug therapies. To address whether these observations are relevant in vivo, we utilized a previously described model of human-in-mouse HER2-positive ductal carcinoma in situ (DCIS), which involves the intraductal transplantation of human HER2-positive SUM225 tumor cells directly into the ductal network of the mouse mammary gland. The intraductal tumors generated are histologically indistinguishable from human DCIS lesions and recapitulate the architecture of the 3D tumor spheroids. The tumors are characterized by organized nests of noninvasive cells confined within a BM surrounded by ECM. These features permit a direct assessment of differential drug response within the tumor. We focused on the tumor cell response to short-term lapatinib monotherapy in vivo. A close examination of the tumor architecture revealed that cells closest to the basement membrane, and nearest to the vasculature, display a striking insensitivity to lapatinib whereas the remainder of the tumor undergoes extensive cell death in response to treatment. Further characterization also revealed that cells closest to the basement membrane largely maintain proliferative capacity despite an overall significant reduction in the total Ki67-positive cell population. These results provide in vivo evidence that basement membrane-attached tumor cells are protected from lapatinib. We confirmed that these cells maintain HER2 status and also observed an overall reduction in pHER2, pAKT and pERK throughout the tumor suggestive of adaptive response mechanisms, which support the proliferation and survival of these cell populations despite inhibition of the HER2 pathway. To further explore potential mechanisms of the adaptive response, we performed reverse phase protein array (RPPA) analysis on protein lysates prepared from tumor biopsy fragments following lapatinib monotherapy. RPPA profile analysis revealed an adaptive response composed of upregulation of multiple RTKs (HER2, IGFI-R) and altered apoptotic protein levels (Bcl-2, Bim, Bcl-xL) in addition to activation of AKT/S6K and ERK/p38 pathway components. These observations suggest that basement membrane-attached tumor cells may escape from lapatinib response via compensatory activation of these survival mechanisms. Each of these components will serve as targets for designing combined therapeutic approaches capable of targeting the protected basement membrane-attached tumor cells. Our results suggest that resistant populations may be a source of residual disease post-therapy, therefore identifying and characterizing these cells will be crucial to the prevention of disease recurrence in the clinic.

S5-4
pCR as a Surrogate in HER2-Positive Patients Treated with Trastuzumab.
Loibl S, von Minckwitz G, Blohmer JU, Costa SD, Eidmann H, Fasching PA, Gerber B, Hanusch C, Hilfirsch J, Huober J, Jackisch C, Kaufmann M, Konecny G, Denkert C, Nekljudova V, Mehta K, Untch M. German Breast Group, Neu-Isenberg; St. Gertrauden Krankenhaus, Berlin; Universitäts-Frauenklinik, Magdeburg; Universitätsklinikum, Kiel; University Hospital, Erlangen; Universitäts-Frauenklinik, Rostock; Klinikum zum Roten Kreuz, München; Henrietten-Stiftung, Hannover; Universitäts-Frauenklinik, Tübingen; Städtische Kliniken, Offenbach; Universitäts-Frauenklinik, Frankfurt; University of California, Los Angeles; Charité, Berlin; Helios Klinikum Berlin-Buch, Berlin

Background: Patients with HER2-positive metastatic disease used to show a more unfavorable prognosis compared to patients with HER2-negative tumors. With the introduction of trastuzumab, patients with HER2-positive metastatic breast cancer show an improved survival compared to patients with HER2-negative tumors (Dawood et al. 2010). So far it has not been shown, if such a switch in prognosis is also achieved in early breast cancer.

Methods: 6377 patients from 7 neoadjuvant German studies with operable or locally advanced, non-metastatic breast cancer were analyzed (for details see von Minckwitz G et al., BCRT 2010). In earlier studies patients (pts) with HER2-positive disease did not receive trastuzumab. Trastuzumab was given in 2 trials parallel to chemotherapy for 12-36 weeks and completed after surgery for up to one year of treatment. All patients with endocrine responsive disease received adjuvant endocrine therapy according to institutional standard. We compared the overall and disease free survival in three subgroups, HER2-negative patients, HER2-positive w/o trastuzumab and HER2-positive patients with trastuzumab according to pCR defined as ypT0, ypN0.

Results: 6377 patients were evaluable. During a median follow up of 46.3 (0-127) months and observation of 22,869 patient years, 1466 (23%) relapses and 775 (12.2%) deaths were observed. 3060 had HER2-negative disease, 665 patients had HER2-positive disease w/o trastuzumab and 662 patients with HER2-positive disease received trastuzumab. No data on HER2 status were available in 1990 (31.2%) patients as measurement of HER2 was only implemented in the study procedures since 2001. Median age of patients at time of study entry was 50.1 (21-81) years. Median tumor size was 4.0 (range 1.2 – 33.0) cm. Overall 15% (955) of patients had a pCR. The pCR rate in HER2-positive pts was 24% in those with trastuzumab and 15.8% in those without. There was no difference in overall DFS in the three groups achieving a pCR (log rank p=0.251). There was a strong trend towards a better OS in pCR HER2+pts being treated with trastuzumab (overall log rank p= 0.067). Cox regression analysis revealed HER2 positive patients with trastuzumab had a better OS than HER2-positive pts w/o trastuzumab (HR: 7.44; 95%CI [0.92-60.1; p=0.06) and HER2negative pts (HR: 3.86; 95% CI [0.5-29.41], p=0.19).

However, for non-pCR pts, DFS was significantly inferior for pts treated with trastuzumab compared to patients without trastuzumab (HR: 0.81, 95% CI [0.63-1.04), p=0.102) or pts with HER2-negative tumors (HR: 0.75; 95% CI [0.61-0.92] p=0.006.(overall log-rank p=0.022). However, OS was not significantly different between the three groups of non-pCR pts.

Conclusion: Patients with HER2-positive primary breast cancer treated with trastuzumab achieve a higher pCR rate. This higher absolute number of pCRs in trastuzumab-treated patients lead to a DFS at least as good as that of HER2-positive not trastuzumab treated and HER2-negative patients and OS even tended to be superior to the other two groups. This supports that pCR can be considered as a surrogate marker in HER2-positive disease. However, HER2-positive, trastuzumab-treated patients without a pCR are at high risk of relapse and are at high medical need for new treatment options.
**S5-5**

A Phase III, Randomized, Double-Blind, Placebo-Controlled Registration Trial To Evaluate the Efficacy and Safety of Pertuzumab + Trastuzumab + Docetaxel vs. Placebo + Trastuzumab + Docetaxel in Patients with Previously Untreated HER2-Positive Metastatic Breast Cancer (CLEOPATRA).

Baselga J, Kim S-B, Im S-A, Hegg R, Im Y-H, Roman L, Pedrini JL, Cortés J, Knott A, Clark E, Ross GA, Swain SM. Massachusetts General Hospital Cancer Center; Boston, MA; Asan Medical Center; University of Ulsan, College of Medicine, Seoul, Korea; Seoul National University College of Medicine, Seoul, Korea; Hospital Pórola Byington, São Paulo, Brazil; Samsung Medical Center; Sungkyunkwan University School of Medicine, Seoul, Korea; Leningrad Regional Oncology Dispensary, St Petersburg, Russian Federation; CPMEC-Mastology Unit of Concópia Hospital, Porto Alegre, Brazil; Vall d’Hebron University Hospital, Barcelona, Spain; Roche Products Limited, Welwyn, United Kingdom; Washington Cancer Institute, Washington Hospital Center; Washington, DC

**Background:**

Pertuzumab (P) is a fully humanized investigational monoclonal antibody that binds to human epidermal growth factor receptor 2 (HER2), preventing dimerization of HER2 with other HER family members and inducing antibody-dependent cell-mediated cytotoxicity. Its mechanisms of action are complementary to those of the anti-HER2 antibody trastuzumab (H) and the two antibodies combined have superior activity compared with either antibody alone in preclinical and clinical studies. In patients with advanced disease, P in combination with H has been shown to be active in patients whose disease has progressed while on H therapy (Baselga et al, *J Clin Oncol* 2010). Furthermore, P has been shown to improve the activity of H and docetaxel (T) in a randomized neoadjuvant study (Gianni et al, *SABCS* 2010, S3-2). No increase in overall toxicity and, in particular, no increase in cardiac events was observed with the addition of P to H and HT regimens.

**Methods:**

In this double-blind Phase III study patients with centrally confirmed HER2-positive metastatic or locally recurrent, unresectable breast cancer were randomized to receive either placebo+H+T or P+H+T. Patients could have received one prior hormonal treatment for metastatic breast cancer and/or prior systemic neoadjuvant or adjuvant therapy including prior H and T. Patients had to have a baseline left ventricular ejection fraction ≥50% and no history of declines to <50% during or after prior H therapy.

Study medication was as follows: P 840 mg loading dose followed by 420 mg q3w; H 8 mg/kg loading dose followed by 6 mg/kg q3w; T 75 mg/m2 q3w (with subsequent dose escalation to 100 mg/m2 if 75 mg/m2 was well tolerated). Patients were recommended to receive at least 6 cycles of T. In the case of chemotherapy discontinuation due to cumulative toxicity, antibody therapy was continued until disease progression, unacceptable toxicity, or withdrawal of consent. Patients were stratified according to region and prior treatment status (adjuvant therapy or de novo metastatic breast cancer).

The primary endpoint for the study was progression-free survival (PFS) as determined by independent review. The primary analysis was planned to take place when approximately 381 independently confirmed PFS events had occurred. This would provide 80% power to detect a 33% improvement in PFS (HR=0.75) at the two-sided significance level of 5%. Secondary endpoints included overall survival, investigator-determined PFS, overall response rate, duration of response, safety, and quality of life.

Patient safety was monitored throughout the study by an independent data monitoring committee and a cardiac review committee.

This study is registered at ClinicalTrials.gov: NCT00567190.

**Results:**

808 patients were recruited for February 2008 and July 2010. The required number of PFS events for analysis of the primary endpoint has been reached and independent assessment PFS is currently being performed. Results of the primary analysis of efficacy and safety will be presented.

**S5-6**

Neoadjuvant Pertuzumab and Trastuzumab Concurrent or Sequential with an Anthracycline-Containing or Concurrent with an Anthracycline-Free Standard Regimen: A Randomized Phase II Study (TRYPHAENA).

Schneeweiss A, Chia S, Hickish T, Harvey V, Eniu A, Hegg R, Tausch C, Seo J-H, Tsai Y-F, Ackrill A, Ross G, Cortès J. National Center for Tumor Diseases, University Hospital, Heidelberg, Germany; British Columbia Cancer Agency - Vancouver Centre, University of British Columbia, Vancouver, Canada; Royal Bournemouth Hospital, Bournemouth University, Bournemouth, United Kingdom; Regional Cancer and Blood Centre, Auckland City Hospital, Auckland, New Zealand; Cancer Institute “I. Chiricuta”, Cluj-Napoca, Romania; Hospital Pórola Byington, São Paulo, Brazil; Breast-Center, Zürich, Switzerland; Department of Internal Medicine, Korea University Guro Hospital, Guro, Korea; Taipey Veterans General Hospital, Department of Surgery, Taipei, Taiwan; Roche Products Limited, Welwyn, United Kingdom; Vall d’Hebron University Hospital, Barcelona, Spain

**Background:**

Pertuzumab (P) is a fully humanized investigational monoclonal antibody that binds to human epidermal growth factor receptor 2 (HER2), preventing homo- and heterodimerization of HER2 and other HER family members and inducing antibody-dependent cell-mediated cytotoxicity. The NeoSphere study demonstrated significantly increased antitumor activity in the neoadjuvant setting for the combination of P and trastuzumab (H) plus docetaxel (T) compared with HT alone (Gianni et al, *SABCS* 2010), consistent with the hypothesis of complementary mechanisms of action of P and H. No increase in cardiac risk was observed with the addition of P to H and HT regimens. Anthracyclines have an important role in the treatment of breast cancer and may be especially efficacious in HER2-positive disease. In the TRYPHAENA study, P and H are being administered either sequentially or concurrently with an anthracycline-containing or concurrently with an anthracycline-free standard regimen in order to establish the tolerability profile of these regimens for testing in the adjuvant setting.

**Methods:**

Patients with centrally confirmed stage II or III (including locally advanced and inflammatory disease) HER2-positive breast cancer (defined as centrally confirmed HER2 IHC 3+ or FISH/CISH+) were randomized to receive:

Study medication: P 840 mg loading dose and 420 mg maintenance; H 8 mg/kg loading dose and 6 mg/kg maintenance; T was given at 75 mg/m2 with dose escalation to 100 mg/m2 if the starting dose was well tolerated (no dose escalation in Arm C); FEC (5-fluorouracil 500 mg/m2, epirubicin 100 mg/m2, and cyclophosphamide 600 mg/m2) and carboplatin AUC 6. All treatments were given intravenously q3w. The study is ongoing. All patients will receive H for 1 year. The primary endpoint is assessment of the safety and tolerability of neoadjuvant treatment. During neoadjuvant treatment, left ventricular ejection fraction is assessed at Cycles 2, 4, and 6 by echocardiogram or multiple-gated acquisition. Safety data are supervised by a data

**Cancer Res; 71(24 Suppl.) December 15, 2011 112s Cancer Research**
and safety monitoring board. The key secondary endpoint is the rate of pathological complete response (pCR) defined as absence of invasive disease in the breast at surgery. Tissue specimens at baseline and post-surgery were required for all patients. This study is registered at ClinicalTrials.gov: NCT00976989.

**Results:** 225 patients have been recruited. No arm has required modification due to safety concerns or to excessive incidence of disease progression. Analysis of the study results is anticipated in Q3 2011. Safety/tolerability and efficacy (pCR) data will be presented.

**SS-7**

Martín M, Bonnetterre J, Geyer, Jr CE, Ito Y, Ro J, Lang I, Kim S-B, Germa C, Vernette J, Vo Van ML, Wang K, Wang K, Awada A. Hospital Universitario Gregorio Marañón, Madrid, Spain; Centre Oscar Lambret, Lille, France; Allegheny Cancer Center, Pittsburgh, PA; The Cancer Institute Hospital of JFCR, Tokyo, Japan; National Cancer Center, Goyang, Korea; National Institute of Oncology, Budapest, Hungary; Asan Medical Center, Seoul, Korea; Pfizer Global Research and Development, Paris, France; Pfizer Inc, Collegeville, PA; Bristol Meyers Squibb, Princeton, NJ; Jules Bordet Institute, Brussels, Belgium

**Background:** Neratinib (N), an irreversible pan-tyrosine kinase inhibitor (TKI), with activity against HER1, -2 and -4, has shown antitumor activity in patients (pts) with HER2+ breast cancer (BC). Lapatinib (L), a reversible HER1 and -2 TKI is approved in combination with capecitabine (C) for treatment of pts with HER2+ advanced or metastatic BC who had prior therapy.

**Materials and Methods:** This phase 2, randomized, open-label study evaluated safety and efficacy of N 240 mg/day vs L 1,250 mg/day plus C 2,000 mg/m²/day (14 days/21 day cycle) in pts with HER2+ locally advanced or metastatic BC. Eligible pts had: ≤2 prior trastuzumab regimens, prior taxane treatment, and no prior anthracycline treatment with cumulative dose >400 mg/m² doxorubicin, >800 mg/m² epirubicin, or >equivalent dose of other anthracycline. Primary endpoint was progression-free survival (PFS; investigator-assessed); secondary endpoints included safety, overall survival (OS), objective response rate (ORR), and clinical benefit rate (CBR; % pts with complete response, partial response, or stable disease ≥24 wks). Tumor assessments were every 6 wks for the first 48 wks, then every 12 wks until progressive disease (PD; RECIST 1.0) or initiation of new anticancer therapy.

**Results:** Overall, 117 pts were randomized to N and 116 to L plus C (LC). Mean age (SD; range) was 53.9 y (10.3; 28-79); 60% were White, 34% Asian, and 6% other. Prior treatments included: trastuzumab (229 pts: 168 metastatic or locally advanced, 51 adjuvant, 10 neoadjuvant), taxanes (230 pts), and anthracycline (156 pts). Median treatment duration (range) was 126.5 days (1-636) for N and 201 days (13-622) for LC. Median relative dose intensity (actual/expected exposure) for N was 100%. As of data cutoff, 84% had discontinued treatment; 65% from PD (N 63%, LC 67%), 9% for adverse events (AEs; N 7%, LC 11%). In the ITT cohort, for N and LC, respectively, median PFS (95% CI) was 4.5 mo (3.1-5.7) and 6.8 mo (5.9-8.2); P = 0.091; hazard ratio = 1.3 (95% CI, 1.0-1.8); median OS (95% CI) was 19.4 mo (19.4-22.2; 41 deaths) and 19.0 mo (16.9-NA; 35 deaths; P = 0.180); ORR (95% CI) was 29% (21-38) and 41% (32-50; P = 0.067); CBR (95% CI) was 44% (35-54) and 64% (54-73; P = 0.003). Most common drug-related treatment-emergent AEs (TEAEs; any grade) were diarrhea (N 84%, LC 67%), nausea (34%, 38%), palmar-plantar erythrodysesthesia (PPE; 5%, 63%), and rash (18%, 34%); for grade ≥3, diarrhea (28%, 10%) and PPE (0, 14%). Dose reductions/discontinuations from diarrhea occurred in 13/3 pts on N, and 15/7 pts on LC. Study deaths for N and LC, respectively, included: 36 pts (31%) and 32 pts (28%) from PD; 5 pts (4%) and 3 pts (3%) from AEs unrelated to study drug.

**Discussion:** In this setting of pts less heavily pre-treated than in the pivotal LC trial, single agent N demonstrated high anti-tumor activity (ORR 29%), confirming results from prior N phase 2 trials. N alone did not appear to be as effective as LC. No unexpected TEAEs were observed; N was well tolerated in pts with HER2+ locally advanced or metastatic BC; while diarrhea was more frequent on N than LC, it was manageable with antiidiarrheals and did not lead to more treatment discontinuations.

Menopausal-Specific and Health-Related Qualities of Life among Post-Menopausal Women Taking Exemestane for Prevention of Breast Cancer: Results from the NCIC CTG MAP.3 Placebo-Controlled Randomized Controlled Trial.

Maunsell E, Richardson H, Ingle JN, Ales-Martinez JE, Chlebowski RT, Fabian CJ, Sarto GE, Garber JE, Pujol P, Hiltz A, Tu D, Goss PE. Université Laval, Quebec City, QC, Canada; Queen’s University, Kingston, ON, Canada; Mayo Clinic, Rochester, MN; Hospital Nira Sra Sonsoles, Avila, Spain; Los Angeles Biomedical Research Institute, Torrance, CA; University of Kansas Medical Center, Westwood, KS; Center for Women’s Health and Health Research, Madison, WI; Dana Farber Cancer Institute, Boston, MA; CHU-Hopital Arnaud de Villeneuve, Montpellier, France; Massachusetts General Hospital Cancer Center, Boston, MA

**Background:** Exemestane, a steroidal aromatase inhibitor, reduced the incidence of invasive breast cancers by 65% among 4560 post-menopausal randomized to exemestane or placebo for 5 years on MAP.3. Differences in quality of life (QOL) were judged to be minimal, but only summary information was reported. **Purpose:** To provide more detailed information about effects of exemestane on menopause-specific and health-related qualities of life. **Method:** Participation in quality of life assessment was an eligibility criterion. Menopause-specific and health-related qualities of life were assessed using the MENQOL (4 scales; physical, vasomotor, psychosocial, sexual) and SF-36 (8 scales; physical health, role function – physical, bodily pain, general health, vitality, social function, role function – emotional, mental health, and 2 summary scales) instruments, respectively at baseline, 6 months and then yearly after randomization. Compliance with QOL questionnaire completion at each follow-up visit ranged from 93-98%, and did not differ by group. Change scores for each MENQOL and SF-36 scale, calculated for each assessment time relative to baseline, were compared using the Wilcoxon Rank-Sum test. Summary scores were used to summarize the QOL scores observed at each time point for each SF-36 dimension and overall mental (MCS) and physical component summaries (PCS) and MENQOL domains. Clinically important worsening of MENQOL change scores was defined as an increase of ≥0.5/8 points. SF-36 change scores were considered worsened if scores decreased by ≥5 points from baseline. **Results:** Both groups were balanced on scores for MENQOL and SF-36 at baseline. Median follow-up was 35 months and the proportion of women who stopped study medication early for toxicity reasons was 15% in the exemestane arm and 11% in the placebo arm. There was a statistically significant difference in change scores for vasomotor symptoms among women on exemestane during the first 4 years (p-values <0.01), compared to
placebo. However, no between-group differences in vasomotor change met the criterion for clinical importance. Women on exemestane had statistically poorer sexual functioning (mean change = -0.02, SD=1.37) compared to placebo (mean change = -0.12, SD=1.32) during the first 6 months on study (p-value = 0.03) but the differences were not statistically significant thereafter or clinically important at any time. Among the 8 SF-36 scales, only bodily pain was statistically different between exemestane and placebo for the first 24 months on study medication (p-value <0.01), but no between-group difference in change scores exceeded 5 points. Overall SF-36 PCS and MCS assessing changes in overall physical and mental health-related QOL did not differ significantly by group at any assessment. Conclusion: Our assessment that early differences in vasomotor symptoms and pain were probably not clinically important is supported by the observation of no between-group differences when overall physical and mental health-related QOL changes were compared. Exemestane does not appear to have a major negative impact on the quality of life among these women.

S6-2
Patient-Reported Predictors of Early Treatment Discontinuation: NCIC JMA.27/E1Z03 Quality of Life Study of Postmenopausal Women with Primary Breast Cancer Randomized to Exemestane or Anastrozole.
Wagner LI, Zhao F, Chapman J-AW, Cella D, Shepherd LE, Sledge GW, Goss PE. Northwestern University Feinberg School of Medicine, Chicago, IL; Dana-Farber Cancer Institute, Boston, MA; NCIC Clinical Trials Group, Queen’s University, Kingston, ON, Canada; Indiana University Simon Cancer Center, Indianapolis, IN; Massachusetts General Hospital, Boston, MA
Background: Patient-reported outcomes (PRO) assess symptom burden and health-related quality of life (HRQL) more accurately than clinical report. We previously found that treatment-emergent adverse events (CTCAE V3.0) did not impact efficacy in the main NCIC MA.27 trial, although many women discontinued treatment early. The purpose of this substudy was to obtain PROs in MA.27/E1Z03 participants to evaluate treatment-related side effects and HRQL between exemestane and anastrozole and to identify predictors of treatment discontinuation.

Methods: The Eastern Cooperative Oncology Group trial (E1Z03) assessed PROs in a sample of MA.27 patients (N=686; 99.3% participation rate). Participants completed the 56-item Functional Assessment of Cancer Therapy–Endocrine Symptoms (FACT-ES) pre-treatment and at months 3, 6, 12 and 24 to assess breast-cancer specific concerns, side effects of hormonal treatments and HRQL. We used 1) Wilcoxon rank sum test to compare treatment-related symptoms and HRQL between trial arms; 3) linear regression to examine the effects of symptoms on HRQL and 4) adjusted Cox regression to assess predictors of treatment duration.

Results: Participants included 371 women randomized to anastrozole and 315 randomized to exemestane. Demographic and disease characteristics were balanced between trial arms. Participants were a mean age of 65.6 yrs (SD=9.2), White (95.9%), ECOG PS of 0 (87.2%), stage T1 (75.5%) or T2 (22.7%), and stage N0 (73.9%) or N1 (16.3%). Prior treatments included partial mastectomy (65.7%), chemotherapy (27.8%) and radiotherapy (51.7%). Treatment-related symptoms measured by 23 items from the FACT-ES did not differ between treatment arms at months 3, 6, 12 and 24 and the timeline change of treatment-related symptoms was similar between treatment arms (p = ns). HRQL was significantly impacted by decreased libido, weight gain, feeling bloated, breast sensitivity, mood swings, irritability, join pain, nausea and bother by treatment side effects (p < 0.001). 248 participants were off-treatment by 4.1 yrs. A Cox model adjusted for other symptoms, demographic and disease characteristics indicated the hazard of discontinuing treatment early increased by 29% when the severity of being bothered by side effects at baseline increased by 1 point (HR=1.29, 95% CI:1.09-1.54). At baseline, patients with prior treatments or taking more medicines reported more bother by side effects (p < 0.001). Increased joint pain in the first 3 months after treatment was also associated with increased hazard of discontinuing treatment early (HR=1.13, 95% CI: 1.01-1.28).

Conclusions: PRO assessment indicated comparable symptom burden and HRQL among postmenopausal women randomized to anastrozole or exemestane, with increasing symptom burden over time negatively affecting HRQL. Patients who 1) initiate an aromatase inhibitor (AI) with bother by side effects from prior treatment and concomitant medications and 2) experience increased joint pain during the first 3 months of AI therapy are at risk for early discontinuation of AI therapy.

Influence of Hospital Factors, Physician Factors and Type of Health Insurance on Receipt of Immediate Postmastectomy Reconstruction in Young Women with Breast Cancer.
Hershcman DL, Neugut AI, Richards CA, Kalinsky K, Charles AS, Wright JD. Columbia University, New York, NY; Mailman School of Public Health, New York, NY
Objective
For women with breast cancer who choose mastectomy, breast reconstruction is known to offer a cosmetic and psychological advantage. Despite this, only a minority of patients undergo post mastectomy reconstruction. Little is known about factors that influence reconstruction in younger women who undergo mastectomy. We evaluated the association of demographic, hospital, physician and insurance factors with receipt of immediate breast reconstruction.

Methods
We used the Perspective database to identify women who underwent a mastectomy for breast cancer from 2000-2010. Perspective is a voluntary, fee-supported database that samples more than 500 acute-care hospitals throughout the United States that contribute data on inpatient hospital admissions. ICD-9 procedure codes were used to identify women who underwent reconstruction at the time of mastectomy. Differences in reconstruction rates over time were examined by age, race, and type of insurance (commercial, Medicaid, Medicare and self-pay). Logistic regression analysis was used to determine factors predictive of immediate breast reconstruction after mastectomy. Additional analyses were done on the population of younger women (<50 years of age).

Results
We identified 106,988 women with breast cancer who underwent mastectomy, and of these, 24,150 (22.6%) underwent immediate reconstruction. From 2000 to 2010, reconstruction rates increased from 15% to 33.3%, increasing the most for women with commercial insurance (25.3% to 54.6%) and women under the age of 50 (29% to 60%); for women under the age of 50 with commercial insurance the rate in 2010 was 67.5%. Multivariable analysis found that reconstruction was significantly less likely with increasing age, black race (OR=0.66), rural hospital location (OR=0.48), non-teaching hospital (OR=0.82) and >2 co-morbid conditions (OR=0.72). Odds of reconstruction increased with commercial (OR=3.0) and public
(OR=1.6) insurance (compared to self-pay), bilateral mastectomies (OR=2.5), being single (OR=1.09) and increased hospital volume (OR=1.94). No association was found with breast surgeon volume. Similar associations were seen in the subgroup of women <50 years of age. Prolonged length of stay was greater for women undergoing reconstruction (29.2% vs. 18.5%, p<0.0001); however, in-hospital complication rates were similar at 5.6% and 5.3%, respectively.

**Conclusion**
Despite its benefits, less than one-third of all women, and half of women under the age of 50, received post mastectomy reconstruction in 2010. Insurance status was one of the largest predictors of immediate reconstruction, and its influence has increased over time. Public policy should ensure that access to reconstructive surgery is available to all women, regardless of insurance type.

**S6-4**
**Protein Kinase Mutation Patterns in Human Breast Cancer.**

**Paszta L, Qi Y, Shi W, Liu C-G, Wang B, Liu X, Booser D, Esteva FJ, Symmans F, Hortobagyi GN. UT MD Anderson Cancer Center; Houston, TX**

**Background:** We performed next generation targeted sequencing of all known human protein kinases (n=530 genes) and 56 additional cancer related genes (BRCA1,2, p53, PTEN, etc.) in 112 samples to assess the kinase mutation landscape of breast cancer. Gene expression profiling was also performed on RNA from each specimen and DNA copy number variations were assessed in a subset of 59 cases using array CGH. The three types of genomic data were mapped to canonical biological pathways to identify frequently genomically disturbed pathways in these cancers. **Methods:** DNA and RNA extracted from fine needle biopsies of 92 breast cancers were analyzed, 20 samples were sequenced in duplicates or triplicates to assess technical variation of the results. Targeted sequencing was performed with Agilent SureSelect Human Kinome kit and the SOLiD sequencing platform. Gene expression profiling and array CGH were performed with Affymetrix U133A chips and Agilent 244K CGH array. Sequence data was mapped to hg19, functional impact scores were calculated with SWIFT, canonical pathways were obtained from the Broad Institute.

**Results:** 0.1% of the entire genome was sequenced and >80% of target base pairs had >20-fold coverage. The mean number of single nucleic acid variants (SNV) and indels per sample was 1043 (range: 493-1583, about 60% homozygous) and 159 (range: 75-269) respectively, 97% of SNVs and 78% of indels were already represented in dbSNP or COSMIC data bases. About 20% of SNVs were predicted to alter kinase or other biological function. The mean number of functionally high impact SNVs was 28 per sample (range 11-47). In addition to known p53 and PI3K mutations we detected frequent mutations in BRCA1 (20%) and observed several predicted high impact SNVs in HER2 (20%) as well as in many MAPK family enzymes. Not all SNVs were distributed equally across disease subsets, SNVs in ULK4, BMP2K, PALB2, ALPK3 were more frequent in triple negative cancers (TNBC) whereas SNVs in EPHA2 was more common in ER+ cancers. Among TNBC, those with residual cancer after neo-adjuvant chemotherapy (n=22) had significantly higher rates of SNVs in HUNK, TRPM7, NEK1 and HER3 compared to cases with pathologic complete response (n=25). When high impact SNVs, DNA copy number alterations and gene over-expression (relative to normal breast n=45) observed in individual cases were mapped to biological pathways a complex network of anomalies emerged for each case. **Conclusion:** We observed several known mutations in cancer genes and also detected many SNVs in important regulatory genes that were previously described as functional, germ-line variants with experimentally validated or suspected impact on protein function. Individual cancers have unique combinations of these events. This suggest that cancers arise in the context of complex genomic “germ line noise” which may determine which types of somatic events can or cannot “drive” individual cancers. The data also suggest therapeutic hypotheses about what biological pathways should be targeted in individuals and in subsets of cancers.

**S6-5**
**Obesity Drives Epithelial-to-Mesenchymal Transition and Tumor Progression in a Novel Claudin-Low Mammary Cancer Model.**

**Duplak SM, Chiao LJ, Nogueria L, Usary J, Perou CM, Varticovski L, Hursting SD. University of Texas, Austin, TX; University of North Carolina, Chapel Hill, NC; National Cancer Institute, Bethesda, MD; University of Texas M.D. Anderson Cancer Center; Smithville, TX**

Background: Epidemiological evidence suggests a potential role of obesity in regulating clinical subtype, differentiation status, and prognosis of breast cancer. Specifically, an elevated waist-hip ratio is associated with increased risk and progression of basal-like breast cancer, an aggressive form characterized by heterogeneous tumors typically enriched in a putative tumor initiating cell (TIC) population. However, the exact mechanism of obesity-driven tumor progression remains unknown. Therefore, we hypothesized that obesity regulates a plastic population of multipotent malignant cells.

**Materials, Methods, and Results:** To test this hypothesis, we generated and characterized two distinct murine mammary tumor cell lines derived from MMTV-Wnt-1 transgenic mice, designated M-Wnt and E-Wnt. M-Wnt cells displayed a mesenchymal morphology while E-Wnt cells had an epithelial morphology. M-Wnt cells harbored a large CD44+/CD24- putative TIC population (62% +/- 7.8), had significant mammosphere forming capacity (>30%) of cells form mammospheres, p<0.0001), and increased ALDH activity (7% are ALDH+, p=0.0004). M-Wnt cells have increased migration (scratch assay) and invasion in vitro (226-fold higher after 30h, p<0.0001). As few as 50 unsorted M-Wnt cells, injected into C57BL/6 mice were capable of forming a tumor. Microarray analysis revealed that M-Wnt cells display gene expression profiles virtually identical to human Claudin-low breast tumors, while E-Wnt cells clustered with basal-like tumors. EMt and stem cell gene expression patterns of M-Wnt cells were maintained in vivo, including decreased E-cadherin and increased N-cadherin, fibronectin, vimentin, SNAI1, TWIST, SLUG, FOXC2, and TGF-β (p<0.05 for all). Using these cell lines in vivo, we tested the hypothesis that energy balance modulation, through diet-induced obesity (DIO) and calorie restriction (CR), regulates the TIC population. We found that M-Wnt tumors, transplanted into ovariectomized syngeneic female C57BL/6 mice, grew at significantly different growth rates depending on the diet treatment (DIO > Control, p=0.011; CR < Control, p=0.012), while E-Wnt tumors were only affected by CR (CR < Control p=0.001; no difference between DIO and Control tumors). DIO enhanced M-Wnt tumor progression, adipocyte infiltration, and central necrosis and drove EMT (decreased E-Cadherin and increased fibronectin and N-Cadherin expression) through modulation of key TIC associated genes, including increased TGF-β, SNAI1, FOXC2, and Oct4 (p<0.05 for all).

**Discussion:** In conclusion, we found that the mesenchymal M-Wnt cell line is highly responsive to changes in dietary energy balance status relative to the E-Wnt differentiated epithelial cell line, which demonstrates that clinical subtypes of breast cancer are differentially regulated by energy balance modulation. Additionally, our data demonstrates, for the first time, that energy balance modulation (ie, CR and obesity) directly regulates EMT, in response to local upregulation of TGF-β signaling.
S6-6
Expression of Key Estrogen-Regulated Genes (ERGs) Differ Substantially across the Menstrual Cycle in ER+ Breast Tumours.

Haynes BP, Vade B, A’Hern R, Smith IE, Dowsett M, Galimberti V, Rotmensz N, Gibelli B. Royal Marsden Hospital, London, United Kingdom; Institute of Cancer Research, Sutton, Surrey, United Kingdom; European Institute of Oncology, Milan, Italy

Aim: To determine whether there are substantial changes in the expression of ERGs in estrogen receptor positive (ER+) breast cancer through the menstrual cycle.

Background: Plasma levels of estradiol (E2) vary from c.100pM to c.1000pM and progesterone levels from <3nM to >50nM through the menstrual cycle. The changes in E2 are proportionally similar to those that occur in postmenopausal women treated with an aromatase inhibitor which lead to profound changes in the expression of ERGs. However, there are only inconsistent data on whether the cyclical changes in hormone levels during the menstrual cycle affect gene expression in ER+ tumours.

Methods: 173 paraffin-embedded ER+ breast carcinomas were analysed from premenopausal patients in which day of menstrual cycle and hormonal data were recorded at the time of surgery. Patients were ascribed to one of 3 pre-defined time windows of the menstrual cycle: window 1: days 27-35 + 1-6 (low circulating E2 and progesterone); window 2: days 7-16 (high E2 and low progesterone); window 3: days 17-26 (moderate E2 and high progesterone). RNA was extracted (RecoverAll; Ambion) and QPCR used to measure expression of ESR1, 4 ERGs (TFF1, PGR, GREB1 and PDZK1) and 3 housekeeping genes.

Results: ESR1 expression did not differ significantly across the menstrual cycle but there was strong evidence of differences in the ERGs (Kruskal-Wallis; p≤0.0015 to 0.093). Gene expression levels of the 4 ERGs were 51-109% higher in window 2 than window 1 (see table) and this was significant for PGR, GREB1 and TFF1 and approached significance for PDZK1. The expression of all the ERGs was lower (14-59%) in window 3 compared to window 2 (significant for TFF1). PGR and GREB1 expression was significantly different (30-40%) in window 3 compared to window 1.

</tbody>
</table>

The average expression of these 4 ERGs gives the AvERG, a previously defined index of estrogen responsiveness. This showed similar changes to the individual ERGs but the reduced variability of the AvERG led to even greater statistical significance. A control set of ER-tumours (n=83) showed very low expression of the ERGs and no cyclical changes.

Discussion: These data reveal significant changes in breast tumour biology across the menstrual cycle. As these changes are likely to occur only in tumours that are estrogen-dependent their measurement may potentially be developed as a test of a tumour’s likely response to estrogen deprivation. Several ERGs are present in currently used molecular profiling tests; variable expression of these markers through the menstrual cycle may affect the interpretation of the tests.

The addition of dasatinib to fulvestrant would increase progression-free survival (PFS) over fulvestrant alone in MBC. Methods: This is a randomized phase II study including patients with evaluable or measurable ER+ MBC whose disease had progressed while on adjuvant or metastatic NSAI. Patients were stratified to ≤ 2 yrs vs > 2 yrs from initial breast cancer diagnosis to first diagnosis of metastatic disease and randomly assigned 1:1 to Arm 1 (loading dose of fulvestrant 500 mg followed by 250 mg IM and dasatinib 100 mg PO QD) or Arm 2 (single-agent fulvestrant 250 mg IM). Following FDA approval in 2010 of the 500 mg dose, a loading dose (500 mg) of fulvestrant on Day 1 was followed by 500 mg on Day 15 of Cycle 1 and on Day 1 of each subsequent cycle (n=40 patients received the higher dose). Arm 2 patients who progressed while on fulvestrant could cross over to receive fulvestrant plus dasatinib. The primary objective was median PFS. Secondary objectives included overall survival (OS), overall response rate (ORR), and safety.

Results: The study included 99 patients, 50 in Arm 1 (combination) and 49 in Arm 2 (fulvestrant alone). Results for Arm 1 and Arm 2, respectively, were: median PFS 6.0 and 5.3 months; median OS 17.0 and 21.7 months; and clinical benefit rates (CBR) (PR+SD≥6 months) were 14 (28.0%, 95%CI=16.2%-42.5%) and 16 (32.7%, 95%CI=19.9%-47.5%) months. In Arm 1 and Arm 2, 24% and 8% developed grade 1/2 pleural effusion; 34% and 10% developed grade 1/2 diarrhea, 40% and 6% developed grade 1/2 nausea, and 30% and 18% developed grade 1/2 fatigue. Six patients on Arm 1 stopped dasatinib due to AEs, mainly pleural effusion and dyspnea. Eighteen (37%) Arm 2 patients crossed over to receive combined fulvestrant/dasatinib at disease progression on fulvestrant. Median PFS for crossover patients was 3.8 months, with the longest duration of treatment being 12 and 15 months in 2 patients.

Conclusions: The addition of dasatinib to fulvestrant in ER+ postmenopausal MBC patients whose disease had progressed through an NSAI did not improve PFS, CBR, or OS. The combination of fulvestrant and dasatinib in patients with ER+ MBC was well.
tolerated. Formalin-fixed paraffin-embedded archival BC tissue is being analyzed for SRC-related signature to determine whether a subset of patients benefit from dasatinib.

**PD01-02**

**Randomized Phase II Study of Dasatinib vs Placebo in Addition to Exemestane in Advanced ER/PR-Positive Breast Cancer [BMS CA180-261 Study].**

Llombart A, Ravaiolli A, Straus L, Sy O, Abrahao F, Geese WJ, Lortholary A, Rea D, Ro J-S, Sohn J, Kim S-B, Curigliano G. Hospital Universitari Arnau De Vilanova, Lleida, Spain; Ospedale degli Infermi di Rimini, Rimini, Italy; Bristol-Myers Squibb, Wallingford, CT; Centre Catherine De Sienne, Nantes, France; City Hospital, Birmingham, United Kingdom; National Cancer Center, Gyeonggi-Do, Korea; Yonsei Cancer Center, Seoul, Korea; Asan Medical Center, Seoul, Korea; Instituto Europeo di Oncologia, Milano, Italy

**Background:** Src-family kinases (SKFs) are involved in estrogen receptor (ER) and progesterone receptor (PgR) signaling pathways, in resistance to hormonal therapy, and in osteoclast function. Dasatinib is a potent oral inhibitor of SKFs and other kinases, but single-agent activity in advanced breast cancer (ABC) is limited. Biomarkers may identify patient subsets with increased benefit. In this Phase II study, the combination of dasatinib with exemestane was evaluated in patients (pts) with ER+ and/or PgR+ ABC resistant to a nonsteroidal aromatase inhibitor (NSAI).

**Methods:** In a randomized double-blind Phase II trial (CA180-261), 157 patients (pts) with ECOG performance status of 0-1, measurable or evaluable disease, and progression (PD) during, or within 1 year after adjuvant, treatment with an NSAI were stratified by symptomatic bone metastasis (SBM) and other factors, and assigned 1:1 to receive dasatinib (100 mg daily) or matched placebo in combination with exemestane (25 mg daily). Progression-free survival (PFS) was the primary endpoint and clinical benefit (CBR; partial response+stable disease ≥24 wks) the key secondary endpoint. The study was designed for 80% power to detect a hazard ratio (HR) of 0.67 between arms, corresponding to median PFS increase from 4 to 6 months using 1-sided α=0.1. Archival tumor samples for biomarker analysis were collected. Patient-reported pain score and a measure of bone lysis (urinary N-telopeptide, uNTX) were collected serially in pts with SBM.

**Results:** Planned analysis was performed after 119 events (PD or death) were recorded, at which time 129 pts had discontinued study treatment. Overall PFS comparison was non-significant (HR=0.86; 1-sided p=0.148), with median PFS of 16 weeks (95% CI 12, 18) in the placebo arm and 18 weeks (95% CI 15.24) in the dasatinib arm. Estimated free-from-progression rate at 24 weeks was 33% in placebo and 43% in the dasatinib arm. Pts with SBM, 40% of study population, had improved PFS on the dasatinib arm (HR=0.68, 1-sided p=0.094). Preliminary CBR at this analysis (31 of 38 censored pts continue on study) was higher in the dasatinib arm. Expected dasatinib-related toxicities were observed, including pleural effusion [23% (5% Gr≥3) in dasatinib vs 1% (0 Gr≥3) in placebo] and diarrhea [25% (1% Gr≥3) vs 1% (0 Gr≥3)]. Musculoskeletal adverse events (AEs) were comparable between arms, but fatigue or asthenia [37% (4% Gr≥3) vs 20% (0 Gr≥3)], skin AEs [28% (1% Gr≥3) vs 11% (0 Gr≥3)] and headache [22% (3% Gr≥3) vs 9% (0 Gr≥3)] were more common in dasatinib arm. Dose interruption or reduction was more frequent for dasatinib compared to placebo. Biomarker analyses are in progress.

**Conclusion:** PFS difference (HR=0.82) was not significant in overall study population, but higher CBR in the dasatinib arm and higher PFS in pts with SBM (HR=0.68) suggests that dasatinib has efficacy in a subset. The safety profile was consistent with dasatinib experience; AEs, including pleural effusion and diarrhea, were more common with dasatinib as compared with placebo. Updated efficacy and biomarker analyses will be presented.

**PD01-03**

**Src Is a Potential Therapeutic Target in Endocrine Resistant Breast Cancer Exhibiting Low Estrogen Receptor (ER)-Mediated Transactivation.**

Guest SK, Pancholi S, Patani N, Dowsett M, Johnston SR, Martin L-A. Institute of Cancer Research, London, United Kingdom; Royal Marsden Hospital, London, United Kingdom

**Aim:** Identification of the mechanisms governing sensitivity to dasatinib in endocrine resistant breast cancer.

**Background:** Despite the effectiveness of endocrine therapies over 40% of women relapse. To identify the molecular mechanisms associated with resistance to estrogen-deprivation on an aromatase inhibitor, we previously assessed changes in gene expression during adaptation to long-term culture of MCF7 human breast cancer (BC) cells in the absence of estradiol (E2) (LTED). Analyses of canonical signaling pathways highlighted FAK as one of the major pathways up regulated at the point of resistance and src as a dominant gene in this pathway. Src phosphorylates a plethora of proteins including ER. Surprisingly dasatinib a pan src inhibitor enhanced proliferation of MCF7 cells in the absence of E2 and had limited anti-proliferative effect in the LTED model. In contrast tamoxifen resistant MCF7 cells (TAMR) were exquisitely sensitive to dasatinib [1].

**Methods:** Proliferation was assessed using Titre Glo™. ER-mediated transcription was measured with an estrogen-response element linked luciferase reporter construct. Protein expression was determined by immunoblotting. Confocal microscopy was used to determine cellular localization of ER.

**Results:** Dasatinib decreased proliferation of the TAMR (IC50 0.05nM) and resensitized them to tamoxifen but had no effect on the wild-type (wt)-MCF7 or LTED cells. Previously a relationship between BC subtype and sensitivity to dasatinib was reported with basal and post-EMT BC cell lines showing the highest sensitivity, which associated with high caveolin (CAV) expression [2]. In ovarian cancer expression of CAV and urinokine plasminogen activator (uPA) also predicted sensitivity to dasatinib [3]. TAMR cells had a 2-fold increase in CAV-1 and 7-fold increase in uPA compared to wt cells. Comparison of LTED and TAMR showed that the TAMR whilst continuing to express high levels of ER, had a 10-fold lower level of ER-transactivation compared to wt-MCF7 and did not express PGR. In contrast the LTED showed a 7-fold increase in ER-transactivation compared to wt cells in the absence of E2. Strong evidence suggests ER in the TAMR cells acts via a non-genomic mechanism with ER expressed throughout the cell rather than being restricted to the nucleus. This implies the TAMR have an impaired luminal phenotype in relation to ER-genomic function. Dasatinib reduced the expression of ER in the TAMR and resulted in nuclear shuttling of ER whilst having no effect on the wt. BT474 (ER+/HER2 amplified) showed a similar distribution of ER to the TAMR cells but were far less sensitive to the antiproliferative effect of dasatinib. Of note the TAMR have increased phosphorylation of HER2 but no amplification.

**Conclusion:** These data suggest src has differential effects in these endocrine resistant cell lines. The anti-proliferative effect of dasatinib was more pronounced in the endocrine resistant cell line with low ER.
genomic activity. Src inhibition warrants further clinical evaluation as a therapeutic target in endocrine resistant breast cancer.

**PD01-04**
Entinostat, a Novel Histone Deacetylase Inhibitor, Added to Exemestane Improves PFS in Advanced Breast Cancer in a Randomized, Phase II, Double-Blind Study.
Yardley DA, Ismail-Khan RR, Klein PM, Sarah Cannon Research Institute, Nashville, TN; Tennessee Oncology, PLLC, Nashville, TN; H. Lee Moffitt Cancer Center, Tampa, FL; PMK Consulting, San Francisco, CA

**Background:** Entinostat is a novel, oral, class I-selective histone deacetylase inhibitor (HDACi) that has been shown pre-clinically to inhibit mechanisms of aromatase inhibitor (AI) resistance through epigenetically driven down-regulation of activated growth factor signaling pathways and normalization of estrogen receptor levels. This provided a strong rationale for the entinostat breast cancer (BC) program, which was designed to evaluate entinostat’s ability to increase and/or restore sensitivity to treatment with an AI. **Methods:** Postmenopausal women with ER+ advanced BC who had ≤ 1 prior chemotherapy and had progressed on a non-steroidal AI were randomized 1:1 to exemestane 25 mg daily + entinostat 5 mg or placebo weekly. Progression free survival (PFS) was the primary endpoint; objective response rate and clinical benefit rate were secondary endpoints and overall survival (OS) was an exploratory endpoint. Prospectively defined subsets of interest included patients with “AI-sensitive and AI-resistant disease”. AI-sensitive was defined as having had a PR, CR or SD for ≥ 6 months (mos) in the metastatic setting or having completed and remained disease free for ≥12 months post adjuvant therapy. All others were considered AI-resistant. Treatment continued until disease progression or unacceptable toxicity. Response assessments were performed every 8 weeks.

**Results:** 130 women were enrolled (64 exemestane+entinostat [E+E]; 66 exemestane+placebo [E+P]). All but 1 patient had Stage IV disease. 82% had measurable disease, of which 60% had visceral involvement. 42% had 1 prior line of hormonal therapy; 58% had >1. Analysis of the intent-to-treat (ITT) population showed significantly (defined prospectively as p<0.10) longer PFS with E+E than with E+P (median 3.72 vs. 1.78 mos; p<0.006) (CI 0.49, 1.09). While not powered, results for pre-defined subsets were consistent with improved PFS in the E+E arm. Interestingly, the subset of patients identified as AI-resistant, demonstrated a HR of 0.61 (CI 0.30, 1.25) (median 3.72 vs. 1.78 mos). While OS is still early, at 18 mos median follow-up at time of abstract submission, the E+E arm demonstrated a median OS of 26.94 mos compared to the E+P arm of 20.33 mos (HR = 0.56) (CI 0.31, 1.02). Entinostat combined with exemestane was well tolerated. The most frequent adverse events (AEs) were fatigue, gastrointestinal disturbances, and hematologic abnormalities. AEs with ≥ 20% higher incidence with E+E than E+P were fatigue (46% vs 26%) and uncomplicated neutropenia (25% vs 0%). Serious AE rate was similar for both arms (13% vs 12%).

**Conclusions:** Adding entinostat to exemestane resulted in improved PFS, the study’s primary endpoint. At a median follow-up of 18 mos, the exploratory endpoint of OS was also increased in the E+E arm. Importantly for a phase II study, the PFS benefit in all subsets evaluated was consistent with the overall improvement seen in the ITT. These data demonstrate that the addition of entinostat to AI therapy may prolong the duration of AI therapy, thereby delaying the initiation of subsequent therapies such as chemotherapy, a goal for many breast cancer patients. A phase III study is planned.

**PD01-05**
Histone Deacetylase Inhibitor LBH589 (Panobinostat) Suppresses the Activated-NFκB Pathway in Acquired Aromatase Inhibitor Resistant Breast Cancer Cells.
Kubo M, Kanaya N, Liu Z, Chen S. Beckman Research Institute of the City of Hope, Duarte, CA

**Background:** Aromatase inhibitors (AIs) are effective in treating postmenopausal patients with estrogen receptor (ER)-positive breast cancer. However, resistance to endocrine therapies remains a major problem in the management of ER-positive breast cancer. Recently, histone deacetylase inhibitors (HDACis) show promise as cancer therapeutics, but the full scope of their utility remains unknown. **Experimental Design:** In order to search for critical genes in developing resistance to AI, a microarray study was performed on AI resistant cells derived from MCF-7aro cells that overexpress aromatase and on AI resistant tumors from our mouse experiments. Moreover, using MCF-7aro cells that are resistant to anastrozole (Ana-R), letrozole (Let-R), and exemestane (Exe-R), as well as LTEDarO, we evaluated the significance of NFκB1 and several regulatory genes in AI resistance, and the anti-NFκB1 activity of HDACi LBH589 in vitro and in vivo.

**Results:** Significant changes (Fold change cutoff > 1.5, false discovery rate < 0.05) in the expression levels of 22 genes among three networks were identified from microarray analysis of our in vitro and in vivo models of acquired AI resistance. NFκB1 is a key player in one of three networks, including 11 genes, and is functionally up-regulated in all AI resistant cells. NFκB1 knockdown suppresses the proliferation of AI resistant cells more than that of MCF-7aro cells. Moreover, AI resistant cell lines are highly sensitive to LBH589 treatment and apoptosis is induced in these cell lines. LBH589 suppressed NFκB1 as demonstrated at both the mRNA and protein levels in LTEDarO and other AI resistant cell lines. Furthermore, the LBH589 treatment abrogated tumor growth in mice, and was associated with significant decreased levels of NFκB1 in tumors.

**Conclusions:** Our findings provide new insights into how the NFκB1-mediated networks play roles in AI resistance, and strongly support that LBH589 offers a novel therapeutic strategy for patients with AI resistant breast cancer.

**PD01-06**
Endoxifen Exhibits Potent Anti-Tumor Activity and Regulates Different Genes Than Tamoxifen in an Aromatase Expressing MCF7 Model Resistant to Letrozole.

**Background:** First in human studies of Z-endoxifen hydrochloride (E), the active metabolite of tamoxifen (T), are underway in metastatic breast cancer. **Experimental Design:** In order to search for critical genes in developing resistance to AI, a microarray study was performed on AI resistant cells derived from MCF-7aro cells that overexpress aromatase and on AI resistant tumors from our mouse experiments. Moreover, using MCF-7aro cells that are resistant to anastrozole (Ana-R), letrozole (Let-R), and exemestane (Exe-R), as well as LTEDarO, we evaluated the significance of NFκB1 and several regulatory genes in AI resistance, and the anti-NFκB1 activity of HDACi LBH589 in vitro and in vivo.

**Results:** Significant changes (Fold change cutoff > 1.5, false discovery rate < 0.05) in the expression levels of 22 genes among three networks were identified from microarray analysis of our in vitro and in vivo models of acquired AI resistance. NFκB1 is a key player in one of three networks, including 11 genes, and is functionally up-regulated in all AI resistant cells. NFκB1 knockdown suppresses the proliferation of AI resistant cells more than that of MCF-7aro cells. Moreover, AI resistant cell lines are highly sensitive to LBH589 treatment and apoptosis is induced in these cell lines. LBH589 suppressed NFκB1 as demonstrated at both the mRNA and protein levels in LTEDarO and other AI resistant cell lines. Furthermore, the LBH589 treatment abrogated tumor growth in mice, and was associated with significant decreased levels of NFκB1 in tumors.

**Conclusions:** Our findings provide new insights into how the NFκB1-mediated networks play roles in AI resistance, and strongly support that LBH589 offers a novel therapeutic strategy for patients with AI resistant breast cancer.
µg/day, sc), endoxifen 25 mg/kg/day p.o. (LDE) endoxifen 75 mg/kg/ day p.o. (HDE) or letrozole, 10 µg/day s.c. for 4 weeks. Tumors were harvested from control, T, and E groups while the L group continued treatment until the development of resistance defined as an increase in tumor volume of at least 300% from day 1. Mice with L-resistant tumors were randomly assigned to T (n=4) or E (n=5) for 4 weeks and then sacrificed. Gene expression in L-resistant tumors was quantified using Affymetrix U133+2 and changes in gene expression profiles [comparing T and E with L-resistant (n=3)] were analyzed. Genes identified as significantly different were confirmed by real-time RT-PCR assays.

Results: At the 4 week time point, both doses of E and L resulted in greater anti-tumor activity than control (Wilcoxon rank sum test: all p < 0.0001); however, tumor burden did not differ between T and control (p=0.095). HDE resulted in significantly less tumor burden than T (p=0.002) but was similar to L. In mice that continued on L, resistance developed at 24 weeks in 9/25 mice. These mice were randomly assigned to either T (n=4) or E (n=5) for 4 weeks. Tumor volume (expressed as a % of its size prior to randomization) was significantly different comparing E (73.3%; range: 69.3 to 80.75%) versus T (148.39%; range: 114.07 to 165.99%) (Wilcoxon rank sum test p=0.016). Compared to control, microarray studies identified 1518 unique probe sets regulated by E (p=0.001) compared to 441 for T including estrogen-regulated genes such as progestrone receptor (PGR) and amphiregulin (AREG) that were significantly down-regulated in the E group [PGR (-6.2 fold, p=0.000008) and AREG (-3.2 fold, p=0.0006) but unchanged or up-regulated in the T group (PGR unchanged and AREG +0.2 fold p=0.0002)]. These findings were confirmed by RT-PCR.

Conclusions: Using the MCF7/AC1 model previously used to show the superiority of AIs over T, HDE demonstrated similar anti-tumor activity to L and was superior to T. In cells resistant to L, E was superior to T and gene expression changes demonstrate that E down-regulates while T activates estrogen regulated genes. These findings support the ongoing development of E for the treatment of ER+ BC.

**PD01-07**

**AR Overexpression and Aromatase Inhibitor Resistance in Breast Cancer.**

Rechoum Y, Iacopetta D, Barone I, Ando 'S, Morales SF , Weigel NL, Fuqua SAW. Baylor College of Medicine, Houston, TX; University of Calabria, Calabria, Italy

Background: Aromatase inhibitors (AIs) have emerged as the therapy of choice for the treatment of estrogen receptor alpha (ERα) positive breast cancer. Although the involvement of the ERα in AI resistance is well established, the role of the androgen receptor (AR) is not known. It has been estimated that about 60%-70% of ERα-positive breast cancer co-express the AR, and that AR agonists can either inhibit or stimulate breast cancer cell proliferation. Thus it is important to determine if there are biomarkers predicting AR’s effects in breast tumors. We have previously shown a role for AR-overexpression in tamoxifen resistance in ERα-positive MCF-7 breast cancer cells; here we hypothesized that AR overexpression might similarly be involved in resistance to the AI anastrozole (Anas).

Materials and Methods: Stable transfection of MCF-7 cells was performed to generate cell lines that express the aromatase gene (MCF-7 BK Arom) and then co-transfected with an AR expression vector (MCF-7 AR Arom). Aromatase and AR expression levels were evaluated by western blot analysis, and the enzyme activity was evaluated using aromatase activity assays. Proliferation was tested using anchorage independent soft agar assays and MTT in the presence of the androgen substrate androstenedione (AD), or AD plus Anas. ERα and AR transcriptional activities were tested with ERE-luciferase reporter assays. Localization of ERα and AR within the cells was visualized using immunofluorescence microscopy. Results: ERα-positive MCF-7 cells were stably transfected with either aromatase, or aromatase plus AR. MCF-7 aromatase clones overexpressing AR were resistant to the growth inhibitory effects of Anas when stimulated with the androgen AD. Resistance was not mediated through changes in aromatase expression or activity. The growth of several of the AR Arom-overexpressing cells was stimulated with treatment of Anas alone, suggesting that Anas was acting as an agonist. As expected, AD treatment stimulated ERα transcriptional activity, but Anas was unable to block AD-stimulated activity in AR Arom-overexpressing cells using ERE-Luciferase reporter assay. Anas was able to enhance AR and ERα colocalization in AR-overexpressing cells. Resistance was not associated with activation of known mechanisms of resistance, such as HER2, IGF-1R, or MAPK. However AR-overexpressing cells had higher constitutive phosphorylation of FAK. Accordingly, resistance to Anas was blocked using an Akt1/2 inhibitor.

Conclusion: Using a model of ERα-positive breast cancer cells expressing exogenous aromatase and AR, we have demonstrated that AR overexpression confers resistance to the AI Anas. These results suggest that in patients recurring on hormonal therapy whose tumors express elevated levels of AR, targeted therapy to Akt might restore hormone sensitivity.

**PD01-08**

**Heterogeneity of Lapatinib Responses in HCC1954 HER2-Overexpressing Breast Cancer Cells Revealed by Single-Cell Automated Microscopy.**

Hardeman KN, Tyson D, Quaranta V. Vanderbilt University School of Medicine, Nashville, TN

In breast cancer, 20-30% of patients present with HER2 overexpression, making them potential candidates for targeted HER2 therapies such as lapatinib. Lapatinib is a dual, intracellular tyrosine kinase inhibitor of HER2 & EGFR and is standard care for metastatic breast cancer. Drug resistance to this type of therapy is a major cause of death in cancer patients. Intra-tumor heterogeneity with respect to drug response can be a driving force for relapse and/or drug resistance. In current drug response end-point assays (IC50), information on heterogeneity is lost because cell differences are averaged out over the whole population. To produce a more realistic appreciation of drug response variability within a tumor, our lab has developed an extension of high content automated microscopy, called Extended Time Resolved Automated Microscopy (ETRAM). ETRAM entails the visual tracking of single cells with fine temporal & spatial resolution, allowing for the calculation of proliferation, death, and quiescence rates from image stacks and movies. HER2+ breast cancer HCC1954 cells were fluorescently labeled w/ a nuclear tag (H2BmRFP) and treated w/ lapatinib in a dose-dependent manner, from 2000 nM to 0 nM (DMSO control). Using the ETRAM method we followed nearly 1000 single cells/treatment condition over 72 hours, acquiring images every 10-12 minutes. Unexpectedly, we discovered that small but significant subpopulations of HCC1954 cells were unaffected by high lapatinib concentrations (2000 nM) and continue to divide. Furthermore, a substantial subpopulation responds to high lapatinib by entering quiescence, not apoptosis. Since HCC1954 cells have a previously reported lapatinib IC50 of 300 nM, our data demonstrate a need to further investigate these subpopulations of cells in order to determine
their contribution to the IC50. Image stacks are being further analyzed to extract cellular metrics of division, quiescence and death rates in the presence of lapatinib. We are also investigating single cells by immunofluorescence of signaling molecules in the HER2 pathway, along with downstream targets such as PI3K, mTOR/AKT, SHC, and RAF1, to assess molecular differences regarding dividing and quiescent subpopulations in lapatinib, versus lapatinib-sensitive cells that apoptose. Our ETRAM-based single cell analyses may stimulate a re-interpretation of lapatinib responses in HER2-overexpressing breast cancer, and hopefully point to improved strategies of lapatinib treatment.

**PD01-09**

Jeff A, Ward TM, Iorns E, Gallas M, Aparicio SA, Pegram MD. Braman Family Breast Cancer Institute, Sylvester Comprehensive Cancer Center, University of Miami Miller School of Medicine, Miami, FL; UBC/BC Cancer Agency, Vancouver, Canada

Background: Overexpression of the epidermal growth factor receptor ERBB2 (HER2) is found in 20% of human breast cancers. Therapies targeting ERBB2 including trastuzumab and lapatinib have significantly improved the outlook for women with ERBB2+ breast cancer. However, resistance to these agents occurs frequently and remains a significant clinical problem. In the case of lapatinib resistance, the mechanism(s) of resistance remain poorly understood, since the current proposed rationale thought to limit lapatinib’s anti-tumor effects has been difficult to reconcile with clinical data. Therefore, we hypothesize that novel mechanisms of resistance could be identified by mapping genomic variations in ERBB2+ cells with acquired resistance to lapatinib. The identification of such mutations may provide insights into mechanisms of resistance and may indicate therapeutic strategies to overcome lapatinib resistance in ERBB2+ breast cancer.

Material and Methods: SKBR3 breast cancer cells resistant to lapatinib were generated through serial passage by exposure of drug sensitive parental SKBR3 cells to increasing concentrations of lapatinib up to the peak plasma concentration observed in human subjects (2.6 μM (SK-lapR)). Multiple signaling pathways in lapatinib sensitive and resistant cells were interrogated by Reverse Phase Protein Array (RPPA) and western blot analysis. To identify genome wide somatic mutations, the Exome of lapatinib resistant and sensitive SKBR3 cells was sequenced utilizing next generation deep sequencing. Following exclusion of germline variants, the acquired gene mutations in lapatinib resistant SKBR3 cells were confirmed by DNA re-sequencing of PCR amplified DNA segments.

Results and Discussion: Analysis of activated signaling pathways in lapatinib resistant and sensitive SKBR3 cells did not confirm any of the previously proposed mechanisms of resistance. In particular, these cells show no activation of AKT or alternative receptor tyrosine kinases such as IGF-IR, ERBB3 or c-Met. However they exhibit sustained activation of mTORC1 and ERK1/2, as well as phosphorylation of STAT3, STAT5, rpS6 and CREB. Initial sequence analysis of exome and transcriptome reveals the presence of 76 single nucleotide variants/Indels differing between sensitive and resistant cells with 34/76 validated as true mutations present in the genome of lapatinib resistant SKBR3 cells, including mutations in LAT52, MAP3K5, SMAD5 and PDGFRA. This is the first exome sequence analysis to be reported which defines a drug resistant phenotype in ERBB2+ breast cancer. Ongoing work includes investigation of mutations as drug resistance mediators and analysis of copy number variations and gene fusions/translocations to systematically search for molecular alterations, with the goal of providing a rationale for the design of new combination therapies aimed at lapatinib resistance for ERBB2+ breast cancer.

**PD02-01**

Impact of Contralateral Prophylactic Mastectomy on Surgical Outcomes.

Background: Among women with unilateral cancer, rates of contralateral prophylactic mastectomy (CPM) are continuing to increase. However, little is known about whether rates and types of complications differ between patients undergoing unilateral mastectomy or bilateral mastectomy, limiting the surgical outcomes evidence that can be presented in pre-surgical decision making for women considering CPM. This study was undertaken to determine whether surgical complications are increased in women undergoing CPM compared to those without CPM.

Methods: Between the years 2005-2010, all patients at UCSF undergoing mastectomy with immediate reconstruction were entered into a prospective database. This database was queried for patients with unilateral cancer who had mastectomy and immediate reconstruction with or without CPM. Surgical outcomes, including implant loss, admission for IV antibiotics, and return to OR were evaluated and compared between patients who did and did not undergo CPM. Patients with bilateral cancer or bilateral prophylactic surgery were excluded; analyses were limited to patients with a minimum of 1 year follow-up.

Results: 468 patients were identified who met study criteria, totaling 667 breasts. Mean follow-up was 22 months (range 12 – 69 months). 269 of the 468 (57.5%) patients had unilateral mastectomy only, while 199 of 468 (42.5%) patients also had CPM. There were no differences in tumor grade, stage, follow-up time, smoking history, or radiation (prior or post-surgery) between the two groups. The only significant differences between the unilateral and bilateral groups were median age at diagnosis (50.7 vs. 45.9 respectively; p < .0001) and receipt of neoadjuvant chemotherapy (34.7% vs. 41.3% respectively; p < .01). Surgical outcomes were compared between groups. The overall rate of major complications differed significantly due to an increased rate of infectious complications and unplanned return to surgery in the CPM group (Table 1). Nevertheless, this did not result in a higher implant loss rate in the CPM group.

p < .01; 1'st not significant

In patients undergoing bilateral mastectomy, overall complication rates were comparable between the index breast and the CPM breast; however, there was a higher implant loss rate in the index breast (22/177 vs. 11/188; p=0.05).

Conclusions: While CPM is an increasingly common procedure, it is associated with an increased risk of major post-operative surgical complications. In this cohort, patients undergoing bilateral mastectomy for unilateral cancer had higher rates of overall complications, greater use of IV antibiotics, and more frequent return to the operating room. Since the majority of CPM cases are not at sufficiently high risk for a second breast cancer to meet clinical criteria
for prophylactic surgery, guidelines and clinical recommendations should consider these increased complication rates when counseling women contemplating CPM.

PD02-02
A Decision Analysis of Contralateral Prophylactic Mastectomy in Women Undergoing Treatment for Sporadic Unilateral Breast Cancer.
Lester-Coll NH, Lee JM, Gogineni K, Hwang W-T, Schwartz JS, Prosnitz RG. University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; Massachusetts General Hospital, Boston, MA; Abramson Cancer Center, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA

Background:
The intent of contralateral prophylactic mastectomy (CPM) is to improve survival after a diagnosis of unilateral breast cancer by reducing the risk of contralateral breast cancer (CBC). CPM rates are rising among women with sporadic breast cancer, despite limited evidence that its benefits outweigh its harms. Although CPM is highly effective in reducing a woman’s risk of CBC, the competing mortality risk from a patient’s index breast cancer may offset its benefits. Furthermore, any examination of CPM needs to consider quality of life effects.

Methods:
We developed a Markov decision analytic model to estimate the effect of CPM in women with newly diagnosed unilateral breast cancer. The primary outcomes examined were gains in life expectancy (LE) and quality-adjusted life expectancy (QALE) for CPM compared with no CPM in 18 hypothetical cohorts of 45-year-old women. Data from the British Columbia Cancer Agency (BCCA) was used to generate AJCC stage and molecular subtype-specific estimates of the risk of developing distant metastases from an index breast cancer. A correction factor was applied to account for the omission of relevant systemic therapy (including trastuzamab) in some women in the BCCA cohort. Additional model parameters, including utilities (quality of life weights) for breast cancer and CPM health states, were identified from the published medical literature. LE and QALE estimates were not discounted in the base case. Univariate sensitivity analysis was used to examine the impact of plausible variation in the key model parameters on model results.

Results:
CPM improved LE in all cohorts (range: 0.06 - 0.54 years, Table 1). AJCC stage had more effect on LE than molecular subtype (stage I mean, 0.43 years, stage III mean, 0.11 years). However, after adjusting for quality of life, a strategy of no CPM was favored in all cohorts. Univariate sensitivity analysis demonstrated that the only model parameter that influenced the outcome of QALE was the utility for health after CPM. In the base case the utility after CPM was 0.81 (compared to 0.85 for No CPM). The preferred strategy did not change from No CPM to CPM unless the utility after CPM exceeded 0.83. Model results were otherwise stable across the ranges of the key parameters examined, including the risk of distant metastases resulting from a patient’s index breast cancer by stage and subtype, duration of survival with metastatic breast cancer, and the risk of CBC.

Conclusions:
The primary drivers of survival after unilateral breast cancer are stage at diagnosis and molecular subtype. Our model demonstrates that CPM confers modest additional LE gains, even in women with early-stage, favorable-subtype breast cancer. Furthermore, this modest benefit is negated if one assumes a small reduction in quality of life due to CPM. The decision to pursue CPM as part of treatment of unilateral breast cancer should include consideration of both patient specific breast cancer characteristics and individual preferences.

PD02-03
The Effect of Breast Conservation Therapy vs Mastectomy on Symptoms, Physical Impairments, and Function.
Kesarwala AH, Pfalzer LA, O’Meara WP, Stout NL. National Cancer Institute, Bethesda, MD; University of Michigan - Flint, Flint, MI; National Naval Medical Center, Bethesda, MD

Background: Early-stage breast cancer (BC) patients choose between breast conservation therapy (BCT) and mastectomy based on comparable recurrence rates and overall survival. In the absence of mortality benefit, consideration of anticipated functional impairments could guide decision making. Although BCT offers less extensive surgery, the administration of radiation therapy (RT) may adversely impact upper extremity (UE) function. The purpose of this analysis is to investigate the effect of BCT vs modified radical mastectomy (MRM) without RT on functional impairments among BC survivors.

Materials and Methods: 196 women diagnosed with BC between 2001-05 were enrolled and treated in a prospective surveillance physical therapy program. 115 received either BCT, including lumpectomy and whole breast RT, or MRM without RT and were analyzed for this report. Participants’ UE range of motion (ROM), strength, and limb volume were assessed pre-operatively and at 1, 3, 6, 9, and 12+ months post-operatively by a physical therapist. Limb volume was assessed using infrared optoelectronic perometry. At 12+ months, overall health status, UE symptoms and function, and physical activity levels were reported using standardized questionnaires. Analysis of variance estimated differences in impairments and self-reported symptoms and function. One-way ANOVA analysis was used to determine significance between groups (p ≤ 0.05).

Results: 65 women (57.5%) received BCT and 50 women (42.5%) received MRM. No significant differences in age, BMI, stage, ER/PR status, and number of dissected lymph nodes were found between groups. At 1 month post-operatively, shoulder internal rotation (p = 0.03), abduction (p = 0.01), and flexion (p = 0.004) were worse in post-MRM patients, with a trend towards worse external rotation (p = 0.06). A higher rate of axillary cording was seen in patients post-MRM (p = 0.02). By 12+ months post-operatively, there were no differences in any of the shoulder ROM variables. BCT patients reported, however, greater weakness (p = 0.03) and diminished ability to perform heavy household tasks (p = 0.03). There was no significant difference between BCT vs. MRM in rates of early lymphedema (40% vs 38%) or seroma (14% vs 22%).

Conclusion: Functional impairments represent an important category of morbidity for BC survivors and should be considered in pre-treatment decision making. Post-operative RT as part of BCT may not contribute significantly to impairment over the first year of treatment. The presence of self-reported weakness and difficulty performing heavy household tasks at 12+ months suggest possible future functional deficits, especially considering the potentially progressive nature of RT-associated tissue changes. Additional research is needed to assess longer-term changes and the impact of RT in the context of aggregate effects of other BC treatment modalities.
PD02-04
A Randomized, Prospective, Multicenter Study of the Impact of Intraoperative Margin Assessment with Adjunctive Use of MarginProbe vs. Standard of Care. 
Schnabel F, Trafta L, The MarginProbe Study Group. NYU Langone Medical Center, New York, NY; The AAMC Breast Center, Annapolis, MD; Dune Medical Devices

Background: The current practice of breast conserving surgery (BCS) involves intraoperative margin assessment according to the surgeon’s gross assessment and judgment. The failure of this intraoperative assessment has been associated with a 20-30% reoperation rate to assure negative margins. MarginProbe (Dune Medical Devices) was developed to provide real-time assessment of lumpectomy specimens to evaluate for the presence of disease at the surgical margins. A 21-center international pivotal study was conducted to determine if adjunctive use of MarginProbe can enable surgeons to identify positive margins intraoperatively, resulting in fewer patients who are candidates for re-excision procedures.

Methods: 664 women with non-palpable lesions undergoing lumpectomy for DCIS and invasive cancer were enrolled and 596 randomized (1:1) in the operating room following standard of care (SOC) lumpectomy. In the device arm, MarginProbe was used to assess all surfaces of the lumpectomy specimen and positive readings required additional resections. All specimens were inked in the operating room by the surgeon. All specimens were examined to verify excision of the target lesion intraoperatively. Pathologists were blinded to study arm. Additional surgeries to re-excite involved margins were performed per each individual site criteria. Patients were followed for 2 months following surgery; additional procedures were documented. Safety was assessed by reports of adverse events.

Results: No safety concerns were raised. Of the 298 patients in each arm, 55% (163/298) patients in the device arm (D) and 49% (147/298) in the control arm (C) had at least one positive margin on the main lumpectomy specimen (≤1mm). Surgeons’ ability to identify and resect all positive margins per patient was significantly improved with device use (D: 72% (117/163), C: 22% (33/147); p < 0.0001). Following lumpectomy, the number of patients having positive margins due to failed intraoperative assessment (excluding skin or fascia) was reduced by 57% in the device arm (D: 42/298(14%), C: 98/298(32.8%), p=0.0001), leading to a 50% reduction in re-excisions for this group (D: 31/298 (10.4%), C: 62/298 (20.8%); p=0.001). There was no significant difference in tissue volume removed (D: 93cc, C: 85cc; 25cc non-inferiority delta, p=0.0001). Normalized to baseline breast size, tissue volume in the device arm was non-inferior to the control arm (D: 15.1%, C: 12.5%, 5% non-inferiority delta, p <0.0001). For patients having at least one positive margin prior to intraoperative assessment, there was a trend in the device arm towards smaller average tissue volume resected to achieve clear margins (D: 99cc, C: 108cc; p=0.6).

Conclusions: Adjunctive use of MarginProbe during BCS significantly improved surgical outcomes by improving surgeons’ ability to identify and immediately resect positive margins, reducing the number of patients requiring re-excision. Overall tissue volume removed was not statistically different in the two arms. Patients in the device arm who had positive margins prior to intraoperative assessment had less average tissue volume removed and required fewer re-excisions to achieve appropriate margins.

PD02-05
MRI Phenotype and Tumor Subtype Affect Breast Conservation Eligibility and MRI Accuracy in the I-SPY 1 Trial.
Mukhtar RA, Hylton N, Rosen M, The I-SPY 1 Trial Investigators, ACRIN 6657 Investigators, Esserman LJ. UCSF; University of Pennsylvania; I-SPY 1 Trial; ACRIN 6657

Background
Neoadjuvant chemotherapy (NAC) in breast cancer allows assessment of response to treatment and increases eligibility for breast conservation treatment (BCT). We previously reported that MRI tumor phenotype (based on loss of containment) predicted response to NAC and ability to achieve BCT. Since tumor subtype can affect MRI features, we sought to validate whether MRI phenotype and/or tumor subtype affected BCT eligibility in a prospective trial, I-SPY (CALGB 150007/ACRIN 6657). We also investigated the accuracy of post-NAC MRI in determining BCT eligibility, and the distribution of tumor subtypes within MRI phenotypes with the goal of identifying clinically useful factors associated with successful BCT.

Methods
We analyzed I-SPY 1 Trial data, a multi-center, prospective NAC trial with serial MRIs. Phenotypes 1 and 2 were well defined masses, while 3, 4, and 5 were more diffuse. Subjects were considered truly eligible for BCT if tumor diameter on surgical pathology was ≤ 4 cm (based on NSABP B-06 trial criteria). Post-NAC MRI and surgical pathology were considered discrepant if longest tumor diameter differed by > 2 cm. Categorical variables were compared using the chi-squared test.

Results
Of the 221 subjects, 198 had pre and post-NAC MRIs, and surgical pathology available. Of these, 174 had a tumor diameter ≥ 4 cm prior to NAC, and were considered initially ineligible for BCT. After NAC, 141 (81%) patients became BCT eligible based on having ≤4 cm of residual tumor. In contrast, 46 (26%) had pathologic complete response (pCR, no invasive tumor). The rate of becoming BCT eligible differed by hormone receptor (HR)/Her2 status (p = 0.005) and MRI phenotype (p = 0.037), with higher rates of eligibility in Her2+ and triple negative tumors, and the well defined MRI phenotypes. Overall, 75 (38%) patients had a size discrepancy between tumor diameter on post-NAC MRI and size on surgical pathology. Subjects with diffuse MRI phenotypes had more size discrepancy than phenotypes 1 and 2 (p = 0.001). Subjects with HR+/Her2- tumors also had more size discrepancy than other subtypes (p = 0.004). The more diffuse MRI phenotypes were more commonly HR+/Her2- tumors, and less commonly HR+/Her2- (p = 0.006). There was no difference in actual receipt of BCT by HR/Her2 status. However, patients with a well-defined MRI phenotype were significantly more likely to actually receive BCT than those with a diffuse MRI phenotype (47% versus 27%, p = 0.023).

Conclusions
Patients with well defined patterns on MRI and with Her2+ or triple negative disease were more likely to become eligible for BCT after NAC. The same factors that predict pCR also predict BCT eligibility, but far more patients achieve BCT eligibility than pCR. MRI after NAC was less accurate in the diffuse phenotypes, which could reflect increased difficulty in measuring tumor size in this setting. Tumor phenotype and subtype can help predict likelihood of achieving eligibility for BCT, and can be useful in setting appropriate expectations for women at the start of NAC.
Outcomes after Total-Skin Sparing Mastectomy and Immediate Reconstruction in 657 Breasts.

Warren Peled A, Stover AC, Foster RD, Alvarado MD, Ewing CA, Hwang ES, Esserman LJ. University of California, San Francisco

INTRODUCTION: Total skin-sparing mastectomy (TSSM) is increasingly offered to women for both therapeutic and prophylactic indications. When combined with immediate breast reconstruction, patients can achieve excellent aesthetic results and high satisfaction. However, the oncologic safety of the procedure remains controversial. Further, the technique can be associated with higher rates of post-operative ischemic complications. We conducted this study to determine oncologic and ischemic outcomes in a large cohort of patients undergoing TSSM and immediate reconstruction.

METHODS: Patient and tumor characteristics and treatment details were collected in a prospectively maintained database. All patients undergoing TSSM and immediate breast reconstruction at our institution from 2001 to 2010 were included in the analysis. The development of any post-operative complications or local or distant recurrence was determined.

RESULTS: TSSM with immediate reconstruction was performed in 428 patients for a total of 657 breasts. Mean patient age was 46.9 years. 210 patients (49%) had neoadjuvant chemotherapy for locally advanced disease. 114 patients (26.7%) had post-mastectomy radiation therapy. 54% of patients had bilateral mastectomies. Prophylactic mastectomies (either unilateral or bilateral) accounted for 244 (37.1%) of cases, which included bilateral mastectomies in 15 patients (30 cases) who were known BRCA-1 or -2 mutation carriers. Expander-implant reconstruction was performed in 80% of the cases, while the rest of the cases involved autologous reconstruction (15.3%) or immediate implant placement (4.7%). On pathologic examination, nipple tissue from 11 breasts (1.7%) contained in situ cancer and from 9 breasts (1.4%) contained invasive cancer; re-excision was performed in 7 of these cases, the nipple-areolar complex was removed entirely in 9 cases, and radiation therapy was given without further excision in the rest of cases. Ischemic or necrotic post-operative complications included 13 cases (1.9%) of partial nipple loss, 10 cases (1.5%) of complete nipple loss, and 78 cases (11.8%) of skin flap necrosis or incisional dehiscence. At a median follow-up of 23 months (range 3-116 months), 5 patients (1.2%) had developed a local recurrence alone, 10 patients (2.4%) had developed a distant recurrence alone, and 6 patients (1.4%) had developed both loco-regional recurrence and distant metastases. In the subset of patients with at least 3 years’ follow-up, rates of local and of distant recurrence were 1.7% at a median of 45 months follow-up. None of the patients who underwent bilateral prophylactic mastectomy for BRCA-1 or -2 mutations developed subsequent breast cancers.

CONCLUSIONS: In this large, high-risk cohort, TSSM was associated with low rates of nipple involvement and loco-regional recurrence. Ischemic complications, although uncommon, often resulted in nipple loss. These short-term outcomes are encouraging, although longer follow-up will be important for confirmation of long-term oncologic safety. Serial improvements in surgical technique can improve selection criteria and reduce post-operative complication rates.

Models Predicting Non-Sentinel Node Involvement in Breast Cancer Also Predict for Regional Recurrence If the Axilla Is Not Treated.

Pepels M, Vestjens H, de Boer M, Bult P, van Dijck J, Mencke M, van Diest P, Borm G, Tjan Y. Maastricht University Medical Centre; Radboud University Nijmegen Medical Centre; Erasmus Medical Center Rotterdam; University Medical Centre Utrecht

Background

Series on breast cancer patients with sentinel node (SN) isolated tumor cells or micrometastases show low recurrence rates in the presence of SN isolated tumor cells, and varying recurrence rates in the presence of SN micrometastases. Non-SN prediction models are frequently used as a decision aid to identify patients that may not need axillary treatment, but this still needs to be validated in respect to regional recurrence.

Patients and Methods

We followed a cohort of 486 patients in the MIRROR-study of whom none received axillary treatment with favorable primary tumor characteristics and pN0(i+)(sn) or pN1(mi)(sn) for a median of 5 years. The patients were categorized into low or high-risk subgroups based on several published non-SN prediction models (cut-off levels between models varied from 3 to 10%), i.e. the Tenon Scoring system, MSKCC nomogram, Stanford nomogram and a Dutch model (Bolster et al.). The primary endpoint was 5-year regional recurrence-free survival.

Results

The overall 5-year regional recurrence rate was 3.0% (+/- 0.1%). Using the Tenon scoring system, we identified 438 patients with a low risk score of 3.5 or lower with a 5-year regional recurrence rate of 2.3% (+/- 0.8%), compared to a recurrence rate of 10.1% (+/- 0.4%) in 48 patients with a score above 3.5. For the MSKCC nomogram a low risk score of 0.10 or lower identified 300 patients with a 5-year recurrence rate of 2.8% (+/- 1.1%), and a score above 0.10 identified 166 patients with a recurrence rate of 3.4% (+/- 1.5%) (20 patients not assessable). By the Stanford nomogram a low risk cutoff level of 10% identified 21 patients without recurrence, whereas 465 patients had a 3.2% (+/-0.9%) recurrence rate. Using a Dutch model, a low risk cutoff score of 20 discriminated between 384 patients with a 5-year recurrence rate of 2.2% (+/- 0.8%) and 102 patients with a recurrence rate of 6.3% (+/- 2.9%). Further analyses with different cut-off values and subgroups will be presented at the conference.

Conclusion

Using several published non-SN prediction models for predicting regional recurrence, the Tenon scoring system outperformed the other models in that it identified the largest subgroup of patients with a low recurrence rate. We would recommend axillary treatment in patients classified as high risk according to the Tenon score.

Validation over Time of a Nomogram Predicting the Sentinel Node Positivity in Early Breast Carcinoma According to the Molecular Subtypes Classification.

Background: The molecular subtypes of breast cancer have different axillary status. A new nomogram including the interaction covariate between estrogen receptor (ER) and HER2 status has been recently
published (Reyal et al. PLOSone, May 2011) and allows to identify before surgery the patients with a high risk of positive sentinel lymph node (SLN). The purpose of our study was to validate this model on an independent population.

**Patients and methods:** We studied 755 consecutive patients treated for operable breast cancer with sentinel node biopsies in 2009, from the Institut Curie breast cancer prospective database. Baseline characteristics were compared between our population and the population used to build the model, using Chi-square test for categorical variables and Kruskal-Wallis test for continuous variables. The multivariate model, including age, tumor size, lymphovascular invasion and interaction covariate between ER and HER2 status, was used to calculate the theoretical risk of positive sentinel lymph node (SLN) for all patients. The performance of the model on our population was then evaluated in terms of discrimination (area under the curve AUC) and of calibration (Hosmer-Lemeshow HL test).

**Results:** Characteristics of our population were significantly different from the training population for the following variables: tumor size (median 12mm [1-60] versus 13mm [1-100] p=0.005), lymphovascular invasion (18.6% versus 23.7% p=0.006), positive ER (91.4% versus 87% p=0.002) and age as followed: 56.7% of patients ≤ 60 versus 63.1%, 17.5% of patients between 60 and 65 versus 14.1% and 25.8% of patients above 65 versus 22.8% p=0.01. The nomogram showed similar results in our population than in the training population in terms of discrimination (AUC= 0.72 [0.68-0.76] versus 0.73 [0.7-0.75]) and calibration (HL p= 0.4 versus p=0.35).

**Conclusions:** Despite significant differences between the two populations concerning variables which are part of the nomogram, the model was validated in our population. Our study shows that this nomogram is efficient and robust over time to predict the likelihood of positive SLN according to molecular subtypes defined by surrogate markers ER and HER2 determined by immunohistochemistry in clinical practice.

**An Integrated Analysis of Three Distinct IBC/nIBC Affymetrix Gene Expression Data Sets Further Unveils the Molecular Biology of IBC.**

Van Laere SJ, Ueno NT, Finetti P, Vermeulen PB,ucci A, Birnbaum D, Robertson FM, van Dam PA, Woodward WA, Viens P, Dirix LY, Reuben JM, Iwamoto T, Cristofanilli M, Bertucci F; Oncology Center - GH Sint-Augustinus, Wilrijk, Antwerp, Belgium; The University of Texas MD Anderson Cancer Center, Houston, TX; Institut Paoli-Calmettes (IPC), Marseille, France; World IBC Consortium; Contributed Equally

Introduction. Several studies have applied gene expression profiling to inflammatory breast cancer (IBC). Most of these studies were underpowered. Here, we present an integrated analysis of 3 distinct gene expression data sets of IBC and non-IBC (nIBC) samples to further uncover the IBC-specific molecular biology with enhanced statistical power.

Materials & Methods. Three Affymetrix gene expression data sets were combined, resulting in a series of 137 IBC and 252 nIBC samples. IBC was diagnosed clinically. Each sample was classified according to several published gene signatures. Transcriptional heterogeneity was investigated using hierarchical clustering, coupled with silhouette score analysis. IBC-specific, molecular subtype-independent differences in gene expression were identified using linear regression modeling. Differentially expressed genes were translated into pathways using Ingenuity Pathway Analysis. Cox regression analysis was used to identify variables influencing distant metastasis-free survival (DMFS) in IBC. Finally, we focussed on the molecular aspects of pathological response to neoadjuvant chemotherapy in patients with IBC.

Results. In our series of IBC samples, 4 robust sample clusters were identified. These sample clusters were mainly associated with the different molecular subtypes (P=0.0001), all of which were identified in IBC with a similar prevalence in nIBC, except for the Luminal A subtype (9% vs. 40%; P=0.0001) and the ErbB2+ subtype (23% vs. 8%; P=0.0002). A total of 632 genes were differentially expressed. Analysis of this gene list identified an IBC-repressed network centered on TGFβ. Activated TGFβ-profiles and SMAD-profiles in the nIBC samples corroborated these findings. Consistent with published poor prognosis signatures, current survival analysis indicated that the molecular subtypes are significantly associated with prognosis in IBC. Surprisingly, in IBC, the Luminal A samples exhibited the shortest DMFS-interval (HR=4.02; P<0.05). Comparison of responders and non-responders to neoadjuvant chemotherapy suggests a prominent role for inflammation/immunity-related processes in determining the efficacy of neoadjuvant chemotherapy in IBC.

Conclusions. IBC, like nIBC, is transcriptionally heterogeneous as exemplified by the identification of 4 robust sample clusters in the present series. This observation is further corroborated by the identification of all known molecular subtypes in IBC, albeit with a different distribution pattern characterized by a low frequency of Luminal A samples. Nevertheless, this phenotype is clinically relevant, as demonstrated by the poor prognosis profile. Our observations can be explained by the IBC-specific repression of TGFβ, which is a key molecule of epithelial-to-mesenchymal transition and is also known to prevent ER-expressing cells from proliferating. Finally, as in nIBC, inflammation- and immunity-related processes are important aspects of response to neoadjuvant chemotherapy in IBC.

**Prognostic and Predictive Predictors for Triple Negative Breast Cancer.**

Karn T, PusztaI L, Ruckhäberle E, Liedtke C, Schmidt M, Müller V, Gütte B, Hanker L, Ahr A, Holtrich U, Rody A, Kaufmann M; Goethe University, Frankfurt, Hessen, Germany; University of Texas M.D. Anderson Cancer Center, Houston, TX; University of Münster; University of Mainz; University Hospital Hamburg-Eppendorf; Saarland-University

Background: Both the prognosis and the therapeutic options in triple negative breast cancer (TNBC) are rather limited. Current prognostic gene expression profiles for breast cancer mainly reflect proliferation status and are most useful in ER-positive cancers. The identification of prognostic gene signatures from TNBC cohorts in previous studies was hindered due to relatively small sample sizes.

Materials and Methods: All currently available TNBC gene expression datasets generated on Affymetrix U133 gene chips were assembled. To minimize inter-laboratory variation we analyzed only highly comparable arrays and data set-biased genes were filtered. Supervised analysis was applied to identify a prognostic signature from a finding cohort of 394 TNBC and validation was performed in an independent cohort of 261 TNBC. The genes from the prognostic predictor were analyzed for their correlation to known molecular phenotypes among TNBC.

Results: Two supervised prognostic signatures consisting of 264 and 26 probesets, respectively, were obtained when applying
different cutoffs for false discovery rates of 25% and < 3.5% in the finding cohort. In multivariate analysis in the independent validation cohort hazard ratios of 4.03 (95% CI 1.71-9.48; P=0.001) and 4.08 (95% CI 1.79-9.28; P=0.001), respectively, were obtained for the two signatures. When compared to 16 metagenes for previously described molecular phenotypes in TNBC the prognostic signatures displayed highest correlation to metagenes for IL-8/ inflammation, VEGF/angiogenesis, and Histones. A subset of genes in the 264-probeset signature was inversely associated with a poor prognosis (29/264=11.0%). Most of these “good prognosis” genes are correlated with immune cell metagenes (21/29=72.4%). In contrast both identified supervised prognostic signatures did not correlate to previously published prognostic signatures (recurrence score, genomic grade index, Amsterdam signature, wound response signature, 7-gene immune response module, stroma derived prognostic predictor, and a medullary like signature). Regarding the response of TNBC to neoadjuvant chemotherapy the predictive value of the B-cell metagene was superior to the 264- and 26-probeset signatures. However combination of the B-cell metagene and the signatures increased the AUC in ROC-analysis from 0.606 to 0.656.

Conclusions: The use datasets consisting only of TNBC allows identification supervised prognostic signatures for TNBC which are unrelated to previously known prognostic signatures.

Identification of Transcription Factors Critical for the Growth of Basal Breast Cancer.
Shepherd JH, Mazumdar A, Tsimelzon A, Hilsenbeck SG, Brown PH. Baylor College of Medicine, Houston, TX; The University of Texas MD Anderson Cancer Center, Houston, TX

**Background:** Basal breast cancers are aggressive, poor prognosis tumors that occur commonly in young women and in African American women. Profiling of breast tumor mRNA has demonstrated that there are differences in gene expression between the basal and luminal subtypes of breast cancer. In this study, we identified response elements in the genes that define basal breast cancers, and identified transcription factors that are critical for the growth of basal breast cancer cells.

**Materials and Methods:** We performed promoter analysis using 4 published microarray studies (PMID: 12829800; PMID: 19435916; PMID: 17157792; PMID: 11562467) to select genes that are highly expressed in basal tumors compared to luminal tumors. For this analysis we selected 61 genes highly expressed in a set of basal breast tumors in any of the 4 microarray studies. We next used the online tool, CORE TF, along with the MATCH algorithm minimizing for the sum of false positives and false negatives to identify binding motifs within the promoter (defined from -1 kb to the first exon) of each gene. The frequency of binding motif occurrence for these 61 basal genes was compared to the frequency within the promoters of 3000 randomly selected genes. Significance was tested using an exact binomial test with a cutoff of p=0.05. RNA expression of motif-identified transcription factors was then analyzed in-silico using all 10 datasets in Oncomine™ that contained annotation for triple-negative status. Expression in triple-negative samples was compared to expression in non-triple-negative samples with a cutoff of p=0.05. We next performed siRNA knockdown studies to determine whether the identified TFs regulate basal breast cancer growth. Basal and luminal cells transfected with control and specific siRNAs were grown in triplicate and mean cell counts at day 6 were compared.

**Results:** Promoter analysis identified 24 binding motifs that were over-represented in basal breast tumor genes compared to a random set of 3000 genes. TransFac analysis indicated that 47 transcription factors bind the 24 identified motifs. Oncomine analysis showed that 8 of the 47 transcription factors were significantly more highly expressed in basal as compared to non-basal tumors. Identified transcription factors include FOXC1, FOXM1, CDC5L, E2F3, CEBP and NF-Y. siRNA to FOXM1 in 2 basal breast cell lines reduced growth by >70% after 6 days, whereas, in the luminal cell line MCF7, growth was reduced by 15%.

**Discussion:** This study identified transcription factors that are highly expressed in basal breast tumors (as compared to non-basal breast tumors). siRNA knockdown studies showed that FOXM1 is critical for basal breast cancer cell growth. These results suggest that transcription factors highly expressed in basal breast cancers may be novel targets for the treatment of this disease.

These studies were supported by a Promise grant from the Susan G. Komen for the Cure (PB, SGH), and by the Norman E. Brinker Award for Research Excellence (PB).

SuperPathway Analyses of Luminal and Basaloid Breast Cancers from the Cancer Genome Atlas (TCGA) Program.
Yau C, Benz S, Sanborn JZ, Stuart J, Haussler D, Benz C. Buck Institute for Research on Aging, Novato, CA; UC Santa Cruz, Santa Cruz, CA

The biological and clinical heterogeneity of breast cancer is clearly evident by its different intrinsic transcriptional subtypes. With exception of the HER2 subtype, pathways and signaling networks driving and distinguishing the other major breast cancer subtypes (basaloid, luminal-A, luminal-B) remain largely undefined. As of April 2011, >300 TCGA breast cancer samples have been characterized by both genomic copy number analysis and mRNA expression profiling (44% luminal-A, 26% luminal-B, 16% basaloid). As well, overall survival (OS) data are presently available on 104 luminal-A and 52 luminal-B cases, showing significantly poorer outcome for the latter of these hormonally driven subtypes (log rank p<0.05). Since the poorer outcome of luminal-B breast cancers may be due to their harboring more TP53 gene mutations (~34%), we used a gene expression signature reported for TP53 mutated estrogen receptor-positive (ER+) breast cancers (Coutant et al., 2011), and confirmed that the TCGA luminal-B cases significantly overexpress this signature relative to luminal-A breast cases in which TP53 mutations are uncommon (6%). Curiously, within each luminal subtype, while this signature correlated with TP53 mutations it did not correlate with TP53 loss of heterozygosity (LOH), which was also higher in luminal-B (~30%) relative to luminal-A (~10%) cases. We used the network analysis tool PARADIGM (Vaske et al., Bioinformatics 26, i247-245) to integrate both DNA copy number and transcriptome data and infer pathway activity and interaction differences between luminal-A and luminal-B cases, and between the luminal and basaloid subtypes. This tool merges features derived from curated signal transduction, transcriptional and metabolic pathways into a Superimposed Pathway (SuperPathway) containing ~3.1K unique activities, 1820 of which revealed significant differences among the breast cancer subtypes (Kruskal-Wallis test, Benjamin Hochberg FDR-corrected p<0.05). From the significant pathway activities differentiating basaloid from luminal-A (1399) or luminal-B (1122) subtypes, assessed using two independent approaches (functional enrichment/EASE scores, subnetwork analysis and hub interconnectivity >10 edges), higher FOXA1 (ER signaling) and lower HIF1A/ARNT transcription factor hub activities emerged as shared luminal differences relative to basaloid breast cancers. Of the 433 significant activities differentiating...
also indicated that RB1 and PTEN, two genes known to be involved in basal-like breast tumor formation, showed a particularly high incidence of these microevents. These microevents may alter expression of the involved gene as well, as suggested by data from microarray and mRNA-seq studies.

Conclusion: Using a high probe density, gene-centric aCGH microarray, we present evidence of small-scale genomic aberrations that may contribute to gene inactivation, and thus, genomic instability and tumor formation through a mechanism not detected using conventional copy number analyses.

PD03-07
Breast Cancer Heterogeneity and Treatment Resistance: Clues from Metaplastic Tumors.
Fielding-Habermann B, O’Sullivan DM, Longier M, MacDermed D, Fernandez-Santidrian A, Steele JB, Telli ML, Jeffrey SS, Murray S, Torkamani A, Cunliffe H, Vaughn SV. The Scripps Research Institute, La Jolla, CA; Scripps Clinic, La Jolla, CA; Stanford University, Stanford, CA; Translational Genomics Research Institute, Phoenix, AZ

At late stage, nearly all breast cancers are heterogeneous and refractory to treatment, like metaplastic breast cancer is at an early stage. These rare carcinomas are highly aggressive and de-differentiated. They are enriched for mesenchymal and stem cell features and essentially fail current therapies. As metaplastic tumors provide a time-compressed picture of breast cancer progression early on, understanding these tumors will yield insight into mechanisms that drive breast cancer into advanced stages and treatment resistance.

To investigate a genetic basis for heterogeneity in metaplastic breast cancer, we established a progression model comprising three cell lines. The cell lines were derived from a primary tumor, a local recurrence and a pleural effusion of a 40-year-old patient. The primary tumor was a stage III invasive metaplastic, triple negative, inflammatory breast cancer, resected after neoadjuvant chemotherapy (capecitabine and taxotere, then adriamycin and one cycle of bevacizumab). The local recurrence, biopsied seven months post mastectomy, developed after the patient received adjuvant carboplatin and gemcitabine for 3 cycles and then radiation to the chest wall. At this time, the patient had lung metastases and was treated with taxol and bevacizumab yielding a mixed response. Local invasive growth continued and a malignant pleural effusion developed four months later. Analyzing the genetic and molecular characteristics of this progression model in vitro, its tumorigenicity and metastasis in vivo, and interrogating lead findings in a growing collection of metaplastic tumors helps us to dissect the genetic heterogeneity in breast cancer, and potentially to identify the cell types that drive disease progression and treatment resistance.

Our gene expression analyses and genomic evaluations identified epithelial to mesenchymal transition (EMT) as a key characteristic in the progression and treatment resistance of this cancer. Major changes in cytoskeletal genes, chemokines and their receptors, amplification of drug transporter proteins, metalloproteinases and matrix proteins seen with increasing motility and invasiveness along with recruitment of host inflammatory responses in the in vivo model, loss of chromosomal regions harboring known and putative tumor suppressors, and deletions of genes encoding proteins for metabolic inactivation of sex hormones in the breast tissue, along with specific loss of clusters of desmosomal genes are guiding our understanding of metaplastic breast cancer progression. The results provide insight into the development, the extremely invasive nature, and treatment resistance of these tumors. Our collaborative network of clinicians, pathologists, translational genomic researchers and bioinformatics specialists will enable us to identify and prioritize genetic events as
disease drivers, prognostic biomarkers of disease progression, and determinants of treatment resistance. Our goal is to identify molecular and functional targets for effective therapy and evaluate them in the clinic. Lessons learned from metaplastic breast cancer will improve our understanding of breast cancer progression in general, and could translate into effective treatments for advanced breast cancer where current standard of care is failing.

**PD03-08**

BRCA1-Like Triple Negative Tumors: Clinicopathological Variables and Chemosensitivity to Alkylating Agents.

Wesseling J, Lips EH, Oonk AMM, Smits RM, van Rijn CCM, Mulder L, Laddach N, Savola SS, Wessels LFA, Nederlof PM, Rodenhuis S, Imholz ALT. Netherlands Cancer Institute-Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands; Deventer Hospital, Deventer, Netherlands; MRC-Holland, Amsterdam, Netherlands

Background

Our group has previously employed array Comparative Genomic Hybridization (aCGH) to assess the genomic patterns of BRCA1-mutated breast cancers. It is reasonable to assume that this pattern indicates ‘BRCA-ness’ and thus serves as a marker for homologous recombination deficiency. This BRCA1-like aCGH profile is also present in about half of all triple negative sporadic breast cancers and has been shown to be predictive for benefit from intensive chemotherapy with DNA crosslinking agents. To study BRCA1-like tumors and conventional dose chemotherapy sensitivity in more detail, we compared clinical factors and survival rates in a uniform cohort of triple negative breast tumors treated with alkylating agents.

Patients and methods

103 patients with triple negative tumors received conventional dose adjuvant chemotherapy with doxorubicin/cyclophosphamide. DNA was extracted from tumor samples and BRCA1-like profiles were assessed. Tumors were classified as BRCA1-like or non-BRCA1-like.

Standard clinical and histopathological factors were determined and compared between both groups. Relapse free survival (RFS), disease specific survival (DSS) and overall survival (OS) after diagnosis were compared between BRCA1-like and non-BRCA1-like tumors.

Results

66 tumors (65%) had a BRCA1-like profile, while 35 tumors (35%) did not show such a profile. Patients with BRCA1-like tumors tended to be younger and had more often node-negative disease compared to the patients with non-BRCA1-like tumors (p=0.058 and p=0.034, respectively). There was no significant difference in survival between BRCA1-like and non BRCA1-like patients after treatment with alkylating agents: the median RFS was 121 vs. 109 months, median DSS was 129 vs. 114 months and OS was 127 vs. 110 months, for BRCA1-like versus non-BRCA1-like tumors. T-stage was the only variable significantly associated with survival.

Conclusion

BRCA1-like tumors occurred in younger patients and were more often node negative, which are features shared with tumors in BRCA1-mutation carriers. We did not observe a difference in survival between BRCA1-like and non-BRCA1-like triple negative breast cancers after treatment with conventional dose chemotherapy with alkylating agents. These results confirm our previous findings that BRCA1-like tumors have similar sensitivity to anthracycline-based adjuvant chemotherapy as other triple-negative tumors. It will be important to establish whether BRCA1-like tumors also share the exquisite sensitivity of BRCA-mutated tumors to PARP-inhibitors.

**PD03-09**

Background: RNA biomarkers discovered by RT-PCR-based gene expression profiling of archival formalin-fixed paraffin-embedded (FFPE) tissue are the basis for very precise and sensitive clinical diagnostic tests, such as the 21 gene Oncotype DX® breast cancer assay. Both inherent limits of technical scalability and the small amounts of patient FFPE RNA available place practical constraints on the number of transcripts that can be interrogated by RT-PCR. We developed new methods for RNA profiling through massively parallel “next generation” sequencing (RNA-Seq) of archival FFPE specimens. We report here the technical performance of this methodology and compare the results to RT-PCR results obtained in one of the studies that were carried out to develop the 21 gene assay.

Methods: RNA was extracted in 2002 from 136 invasive breast tumors that were formalin-fixed and paraffin-embedded between 1990 and 1997. RNA-Seq was carried out using minor modifications to methods we have reported previously (Sinicropi et al., Advances in Genome Biology and Technology Conference, p. 170, 2010 and p. 198, 2011). Briefly, 0.1 mg of total RNA was selectively depleted of ribosomal RNA and sequencing libraries were prepared using a modification of the ScriptSeq™ kit from Epicentre. The libraries were sequenced on an Illumina HiSeq 2000 instrument with multiplexing of two libraries per lane for 50 cycles in one direction. The resulting FASTQ sequences were mapped to version hg19 of the human genome using the Illumina CASAVA pipeline. The total number of sequences (reads) that uniquely mapped to all exons of each RefSeq entry was used for quantification of expression levels.

Results: On average, there were 43 million reads per sample (range 31 – 58 million; SD=4.6 million) of which 69% uniquely mapped to the human genome. Ribosomal RNA was effectively removed and accounted for <0.3% of total counts. Significant coverage of a high proportion of the human genome was obtained, with 40% of RefSeq transcripts represented by a median of more than 100 reads. Using Cox proportional hazards analysis to evaluate the association of quantitative gene expression with breast cancer recurrence, the standardized hazard ratios and p-values for the 21 Oncotype DX genes determined by RNA-Seq were comparable to those originally obtained using RT-PCR. Moreover, whole transcriptome RNA-Seq identified more than 1800 new coding, intronic, and intergenic transcripts that strongly associated with breast cancer recurrence risk (at a false discovery rate <10%) and revealed heretofore unappreciated co-expressed gene networks. Summary: New methodology has been developed for application of next generation sequencing-based whole transcriptome profiling to small amounts of archival FFPE tissue. This technology has sensitivity and selectivity comparable to RT-PCR, can provide a vast increase in the number of interrogated transcripts, can reveal new biological relationships, and has excellent performance suitable for the discovery of RNA biomarkers.
PD03-10

Background: We and others have shown that high expression of proliferation and immune related genes are associated with pathological complete response (pCR) after neoadjuvant chemotherapy in breast cancer (BC). Here, we performed a meta-analysis to validate these findings and to interrogate the association between pCR and several other gene expression modules beyond standard clinico-pathological characteristics in BC subtypes.

Methods: We searched for publicly available gene expression studies evaluating anthracycline + taxane-based neoadjuvant chemotherapy. We identified 7 studies with complete genomic and clinico-pathological data including pCR totaling 788 patients. Relapse-free survival (RFS) data were available for 427 patients. We used gene expression data generated from pretreatment biopsies and computed 17 gene modules corresponding to proliferation-driven signatures, immune response, stroma activation, phosphatase and tensin homolog (PTEN) loss, chromosomal instability, and several other oncogenic pathways. We calculated odds ratios (OR) for pCR for one-unit increases in scaled modules, all adjusting for pretreatment clinico-pathological characteristics. Moreover, we tested for interactions between gene modules and ER or HER2 status for their association with pCR after adjusting for clinico-pathological characteristics. We used the false discovery rate (FDR) to adjust for multiple testing.

Results: We observed pCR in 178(22.6%) of 788 patients: 112(30.1%) of 372 with ER-/HER2- BC, 41(36%) of 113 with HER2+ BC, and 25(8.2%) of 303 with ER+/HER2- BC. High values of the proliferation-driven modules were associated with increased pCR rates in ER-/HER2- (e.g. Gene70 OR=2.34, 95%CI 1.22-4.59, p=0.01, FDR=0.10) and ER+/HER2- (e.g. Gene70 OR=3.26, CI 1.13-9.60, p=0.03, FDR=0.16), but not in the HER2+ subtype (e.g. Gene70 OR=0.82, CI 0.23-2.67, p=0.74, FDR=0.86). There was a trend for interaction between proliferation-driven modules (e.g. Gene70) and HER2 status (p=0.08, FDR=0.23). Interestingly, we demonstrated a strong association between high values of immune module and increased pCR rates in the HER2+ (OR=6.58, CI 2.20-23.40, p<0.01, FDR=0.03) and ER-/HER2- (OR=1.75, CI 1.12-2.76, p=0.02, FDR=0.10) but not in the ER+/HER2- subtype (OR=1.50, CI 0.63-3.42, p=0.35, FDR=0.49). Moreover, high values of AKT activation module were associated with decreased pCR rates in HER2+ (OR=0.38, CI 0.14-0.98, p=0.05, FDR=0.29) but not in the HER-/HER2- (OR=0.87, CI 0.56-1.37, p=0.56, FDR=0.68) or ER+/HER2- (OR=1.81, CI 0.65-5.30, p=0.27, FDR=0.47) subtype. Interactions between immune module and HER2 status and between AKT module and HER2 status were nominally significant (p=0.04 and p=0.05, respectively), but came with an FDR of 0.23. Of interest after a median follow-up of 3.47 years, (95% CI 3.18-3.70 years) patients with pCR had significantly longer RFS irrespective of BC subtypes (HR=0.20, 95% CI 0.08 to 0.50, p=0.001).

Conclusion: Different biological processes namely proliferation, immune response and AKT activation are associated with pCR in different BC subtypes. Our results suggest that new drugs that modulate immune responses in ER-/HER2- and HER2+ BC and target AKT activation in HER2+ BC might be evaluated in these subtypes.

PD04-01
Predictors of Recovery of Ovarian Function during Aromatase Inhibitor (AI) Therapy.
Henry NL, Banerjee M, Hayden J, Yakim E, Schott AF, Stearns V, Partridge AH, Hayes DF. University of Michigan Medical School, Ann Arbor; MI; Johns Hopkins School of Medicine; Dana Farber Cancer Institute.

Background: AIs may cause a paradoxical rise in estrogen levels due to re-activation of ovarian function in women with chemotherapy-induced ovarian failure (CIOF). Therefore, identification of residual ovarian estradiol production is critical if such women are treated with adjuvant AI therapy rather than tamoxifen. We performed a prospective registry trial to identify predictors of recovery of ovarian function during AI therapy.

Methods: Women with hormone receptor (HR) positive breast cancer who were pre- or peri-menopausal at diagnosis and who remained amenorrheic for ≥ 28 weeks after cyclophosphamide-containing adjuvant chemotherapy were enrolled in a multi-institutional, open-label clinical trial of anastrozole (1 mg/day). Following confirmation that serum estradiol (E2) levels were <20 pg/ml using an ultrasensitive E2 assay (Quest Diagnostics), subjects initiated anastrozole. Serum E2 was assessed biweekly for 12 weeks, then less frequently, for 72 weeks. Multivariable logistic regression was used to evaluate clinical predictors (age at AI initiation OR chemotherapy, menopausal status at chemotherapy, body mass index (BMI), baseline E2) of recovery of ovarian function defined as elevated serum E2 levels or return of menses.

Results: Sixty-nine women were enrolled; current status is given in Table 1.

Median age at initiation of chemotherapy was 47.2 yrs (range 37-55), median time since chemotherapy was 0.8 yrs (range 0.3-6.4), and median age at enrollment was 49.8 yrs (range 40-58). Thirty-six had received tamoxifen. We observed elevated E2 concentrations or return of menses during AI therapy in 21 subjects after a median 2.0 mo (range 0.6-17); for that cohort, median age at chemotherapy was 43.8 yrs (range 37-51) and median age at AI initiation was 45.8 yrs (range 40-56). In contrast, for the 15 subjects who had postmenopausal E2 levels for at least 48 wks, median age at chemotherapy was 49.2 yrs (range 44-52) and median age at AI initiation was 50.7 yrs (range 44-55). Age at chemotherapy (p=0.0006) and age at AI initiation (p=0.001) were statistically significant different between the 2 cohorts. On multivariable analysis, age at chemotherapy and age at AI initiation remained significant when each was adjusted for menopausal status, BMI, and baseline E2 (odds ratio (OR) 1.64, p=0.0102 and OR 1.47, p=0.015, respectively).

Conclusions: A significant proportion of women who develop CIOF recover ovarian function during AI therapy. Although recovery is usually rapid, it can occur at least one year following initiation of AI therapy. Younger age was the strongest predictor of recovery of ovarian function, although 2 of 21 women who developed elevated E2 levels or return of menses were older than 50 yrs at the time of chemotherapy. Tamoxifen remains the standard of care for women with CIOF; if use of an AI is necessary, patients should be monitored frequently with high-quality E2 assays for recurrent ovarian function.
**PD04-02**

Recovery of Ovarian Function in Breast Cancer Patients with Chemotherapy-Induced Amenorrhea Receiving Anastrozole in the Dutch DATA Study.

Tjjan-Heijnen VC, Smorenburg CH, de Graaf H, Erdkamp F, Honkoop A, Wals J, van Gastel S, van der Sangen M, Seynaeve C, Nortier JW, Borm G. Maastricht University Medical Centre, Netherlands; Medical Centre Alkmaar, Netherlands; Medical Centre Leeuwarden, Netherlands; Orbis Medical Centre, Netherlands; Isala Clinics, Netherlands; Atrium Medical Centre, Netherlands; Comprehensive Cancer Centre Netherlands Nijmegen, Netherlands; Catharina-Hospital, Netherlands; Erasmus University Medical Centre, Netherlands; Leiden University Medical Centre, Netherlands; Radboud University Nijmegen Medical Centre, Netherlands

**Background:** In early stage hormone receptor positive breast cancer, aromatase inhibitors (AIs) are established as adjuvant therapy for postmenopausal women. In daily practice AIs are also offered to patients with chemotherapy-induced amenorrhea (CIA). The impact of AIs on estrogen (E2) levels in these patients has not extensively been studied, although this could be very relevant for the efficacy and safety of the adjuvant hormonal treatment. The Dutch phase III DATA study is assessing the impact on disease-free survival of 3 vs. 6 years of anastrozole after 2-3 years of tamoxifen (N=1900 patients in total), and has included both postmenopausal patients and patients with CIA. The current analysis reports on the hormonal data in the CIA group.

**Patients and methods:** We identified patients from the DATA study < 55 years of age at randomization who had received adjuvant chemotherapy and developed CIA, and excluded patients with ovariectomy or use of LHRH agonist. Patients were considered as having CIA if they were in amenorrhea since 3 months before start of chemotherapy up to 6 months after start of chemotherapy, and did not resume menses during tamoxifen therapy. Patients were eligible if postmenopausal E2 levels were confirmed within the last three months before randomization. Plasma FSH and E2 levels were serially determined at 6-month intervals.

**Results:** A total of 285 patients with CIA were identified in the DATA study. Median age was 50.8 years (range 35.9 - 54.9). Results on E2 and FSH levels are presented in the Table. During treatment with anastrozole, FSH levels tended to increase over time and E2 levels didn’t decline. Of note, FSH increased in nearly all patients with significantly elevated (premenopausal) E2 levels, in contrast to the pattern seen in spontaneous recovery of ovarian function. During follow-up, 4 patients had vaginal bleeding, 2 of them having postmenopausal E2 levels. In 8 (2.8%) patients E2 levels became > 200 pmol/l (considered premenopausal) after 12-30 months use of AI. Using a more strict cutoff value of E2 (≥ 100 pmol/l), 62 (21.8%) patients had elevated levels of E2 during AI treatment. With 70 pmol/l as cutoff value, 117 (41.0%) patients had at some point during treatment an increased E2 level. Updated and detailed analyses will be presented at the meeting.

**Conclusion:** In this first series of a large number of CIA patients with available data on E2 and FSH levels during anastrozole therapy, we observed high E2 levels in a substantial number of patients. The combination of increased E2 and FSH levels may indicate continuous stimulation of remaining ovarian follicles. The efficacy of AIs in women with CIA without strict E2 monitoring and adequate treatment modification in the presence of increasing E2 can be questioned. Further data hereon are warranted.

**Supported by:** AstraZeneca NL and the Dutch Breast Cancer Trials’ Group (BOOG).

---

**PD04-03**

**Background:** Sexual dysfunction is reported after chemotherapy and endocrine therapies. However, the prevalence and severity of sexual dysfunction in premenopausal women undergoing therapy for both local and metastatic disease is not well defined. This study was performed in order to understand the impact of contemporary breast cancer treatment on the prevalence and severity of sexual health in premenopausal women.

**Methods:** We developed a survey that includes a previously validated questionnaire, the Female Sexual Function Index (FSFI), as well as an established measure of health-related quality of life (the EuroQol EQ-5D), and disease-specific items to characterize sexual dysfunction and its causes based on literature review and expert consultations. Anonymous administration of the surveys was conducted in outpatient clinic waiting areas of the Breast Cancer Center at Memorial Sloan-Kettering Cancer Center (MSKCC), under an IRB waiver of consent.

**Results:** 372 consecutively approached premenopausal women with breast cancer of any stage, undergoing treatment were each queried once. The mean age was 47. 87% reported current or past hormonal treatment, and 86% reported current or past chemotherapy (76% adjuvant; 24% for metastatic disease). Sexual dysfunction attributed to breast cancer or its treatment, defined as an FSFI score <26, was reported by 75% of respondents with a mean score of 16.3. Among these women, 79% of patients considered their sexual symptoms to be bothersome, with 51% noting moderate or severe levels of bother (score >=5/10). In a multivariate analysis, metastatic disease, development of amenorrhea from cancer treatment, antidepressant use and poorer overall health were each significantly associated with worse FSFI scores. Lower FSFI scores were also significantly associated with worse health-related quality of life.

**Conclusion:** Sexual dysfunction is prevalent in premenopausal women treated for breast cancer and should be discussed with patients as a potential adverse effect of therapy. Assessment of sexual symptoms throughout treatment and beyond may facilitate the use of potential interventions such as lubricants, dilators, treatment modification and counseling.

**PD04-04**

Sexual Dysfunction in Women with Early Stage Breast Cancer on Endocrine Therapy: Encouraging Results from a Prospective Study.

Frechette D, Paquet L, Verma S, Clemons M, Wheatley-Price P, Gertler SZ, Song X, Graham N, Dent S. The Ottawa Hospital Cancer Centre, Ottawa, ON, Canada; Carleton University, Ottawa, ON, Canada

**Background:** While the side effects of endocrine therapy (ET) for early stage breast cancer (EBC) have been extensively studied, the link between ET and sexual dysfunction (SD) remains a contentious issue. Most studies have focused on documenting only the presence of problems in specific domains of endocrine symptoms (ES) (e.g.
hot flushes, vaginal dryness) and sexual functioning (SF) (interest, satisfaction, arousal, lubrication) without also taking sexual distress into account. To our knowledge, there have been no prospective longitudinal studies evaluating SF and SD before the onset of ET and after treatment initiation. We report the initial 6 month results of this study of SD in women initiating ET for EBC.

Methods: Hormone receptor positive EBC post-menopausal women were approached for a larger study of SF aimed at comparing the prevalence of SD across endocrine agents (tamoxifen vs aromatase inhibitor) and at evaluating the impact of anxious predisposition and ES on SD. Here we report on changes in ES, SF and SD after 6 months of ET. SF was evaluated with the Female Sexual Function Index (FSFI) while sexual distress was assessed with the Female Sexual Distress Scale. ES were measured with FACT-B ES subscale. Participants completed questionnaires prior to initiation (T0) of ET and at 6 months (T1). SD was assessed using the APA classification.

Results: Between January 2009 and May 2011, 118 EBC patients entered the study and 83 have completed both assessments (mean age 62: 30% received chemotherapy). Over time, the levels of ES increased (p < 0.001). Despite the worsening of ES at T1, no decline in SF was observed, this for each FSFI domain (desire, arousal, lubrication, discomfort during intercourse and satisfaction). There was no change in the percentage of women reporting 1 or more sexual problems over time (85% vs 87%, ns) nor in the percentage who were sexually distressed (32% vs 34%, ns). The prevalence of SD did not increase after 6 months of ET (T0=28% vs T1=33%, ns). There were no differences in the percentage of women who worsened (i.e., no SD at T0 but SD at T1, 12%) and those who improved (SD at T0 but no SD at T1, 7%) over time (McNemar X², p >.5) Importantly, women classified as experiencing SD at T0 were more likely to also experience SD at T1 (OR=4.5, 95% CI=2.162 to 9.366) than women who had no SD at T0.

Discussion: This is the first prospective case cohort study evaluating ES, SF and SD in women with EBC on ET. The good news for women is that although ES increased during ET (p < 0.001), this did not have a negative impact on sexual problems (85% vs 87%, ns) or SD (32% vs 34%, ns). This is encouraging news but longer follow-up of these women will provide further insight into the impact of ET on ES and SD over time (>6 months). The impact of specific types of ET on ES, and SD will also be evaluated. Of interest, the high uptake and high completion rate (>80%) of questionnaires, indicate this is a matter of relevance and importance to women taking adjuvant ET and merits acknowledgement and sensitive discussion.

PD04-06

Rosenberg SM, Tamimi RM, Gelber S, Kereakoglow S, Borges V, Come S, Schapira L, Winer E, Partridge A. Harvard School of Public Health, Boston, MA; Dana-Farber Cancer Institute, Boston, MA; University of Colorado Cancer Center, Denver, CO; Beth Israel Deaconess Medical Center, Boston, MA; Massachusetts General Hospital, Boston, MA

Background: While there is evidence that younger women with breast cancer are more likely to experience compromised quality of life compared to older women, few studies have prospectively explored the impact of treatment, including surgery, chemotherapy, and hormone therapy, on body image, in particular, in very young women (≤40 years old). This analysis examined treatment-associated differences in self-reported body image among a large cohort of young women diagnosed with breast cancer. Methods: 431 women enrolled in an ongoing multi-center prospective cohort study with Stage 0-Stage III breast cancer were included in this analysis. Body image was measured at baseline (1-12 months following diagnosis) using three items from the Cancer Rehabilitation Evaluation System (CARES) survey. CARES scores range from 0-4, with higher scores indicative of greater image concerns. Mean differences in CARES scores between treatment groups (chemotherapy within the last month vs. none; hormone therapy vs. none; lumpectomy vs. mastectomy alone vs. mastectomy + reconstruction) were estimated using T-tests and one-way ANOVA. To control for concurrent treatment, stage, and time since diagnosis, multiple linear regression models were fit and least squares means estimated and compared between treatment groups. Multiple comparisons were adjusted for using the Bonferroni correction. Results: Median age at diagnosis was 37 (range: 17-40) and median time from diagnosis to study enrollment was 5 months (range: 1-12 months). In the unadjusted analysis, there were no significant differences in scores between women who had received chemotherapy within the last month and those who did not (p=0.80), while women who reported hormone treatment had higher mean CARES scores compared to women who did not (p=0.04). Among women who had undergone surgery (n=370), women who had lumpectomies had a mean CARES score of 0.95, which was significantly lower (p<0.0001) compared to both women who had undergone mastectomy alone (CARES: 1.89) and women who reported mastectomy + reconstruction (CARES: 1.53). After adjusting for concurrent treatment (including radiation), time since diagnosis, and stage of disease, only differences between surgical groups remained significant (p<0.0001), with mean scores among women who had either undergone mastectomy alone (CARES: 2.02) or together with reconstruction (CARES: 1.58) higher compared to those who had a breast conserving procedure (CARES: 0.92)

Conclusion: To the best of our knowledge, this is the largest analysis of treatment-related body image issues in young women with breast cancer. Treatment with chemotherapy and hormonal therapy did not appear to affect short-term body image. However, women who had a breast conserving procedure had the fewest body image concerns as measured by the CARES, while women undergoing more radical surgery appear to be at increased risk for low perceived body image though this may be mitigated to a degree by reconstruction. Further analyses will explore whether differences between surgical groups persist over time as well as examine the trajectory of change over the course of follow-up.

PD04-06

A Randomised Controlled Trial of Quality of Life and Fatigue after Support Group Intervention in Primary Breast Cancer Patients.

Granstam Björneklett H, Lindemalm C, Ojutkangas M-L, Berglund A, Letocha H, Strang P, Bergkvist L. Centre for Clinical Research, Västerås, Sweden; Cancer Centre Karolinska, Solna, Sweden; Centre for Clinical Research, Central Hospital, Västerås, Sweden; Karolinska Institute, SSH, Stockholm, Sweden; Karolinska Institute, Stockholm, Sweden

Background: When diagnosed with breast cancer, most women’s lives change as well as their perspectives on and appreciation of life. The aim of the present study was to evaluate whether psychosocial support intervention could influence health-related quality of life and fatigue during the first year after diagnosis.

Material and Methods: Of 1382 patients with newly diagnosed breast cancer, 191 + 191 patients were randomized to an intervention group or to a routine control group respectively.
The intervention group received support intervention that lasted one week on a residential basis, followed by four days of follow-up two months later. The support intervention included informative-educational parts, relaxation training, mental visualisation and non-verbal communication. Health-related quality of life was measured using the EORTC-QLQ 30 and QLQ-BR23 questionnaires and fatigue with the Norwegian version of the Fatigue scale at baseline, 2, 6 and 12 months after intervention.

Result: There were a time-dependent improvement in both functional and symptom scales between baseline and 12 months as measured by the EORTC QLQ 30 and BR 23 questionnaires and there was a decrease in fatigue between baseline and after 2 months with further improvement up to 12 months in both groups but there were no differences between the intervention and control groups at any point in time.

Conclusion: Health related Quality of Life improves and symptoms of fatigue decreases over time, but we could not see any additional effect from the rehabilitation program in this setting.

Key words: Support intervention, breast cancer, health-related quality of life, fatigue, EORTC-QLQ 30 and BR 23, the Norwegian version of the fatigue scale.

Cognitive Function and Reproductive Hormones in Women Receiving Anastrozole.

Bender CM, Sereika SM, Ryan CM, Berga SL. University of Pittsburgh, Pittsburgh, PA; Emory University, Atlanta, GA

Background: The effects of adjuvant hormonal therapy on hormone levels may contribute to deterioration in cognitive function experienced by women with breast cancer. Estrogen receptors are present throughout the central nervous system. Estrogen binding increases ChAT, synaptogenesis and dendritic spine density in the hippocampus and hypothalamus and decreases monoamine oxidase activity. Aromatase inhibitors, such as anastrozole, interrupt estrogen biosynthesis resulting in profound estrogen reductions. We studied whether changes in reproductive hormone levels mediate changes in cognitive function in 3 cohorts of postmenopausal women; women with breast cancer who receive chemotherapy+anastrozole (CA; n=41) or anastrozole only (AO; n=50) or healthy women (n=44).

Methods: We assessed cognitive function and reproductive hormones (E2, LH, FSH) before therapy and at 6, 12 and 18 months post-therapy initiation. A battery of neuropsychological measures was used to assess multiple cognitive domains. Using mixed effects modeling, we analyzed changes in hormone levels from pretreatment to 6, 12 and 18 months post-therapy initiation and then explored intercorrelations between changes in hormone levels and cognitive function at all timepoints.

Results: Women were an average 59.3 years of age with an average 14.9 years of education. No significant group-by-time effects were found for LH. However, we found significant group by time effects for E2 when comparing CA with controls (p=.0002) and AO with controls (p=.0001) and for FSH when comparing AO with controls (p=.03). We found that E2 declined from pretreatment in the breast cancer groups as follows; CA [E2 declined from pretreatment to immediately post-chemotherapy (p = .09), and at 6 (p = .0002) and 12 (p = .014) months post-anastrozole initiation, and AO [E2 declined from pretreatment to 6 (p < .0001), 12 (p = .004) and 18 (p = .0001) months post-anastrozole initiation]. We also found increases in FSH in the AO group from pretreatment to 6 (p = .002) and 12 (p = .05) months. No significant within-group changes for E2, FSH, or LH were observed for controls. For the full sample, the intercorrelations revealed that reductions in E2 were related to poorer psychomotor efficiency from baseline to 18 months post-baseline (r = .358, p = .02). For the AO group, reductions in E2 were related to poorer executive function (r = .600, p = .002) from 6 to 12 months post-anastrozole initiation and poorer psychomotor efficiency (r = .453, p = .07) from pretreatment to 18 months post-anastrozole initiation. For the CA group, reductions in E2 were marginally significantly related to poorer attention (r = .307, p = .08) from pretreatment to post-chemotherapy; and to poorer executive function from pretreatment to 6 months (r = .446, p = .06) and 12 months (r = .651, p = .03) post-anastrozole initiation. No significant relationships between changes in E2 levels and cognitive function were found in the controls.

Conclusions: Reductions in E2 may be related to cognitive deterioration in women with breast cancer. Further examination of these relationships is needed to confirm the results and determine whether these relationships persist through the remainder and after the conclusion of therapy.

Cimprich B, Hayes DF, Asken MK, Jung MS, Berman MG, Therrien B, Reuter-Lorenz PA, Zhang M, Pelletier S, Noll DC. University of Michigan, Ann Arbor, MI

Background: The underlying brain mechanisms of altered cognitive function associated with adjuvant chemotherapy for breast cancer, commonly designated “chemobrain”, have yet to be determined. Recent research indicates that compromised cognitive function may already exist prior to treatment, adding to the complexity of determining the true impact of adjuvant chemotherapy on brain function. We examined whether two common symptoms associated with breast cancer diagnosis, worry and fatigue, might influence neurocognitive responses during functional magnetic resonance imaging (fMRI) before adjuvant therapy.

Methods: Seventy-five women (29 -75 years) awaiting either adjuvant chemotherapy (n=25) or radiation therapy (n=25) for localized breast cancer and age-matched controls without breast cancer (n=25) were enrolled. Participants performed a verbal working memory task (VWMT) with varying levels of demand for cognitive control during fMRI scanning and provided self-reports of worry and fatigue after scanning. Imaging data were analyzed using the general linear model implemented in SPM5; comparative statistics were used to determine group differences in self-report and behavioral measures.

Results: In general, the pre-chemotherapy group showed compromised cognitive functioning relative to the other groups. Specifically, they reported higher worry than the pre-radiation therapy (p = .036) and control (p = .047) groups. The pre-chemotherapy group also identified greater fatigue than controls (p = .04); the pre-radiation group reported a fatigue level between the other two groups. In the VWMT, the pre-chemotherapy group was less accurate than controls (p = .05), while the mean accuracy for the pre-radiation group again fell between these two groups. fMRI results showed that the control group selectivity increased recruitment of executive control brain regions including the left inferior frontal gyrus (LIFG) and the anterior cingulate cortex (ACC) in response to high vs. low demand conditions. However, recruitment of LIFG and ACC by the control
group was greater than that by both the pre-chemotherapy (p = 0.01 and p = 0.03 respectively) and the pre-radiation groups (p = 0.07 and p = 0.02 respectively). Overall, higher fatigue was correlated with failure to increase recruitment of the LIFG and ACC in high vs. low demand conditions (p = 0.002 and p = 0.078 respectively). Greater worry was correlated with failure to suppress task-relevant activation of default network regions, particularly the posterior cingulate cortex, in high vs. low demand conditions, and with lower accuracy in the VWM task (p = 0.01). Thus, fatigue and worry made independent contributions to altered neurocognitive responses prior to any adjuvant treatment.

Discussion: These findings suggest that women awaiting adjuvant chemotherapy are vulnerable to compromised cognitive functioning, specifically in the domains of attention and working memory, related to higher worry and fatigue. Worry and fatigue may contribute to the cognitive impact often attributed to adjuvant chemotherapy. Therapeutic interventions to counteract worry and fatigue hold potential for optimizing cognitive function prior to adjuvant treatment for breast cancer.

PD04-09
Self-Reported Cognitive Attributes and Fatigue Improve over Long-Term Follow-Up in Breast Cancer Survivors; Some Cognitive Attributes Are Worse in Breast Cancer Patients Than in Non-Cancer Controls.
Hsu T, Ennis M, Hood N, Goodwin PJ. University of Toronto, Toronto, ON, Canada; Applied Statistician, Markham, ON, Canada; Mount Sinai Hospital, Toronto, ON, Canada; Mount Sinai and Princess Margaret Hospitals, Samuel Lunenfeld Research Institute, University of Toronto, Toronto, ON, Canada

Background: Cognitive deficits and fatigue have been reported in breast cancer (BC) patients undergoing a variety of treatments, including chemotherapy; in some studies these concerns persist after completion of treatment. We examined these factors over time (median 11 years) in a longitudinal study of BC patients and compared the status of long-term BC survivors to non-BC controls.

Methods: 535 T1-3, N0-1, M0 BC patients were enrolled 1989-96; 260 women survived without metastases to participate in long-term follow-up (LTFU) measurements in 2006-8. 161 controls without BC were enrolled 2007-8. Questionnaires examined a range of QOL attributes; here we focus on items related to cognition and fatigue, including: EORTC QLQ C30 (cognitive functioning, fatigue), Profile of Mood States (POMS - confusion/bewilderment, fatigue/inertia, vigor/activity), Fatigue Symptom Inventory (FSI - average fatigue past week, total disruption index), Everyday Problems (EDP - forgetfulness, difficulty concentrating, easily distracted). 166 of the BC patients had also completed EORTC and POMS at diagnosis and 1 year, and change in items on these questionnaires was calculated. Age and income adjusted differences between BC (LTFU) and controls were analyzed. Clinical significance was defined as ≥5% of the scale range or an effect size of ≥0.2 and statistical significance as p < 0.05.

Results: BC cases were older than controls (62.3 vs 59.1 years), had lower education (24.6 vs 10.2% high school only) and family income (38.2 vs 19.8% < $60,000 annually) (all p < 0.01). Cognitive attributes: BC patients showed clinically and statistically significant improvements between diagnosis and LTFU on POMS confusion/bewilderment but not EORTC cognitive functioning. Comparing BC (LTFU) to controls, in multivariate analyses adjusted for age and income, EORTC cognitive functioning (81.5 vs 87.4) and EDP forgetfulness (0.9 vs 0.6) were clinically and statistically significantly worse in BC patients than controls. In contrast, POMS confusion/bewilderment, EDP difficulty concentrating and EDP easily distracted scores were similar in BC patients at LTFU and controls. Fatigue: BC patients showed clinically and statistically significant improvements between diagnosis and LTFU on EORTC fatigue, POMS fatigue/inertia and POMS vigor/activity. After adjustment for age and income there were no clinically and statistically significant differences between BC (LTFU) and controls on any fatigue items.

Conclusions: Fatigue items, as well as some cognitive items, improved over time in BC patients and scores were comparable to scores in non-BC controls at LTFU. However, scores on some cognitive items were worse in LTFU BC patients than in non-BC controls raising concerns that BC diagnosis and treatment may be associated with long-term adverse effects on some aspects of self-reported cognitive attributes.

Modena University Hospital, Modena, Italy; Medical Oncology, Ferrara University Hospital; Modena University Hospital; Istituti Ospitalieri, Cremona; Ravazzini Hospital, Carpi; Arcispedale Santa Maria Nuova, Reggio Emilia; Ospedale Infermi, Rimini; Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori, Meldola (FC); Parma University Hospital; Hospital of Piacenza; Ospedale di Circolo e Fondazione Macchi, Varese; Perrino Hospital, Brindisi; GlaxoSmithKline, Verona

Introduction: The CHER-Lob study is a randomized phase II trial of preoperative sequential taxanes-anthraclycines in combination with trastuzumab, lapatinib, or combined trastuzumab and lapatinib in HER2 positive, stage II-III breast cancer patients. A translational program to evaluate predictors of response as well as treatment effects on tissue biomarkers was pre-planned.

Methods: The CHER-Lob translational program includes the central evaluation of HER2, p95HER2, PTEN, pAKT, Ki67 on pre and post-therapy samples. All these biomarkers have been evaluated by immunohistochemistry. FISH analysis was performed in case of HER2 IHC 2+, and in all the discordant cases between central and local laboratories. Biomarkers change from baseline to surgery has been evaluated with the Wilcoxon signed-ranks matched-pair test.

Results: 121 patients have been randomized. The pathologic complete response rate (breast and axillary lymphnodes) was 26% in Arm A (chemotherapy + trastuzumab), 28% in arm B (chemotherapy + lapatinib) and 44% in arm C (chemotherapy + trastuzumab and lapatinib). The concordance between central and local HER2 assessment on pre-treatment biopsy was 97%. The mean (min;max) PTEN expression pre- and post-therapy were 66% (0;100) and 68.4% (0;100) respectively. The mean (min;max) pAKT expression pre- and post-therapy were 23.3% (0;100) and 8.8% (0;90) respectively. A significant decrease was observed in the overall samples (p=0.01). When analyzing the lapatinib alone arm, the difference was no longer significant (p=0.06), while it maintained significance when evaluating the two trastuzumab containing arms (p=0.0013). The mean (min;max) ki67 expression pre- and post-therapy were 29.5% (4;90) and 16.6% (1;50) respectively. A significant decrease was observed when looking at the...
whole population ($p<0.0001$). A significantly higher ki67 inhibition was observed in the dual vs single anti-Her2 therapy ($p=0.003$). **Conclusions:** The central HER2 retesting showed a high concordance with local laboratories. Treatment induced a suppression in pAKT expression, that was higher in patients receiving trastuzumab. The dual anti-Her2 blockade induced a higher Ki67 inhibition as compared to single anti-Her2 blockade. The evaluation of the predictive and prognostic role of these biomarkers is ongoing. Supported by GlaxoSmithKline

Effect of HER2/Topoisomerase II alpha (TOP2A) Gene Status or Protein Expression and Chromosome 17 (CEP17) Polysomy on the Outcome of Breast Cancer Patients Treated with Anthracycline-Containing Dose-Dense Sequential Adjuvant Chemotherapy with or without Paclitaxel – A Pooled Analysis of Two Hellenic Cooperative Oncology Group (HeCOG) Phase III Trials. Dafni U, Bobos M, Tsoiki E, Batistatou A, Kolesta F, Televantou D, Gogas H, Linardou H, Pectasides D, Kalogeras KT, Galani E, Koutras A, Papadimitriou CA, Fountzilas G. Hellenic Cooperative Oncology Group (HeCOG), Athens, Greece

**Background:** The HER2 gene has been established as a valid biomarker in the treatment of breast cancer patients with trastuzumab and probably with other agents, such as paclitaxel or anthracyclines. The TOP2A gene has been associated with response to anthracyclines. The relationship of HER2/TOP2A gene status in the presence of CEP17 polysomy with patients’ outcome following adjuvant treatment with anthracyclines with or without paclitaxel is not established.

**Patients and methods:** Formalin-fixed paraffin-embedded (FFPE) tumor tissue blocks from 1,033 patients (61.5% of 1,681 randomized patients) with high-risk operable breast cancer enrolled in two sequential phase III trials were assessed in a central laboratory for HER2/TOP2A gene amplification and CEP17 polysomy by fluorescence in situ hybridization (FISH) and tumors were categorized according to the 2007 American Society of Clinical Oncology/College of American Pathologists guidelines. HER2 and TOP2A amplification was defined as a gene/CEP17 ratio of $\geq$2.2 and $>=$2.0, respectively or a gene copy number of $>6$. Additionally, HER2, TOP2A, ER/PgR, Ki67, CK5 and EGFR protein expression were assessed by immunohistochemistry (IHC) and all patients were classified according to their IHC phenotype. Treatment consisted of epirubicin-based dose-dense sequential adjuvant chemotherapy followed by hormonal therapy and radiation, as indicated.

**Results:** Disease-free survival (DFS) and overall survival (OS) did not differ significantly between treatment groups. Median follow-up was 92 months, while 5-year DFS (OS) rates were 74% (88%), 69% (81%) and 75% (86%) for the E-T-CMF, E-CMF and ET-CMF groups, respectively. HER2 amplification was found in 24.1% of the patients and TOP2A amplification in 10.3%. In total, 46.7% of HER2 amplified tumors demonstrated TOP2A co-amplification. The median (range) of HER2, TOP2A and CEP17 copy numbers was 2.55 (0.70-45.15), 2.2 (0.50-26.15) and 2.05 (0.45-26.55), respectively. 21% of the tumors were considered to be polysomic (32.5% of those with HER2 amplification). Adjusting for treatment groups in the Cox model, TOP2A amplification, CEP17 polysomy and HER2/TOP2A co-amplification were not associated with either DFS or OS. Treatment with paclitaxel was associated with improved survival in the HER2-amplified subgroup (HR=0.493, interaction $p=0.036$; adjusting for clinicopathological prognostic factors: HR=0.553, interaction $p=0.054$), an association that was not apparent for DFS. Conclusions: HER2 amplification was predictive for OS benefit from adjuvant treatment with paclitaxel in patients treated with epirubicin-based dose-dense sequential adjuvant chemotherapy, but not for DFS. TOP2A amplification, CEP17 polysomy and HER2/TOP2A co-amplification were not associated with outcome.

**PD05-03**

Impact of Quantitative Measurement of HER2, HER3, HER4, EGFR, ER and PTEN Protein Expression on Benefit to Adjuvant Trastuzumab in Early-Stage HER2+ Breast Cancer Patients in NCCTG N9831. Perez EA, Ballman KV, Reinholz MM, Dueck AC, Cheng H, Jenkins RB, McCullough AE, Chen B, Davidson NE, Martino S, Kaufman PA, Kutheh LA, Sledge GW, Geiger KJ, Ingle JN, Tenner KS, Harris LN, Gradow JR, Rim DL, Mayo Clinic, Jacksonville, FL; Mayo Clinic, Rochester, MN; Mayo Clinic, Scottsdale, AZ; University of Pittsburgh Cancer Institute, Pittsburgh, PA; Angeles Clinic and Research Institute, Santa Monica, CA; Dartmouth Hitchcock Medical Center, Lebanon, NH; Oncology Associates of Cedar Rapids, Cedar Rapids, IA; Indiana University Medical Center Cancer Pavilion, Indianapolis, IN; Yale University, New Haven, CT; Seattle Cancer Care Alliance, Seattle, WA

**Background:** Prediction of benefit from trastuzumab in patients (pts) with HER2+ breast cancer remains an important goal. We sought to investigate the predictive value of quantitative measurement of HER2, HER3, HER4, EGFR, ER and PTEN protein expression on the benefit of trastuzumab in the phase III HER2+ adjuvant N9831 study for pts randomized to chemotherapy alone (Arm A) or chemotherapy with sequential (Arm B) or concurrent trastuzumab (Arm C).

**Methods:** For each marker, we evaluated quantitative expression, relationship with demographic data, and association with disease-free survival (DFS) of pts. Freshly cut tissue microarray slides with up to three-fold redundancy per specimen from the N9831 cohort were treated identically using the AQUA (Camp, et al; Nat Med 2002, JCO 2008) method of quantitative immunofluorescence for each marker. HER2 was tested with CBB11 (mouse monoclonal, Biocare, Inc.) and preliminary results were available for 698 of nearly 1400 pt specimens to be tested. The minimum value per pt was used in statistical analysis. Specimens were classified with high versus low expression based on a median value cutoff for each marker. Median follow-up was 7.0 yrs.

**Results:** Quantitative HER2 was compared with centrally performed HER2 testing by IHC and FISH. Median quantitative HER2 via AQUA was 10,017 units for the HER2 IHC 3+ group (n=607) versus 1054, 831, and 970 for the HER2 IHC 2+ (n=68), 1+ (n=11), and 0 (n=11) groups, respectively. The Spearman correlation between quantitative HER2 and FISH HER2/CEP17 ratio was 0.32 ($p<0.001$). High quantitative HER2 was associated with lower percentage of hormone receptor positivity (48% vs 59%, chi-sq $p=0.003$) but not associated with age, race, nodal positivity, tumor histology, grade, or size. High HER2 did not impact DFS in any arm of the study (See Table). Data for additional HER2 testing, HER3, HER4, EGFR, ER and PTEN are in process and will be ready by September, 2011.

**Conclusions:** Similar to results based on standard HER2 testing by IHC and FISH in N9831, quantitative HER2 did not impact benefit from adjuvant trastuzumab. Results for additional markers will be presented. Our complete quantitative results for a second epitope on HER2 and FISH HER2/CEP17 ratio in N9831 are presented. Our complete quantitative results for a second epitope on HER2 and FISH HER2/CEP17 ratio in N9831 are presented.
HER2, HER3, HER4, ER and EGFR will be the first report of these markers in a large patient cohort in the adjudant setting.

### PD05-04
**Quantitative Measurement of Antigen Degradation in NCCTG N9831 Tissue Microarrays.**
Cheng H, Rimm DL, Reinholz MM, Lingle WL, Ballman KV, Dueck AC, Chen B, McCullough AE, Jenkins RB, Perez EA. Yale University School of Medicine, New Haven, CT; Mayo Clinic, Rochester, MN; Mayo Clinic, Scottsdale, AZ; Mayo Clinic, Jacksonville, FL.

**Background:** Unstained recuts from formalin-fixed paraffin-embedded tissues are commonly collected for cooperative group studies. There is concern among pathologists that improper storage conditions can lead to antigen degradation. In an effort to quantify this effect, we compared the expression of HER1 and HER2 on two sets of identical cohort tissue microarrays (TMAs) from the N9831 HER2+ adjuvant phase III trial (NCT00005970; www.clinicaltrials.gov); one freshly cut set (cut April 18, 2011) and a second set stored at 4 degrees for over two years (cut between Nov, 2007 and Jan, 2008).

**Methods:** The two sets of TMA slides containing 1580 tumor samples from the N9831 cohort were treated identically using the AQUA method of quantitative immunofluorescence. HER1 was tested with D38B1 (rabbit monoclonal, Cell Signaling Technology, Inc.) and HER2 with CB11 (mouse monoclonal, Biocare, Inc.) on tumors from 695 patients (712 specimens) in the fresh TMAs and 779 patients (800 specimens) in the old TMAs in up to three-fold redundancy per specimen.

**Results:** Frequency distributions of the expression of HER2 revealed bimodality in the fresh TMAs compared to an attenuated distribution of the old cases. The average score of the entire cohort was significantly lower in old TMAs compared to fresh cuts (paired t-test, p<0.0001). Linear regression of the average HER2 scores from new TMAs versus the average scores from old TMAs showed a slope term of 0.52, which is statistically significantly different from the hypothetical value of 1 (p<0.0001). Regressions between any two fresh slides showed slopes close to 1.0. Similar results were seen for HER1, but fewer positive cases made the changes less dramatic.

**Conclusions:** The storage condition of tissue slides is a critical pre-analytical variable that can dramatically lower the score of HER1 and HER2, artificially. Thus, studies done on inadequately stored slides, either whole sections or TMAs, must be interpreted with caution. Tissue collection and analysis of biomarkers for cooperative group studies should not include unstained recuts, but rather, entire blocks or large cores from tissue blocks.

### PD05-06
**Determination of HER2 Status with Analysis of Plasma DNA by Digital PCR in Patients with Metastatic Breast Cancer.**
Graser EA, Gevensoelen H, Smith IE, Ashworth A, Turner NC. Institute of Cancer Research, London, United Kingdom; Royal Marsden Hospital, London, United Kingdom.

**Background:** A small proportion of originally HER2 negative primary breast cancers relapse with HER2 amplified disease. Identification of these cancers is important as these patients may benefit from HER2 targeting therapies. A proportion of free plasma DNA originates from the cancer, and accurate determination of HER2 copy number in plasma DNA has the potential to non-invasively determine HER2 status in patients with metastatic breast cancer. Digital PCR can differentiate small increases in DNA concentration with a much higher degree of accuracy than conventional quantitative PCR, and here we assess the potential of plasma DNA digital PCR to determine HER2 status.

**Methods:** We examined a cohort of 44 patients with metastatic breast cancer treated at the Royal Marsden Hospital who had received a median of 1.5 prior courses of chemotherapy for recurrent disease; 34 patients had ER positive and 9 HER2 positive (all 3+ positive HercepTest) disease as determined on biopsy of recurrent disease. Following informed consent, plasma samples were taken, free plasma DNA was extracted and concentration determined with LINE1 quantitative PCR. We designed a custom HER2 copy number TaqMan MBG-probe (Applied Biosystems) and two chromosome 17 peri-centromeric control probes TUFMP1 and UBBP4, avoiding known SNPs and regions of normal copy number variation. Digital PCR was performed in 384 well format on a 7900HT Fast RT-PCR system, with copy number ratio determined using the Poisson distribution.

**Results:** HER2 Digital PCR assay was initially tested on DNA from 9 HER2 amplified cell lines. HER2/UPPB4 ratio was increased in 9/9 HER2 amplified cell lines, and HER2/TUFMP1 in 7/9 due to co-amplification of the 17q peri-centromeric DNA in 2 cell lines. Dilution

Discordance between primary and metastatic tumors can impact significantly on patient management and suitability for HER2 targeted therapies in the setting of recurrent distant disease.

**Methods:** A literature search of the PubMed database was performed to identify all primary studies comparing HER2 status in matched primary and distant metastatic tumors between January 2005 and February 2011. Review and data extraction was performed by two independent reviewers. Eligible studies evaluated HER2 status by current ASCO guidelines. Studies comparing paired primary and axillary lymph nodes or synchronous primaries and metastases were excluded. Weighted pooled estimates were calculated.

**Results:** The original search strategy retrieved 1703 studies for which there were 62 eligible studies for full evaluation. Metastatic sites included bone, brain, lung and liver. Traztuzumab was received in three studies. Weighted summary estimate for negative to positive discordance was 23% (95% CI, 16.0-28%). Positive to negative discordance had a weighted summary estimate of 4% (95% CI, 0.0-6%).

**Discussion:** Meta analysis of studies adhering to ASCO guidelines for HER2 status determination revealed a significant rate of change to HER2 positive metastatic disease in HER2 unamplified primary breast cancers. This data suggests that nearly one quarter of patients may be denied the benefit of HER2 targeted therapy if HER2 primary status alone is used a the sole measure in determining therapeutic options upon distant recurrence.
experiments with SKBR3 DNA in non-amplified DNA demonstrated sensitivity down to ~1% levels. We selected HER2/UBBP4 digital PCR for examination of patient samples. Plasma DNA Digital PCR HER2/UBBP4 ratios differed substantially between HER2 non-amplified (mean 1.047, SD 0.149, median 1.046, range 0.70-1.264), and HER2 amplified cancers (median 2.231, range 1.138-7.89, p<0.001). Digital PCR HER2 ratios had a high diagnostic accuracy with ROC curve AUC 0.967 (95% CI 0.955-0.979). With a threshold Digital PCR HER2 ratio of 1.3 the test had 100% specificity and 89% sensitivity, with negative predictive value 97%. The single miscarried HER2 amplified patient had a low tumour burden. Results of a test set using sequential probability ratio test analysis will be presented at the conference.

Conclusions: Plasma DNA Digital PCR accurately determined HER2 status in patients with metastatic breast cancer. Analyses of plasma DNA have the potential to replace biopsy sampling of metastatic disease to guided targeted therapy.

PD05-07
Prospective Validation and Characterization of HER2 Positive Circulating Tumor Cells in Patients with HER2 Negative Metastatic Breast Cancer.

Background: Circulating tumor cells (CTCs) with evidence of HER2 amplification can occur in patients (pts) with clinically HER2 negative metastatic breast cancer. While these findings potentially have profound implications for CTCs as a biomarker for treatment, prospective validation and characterization of this subgroup is necessary.

Methods: We created a prospective cohort of pts with metastatic breast cancer that were HER2 negative by IHC and/or FISH on all available primary and metastatic biopsies. Blood samples were collected at study entry and then again at ≥ 3 weeks if available. CTCs were enumerated by a modification of the Veridex CellSearch Profile kit. FISH was performed on each CTC sample and reported as positive if the HER2/CEP17 ratio was ≥ 2.0. Analyses are descriptive.

Results: 66 pts were consented for study and this report includes the 65 pts with detectable CTCs. Median number of CTCs was 226 (range 112 to > 3000). At initial testing, 23 pts (35%) had HER2 positive CTCs, median HER2/CEP17 ratio of 3.4. 50% (11 of 22) of the pts with lobular or ductal/lobular histology had HER2 amplified CTCs, compared to only 27% (10 of 36) of patients with ductal histology. Women with ER positive disease had HER2 positive CTCs in 40% of cases (20 of 49) compared to 19% of ER negative pts (3 of 16). To assess concordance of HER2 amplification of CTCs over time, in 83% (10 of 12) pts; the 2 women with discordant HER2 amplified patient had a low tumour burden. Results of a test set using sequential probability ratio test analysis will be presented at the conference.

Conclusions: Plasma DNA Digital PCR accurately determined HER2 status in patients with metastatic breast cancer. Analyses of plasma DNA have the potential to replace biopsy sampling of metastatic disease to guided targeted therapy.

PD06-01
Molecular Classification with 21 Gene Assay (OncoType DX®) Shows in 196,967 ER Positive Patients High Frequency of Low Recurrence Score [LRS] in Both Node Positive (N+) and Negative (N-) Breast Cancer (BrCa) Cohorts. Definition of Chemoresistance Based on LRS with Cost and Guideline Implications.

BACKGROUND
Key retrospective analyses have shown no benefit from adjuvant CT [CT] in ER+, N-ve and N+ve BrCa pts with LRS by OncoType DX assay. (For N-ve, hazards [RR] = 1.31, 95% C.I.: 0.46, 3.78 (Paik et.al., 2006); for N+ve, RR=1.01, 95% C.I.: 0.54, 1.93 (Albain et.al. 2009)). LRS (RS<18) can therefore be equated to CT resistance (CTRES).

OBJECTIVES
1. To determine the frequency of CTRES determined by OncoType DX in the Genomic Health database of ER+, N-ve and N+ve pts.
2. To estimate the net cost savings resulting from avoidance of CT for CTRES pts, based on universal OncoType DX testing in ER+ pts being considered for CT.

METHODOLOGY
STEP 1
OncoType DX results were analyzed according to nodal status in the 196,967 ER+ tumor samples for CT candidates submitted to Genomic Health between Jan 2007 – Apr 2011.

STEP 2
We then calculated the $ cost saved, result of Oncotype DX, assuming:
i. of new BrCa pts, 42% could be candidates Oncotype DX and CT (ER+, high risk N-ve; and all ER+ N+ve)
ii. either 50% or 100% CT avoidance – according to oncology practice - among LRS cases, estimating the CT cost/pt = $15,000 US; and OncoType DX cost/pt = $4,000 US.

RESULTS - STEP 1
LRS based on OncoType DX was more prevalent in N+ pts (chi sq p <0.0001)

</tbody>
</table>

Thus, in USA, with 225,000 new BrCa pts / year, and 94 500 [42%] candidates for Oncotype DX, over 47,250 pts will have LRS, with overall savings of $330.8 mil /year with 100% CT avoidance. In Canada, with 25,000 estimated new BrCa pts/year, corresponding savings will be $46.2 mil /year.

CONCLUSIONS:
1. Low RS status, presently the most reliable CTRES biomarker, is expressed with higher frequency among N+ve (59%) vs N-ve (54%) ER+ breast cancer pts.
2. If all eligible cases had the Oncotype DX test, and all with LRS would avoid CT, close to 50,000 pts in USA, and over 5,200 in Canada will be spared ineffective CT and associated toxicity / year, with hundreds of million dollars saved each year.
Conclusions: Reallocation of adjuvant chemotherapy based on Oncotype DX test results was associated with improvements in survival and quality-adjusted life expectancy in this modeling analysis. At a willingness to pay threshold of GBP 20,000 per QALY (commonly quoted as representing good value for money in the UK), probabilistic sensitivity analysis showed that there was a 99.6% probability that Oncotype DX would be cost-effective versus current clinical practice.

PD06-03
Cost Effectiveness Analysis of BRCA1/2 Genetic Testing.
Li Q, Holland M, Huston A, Noyes K. University of Rochester School of Medicine, Rochester, NY

Background: Family history of breast and/or ovarian cancer is associated with an increased risk to carry a BRCA1 or BRCA2 gene mutations which significantly increase a woman’s risk to develop breast and/or ovarian cancer. This study examines whether BRCA1/2 genetic testing (intervention) remains cost-effective compared to no genetic testing strategy (control) from the societal and private payer perspectives given updates in healthcare practice, policy and clinical specificity of testing in the last 10 years.

Data and method: We updated a previous published semi-Markov model (Holland et al., Value in Health, 2009. 12(2): p. 207) to include new information about associated costs and treatment strategies and test specificity. The target population is 35 year old asymptomatic US women with an elevated risk of BRCA1/2 genetic mutation. The estimates of probability (prevalence, risk, preference and mortality), cost, and utility are derived from published reports and BRCA1/2 test technical documentation. We conducted the basecase cost-utility analysis and a series of sensitivity analyses by varying pretest probability of BRCA1/2 mutation, clinical sensitivity of BRCA1/2 testing, initial utility after BC diagnosis and patient preference in the first year after mastectomy, cost of BRCA1/2 testing, and out-of-pocket costs.

Results: From the societal perspective, the “no test” strategy was estimated to cost $162K and resulted in 20.2 QALY gain over a patient’s lifetime. The “test” strategy was estimated to cost $172K and result in 20.5 QALY gain, resulting in the incremental cost-effectiveness ratio (ICER) of $30.6K/QALY. From a private payer perspective, the ICER was $36.8K/QALY. By conducting sensitivity analyses, we concluded that the model was robust to variation in the model parameters. Within the ranges of most variable estimates, the test strategy was more cost effective compared to the no-test strategy. The initial utility after BC diagnosis (basecase value 0.75) does not impact the choice of preferred strategy (testing is always preferred). Based on the probability of mutation for women with family history (basecase value 8.7%), testing is preferred if probability is greater than 3.1%, while no testing is preferred for values <3.1%. Only if cost of genetic testing is greater than $8,948 testing would it no longer be cost effective, which is however far beyond even the upper bound of cost estimate ($4,500). As long as the sensitivity of BRCA testing remains greater than 80% and initial utility after mastectomy <0.9, the testing is preferred over no testing.

Discussion: The strategy of BRCA1/2 testing of women at high risk for BRCA1/2 mutations and treatment of BRCA1/2 positive women is cost-effective compared to “no genetic testing” strategy. Cost of the actual test is not a barrier to its cost-effectiveness. Despite adding MRI to breast cancer surveillance in high risk population and increases in healthcare costs, BRCA1/2 testing remains cost-effective from both the societal and from a private payer perspectives for an unaffected population with BRCA1/2 prevalence of greater than 3%.

**PD06-02**
Cost-Effectiveness Evaluation of the Oncotype DX® Breast Cancer Assay in Clinical Practice in the UK.

Holt SDH, Bennett H, Bertelli G, Valentine WJ, Phillips CJ. Prince Philip Hospital, Llanelli, United Kingdom; Cardiff Research Consortium, Cardiff, United Kingdom; Singleton Hospital, Swansea, United Kingdom; Ossian Health Economics and Communications, Basel, Switzerland; Swansea University, Swansea, United Kingdom

Objective: Optimizing therapeutic regimens for breast cancer patients has an important role to play in improving outcomes and planning the best use of National Health Service resources. Oncotype DX® testing has been shown to provide clinically valuable information in addition to traditional measurements (such as tumor size, tumor grade and lymph node status) to support chemotherapy treatment decision making in women with estrogen receptor positive (ER+), node-negative and up to 3 node-positive breast cancer. The aim of this study was to evaluate the cost-effectiveness of Oncotype DX testing to support adjuvant therapy decision making versus current clinical practice in the treatment of patients with ER+, early-stage breast cancer in the UK.

Methods: A Markov model was developed to make long-term projections of distant recurrence, survival, quality-adjusted life expectancy and direct medical costs for patients with ER+, node-negative or micrometastatic (pN1mic) early-stage breast cancer. Scenarios using conventional diagnostic procedures (including Adjuvant! Online and the Nottingham Prognostic Index) or Oncotype DX testing to inform treatment recommendations for adjuvant therapy were modeled. The model relied on data from an ongoing study in Wales for treatment recommendations (with and without Oncotype DX), landmark Oncotype DX studies for the risk of recurrence, and UK-specific life tables for mortality. Costs were derived from published UK sources and expressed in 2010 Pounds Sterling (GBP). Future costs and clinical benefits were discounted at 3.5% annually. Probabilistic and deterministic sensitivity analyses were performed.

Results: Oncotype DX was projected to increase mean life expectancy by 0.16 years and mean quality adjusted life expectancy by 0.14 years compared to current clinical practice over a 30-year time horizon (see table). Clinical benefits were driven by optimized allocation of adjuvant chemotherapy in the Oncotype DX group. Direct medical costs were estimated to be higher with Oncotype DX testing, leading to an incremental cost-effectiveness ratio (ICER) of approximately GBP 6,232 per QALY gained for Oncotype DX versus current clinical practice in the UK. Sensitivity analysis showed that the cost-effectiveness of Oncotype DX testing was most sensitive to variations in patient age and net changes in chemotherapy for low risk patients.

**Uptake and Economic Impact of First-Cycle Colony Stimulating Factor Use during the Adjuvant Treatment of Breast Cancer.**

**Hershman DL, Wilde ET, Wright JD, Buono DL, Kalinsky K, Malin J, Tsai WY, Neugut AI. Columbia University, New York, NY; Mailman School of Public Health, New York, NY; Greater Los Angeles VA Healthcare System, Los Angeles, CA**

**Background:** In 2002, pegfilgrastim was approved by the FDA and the benefits of dose-dense breast cancer (BC) chemotherapy were reported. A meta-analysis revealed these benefits were limited to hormone receptor negative tumors (20% risk reduction), where hormone receptor positive cancers had a minimal 2% risk reduction. We examined first-cycle growth factor use (FC-CSF) before and after 2002 and estimated US expenditures for dose-dense chemotherapy by hormone receptor status.

**Methods:** We identified subjects in SEER-Medicare >65 years old with stage I-III BC between 1998 and 2005 who had ≥1 chemotherapy claim within one year of diagnosis. We classified those with an average cycle length <21 days as having had dose-dense therapy. The associations of patient, tumor, and physician-related factors with receipt of any CSF and FC-CSF use were analyzed using GEE. Costs and event-free life-years saved were estimated for patients by HR status.

**Results:** Among the 11,143 patients identified, 5,356 (48.1%) had CSF claim during therapy and 2,095 (18.8%) had FC-CSF. CSF use increased from 25.4% to 70.9%, FC-CSF increased from 6.4% to 46.9% and pegfilgrastim increased from 5% to 85%. During this time receipt of the combination of an anthracycline and a taxane increased from 12% to 47%. In a multivariable analysis, any CSF use was associated with age, treatment by an oncologist, and chemotherapy type; and negatively associated with black/Hispanic race, rural residence and shorter chemotherapy duration. FC-CSF use was associated also with higher SES. For hormone receptor negative patients, the cost per event-free life-year saved was estimated for patients by HR status.

**Conclusions:** Our study demonstrated a widespread increase in the use of CSF’s and specifically first cycle pegfilgrastim in elderly women receiving adjuvant chemotherapy for breast cancer. This 4-fold increase came shortly after published reports of the benefits of dose-dense therapy. While this approach is very cost-effective in women receiving adjuvant chemotherapy for breast cancer. This approach is very cost-effective in women receiving adjuvant chemotherapy for breast cancer. This approach is very cost-effective in women receiving adjuvant chemotherapy for breast cancer. This approach is very cost-effective in women receiving adjuvant chemotherapy for breast cancer.

**Primary and Secondary Pegfilgrastim Utilization in Adjuvant Chemotherapy for Breast Cancer in the Community.**

**Patt DA, Espirito JL, Turnwald B, Hoverman JR, Neubauer MA, Busby LT, Brooks BD, Kołodziej MA, Anderson RW, Beveridge RA. On Behalf of US Oncology Pathways Task Force and Clinical Content Development Team. Texas Oncology, TX; US Oncology, TX; Kansas City Cancer Center, KS; Rocky Mountain Cancer Center, CO; New York Oncology Hematology, NY**

**Background**

Various factors are taken into consideration in the selection of adjuvant breast cancer (BC) chemotherapy (CT) regimens for patients. Choice of CT, schedule, duration, and supportive care affects costs and toxicity. Understanding clinical practice utilization patterns are important when making cost estimates of adjuvant therapy. Because pegfilgrastim is a large driver of cost it is important to understand the utilization characteristics. We aimed to characterize primary and secondary pegfilgrastim use during neoadjuvant/adjuvant (N/Ad) chemotherapy by regimen type. While initial data suggests the incidence of febrile neutropenia (FN) is low among some docetaxel containing regimens, we wanted to further characterize pegfilgrastim utilization, as previous utilization studies suggested it was higher than expected.

**Methods**

Using the US Oncology iKnowMed™ EHR database, we retrospectively identified female BC patients (pts) diagnosed with stage I-III BC, between 7/2006 and 11/2010. Secondary diagnoses were excluded. Pts were characterized by age, ER and HER2 status, tumor size, grade, and nodes. CT utilization was determined by the number of pts assigned an N/Ad line of therapy (LOT) during the study period. Regimens were categorized by CT title and drugs. Clinical trial pts were included. Pegfilgrastim utilization was characterized if administered within 6 months of being assigned to an N/Ad CT regimen, and was captured as primary prophylaxis if the first dose was administered ≤5 days of C1D1 of a regimen, and secondary prophylaxis if >5 days.

**Results**

General chemotherapy and pegfilgrastim utilization characteristics were previously reported. This report captures primary vs. secondary pegfilgrastim use. During the time period, 40,881 BC pts were identified. Of these, 15,328 pts (37%) were assigned an N/Ad CT regimen and 72% (11,022 pts) received pegfilgrastim at any time within 6 months of their N/Ad regimen. Docetaxel containing regimens (TC, TAC, TCH) and dose-dense regimens accounted for the majority of all pegfilgrastim use. Pegfilgrastim utilization with the TC regimen was 70%, and represented 25% of all N/Ad pegfilgrastim utilization. The vast majority of utilization for TC and TCH was primary prophylaxis as detailed below:

<table>
<thead>
<tr>
<th>Regimen</th>
<th>Primary utilization % of total</th>
<th>Secondary utilization % of total</th>
<th>None % of total</th>
<th>% of total</th>
<th>Grand Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>TC</td>
<td>2089 53%</td>
<td>637 16%</td>
<td>1183 30%</td>

<tr>
<td>TCH</td>
<td>795 53%</td>
<td>302 20%</td>
<td>398 22%</td>
<td>1495</td>
<td></td>
</tr>
</tbody>
</table>

**Conclusions**

While primary prophylaxis in regimens like dose-dense AC and TAC are expected, the primary utilization of pegfilgrastim in TC and TCH is higher than expected based on published clinical trial experience. The incidence of FN has been reported at 5% in the clinical trial by Jones et al with TC, however subsequent reports suggest the incidence of FN may be higher than expected. Our results demonstrate high primary prophylaxis utilization adoption in clinical practice. With the availability of generic docetaxel, commonly used drugs in adjuvant BC except trastuzumab have generic equivalents. Pegfilgrastim will be the largest cost driver in women receiving adjuvant chemotherapy.
and should be considered among cost estimates. This study may underestimate utilization of pegfilgrastim if it was administered outside of the cancer center.

**PD06-06**

**Is Adjuvant Trastuzumab Economically Justified in Her-2/neu Positive T1bNO Breast Cancer?**

**Skedgel C, Rayson D, Younis T, Capital Health, Halifax, NS, Canada**

**Background:** A number of clinical trials and cost-utility analyses of adjuvant trastuzumab (aTZ) for Her-2/neu positive breast cancer suggest favourable efficacy and safety along with acceptable cost-effectiveness. These evaluations, however, were based on patient cohorts with moderate-to-high risk disease, including node positive or high risk node negative disease with tumor sizes greater than 1 cm (≥T1cN0). The role of aTZ for patients with lower risk disease, such as T1bN0, remains unclear in light of the varying 10-year relapse risks (10-30%) reported to date.

**Objective:** To estimate the cost-utility of chemotherapy plus aTZ versus chemotherapy alone in Her-2/neu positive breast cancer patients with lower recurrence risk in terms of cost per quality-adjusted life year (QALY) gained.

**Methods:** A state-transition economic model was developed to estimate the incremental costs and quality-adjusted life year (QALY) gains associated with a strategy of chemotherapy plus aTZ relative to chemotherapy alone over a 25-year analysis horizon. The model consisted of four broad health states, stratified with or without cardiotoxicity: 1) disease-free, 2) local recurrence, 3) distant recurrence and 4) death. Given the variability in reported risk estimates for T1bN0 disease, a range of 10-year baseline recurrence risks (10-30%) in the absence of chemotherapy or aTZ was examined. The clinical benefit of chemotherapy was assumed to differ according to age (<50 vs. ≥50 years). The hazard ratio of recurrence with aTZ (HR=0.64) and the rate of associated adverse cardiac events were derived primarily from the HERA clinical trial. Utility weights and the costs of local and distant cancer recurrence were derived from the literature, while the costs of adjuvant and palliative TZ were derived from our previous work. The model took a direct payer perspective, with costs reported in 2011 Canadian dollars (CDN$). Costs and QALYs were both discounted by 3% annually. The reference analysis assumed 3 years of clinical benefit from chemotherapy and aTZ. A series of one-way sensitivity analyses tested the impact of longer benefit as well as the impacts of measuring outcomes in terms life years rather than QALYs, a lifetime analysis horizon and different HRs.

**Results:** The reference analysis observed that the cost per QALY gained was greater than CDN$100,000 across the entire range of recurrence risks tested. One-way sensitivity analyses observed that considering life years rather than QALYs, a lifetime analysis horizon, extending the duration of benefit to 5 years or improving the HR to 0.54 each little to improve the overall economic favorability of aTZ, even at the higher range of recurrence risk.

**Conclusions:** The cost-utility of adjuvant trastuzumab appears unfavourable in Her-2/neu positive breast cancers with a baseline 10-year relapse risk of less than 30% without treatments, such as in T1bN0 disease. Specific estimates of cost-utility await more precise estimates of the recurrence risk in patients with T1bN0 disease.

**PD06-07**

**COMPliance and Arthralgias in Clinical Therapy (COMPACT): Assessment of the Incidence and Severity of Arthralgia, Treatment Costs and Compliance within the First Year of Adjuvant Anastrozole Therapy.**

**Hadji P, Blettner M, Bolten WW, Harbeck N, Hindenburg H-J, Jackisch C, König K, Lueck H-R, Rief W, Zaan S, Klein P, Kreienberg R. Philipps-University, Marburg, Germany; Institute for Medical Biometry and Epidemiology, Mainz, Germany; Klaus-Miehlke-Klinik for Rheumatology, Wiesbaden, Germany; Breast Center, Women’s University Hospital, Cologne, Germany; Berufsverband Niedergelassener Gynäkologischer Onkologen e.V., Berlin, Germany; Klinikum Offenbach, Germany; Berufsverband der Frauenärzte e.V., Germany; Gyn. Oncological Practice, Hannover, Germany; AstraZene, Germany; DSH Statistics, Germany; University Women’s Hospital, Ulm, Germany**

**Introduction:** Aromatase inhibitors (AI) are well established as adjuvant endocrine treatment for postmenopausal (PMP) women with HR+ early breast cancer (EBC). However, according to retrospective data, compliance to adjuvant endocrine therapy for EBC may drop to below 70% after one year and to as low as 50% by year 4. In clinical trials, AI are significantly more frequently associated with arthralgia than tamoxifen. Yet, prospective real world data on the effects of AI-associated arthralgia on patient compliance, patient outcomes as well as treatment costs of arthralgia are lacking.

**Methods:** COMPACT is an open, prospective, non-interventional study assessing the incidence and severity of arthralgia, treatment costs, and compliance within the first year of adjuvant anastrozole therapy in PMP women with HR+ EBC. The study is sponsored by AstraZeneca Germany and supported by three major German health insurance funds [GWQ ServicePlus AG, DAK, TK]. Patients on adjuvant treatment for 3–6 months were enrolled at 620 breast centres and practices throughout Germany and stratified by, a) initial adjuvant anastrozole therapy or, b) switch from tamoxifen to anastrozole. All patients receive regular standardized information about EBC from baseline to week 20 to support treatment compliance. Data on patient demographics, occurrence of and treatment of arthralgia, and quality of life will be collected at baseline, 3, 6 and 9 months. Primary endpoints are scaled data on arthralgia, assessed with a visual analogous scale (VAS) via patient questionnaire, and compliance to anastrozole in both strata, assessed by patient and investigator questionnaire. Secondary endpoints include the incidence of arthralgia, treatment costs, reasons for non-compliance, and the influence of arthralgia on clinical outcome. For a subgroup of patients data on arthralgia treatment and compliance will be validated with corresponding data of the participating health insurance funds.

**Results:** Between April 2009 and February 2011, 2313 patients were recruited, 2007 receiving upfront anastrozole and 306 patients on switch therapy. Preliminary baseline data for 2313 patients show the following patient characteristics: mean age 64.5 years, mean BMI 27.7. Only 16.8% of patients had received hormone replacement therapy prior to their cancer. 41.5 % of patients had concomitant symptoms relating to skeleton or musculature, and 11.9% stated arthralgias existing prior to anastrozole treatment. 13.1% reported a worsening of pre-existing arthralgias or new arthralgia after starting on anastrozole treatment.

**Conclusion:** COMPACT aims to provide valid real world data on the incidence and severity of AI-associated arthralgia, treatment modalities and treatment costs. Our results will help to understand and better counsel patients about AI-associated arthralgia to improve adherence to AI-treatment, breast cancer outcomes, and therapy costs.
**PD06-08**  
Projecting the Impact of Adopting Trial Results  
Esserman LJ, Mohan AJ, Park C, Berry DA, Ozanne E, Alvarado MD. UCSF; M.D. Anderson  

**Background:** There is often a substantial delay between the presentation of clinical trial results and change in practice. Reasons for slow adoption include the disruption of practice routines, doubt about the validity of results, financial disincentive, and resistance to change. We propose a decision-making process to inform adoption that considers three factors: likelihood the trial's conclusions will not change with longer follow up, and consequences of early and late adoption. We apply this framework to the published 4-year results of the international TARGIT-A trial, which compares intraoperative radiation therapy (IORT) to external beam radiation therapy (EBRT).

**Methods:** To find whether the trial results will remain robust, we reviewed the TARGIT-A trial's annual hazards for local recurrence (LR). We then reviewed 5-10 year LR rates from recent clinical trials with similar patient populations undergoing RT, no RT or partial breast RT. To assess the impact of an early change in practice, a Markov model was used to evaluate life expectancy, quality adjusted life years (QALYs), and cost. Sensitivity analysis estimated the impact of varying the LR rate 1-20x the TARGIT-A 4 year results. To estimate the impact of late adoption, we generated the expected number of N0, grades 1 & 2, ductal cancers in postmenopausal women (>50 yrs) from SEER and US Census Bureau data. Using Medicare rates, costs of EBRT vs. IORT were compared and potential savings to the health care system calculated.

**Results:** The TARGIT-A peak hazard for LR for IORT and EBRT occurred at 3 years. In the START and ATAC trials, the peak local recurrence Kaplan Meier estimates are between 2 and 3 years. In other trials (ATAC, and in the 2005 RT Lancet overview) there is no second peak of recurrence, making it unlikely that longer follow up will change the conclusion of the TARGIT-A results. The LRR in similar trials have dropped steadily over time for post menopausal, stage I patients with or without RT. Impact of early adoption: If treatment were adopted early, the impact on life expectancy and QALYs would be minimal unless IORT LR rate exceeds 20% over a 10 year period of time. Impact of late adoption: In the US, 45% of new breast cancer cases fit the described population. EBRT costs $6,400 more than IORT per patient on average. If adoption were delayed 5 years to allow the trial results to mature, 70,136 patients per year are expected to receive EBRT resulting in a societal burden of >$2.2 billion barring the capital investment required for new technology. This also assumes that patients have equal utility for a single dose of IORT as they do for 3-6 weeks of postoperative radiation therapy. If IORT utility is higher than that of EBRT, then the IORT strategy is both more effective and less costly.

**Conclusion:** The process of modeling the impact of both early and late adoption when considering the stability of trial results can serve as a tool to evaluate whether to change practice. This analysis was tested on the results of the TARGIT-A trial, and demonstrated that prompt adoption of the IORT intervention would cause minimal harm, provide an improved quality of life, and offer significant societal savings.

**PD06-09**  
Early Predictors of Prolonged Unemployment after a Diagnosis of Breast Cancer.  
Blinder V, Patil S, Eberle C, Maly RC. Memorial Sloan-Kettering Cancer Center, New York, NY; University of California, Los Angeles, CA  

**Introduction:** Low-income women may be more vulnerable to job loss and prolonged work absence after a diagnosis of breast cancer than their higher-income counterparts. This can have important adverse financial consequences on breast cancer survivors. The identification of early risk factors for long-term unemployment could inform interventions to help patients avoid this outcome.

**Methods:** A consecutive sample of 921 low-income, underinsured or uninsured, English and/or Spanish-speaking women treated for breast cancer through the California Breast and Cervical Cancer Treatment Program was recruited and surveyed 6 months after a diagnosis of breast cancer. Participants completed follow-up telephone surveys at 18, 36, and 60 months post-diagnosis; 539 remained in the cohort at 60 months. This analysis includes only the 315 (58%) women who were employed before diagnosis. Our primary study outcome was prolonged unemployment, defined as being unemployed at every survey. Baseline characteristics (measured in the 6-month survey) were compared between women with prolonged unemployment and those who were working 60 months after diagnosis. Results: The median age of the study sample was 50, and 98% had a baseline annual household income <$40,000. Eighty-five of 315 (27%) women who were employed before diagnosis had prolonged unemployment after diagnosis. In contrast, 168 (53%) were working at 60 months. Baseline predictors of prolonged unemployment after diagnosis include lower household income (p=0.003), inadequacy of financial resources to cover needs (40% vs. 23%, for inadequate vs. adequate, p=0.006), lower education (43%, 30%, and 23% among those who did not complete high school, had a high school diploma, and had a college diploma, respectively, p=0.04), higher comorbidity burden (p=0.006), higher cancer stage at diagnosis (p=0.001), and receipt of chemotherapy (p=0.008). Variables found not to be associated with prolonged unemployment include age, ethnicity, acculturation, marital status, children in the home, social support, job type, type of breast surgery, type of axillary surgery, endocrine therapy, and radiation therapy. In a multivariable analysis that included ethnicity, education, income, chemotherapy, and comorbidity, the latter three variables remained statistically significant predictors of prolonged unemployment, but education and ethnicity were not significantly associated with the outcome. Discussion: More than a quarter of women treated for breast cancer never returned to work during the five years after their diagnosis. In this low-income sample, those with the lowest income appeared to be especially vulnerable to prolonged unemployment, even when controlling for education. It is possible that the income provided by a low-paying job provides a marginal benefit, if any, over disability income, and additional research is needed to better understand this relationship and its financial and psychosocial consequences. Clinical variables also were important predictors of prolonged unemployment. Women with a higher comorbidity burden and those treated with chemotherapy appear to be most vulnerable to prolonged unemployment. This may have clinical implications for informed decision-making between oncologists and their patients.
PD06-10
Breast Cancer Patient Distress Associated with Difficulties Navigating the Costs Associated with Care: Results from a National Education Program.

Compounding the stressors related with a diagnosis of breast cancer can be the associated direct and indirect costs of cancer care. To address this need, the Cancer Support Community (CSC) in 2009 developed an evidence-based, professionally-led national education workshop for cancer patients and caregivers entitled Frankly Speaking About Cancer: Coping with the Cost of Care. As part of this workshop, participants completed a survey describing their experiences coping with the cost of cancer care. To date, responses from 465 participants (representing 46 workshops) have been analyzed. Of those participants, 105 are women diagnosed with breast cancer. Though workshop participants were affected by a wide variety of cancer diagnoses, half of those with cancer attending the workshop (50%) were affected by breast cancer. No significant differences between breast cancer patients and individuals with other cancers were found. Analyses are based on responses from breast cancer patients only. Participants’ pre-workshop rating of their understanding about the financial aspects of their breast cancer care was low (m = 2.8, s.d. = 1.0) and was significantly less than their level of knowledge post-workshop (m = 4.1, s.d. = 0.7, p < .05).

Most attendees (72.8%) reported experiencing some degree of emotional distress from trying to manage cancer care costs, and nearly one-third of attendees (30.1%) reported significant distress. Most (64.8%) reported that their healthcare team did not discuss financial aspects of care with them. Of attendees whose team did discuss it with them, typically it was a social worker, physician, or nurse. Of those who had this discussion, only 34% reported that this information was actually useful to them. Not surprisingly then, attendees reported they had looked elsewhere for information about managing the costs of care, such as patient support organizations (40.2%), the Internet (43.5%), and other patients (41.3%).

A positive to arise from the workshop is that most participants (69.9%) reported the intention to discuss financial aspects of their care with their healthcare team based on what they had learned from the workshop. Intention to have this discussion with their healthcare team was both positively correlated with having experienced emotional distress about the cost of their care (r = .29, p < .05) as well as negatively correlated with their level of pre-workshop knowledge about financial issues in breast cancer care (r = -.28, p < .05). Taken together, these data highlight significant obstacles that individuals face in receiving meaningful information relevant to managing the costs associated with cancer care.

PD07-01
Sequential Treatment with Epirubicin/Cyclophosphamide, Followed by Docetaxel vs. FEC120 in the Adjuvant Treatment of Breast Cancer Patients with Extensive Lymph Node Involvement: Final Survival Analysis of the German ADEBAR Phase III Study.
Janni WJ, Harbeck N, Sommer H, Rack B, Salmen J, Augustin D, Simon W, Jueckstock J, Wischnik A, Anneke K, Melcher C, Friese K, Kiechle M, Heinrich-Heine-University, Duesseldorf, Germany; University Cologne, Cologne, Germany; Ludwig-Maximilians-University, Munich, Germany; Mammazentrum Ostbayern, Deggendorf, Germany; Robert-Bosch-Krankenhaus, Stuttgart, Germany; Zentalklinikum, Augsburg, Germany; Technische Universität, Munich, Germany

Background: Based on meta-analytic evidence, taxane containing adjuvant chemotherapy has been established as standard treatment in node-positive breast cancer. However, in the MA-21 study, adriamycin-cyclophosphamide, followed by paclitaxel (AC-P) was significantly inferior to the gold standard of anthracycline treatment, FEC120 (Burnell, SABCS 2006). We prospectively compared a sequential epirubicin-docetaxel chemotherapy regimen to FEC120.

Patients and Methods:
The ADEBAR study was a multicenter phase III trial (n=1502) to evaluate whether breast cancer (BC) pts with > 3 axillary lymph node metastases benefit from a sequential anthracycline-docetaxel regimen (E90C–D: 4 cycles epirubicin [E] 90 mg/m² plus cyclophosphamide [C] 600 mg/m² q21 days followed by 4 cycles docetaxel [D] 100mg/m² q21 days) compared to dose-intensive anthracycline-containing polychemotherapy (FE120C: 6 cycles E 60 mg/m² d 1+8, 5-FU 500mg/m² d 1+8 and C 75 mg/m² d 1-14, q4 weeks). The median follow-up time will be 60 months.

Results:
Treatment was stopped prematurely in 3.7% of the pts in the E90C–D arm and in 8.0% in the FE120C arm due to toxicity (p=0.0009). Antibiotic treatment was given in 10.4% (E90C–D) vs. 19.7% (FE120C), G-CSF support in 39.2% vs. 61.4%, respectively (p=0.0001). Haematological toxicity (leucopenia, neutropenic fever, thrombocytopenia, anemia) was significantly higher in the FE120C-arm. Mature final 5-year-survival data will be presented at the SABCS meeting 2011.

Conclusion:
Different toxicity profiles given, hematological toxicity in the FE120C group was more severe than in the E90C–D. Maturity survival data will be discussed in this context.

PD07-02
Docetaxel Is Superior to Paclitaxel Given Every Three Weeks in Post Operative Patients with Node-Positive Breast Cancer: Results of the Final Analyses of the NSAS-BC (National Surgical Adjuvant Study of Breast Cancer) 02 Trial from Japan.
Watanabe T, Kuranami M, Inoue K, Masuda N, Aogi K, Ohno S, Iwata H, Mukai H, Uemura Y, Ohashi Y. Hamamatsu Oncology Center, Hamamatsu, Japan; Kitasato University Hospital, Sagamihara, Japan; Saitama Cancer Center; Inachou-Okumo, Japan; NHO Osaka National Hospital, Osaka, Japan; Shikoku Cancer Center, Matsuyama, Japan; Kyushu Cancer Center, Fukuoka, Japan; Aichi Cancer Center, Nagoya, Japan; National Cancer Center, Kashiwa, Japan; University of Tokyo, Tokyo, Japan

Background: Four cycles of doxorubicin plus cyclophosphamide (4-AC) followed by four cycles of a taxane is widely used for
postoperative chemotherapy in breast cancer (BC). Concern about relatively rare, but life-threatening toxicity of anthracyclines such as heart failure and secondary leukemia has promoted research to seek anthracycline-free regimens. Since 1990’s when taxanes were introduced, docetaxel (DTX) is used interchangeably with paclitaxel (PTX) for the treatment of BC, but they may differ more than initially anticipated. We conducted this trial to test two hypotheses: (1) Eight cycles of a taxane is not inferior to 4-AC followed by four cycles of a taxane; (2) one taxane is superior to the other.

**Methods:** Eligibility included a diagnosis of clinical stage I-IIIA and axillary node-positive BC, an age younger than 71 years and with performance status of 0 to 1. Patients were randomly assigned to receive either one of the following regimens; ACP: 4-AC (doxorubicin 60 mg/m² and cyclophosphamide 600 mg/m² q3w x 4) followed by 4-PTX (175 mg/m² q3w x 4)

ACA: 4-AC followed by 4-DTX (75 mg/m² q3w x 4)

8-PTX: PTX (175 mg/m² q3w x 8)

8-DTX: DTX (75 mg/m² q3w x 8)

Comparisons included PTX vs. DTX (ACP + 8-PTX vs. ACD + 8-DTX) and +AC vs. -AC (ACP + ACD vs. 8-PTX + 8-DTX). The primary endpoint was disease-free survival (DFS), and the secondary endpoints include overall survival (OS). The trial was powered to prove the non-inferiority of +AC to -AC (threshold hazard ratio 1.32) in terms of DFS. DFS was also compared between PTX and DTX to determine any superiority.

**Results:** A total of 1,060 eligible patients were accrued at 84 centers between December 2001 and April 2006. There were 348 DFS events between December 2001 and April 2006. There were 348 DFS events and 166 deaths after a median followup of 72.2 months. DTX was introduced, docetaxel (DTX) is used interchangeably with paclitaxel (PTX) for the treatment of BC, but they may differ more than initially anticipated. We conducted this trial to test two hypotheses: (1) Eight cycles of a taxane is not inferior to 4-AC followed by four cycles of a taxane; (2) one taxane is superior to the other.

**Nausea and vomiting** were more frequent with +AC than -AC. Edema and febrile neutropenia were more frequent with DTX than PTX. The incidence of sensory neuropathy was higher with PTX than DTX and it lasted for more than one year of the end of PTX treatment.

**Conclusions:** When AC, PTX and DTX were given every three weeks, both DFS and OS were better in the arms including DTX than in those including PTX. AC followed by a taxane can be replaced by 8-DTX.

**PD07-03**

**Phase II Trial of Adjuvant TC (Docetaxel/Cyclophosphamide) Plus Trastuzumab (HER TC) in HER2-Positive Early Stage Breast Cancer Patients.**

Jones S, Collea R, Paul D, Oritz R, Sedlacek S, Favret AM, Gore, Jr H, Lindenquest DL, Holmes EA, Allison MAK, Steinberg MS, Stokoe C, Portillo RM, Crockett M, Wang Y, Asmar L, Robert N, O’Shaughnessy J. US Oncology, The Woodlands, TX; Baylor Sammons Cancer Center, Dallas, TX; New York Oncology Hematology, Albany, NY; Rocky Mountain Cancer Center, Denver, CO; Physician, New York, NY; Virginia Cancer Specialists, PC, Fairfax, VA; Birmingham Hematology and Oncology, Birmingham, AL; Arizona Oncology Associates, Sedona, AZ; Texas Oncology, Houston, TX; Comprehensive Cancer Center; Henderson, NV; Virginia Oncology Associates, Virginia Beach, VA; Texas Oncology, Plano, TX; Texas Oncology, El Paso, TX

**Introduction:** TC is an effective adjuvant chemotherapy regimen in early stage breast cancer (ESBC) patients. Jones et al (J Clin Oncol 2009 Mar 10;27(3):1177-1183) demonstrated a significantly superior 5-year DFS and OS for TC compared to AC. Because TC was superior to AC in a subset analysis of HER2+ breast cancer treated without trastuzumab, we tested TC in combination with 1 year of trastuzumab in lower risk HER2+ ESBC, predominately node negative disease.

**Methods:** This was an open-label, phase II study of TC+H in HER2+ patients based on HER2 overexpression determined at the local level. Tissue was collected for central review of HER2 and TOP2A status. There was no lower limit of tumor size for lymph node negative cancers. Every 21 days, patients received docetaxel (T) 75mg/m² IV, plus cyclophosphamide (C) 600mg/m² IV, plus weekly trastuzumab (H) 4mg/kg IV (loading dose) and 2mg/kg IV thereafter for a total of 4 cycles. After 4 cycles of TC+H, patients continued on H for a total of 1 year. Appropriate patients received radiotherapy. Cardiotoxicity (decreased left ventricular ejection fraction) was assessed by MUGA or ECHO at baseline, at completion of TC+H, and then at 3-month intervals until completion of trastuzumab treatment. The primary endpoint was DFS at 2 years with continued follow-up for 3 years. Secondary endpoints were OS and safety.

**Results:** 486 patients received treatment, and 397(82%) completed a full year of H. Median age was 55 years (range: 24-75.8), ECOG 0-1, and 95% of patients were Stage II, and 6(1.2%) were Stage III. Disease-free survival and OS at 2 and 3 years are listed in the table below according to various features.

</tbody>
</table>

The most common Grade 3/4 toxicities were neutropenia (47.1%) and febrile neutropenia (6.2%). There were 5 deaths: 1 due to PD, 1 aspiration, and 1 respiratory distress syndrome (possibly related to treatment), 1 cardiopulmonary arrest, and 1 unknown. There were 13 cases of recurrent breast cancer (local 5, or local/distant 8). Cardiac dysfunction occurred in 28(5.8%) patients, with 12(2.5%) being Grade 1, 14(2.9%) Grade 2, and 2(0.4%) grades 3/4. Sixteen patients had to stop H due to cardiac dysfunction with H. Central assessment of TOP2A status was performed by FISH in 90% of cases: TOP2A-amplified (42%), deleted (27%), and normal (31%). However TOP2A status had no effect on outcome.
Conclusions: 1) The HER TC regimen was evaluated in 486 patients with HER2 overexpressed ESBC and found to be effective at the primary endpoint of 2 years. 2) Efficacy was demonstrated in node negative cancer including 94 cancers <1 cm. 3) Toxicity was acceptable with a low rate of cardiac dysfunction, mainly reversible. 4) The HER TC regimen is an option for patients with lower risk HER2 overexpressing ESBC.

PD07-04
Lapatinib vs Trastuzumab in Combination with Standard EC-D Chemotherapy in the Neoadjuvant Treatment of HER2+ Patients.

Results from the GEICAM 2006-14 Phase II Randomized Trial. Alba E, Albarello J, de la Haba J, Barnadas A, Calvo L, Sánchez P, Ramos M, Rojo F, Burgués O, Porras I, Tibau A, Carrasco E, Cámara MC, Lluch A. Hospital Virgen de la Victoria, Malaga, Spain; Hospital del Mar, Barcelona, Spain; Hospital Universitario Reina Sofia, Córdoba, Spain; Hospital Santa Creu i Sant Pau, Barcelona, Spain; Complejo Hospitalario Universitario de A Coruña, A Coruña, Spain; Hospital General de Jaén, Jaén, Spain; Centro Oncológico de Gálicia, A Coruña, Spain; Fundación Jiménez Díaz, Madrid, Spain; Hospital Clínico Universitario de Valencia, Valencia, Spain; GEICAM (Spanish Breast Cancer Research Group), San Sebastián de los Reyes, Madrid, Spain.

Background: The addition of trastuzumab (T) to neoadjuvant chemotherapy increases pCR rate in patients with HER2+ breast cancer. Lapatinib (L) in combination with chemotherapy is also an active drug in breast cancer patients. This study investigates the efficacy of trastuzumab or lapatinib added to chemotherapy in the neoadjuvant setting.

Methods: Patients (P) with tumors greater than 2 cm (or less with positive axilla) and HER2+ (Herceptest 3+ or 2+ with FISH+) that have not received any prior treatment for breast cancer were recruited. Pts were randomized to receive epirubicin 90 mg/m2 plus cyclophosphamide 600 mg/m2 x 4 cycles (cy) followed by docetaxel 100 mg/m2 (with growth colony stimulating factor support) plus either T 8 mg/kg loading dose and then 6 mg/Kg intravenous (EC-DT) or L 1250 mg orally (EC-DL). Patients were stratified according to tumor size (T1-2 vs T3-4), and estrogen receptor status (positive vs negative). The primary end-point was pathological complete response (pCR) in the breast measured by Miller and Payne criteria. Secondary end-points were clinical response (by imaging test), toxicity and correlation between pCR and tumor biomarkers.

Results: From February-09 to October-10, 102 pts were randomized (50 EC-DT, 52 EC-DL). Pts characteristics were well balanced between arms. Median age was 48 years (30-79), 56% of pts were premenopausal. 7% grade I, 45% grade III. 14/59/12/15% were T1/T2/T3/T4 and 69% N+. 58% were estrogen receptor positive and 44% progesterone receptor positive. Three patients were FISH negative after central assessment and were not considered evaluable for efficacy, pCR rate in the breast was 52% (95% CI: 38-66) for EC-DT and 25% (95% CI: 13.5-37.5) for EC-DL (p-value=0.0065). pCR---pN0 was 48% (95% CI: 34-62) for EC-DT and 24% (95% CI: 12 – 35) for EC-DL (p-value=0.01). Clinical response was 77% with EC-DT and 65% with EC-DL (p-value=0.176). Grade III-IV toxicity was similar between arms except for diarrhea that was more frequent in EC-DL 14% than in EC-DT 2% (p-value=0.03); more patients discontinue treatment due to toxicity with EC-DL (1 vs 6; p-value=0.055).

Conclusions: Our study shows that EC-DT was more efficacious and less toxic than EC-DL in the neoadjuvant treatment of HER2+ pts. Biomarker profiling in the tumors, including activation levels of tyrosine-kinase receptors, signaling pathways and surrogate markers (proliferation and apoptosis) is ongoing; their correlation with pCR will be presented at the meeting.

PD07-05
Local Recurrence Risk in 6377 Patients with Early Breast Cancer Receiving Neoadjuvant Anthracycline-Taxane +/- Trastuzumab Containing Chemotherapy.

Background: Locoregional recurrence (LRR; defined according to Hudis C, JCO 2007) risk after neoadjuvant systemic treatment is considered as a possible hazard of this treatment approach. However, few data exist on the incidence and risk factors for LRR after anthracycline-taxane +/- trastuzumab (AT +/- H) containing neoadjuvant treatment. We analyzed individual data of 7 prospective neoadjuvant trials conducted by the German Breast Group and the AGO Breast Group.

Patients (Pts) and methods: 6377 Pts with operable or locally advanced, non-metastatic breast cancer were analyzed (for details see von Minckwitz G et al, BCRT 2010). Postsurgical radiotherapy was indicated after breast conservation for all patients and after mastectomy for patients with cT3/4 or cN+ disease. Endocrine treatment was given to ER- and/or PgR-positive patients. 485 LRR were observed during a median follow up of 46.2 (0-127) months.

Results: LRR was similar for patients treated by tumorectomy (7.2% of N=1123), segmentectomy (6.8% of N=1112), quadrantectomy (7% of 557), or breast conservation (BCT) (not otherwise specified) (7.7% of N=819), but higher in patients treated by mastectomy (ME) (12.1% of N=1670) (p<0.001). Rate of breast conservation decreased by increasing initial tumor size (cT1(N=198): 77.7%, cT2(N=3675): 78.1%, cT3(N=795): 49.4%, cT4a-c(N=348): 35.9%, cT4d(N=235): 19.1%). LRR in patients treated by BCT or ME were 9.1% vs 9.1% for cT1 (p=0.9), 6.9% vs. 9.8% for cT2 (p=0.001); 9.7% vs 14.2% for cT3 (p=0.04); 3.2% vs. 11.7% for cT4a-c (p=0.004; and 22.2% vs 18.9% for cT4d (p=0.4). LRR increased with surgical yT-stage from 4.7% for ypT0 (N=990), 11.8% for ypTis (N=340), 9.1% for ypT1 (N=1555), 8.2% for ypT2 (N=926), 13.8% for ypT3 (N=232), 20% for ypT4a-c (N=80), to 31.2% for ypT4d (N=16) (p<0.001). Comparable results were obtained for cN and cNp stages. Patients with a pathological complete response (pCR = ypT0 ypN0) showed a lower LRR of 3.7% compared to patients not achieving a pCR (3.7% vs 9.9% (HR 0.36 p<0.001). Patients with a pCR showed low LRR in all intrinsic subtypes except Luminal B/HER2- like tumors (Luminal A-like tumors (N=105; 3.8%), Luminal B/HER2- like (N=40; 0%), Luminal B/Her2+ (N=124; 8.1%), HER2+ (non-luminal)-like (N=158; 1.9%), triple-negative (N=276; 2.5%) (p=0.016). Patients without a pCR showed an excessive LRR for HER2+ (non-luminal) and triple-negative tumors (Luminal A-like
tumors (N=1498; 5.1%), Luminal B/HER2-like (N=304; 11.9%), Luminal B/HER2+ like (N=602; 8.5%), HER2+(non-luminal)-like (N=367; 18%) and triple-negative (N=276; 17.8%) (p<0.001). cT, cN, ypN, intrinsic subtype, but not ypT stage and type of surgery were independent predictors of LRR for patients without pCR in a Cox regression model. None of these factors except Luminal B/HER2+ (p=0.012) were significant in patients with pCR.

**Conclusions:** LRR in this large pooled analysis occurring after AT+/-H containing neoadjuvant treatment appears to be low, especially in all patients with a pCR except Luminal B/HER2+. In patients without a pCR low cT, cN, ypN and Luminal tumor type predict a low LRR. Other stages and subtypes without pCR should be carefully followed up irrespective of type of surgery.

**PD07-06**

**Adjuvant Chemotherapy with or without Darbepoetin alpha in Node-Negative Breast Cancer: Survival and Quality of Life Analysis from the Prospective Randomized WSG ARA Plus Trial.**

Nitz U, Glue O, Oberhoff C, Reimer T, Schumacher C, Hackmann J, Warm M, Uele C, Runde V, Kuemmel S, Zana J, Harbeck N, West German Study Group, Moenchengladbach, Germany; Bethesda Hospital, Moenchengladbach, Germany; Bethesda Hospital, Wuppertal, Germany; University Hospital Essen, Essen, Germany; Catholic Hospital Essen North, Essen, Germany; University Hospital Suedstadt, Rostock, Germany; St. Elisabeth Hospital, Cologne, Germany; Marien-Hospital Witten, Witten, Germany; University Hospital Cologne, Cologne, Germany; Krankenhaus Koeln-Holweide, Cologne, Germany; Gynecoological Practice, Hildesheim, Germany; Wilhelm-Anton-Hospital Goch, Goch, Germany; Hospital Essen-Mitte, Essen, Germany

**Background:** Darbepoetin alpha (ARA) is currently used to reduce chemotherapy-associated anemia (CAA) rates in various solid tumors. A possible negative impact of ARA on patient survival has been suggested in some clinical trials. The objective of the prospective randomized phase III ARA Plus trial is to compare the survival effect of darbepoetin alpha use (ARA+/ARA-) in combination with modern standard adjuvant chemotherapy targeting guideline-recommended HH-levels in high-risk breast cancer (BC).

**Methods:** ARA Plus compared 6 cycles T90 A10 C825 q3w or 6 cycles F180 E100 C50 q3w (at discretion of each center) in patients with node positive BC (aged 18-65 years). Patients were randomized to darbepoetin (ARA+) 500 μg q3w until completion of radiotherapy or to standard supportive care (ARA-). ARA was started at Hb-levels ≥13 g/dL (amendment 01/2008: Hb <12 g/dL) and stopped at >14 g/dL. Primary endpoint is event-free survival (EFS: relapses, death without disease evidence, second malignancy). Overall survival (OS), toxicity, Hb-levels and quality of life are secondary endpoints. Survival analysis was planned after 7 years of study duration. EFS was compared with a log-rank test (α=0.05) with a statistical power of 80% and log-rank test. Quality of life was measured using FACT questionnaires at beginning of therapy, mid, end of therapy, and at 1 year afterwards.

**Results:** 1234 pts (616 ARA+/618 ARA-) from 70 centers in Germany were randomized between 01/04 and 06/08. 1198 intent to treat patients (ITT) were analysed (1096 TAC; 102 CEF). Baseline characteristics were well balanced in ARA+ and ARA- arms: median age 53/53 years; tumor size 2.4/2.4cm; number of + LN 3/3; HR+ 80%/ 83.5%, G3 40%/36.7%. Toxicity data have been reported earlier (SABCS 2008).

At median follow up of 40 months, 168 events (81 ARA+, 83 ARA-) and 134 relapses (65 ARA+, 69 ARA-) were reported. There was no significant difference in 3-year EFS between ARA+ and ARA- arms (89.2% vs. 87.6%, p=0.97, χ2-test). 37 deaths were reported in the ARA- and 36 in the ARA+ arm. 3-year OS was 95.4% and 95.1% for ARA+ and ARA-, respectively (p=0.85). Only nodal involvement (≥4 vs. 1-3), negative HR, tumor size ≥2 cm and G3 were significant survival predictors by multivariate analysis. Unplanned retrospective analysis revealed better EFS for ARA+ vs. ARA- in HR- (p=0.05), and no difference in HR+ group (p=0.6). In ARA+ patients, Hb-levels were stable over the whole treatment period with rare overstimulation. In ARA- patients, Hb-levels decreased during therapy (median of all cycles ARA+/ARA-: 12.5/11.6 g/dL). There was no correlation between mean Hb-levels and survival in either study arm. There were no significant differences in mean FACT scores changes (general, anemia, cognitive) from begin to end of therapy in either study arm. More detailed analyses are ongoing.

**Conclusions:** To date, the WSG ARA plus trial is the only prospectively randomized trial in early high-risk BC exclusively focusing on the impact of adjuvant ARA on patient outcome. Supportive administration of ARA appears to be safe and to have no significant survival effect when used in combination with TAC or CEF according to current guidelines.

**PD07-07**

**Combination of Paclitaxel and Bevacizumab without or with Capcitabine as First-Line Treatment of HER2-Negative Locally Recurrent or Metastatic Breast Cancer (LR/MBC): First Results from a Randomized, Multicenter, Open-Label, Phase II Study of the Dutch Breast Cancer Trialists’ Group (BOOG).**

Lam SW, de Groot SM, Honkoop AH, Jager A, ten Tije AJ, Bos MM, Emmink SC, van den Bosch J, Nortier J, Brau J, de Graaf H, Portielje J, Los M, Gooyster DD, van Tinteren H, Boven E, VU University Medical Center, Amsterdam, Netherlands; Comprehensive Cancer Centre the Netherlands, Netherlands; Isala Clinics, Zwolle, Netherlands; Erasmus Medical Center-Daniel den Hoed Cancer Center, Rotterdam, Netherlands; Tergooi Hospitals, Hilversum, Netherlands; Reinder de Graaf Hospital, Delft, Netherlands; The Netherlands Cancer Institute-Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands; Albert Schweitzer Hospital, Dordrecht, Netherlands; Leiden University Medical Center, Leiden, Netherlands; Vlietland Hospital, Schiedam, Netherlands; Medical Center Leeuwarden, Leeuwarden, Netherlands; Haga Hospital, The Hague, Netherlands; St. Antonius Hospital, Nieuwegein, Netherlands; Franciscus Hospital, Roosendaal, Netherlands

**Background:** First-line treatment of HER2-negative LR/MBC with paclitaxel (T) and bevacizumab (A) has demonstrated improved progression-free survival (PFS) and overall response rate (ORR) when compared with T alone (E2100). We determined whether addition of capcitabine (X) to AT is safe and would be better effective than AT in women with HER2-negative LR/MBC.

**Methods:** Eligibility criteria were age ≥18 & ≤75 years, measurable or non-measurable HER2-negative LR/MBC, ECOG PS 0–1 and no prior chemotherapy for LR/MBC. Patients were randomized in 1:1 ratio to receive AT (4-week cycle of T 90 mg/m2 on days 1, 8, 15 and A 10 mg/kg on days 1, 15 for 6 cycles, followed by A 15 mg/kg on day 1 given 3-weekly for subsequent cycles) or ATX (3-week cycle of T 90 mg/m2 on days 1, 8, A 15 mg/kg on day 1 and X 825 mg/m2 bid on days 1–14 for 8 cycles, followed by A 15 mg/kg on day 1 and X 825 mg/m2 bid on days 1–14 given 3-weekly for subsequent cycles). Treatment was discontinued at disease progression, unmanageable toxicity or withdrawal of consent. The primary endpoint was PFS.
Secondary endpoints were overall survival, ORR, duration of response and toxicity. Efficacy was evaluated according to RECIST 1.0 and toxicity was assessed according to NCI CTCAE 3.0.

**Results:** From June 2007 till December 2010, 312 patients were recruited at 36 sites. The median age was 56 years (range 32–76). Among all patients, 52% had ECOG 0, 85% were hormone-receptor positive, 86% had measurable disease and 8% had bone-only metastases. These factors were well balanced between both arms. A total of 48% and 33% of patients, respectively, received prior hormonal therapy or radiotherapy for LR/MBC. At the data cut-off of 1st June 2011, the median follow-up duration was 23 months. 311 patients received at least one cycle of treatment and were evaluable for safety. The median number of treatment cycles in AT was 9 and in ATX was 11 (both 33 weeks). An ORR of ≥40% was reached in patients with measurable disease in both groups. The incidence of serious adverse events (SAEs) was 47% and 40% for AT and ATX, respectively, while that of treatment-related SAEs was 12% and 19%, respectively. Treatment-related deaths were 2% for AT and 2% for ATX. The overall rate of AEs grade 3 or 4 was similar in both arms as shown in Table 1, except for hand-foot syndrome grade 3 and neutropenia grade 3 in ATX. In addition, 6 patients with pulmonary embolism were reported in ATX.

**Conclusions:**
ATX was well tolerable, although more patients experienced hand-foot syndrome grade 3 and thromboembolic events than patients treated with AT. The efficacy data will be presented at the meeting.
Support: This study was supported by Roche.

The Effect on Surgical Complications of Bevacizumab Added to Neoadjuvant Chemotherapy; NSABP Protocol B-40.

Bauer HD, Tang G, Rastogi P, Geyer CE, André R, Atkins JN, Baez-Diaz L, Brufsky AM, Mehta RS, Fehrenbacher L, Pajon ER, Senecal FM, Gaur R, Margoese RG, Adams PT, Gross HM, Costantino JP, Swain SM, Mamounas EP, Wolmark N. National Surgical Adjuvant Breast and Bowel Project (NSABP); Virginia Commonwealth University, Massey Cancer Center; University of Pittsburgh Graduate School of Public Health; University of Pittsburgh Cancer Institute School of Medicine; Allegheny General Hospital; Centre Hospitalier de l’Université de Montréal; Southeast Cancer Control Consortium CCOP; San Juan MBCCCOP; University of Pittsburgh Magee Women’s Hospital; University of California at Irvine, School of Medicine, Chao Family Comprehensive Cancer Center; Kaiser Permanente, Northern California; CCOP, Colorado Cancer Research Program; CCOP, North-West Medical Specialties; Kansas City Clinical Oncology Program; Jewish General Hospital, McGill University; Genesys Regional Medical Center; Dayton CCOP; Washington Cancer Institute, Washington Hospital Center; Aultman Health Foundation

The NSABP trial B-40 was designed to determine whether adding capcitabine or gemcitabine to docetaxel followed by AC would increase the pathologic complete response (pCR) rates in patients with operable HER2-negative breast cancer and to determine whether the addition of bevacizumab to three docetaxel-based regimens followed by AC would increase pCR rates. Secondary endpoints include the percentage of surgical complications after mastectomy, lumpectomy, and axillary staging procedures in the patients who received chemotherapy versus those who received chemotherapy and bevacizumab.

**Methods:** Women with HER2-negative operable breast cancer received one of the following docetaxel-based regimens with or without bevacizumab (15mg/kg) every 3 weeks for four cycles: docetaxel 100 mg/m² IV; docetaxel 75 mg/m² and capcitabine 825 mg/m² po BID days 1-14; and docetaxel 75 mg/m² day 1 and gemcitabine 1000 mg/m² IV days 1 and 8. These regimens were followed by preoperative standard AC on day 1 every 21 days for four cycles with or without bevacizumab 15 mg/kg given with the initial 2 cycles of AC. Treatment groups randomized to receive bevacizumab resumed postoperative bevacizumab 15 mg/kg IV every 3 weeks for an additional 10 doses. Assessment of surgical complications was performed from the date of surgery through 24 months following study entry.

**Results:** Planned analysis for surgical complications will be conducted in October 2011 and will be presented along with breast reconstruction data.

Funded by NCI PHS grants U10-CA-37377, U10-CA-69974, U10-CA-12027, U10-CA-69651, and U10-CA-52667, with additional support from F. Hoffmann-La-Roche, Ltd., Genentech, USA, and Eli Lilly and Company.

JNK2 Regulates Mammary Lineage Differentiation in Tumors and Normal Glands through Notch1 and p53.

Cantrill MA, Ebelt ND, Van Den Berg CL. University of Texas at Austin, Austin, TX

The classification of patient tumors by clinical subtype has gained wide acceptance due to the implications for prognosis and treatment. However, recent studies have cast doubt on previously advocated normal mammary origins of these subtypes. Thus, the link between the normal mammary gland and mammary tumors is more complex than expected. C-Jun N-Terminal Kinase-2 (JNK2) is a protein that is involved in numerous developmental processes and our previous work has shown it to be important for DNA damage response in mammary tumors. In attempt to gain insight into the link between mammary development and tumorigenesis, we compared normal mammary glands of JNK2 knockout (jnk2ko) mice to jnk2ko mammary tumors expressing or lacking wildtype p53 (p53ko). These studies showed that jnk2ko glands possess 35% fewer basal cells (p=0.0078) with a corresponding increase in luminal epithelial cell populations (p=0.100). This luminal response is corroborated by in vitro 3D assays of primary mammary epithelial cells (MECs) where luminal cell differentiation is normalized by inhibition of Notch signaling. Expression notch-1, a well-known regulator of MEC differentiation, is increased jnk2ko mammary glands. Increased expression of the Notch-1 target gene, hes-1, was also seen (p=0.005). Histology revealed that increased expression of active Notch-1 is localized to the mammary stem cell niche, the terminal end bud. Similar to the normal gland, jnk2ko mammary tumors possessing wildtype p53 exhibit decreased proportions of basal cells (p=0.0002) and increased proportions of luminal cells (p=0.0411) relative to wildtype. Jnk2ko cell lines derived from these tumors show decreased expression of notch-1 (p=0.0018) and hes-1 (p=0.0602) following introduction of JNK2. Luciferase assays comparing activity of the notch-1 promoter to a notch-1 promoter with mutated p53 response elements revealed...
a dependence of increased notch-1 promoter activity in jnk2ko cells on the p53 response element. P53ko tumor cells, by contrast, do not exhibit alterations in notch-1 promoter activity in the absence of p53 response elements, regardless of JNK2 status. QPCR showed that loss of JNK2 in normal mammary glands and tumors causes increased p53 expression—thus providing a potential mechanism. In support that Notch upregulation in the absence of JNK2 is dependent upon p53, normal glands lacking p53 show no differences in lineage differentiation. P53ko tumors also show no differences in basal lineage differentiation, however, increases in luminal differentiation are maintained in the absence of JNK2. Consistent with increased luminal differentiation, jnk2ko caused decreased expression of markers involved in the epithelial to mesenchymal transition phenotype. This data suggests that JNK2 is important not only for lineage differentiation in normal mammary glands, but in mammary tumors and that the effect is dependent on both Notch1 and p53.

Targeting BCL-2 Expressing Breast Tumors with BH3-Mimetics – A New Class of Drugs in Breast Cancer?
Lindeman GJ, Oakes SR, Vaillant F, Lim E, Lee L, Breslin K, Feleppa F, Deb S, Ritchie ME, Takano E, Ward T, Fox SB, Generali D, Smyth GK, Strasser A, Huang DCS, Visvader JE. The Walter and Eliza Hall Institute of Medical Research, Parkville, VIC, Australia; The Royal Melbourne Hospital, Parkville, VIC, Australia; The University of Melbourne, Parkville, VIC, Australia; Peter MacCallum Cancer Centre, East Melbourne, VIC, Australia; Ospitalieri di Cremona, Cremona, Italy

**Background:** Impairment of apoptosis is a hallmark of cancer and can result in resistance to chemotherapy. Tumor resistance to apoptosis is frequently acquired through deregulated expression of BCL-2 family members or inactivation of the p53 tumor suppressor pathway. Over-expression of the pro-survival protein BCL-2 is common in breast cancer (where it is readily detected by immunostaining), and has been shown to be an important prognostic marker. A potential role for BCL-2 as a *therapeutic target* in breast cancer, however, has not been explored. Recently, small molecules termed ‘BH3-mimetics’ have been developed that mimic the action of pro-apoptotic BH3-only proteins. These bind and neutralize pro-survival proteins including BCL-2. Here we have derived a panel of primary breast tumor xenografts (that include basal-like breast tumors) to study the efficacy of the BH3-mimetic ABT-737 combined with docetaxel in targeting BCL-2-positive breast cancer.

**Methods and Results:** We first studied the expression of BCL-2, pro-survival family members BCL-XL and MCL-1, and the pro-apoptotic protein BIM in tissue microarrays of 197 primary breast tumors, which were subclassified on the basis of ER, PR, HER2, CK5/6 and EGFR expression. BCL-2 was overexpressed in luminal (83.3%), HER2-positive (50.0%), basal-like (18.5%) and ‘marker-null’ (41.4%) breast cancers. BCL-2-positive tumors generally co-expressed BCL-XL (96.2%), MCL-1 (94.7%) and BIM (93.5%).

To determine whether the BH3-mimetic ABT-737 (which neutralizes BCL-2, BCL-XL and BCL-W) was effective in targeting BCL-2-expressing breast tumors, we generated a panel of 28 primary breast tumor xenografts in immunocompromised NOG mice. Five xenograft lines (838T, 24T, 315T, 13T and 806T) were selected for further analysis. Four were basal-like, and one (315T) was a luminal B tumor, as determined by gene profiling. Mice bearing tumor xenografts were treated with ABT-737 (50 mg/kg i.p. d1-10), docetaxel (10 mg/kg i.p. d1) or a combination in q21d cycles. Tumor response and overall survival were significantly improved by combination therapy, but only for tumors that expressed elevated levels of BCL-2. Treatment with ABT-737 alone was ineffective, suggesting that ABT-737 sensitized tumors to docetaxel. Combination therapy was accompanied by a marked increase in apoptosis and dissociation of BIM from BCL-2, indicating that a perturbation of BIM complexes may contribute to the activation of the apoptotic cascade. Notably, ABT-737 appeared effective in targeting BCL-2-expressing basal-like tumor xenografts (838T and 24T) harboring p53 mutations.

**Discussion:** Primary breast tumor xenograft models that recapitulate the phenotype of the primary tumor have been developed as useful ‘proof-of-principle’, pre-clinical models. Here we provide the first *in vivo* evidence that BH3-mimetics can be used to sensitize primary BCL-2-expressing breast tumors to taxane chemotherapy. Our results suggest that elevated BCL-2 expression constitutes a predictive response marker in breast cancer. These findings provide a rationale for the development of clinical protocols using the oral analogue ABT-263 (navitoclax) as an adjunct to taxane chemotherapy in BCL-2-expressing basal-like and luminal breast cancer.

Inhibition of MEK/ERK- and JNK-Dependent Expression of Interleukin-6 and Interleukin-8 Targets Basal-Like Breast Cancer Stem Cells.
Balko JM, Cook RS, Kuba MG, Miller TW, Bhola NE, Sanders ME, Mezeyo IM, Dowsett M, Gomez H, Arteaga CL. Vanderbilt University, Nashville, TN; Royal Marsden Hospital, United Kingdom; Instituto Nacional de Enfermedades Neoplasicas, Lima, Peru

**Background:** Neoadjuvant chemotherapy (NAC) induces a pathological complete response in approximately 30% of triple-negative or basal-like breast cancers (BLBC). However, patients with residual disease often recur after surgery, presumably due to persistent drug-resistant subpopulations with cancer stem cell (CSC)-like properties. Thus, elimination of this CSC compartment in BLBC has the potential to improve survival by reducing post-surgical metastatic recurrences.

**Methods:** We sampled 49 post-NAC breast cancer samples including 22 BLBCs and quantified RNA for 355 cancer-related transcripts using Nanostring technology. Transcripts associated with a high Ki67 in the residual disease (a biomarker of early recurrence) were identified and bioinformatically examined for an association with drug resistance and a CSC phenotype. Loss of DUSP4, a negative feedback regulator of ERK1/2 and JNK1/2, was highly associated with a high post-NAC Ki67. We examined the role of loss of DUSP4 in promoting a drug-resistant, CSC phenotype.

**Results:** Low DUSP4 expression in post-NAC tumors was associated with high ERK1/2 activation and BLBC gene expression. siRNA knockdown of DUSP4 enhanced resistance to anti-cancer chemotherapy (docetaxel, camptothecin). Alternatively, forced DUSP4 expression in breast cancer cell lines abrogated the activation of transcription factors downstream of ERK and JNK, and sensitized cells to docetaxel-induced apoptosis. In highly metastatic BLBC cell lines, MEK inhibition with AZD6244 and JNK inhibition with SP600125 significantly reduced mammosphere formation and self-renewal. Inhibition of JNK and MEK reduced DUSP4 expression in breast cancer cell lines, indicating that a perturbation of DUSP4 expression in breast cancer cell lines may be a novel mechanism to target breast cancer stem cells.
expression in a cohort of 113 post-NAC triple negative breast cancers. Conclusions: Our data demonstrate that loss of DUSP4 in BLBC promotes ERK and JNK activation by impairing negative feedback of these pathways. Activation of ERK and JNK drives expression of IL6 and IL8 expression, possibly through ETS-1 activation. Thus, targeting these signaling pathways may eliminate residual cancer stem cells after neoadjuvant chemotherapy and improve cure rates in BLBC.

**Inhibition of the TGFβ/TGFβR2 Pathway Prevents Enrichment of Drug-Resistant Breast Cancer Stem Cells by Anti-Cancer Chemotherapy.**

**Bhola N, Arteaga C. Vanderbilt University Medical Center; Nashville, TN**

Triple-negative breast cancer (TNBC) is the most virulent form of breast cancer and is associated with a worse prognosis compared to hormone receptor- and HER2-positive tumors. The standard treatment of TNBC is cytotoxic chemotherapy. TNBC patients tend to display a good initial response to chemotherapy; however, they exhibit higher recurrence rates and overall poor long-term survival. Reasons for this high metastatic recurrence rate and mortality are believed to be the existence of a chemo-resistant tumor-initiating population called cancer stem cells (CSCs). CSCs are defined as cells with the ability to self-renew, differentiate into non-tumorigenic cells, and initiate tumors in vivo. CSCs isolated from breast cancer tissue display increased transforming growth factor (TGF) β and TGFβ type II receptor (TGFβR2) mRNA expression compared to non-NCSC population. Furthermore, breast CSCs exhibit characteristics of an epithelial to mesenchymal transition (EMT), a process driven by the TGFβ signaling and associated with metastatic progression. Therefore, we hypothesize that inhibiting the TGFβ/TGFβR2 pathway can abrogate the breast CSC population and sensitize TNBC to chemotherapy, thus reducing metastatic recurrences and tumor progression.

To address this hypothesis, we used the TNBC cell lines SUM159 and BT549. We examined the effect of TGFβ1, the TGFβ receptor I/II kinase inhibitor LY2157299, the TGFβRII receptor and TGFβ1 neutralizing antibodies TR1, and LY2424087 and paclitaxel on the CSC population of these cell lines by 1) flow cytometric analysis of stem cell markers (ALDH, CD44, and PROCR); and 2) mammosphere formation assays. In both cell lines, LY2157299, LY2424087, and TR1 abrogated TGFβ-mediated CSC enrichment and mammosphere formation (p≤0.01). Treatment with paclitaxel resulted in an enrichment of CSCs as measured by FACS and mammosphere formation (p≤0.005) both in vitro and in SUM159 xenografts established in athymic mice. Further, treatment with paclitaxel upregulated TGFβR2 and TGFβ1 mRNAs and phosphorylated SMAD2 levels in CSCs sorted from post-therapy SUM159 xenografts. RNAi-mediated knockdown of TGFβR2 in BT549 cells decreased mammosphere formation but did not affect the proportion of CSCs analyzed by FACS (p≤0.005 and p=0.03, respectively). TGFβR2 and SMAD4 siRNA decreased the CD44+/CD24+ population in both cell lines. SMAD4 siRNA also increased CSCs, mammosphere formation, and viability in SUM159, BT549, and MDA-231 basal-like and HCC1954 (HER2+) cells. SMAD4 knockdown resulted in a significant decrease in the CSC-associated genes interleukin-8 (IL-8) and Nanog. Finally, a combination of either LY2157299 or SMAD4 siRNA with paclitaxel decreased both stem cell marker expression, IL-8 and mammosphere formation compared to each treatment alone (p≤0.006).

These findings suggest that autocrine TGFβ signaling plays a maintenance role in breast CSCs viability. Second, blockade of the TGFβ/TGFβR2 pathway with genetic or pharmacological inhibitors can ameliorate or prevent the enrichment of drug-resistant CSCs by anti-cancer chemotherapy. These studies provide a rationale for studies of chemotherapy ± TGFβ inhibitors in patients with TNBC using stem cell markers as surrogates of clinical response.

**PD08-05**

**Stat3 Signaling in Human Breast Cancer Stem Cells.**

**Wei W, Zhang M, Tweardy D, Rosen J, Lewis M. Baylor College of Medicine**

Recent data suggest the existence of a unique subset of breast cancer cells capable of initiating tumor growth and giving rise to all other cells characteristic of a given tumor. These cells have been termed “cancer stem cells” or “tumor-initiating cells”. Breast cancer stem cells appear to be resistant to chemo- and radiotherapies and may be responsible for recurrence and metastasis in breast cancer patients. Identifying the cellular signaling pathways responsible for breast cancer stem cell maintenance and self-renewal represents a critical hurdle for developing effective therapeutics.

The Stat3 pathway is a critical regulator of the function of normal stem cells, and shows altered expression in human breast cancers [4]. Moreover, IL-6, the Stat3 signaling agonist, is required for breast cancer stem cell function in human breast cancer cell lines. All these suggest an important role of Stat3 signaling in breast cancer stem cells. However, due to lack of method for pathway-activity-based live cell separation, whether Stat3 functions in the cancer stem cells themselves or whether it may function in surrounding niche cells remain unknown. We have constructed a lentiviral fluorescent reporter for Stat3 signaling which contains four copies of M67 Stat3 binding sites upstream of enhanced Green Fluorescent Protein. This reporter system enables FACS-sorting of cells with active Stat3 signaling and in vivo/in situ localization of Stat3 responsive cells. In addition, C188-9, the first Stat3 specific competitive inhibitor, has been developed in our collaborator’s lab, which provides us an advanced tool in studying Stat3 function.

We hypothesize that Stat3 signaling is preferentially active in stem-like subpopulation and depend on non-stem cancer cells to maintain its activation. Three aims to test this hypothesis include: 1. To test whether cancer cells with activated Stat3 signaling are enriched for breast cancer stem cells or whether they may serve as niche cells. 2. To test whether small molecule antagonists of Stat3 signaling can inhibit cancer stem cell function. 3. To identify novel targets of Stat3 signaling that may serve as indicators of responsiveness to Stat3 antagonist or predict treatment response.

So far, our GFP reporters for Stat3 signaling effectively report Stat3 activity in both patient xenografts and human breast cancer cell lines in vivo and in vitro, which enables effective separation of Stat3+ cells for functional study. MDA231 and SUM159 tumors with reporters have been established. Tumor cells will be sorted according to Stat3 activity and perform limiting dilution and MSFE assays. Tumors with reporters will also be treated by C188-9, Chemo, or in combination to study synergistic effect of Stat3 inhibitors on tumor growth. Preliminary data based on inhibitor and limiting dilution studies suggested that Stat3 signaling is required for stem cell function. However, neither Stat3+ nor Stat3- cells are self-sufficient in performing these functions, indicating communications between subpopulations.
PD08-06
ERK2 Promotes Stem Cell-Like Characteristics in Triple-Negative Breast Cancer.
Bartholomeusz C, Saso H, Daddin A, Kazuharu K, Hortalobygi GN. The University of Texas MD Anderson Cancer Center, Houston, TX
Background: Triple-negative breast cancer (TNBC) is resistant to targeted therapies such as hormonal therapy and HER2-targeted therapies. Thus, no specific targeted therapy is currently available for TNBC. ERK2, a component of the MAPK pathway, plays an important role in epithelial-mesenchymal transition (EMT) in MCF-7-10A, a nontransformed human mammary epithelial cell line and is required for full acquisition of stem cell-like characteristics. Inhibition of ERK2 dramatically reduces cell growth, whereas inhibition of ERK1 significantly facilitates proliferation. ERK1 mutant mice have a strikingly milder phenotype than ERK2 mutant mice, which die early in development. In addition, we have shown that the upstream target of ERK, MEK, may be a target for treating TNBC with the MEK inhibitor selumetinib. Our reverse-phase protein array analysis showed that of patients with TNBC, those with ERK2-overexpressing tumors were at higher risk of death than those with low-ERK2-expressing tumors. Therefore, we hypothesized that ERK2 promotes the tumorigenesis and metastasis of TNBC. We sought to determine the role of ERK2 in the tumorigenic and metastatic activities in TNBC and whether ERK2 is required for acquisition of stem cell-like characteristics in TNBC.
Methods: We studied the role of ERK1 and ERK2 in the TNBC cell line SUM-149. We used shRNA to specifically knockdown ERK1 and ERK2 (shERK1 and shERK2) and examined whether knocking down ERK1 and ERK2 correlated with EMT regulation, migration, and tumorigenicity in TNBC cells.
Results: Compared with parental SUM-149 cells, stable clones that constitutively expressed shERK1 or shERK2 showed no difference in growth rate. However, knocking down ERK2 significantly inhibited migration and the acquisition of stem cell-like characteristics (CD44+/CD24-) in SUM-149 cells in vitro. In addition, knockdown of ERK2 also inhibited anchorage-independent growth, an indicator of in vivo tumorigenicity, whereas knockdown of ERK1 did not inhibit anchorage-independent growth. However, inhibition of ERK1 or ERK2 in 2D or 3D cell culture did not correlate with changes in epithelial and mesenchymal markers by western blot analysis.
Conclusion: Our data demonstrate that ERK2 may promote the tumorigenesis of TNBC via enriching cancer stem cells. Our long-term goal is to develop ERK-targeted therapy for TNBC.

PD08-07
Wound-Healing Drainage Fluids Promote Triple Negative Breast Cancer Progression.
Campiglio M, Sassò M, Bianchi F, Plantamura I, Iorio M, De Cecco L, Giustarini E, Agresti R, Ghibellini C, Crocchetta M, Tripodo C, Tagliafure E. Fondazione IRCCS-Istituto Nazionale Tumori, Milan, Italy; University of Palermo, Palermo, Italy
Triple negative breast cancers (TNBC) account for 15% of breast cancers. TNBCs carry a high risk of recurrence and deaths, due to the high rate of local and systemic relapse in these patients and no therapeutic options except chemotherapy are currently available. The TNBC pattern of recurrence present a distant recurrence peak at approximately 3 years and then declines rapidly thereafter, whereas in all non-TNBC types the recurrence risk seems to be constant over time. TNBC relapse risk is comparable to that of HER2-positive tumors subtype, in which growth-factors released during the healing process accelerate the early recurrences in HER2-positive patients.

Thus, we speculate that also TNBC early relapse may depend on their capability to respond to wound-healing stimulation. To this aim, TNBC were treated with drainages to identify which receptors/pathways can be activated and play a driving role in TNBC progression. A pilot reverse phase protein microarray (RPMA) experiment on MDA-MB-231 TN cells drainage-fluids stimulated revealed a specific activation of PDGFR and VEGFR and their downstream pathways, whereas no significant changes were observed in other receptors, such as EGFR, IRS, Met and ERB3. The type of activated receptors suggested the involvement of endothelial receptors upon drainages stimulation and, indeed TNBC cell lines expressed endothelial molecules, such as CD34, CD31, CD146. Beside the proved role of some of these receptors in cellular proliferation, the TNBC endothelial-like phenotype prompt us to analyzed TNBC cell lines capability to form vascular-like channels when seeded on matrigel. Drainages were able to accelerate the formation of vascular channels in TNBC cell lines and, moreover to consistently increase proliferation of TNBC cells compared to non-TNBC cells. To prove whether receptors found activated by drainages play a key role in TNBC progression, we targeted PDGFR, VEGFR and other receptors possibly involved in angiogenesis and vasculogenic mimicry with sunitinib (targeting PDGFR, VEGFR, FGF and c-kit), anti-bFGF antibody (Ab)(targeting the ligand bFGF) and bevacizumab (targeting the VEGF) in TNBC cells drainage-stimulated in vitro. Sunitinib and anti-bFGF Ab halved the proliferation of TNBC cell lines and reduced of almost 60% the formation of vascular-like channels in TNBC cells, whereas bevacizumab modestly affect proliferation but not vasculogenic properties. Notably, sunitinib and anti-bFGF Ab strongly inhibited MDA-MB-231 and MDA-MB-468 xenografts tumor growth (sunitinib: 80%, and 70% Growth Index (GI), respectively; anti-bFGF Ab 70% and 60% GI, respectively) whereas bevacizumab determined no more than 30% decrease of tumor volume. Unfortunately, all these drugs did not efficiently control the development of lung metastases, that indeed significant increased compared to their control, possibly through induction of hypoxia processes. In conclusion, wound healing promotes TNBC progression by sustaining proliferation and vasculogenesis. The use of sunitinib and anti-bFGF antibody strongly inhibited tumor growth in mice models, but significantly increased lung metastases suggesting a combined use of these drugs with molecules able to interfere with hypoxia pathway.

PD08-08
Preclinical Efficacy of the Combination of Met and Src Family Kinase Inhibitors in Triple-Negative Breast Cancer.
Gartner EM, Kim EMH, Choi L, Boerner J. Karmanos Cancer Center at Wayne State University, Detroit, MI
Background: Epidermal growth factor receptor (EGFR), although overexpressed in almost 60% of all triple-negative breast cancers, has yet to be identified as an effective therapeutic target for the treatment of the disease. We have previously shown in cell culture models of triple-negative breast cancer that primary resistance to EGFR tyrosine kinase inhibitors through ligand-independent phosphorylation can be overcome by co-inhibiting EGFR with either Met or Src family kinases (SKFs). We also demonstrated that inhibiting Met kinase activity reduced EGFR and c-Src phosphorylation and inhibiting SKF reduced EGFR phosphorylation. Taken together, these data suggest that EGFR, Met and SKFs regulate the activity of each other through transphosphorylation. This process of transphosphorylation, or crosstalk, allows for the continued activation of key signaling proteins required for proliferation and transformation. Here we demonstrate that inhibiting both Met and SKFs decreases cell viability.
and eliminates the need for inhibition of EGFR tyrosine kinase activity, as the autophosphorylation sites of EGFR were lost with the combination treatment.

Methods: Seven triple-negative (SUM102, SUM149, SUM229, SUM1315, BT20, BT549, MDA-MB-231), two HER2+ (SUM190 and SKBr3), and two ER/PR+ (MCF7 and T47D) breast cancer cell lines were used to test the efficacy of the combination of Met and SFK inhibitors, Arq-197 and dasatinib, respectively. Cell viability after drug treatment was assessed by MTT assays. IC50 values were calculated and drug synergy calculations were performed. Transphosphorylation was measured by immunoblotting using phospho-specific antibodies.

Aptosis was characterized by immunoblotting.

Results: All seven triple-negative breast cancer cell lines demonstrated decreased cell viability with the combination of Arq-197 and dasatinib when compared with either drug alone. In contrast, none of the HER2+ or ER/PR+ breast cancer cell lines had any additional loss of viability with the combination treatment. We found that the interactions between Arq-197 and dasatinib were synergistic in several of the breast cancer cell lines. Specifically, in one such cell line (BT20), the combinatorial index values were less than 1.0. Interestingly, in this cell line, the tyrosine phosphorylation levels on residues 1068 and 992 of EGFR were significantly altered with the combination treatment and activation of apoptotic proteins, including PARP, occurred.

Conclusions: These data demonstrate that two tyrosine kinases, known to be downstream of EGFR activation, interact to promote resistance to EGFR inhibitors. However, inhibiting both Met and SFKs was sufficient to decrease cell viability and stimulate apoptosis in triple-negative breast cancer cells. Further studies to validate the relevance of these findings are ongoing.

PD08-09
PTPN12 Gene Expression Signature in Triple Negative Breast Cancer Cohort.
Ghazalpour A, Bender RP, McGinniss MJ, Ashfaq R. Caris Life Sciences, Phoenix, AZ

PTPN12 tyrosine phosphatase may play a role in tumor development/progression in triple negative breast cancer patients (TNP). The effects of PTPN12 appear to be mediated through several tyrosine kinase receptors including EGFR, HER2, and PDGFR-beta. We investigated the variability associated with PTPN12 transcript in the microarray gene expression data obtained from 105 TNP as determined by IHC for ER and PR and IHC and FISH for HER2 during our clinical molecular profiling on solid tumors. The mRNA levels of PTPN12 in our cohort was highly variable suggesting a complex genetic regulation of PTPN12 transcription in TNP patients. The highly variable nature of PTPN12 mRNA levels lead us to perform a correlation-based analysis of the transcriptome in TNP samples to gain insight into pathways and cellular processes associated with PTPN12 variation. Specifically, we quantile-normalized and performed two-dimensional hierarchical clustering of the 1000 top correlated genes with PTPN12 expression across the 105 TNP samples. We identified seven distinct gene clusters and three distinct patient subpopulations. The three distinct subtypes of TNP were comprised of low expressing PTPN12 (median log2 expression of 12.3), medium expressing PTPN12 (median log2 expression of 13.1), and high expressing PTPN12 (median log2 expression of 13.4). From the 7 gene clusters identified, 6 were positively correlated and one cluster (cluster 3) was negatively correlated with PTPN12 expression. Upon examining the genes within each cluster, we found that all contain unique set of genes related to cell proliferation, cell death, cell motility, cell cycle regulation and other cancer related pathways. From the 7 clusters, clusters 1, 6 and 7 had the highest fraction of such genes. The gene expression pattern and the gene content of these three clusters is as follows: Cluster 1 (208 genes) were genes that were highly expressed in all three TNP groups and the expression of the genes was highest in high PTPN12 expressing patients. Functional classification of genes by the DAVID bioinformatics tool at NCBI showed several genes related to cancer, including 19 MAP kinase signaling genes, and 15 genes involved in regulation of apoptosis. Cluster 6 (150 genes) contained genes showing very low expression in low-expressing TNP, moderately expressed in medium expressing TNP, and highly expressed in high-expressing TNP. Cluster 7 had the highest fraction of cancer related genes including 7 mitosis and cell cycle check point genes, 6 cytoskeletal genes, 4 phosphatases and 6 kinases including KRAS, 4 DNA repair genes, 8 signal transduction genes, 3 positive regulator of apoptosis, and 22 genes involved in regulation of gene expression. Cluster 7 (166 genes) contained genes that were expressed at low level throughout the three TNP groups but the severity of under-expression was higher in TNP patients with low PTPN12 expression. In cluster 7 there were 5 genes belonging to the EGFR and FGF signaling pathways, and 6 genes involved in mitosis. It is worth noting that EGFR pathway has been postulated to crosstalk with PTPN12 protein. All together our results provide support for the involvement of PTPN12 in cancer development and highlights a promising therapeutic target for TNP patients.

PD08-10
High Frequency of Triple Negative Mammary Carcinomas in the Dog as Model of Human Breast Cancer.
Nguyen F, Abadie J, Loussouarn D, Ibisch C, Rieder N, Campion L, Belousov A, Benelmans I, Hanzenne C, Campone M. Ecole Nationale Vétérinaire-ONIRIS, Site Chantrerie- BP4076, Nantes, France; Roche Diagnostics GmbH; Nonenwald 2, Penzberg, Germany; CHU de Nantes, Site Nord-Laennec, Nantes, France; Institut de Cancérologie de l’Ouest, Site Gauducheau, Bvd J Monod, Saint-Herblain (Nantes), France

Background Information: Relevant animal models of human breast cancer are currently lacking, especially regarding the triple-negative breast cancer (TNBC) subtype, for which efficient therapies are needed. Recent studies indicate that spontaneous canine mammary carcinomas (CMCs) (which are common in France due to absence of early neutering) resemble human breast cancers, by pathology, tumor genetics, and biological behavior. However, the current molecular classification of human breast cancer has not been evaluated in canine samples yet.

Objective: To establish the prognostic value of the human immunophenotypic classification in dogs To evaluate CMCs as a model of human breast cancer including TNBC.

Methods: 350 CMCs treated by surgery alone were obtained from the Nantes Atlantic College of Veterinary Medicine, Food Science and Engineering (France) from 2005 to 2008. Recorded clinical data included breed, neutering, age at diagnosis, presence of metastases, cause and time to death. Histological records included the subtype of carcinoma, Elston & Ellis grade, presence of emboli and lymph node metastasis. By immunohistochemistry (IHC) using ER, PR, Her2 (Herceptest and Pathway® Her2), CK5/6, EGF-R and Ki67, CMCs were classified into the subtypes of human breast cancer according to Nielsen et al. IHC analyses were independently reviewed by four pathologists.

Results: The preliminary data in this abstract are based on 200 cases. The mean age at diagnosis was 10.8±2.1 years. 72.7% of dogs were intact female (27.3% of late neutering). 41% of dogs died due to
cancer progression (metastasis rate of 30%). The most common histologic subtype was simple tubulopapillary CMC (53%), then solid CMC (32%). The most common grades were grade II (49%) and III (43%). 53% of the tumors showed lymphatic emboli. 4 immunophenotypes were defined: luminal A (11.9%), luminal B (5.1%), basal-like (59.3%) and non basal-like (23.7%) triple negative CMCs. 8.8% of the CMCs were scored Her2 2+ but none were considered Her2-overexpressing as defined by a score of 3+; however, Her2 immunohistochemistry. 83% of CMCs were of the triple-negative subtype, associated with a shorter survival, as reported in human breast cancer. Infiltrative mammary cancer in dogs could be an interesting model for preclinical investigations. Final data based on 350 animals will be presented at the meeting.

PD08-11
Targeting Porcupine, a Critical Node for Wnt Signalling in Cancer.

Wnt ligands were first discovered based upon their transforming activity in the setting of mouse mammary tumor virus (MMTV) induced mammary carcinogenesis. Wnt signalling is required for normal development of the mammary gland and dysregulated Wnt signalling is implicated in cancers of the breast and colon among others. Furthermore, lobular breast cancer commonly shows reduced expression of E-cadherin that can lead to release of membrane-bound β-catenin into the cytoplasm and potentially increase Wnt signalling in the presence of Wnt ligand. To date, however, low-molecular weight therapeutic inhibitors of the Wnt pathway have not been developed. We set out to discover key points of intervention in the Wnt pathway and to develop low molecular weight inhibitors against such nodes. To this end, a cellular high-throughput screen for small molecule inhibitors of the Wnt pathway was performed. In this assay, cells secreting Wnt3a were co-cultured with cells harboring a luciferase reporter driven by the Wnt/beta-catenin responsive elements. Potent and specific Wnt pathway inhibitors were identified from this screen. To discern the mechanism of action of these compounds, a lead inhibitor was radiolabeled and used to probe protein targets in a radioligand binding assay. From these assays a candidate target of the inhibitor was identified as Porcupine. Porcupine is a membrane bound O-acetyltransferase enzyme that is required for and dedicated to palmitoylating Wnt ligands, a necessary step in the process of Wnt ligand secretion. Inhibition of Porcupine blocks Wnt dependent activities, including LRPs phosphorylation and the expression of Wnt target genes, such as Axin2, which in turn reduces the growth of cancer cells dependent on autocrine or paracrine Wnt signaling. A selective and orally bioavailable Porcupine inhibitor (NVP-LGK974) that inhibits the Wnt pathway in vitro and in vivo was developed through medicinal chemistry optimization. In preclinical evaluation, the compound robustly suppressed Wnt pathway signaling in vivo resulting in tumor regression in a murine breast cancer model driven by MMTV-Wnt1. In addition, this inhibitor attenuated tumor growth as a single agent and induced tumor regression in combination with Taxol in a human primary breast tumor model. Wnt signalling is also important for the maintenance and homeostasis of normal tissues including gastrointestinal tissue. However, preclinical rodent efficacy models of cancer demonstrate that intermittent pharmacological inhibition of Porcupine can be effective against the tumor and mostly spare the normal gastrointestinal tissue, with an acceptable therapeutic window.

A Phase I dose escalation study of NVP-LGK974 in patients with melanoma and lobular breast cancer to evaluate the safety, tolerability, PK, and PD properties is expected to begin this year.

PD09-01
Target-Based Therapeutic Matching in Early-Phase Clinical Trials in Patients with Advanced Breast Cancer and PIK3CA Mutations.
Janka F, Moulder SL, Wheeler JJ, Stepanek V, Falchook GS, Naing A, Hong DS, Fu S, Pika-Paul SA, Luthra R, Tsimeridou AM, Kurzrock R. The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Therapeutic matching based on underlying molecular abnormalities showed promising results in early-phase clinical trials. PIK3CA mutations may predict response to therapies with PI3K/AKT/mTOR inhibitors.

Methods: Tumors from patients with breast cancer referred to the Clinical Center for Targeted Therapy (Phase I Program) were analyzed for PIK3CA mutations. Patients with PIK3CA mutations were treated, whenever feasible, with agents targeting the PI3K/AKT/mTOR pathway.

Results: Of 54 patients analyzed, 15 (28%) had PIK3CA mutations. PIK3CA mutations were found in 5/9 (56%) metastatic, 3/8 (38%) HER2-positive, 7/29 (24%) hormone receptor-positive, and 0/8 (0%) triple negative (excluding metastatic) breast cancers (P=0.07). Of the 15 patients with PIK3CA mutations, 12 (80%) were treated in clinical trials containing a PI3K/AKT/mTOR pathway inhibitor (median age, 54; median number of prior therapies, 3). Of these 12 patients, 3 (25%, 95% CI 0.09-0.53) had stable disease for more than 6 months (SD≥6 months; n=1) or a partial response (PR; n=2). Breast cancer patients without PIK3CA mutations treated on the same protocols had a rate of SD≥6 months/PR rate of 25% on 4 patients with a H1047R mutation treated with agents targeting the PI3K/AKT/mTOR pathway, 3 (75%) had SD≥6 months (n=1) or a PR (n=2) compared to 0 of 8 patients (0%) with other PIK3CA mutations (P=0.045). Patients with H1047R mutations had a median progression-free survival (PFS) of 8.5 months compared to 2 months in patients with other PIK3CA mutations (p=0.13).

Conclusion: Heavily pretreated patients with PIK3CA-mutant advanced breast cancer had a SD≥6 months/PR rate of 25% on protocols incorporating PI3K/AKT/mTOR inhibitors. Patients with mutation H1047R had significantly longer SD≥6 months/PR rate compared to those with other PIK3CA mutations. Our observations suggest that screening for PIK3CA mutations is warranted in larger numbers of patients with advanced breast cancer when treatment with PI3K/AKT/mTOR pathway inhibitors is planned.

PD09-03
Phase I/II Study of BKM120 in Combination with Trastuzumab in Patients with HER2 Overexpressing Metastatic Breast Cancer Resistant to Trastuzumab-Containing Therapy.
Saura C, Bendell J, Jerusalem G, Graña-Suárez B, Su S, Ru Q, De Buck S, Devisse C, Bosch A, Urruticoechea A, Beck JT, DiTomaso E, Rouyre N, Sternberg DW, Massacesi C, Hirawat S, Dirix L, Baselga J, Hospital Vall d’Hebron, Barcelona, Spain; Sarah Cannon Research Institute, Nashville, TN; C.H.U. Sart-Tilman, Liege, Belgium; Novartis Pharmaceuticals, Florham Park, NJ; Novartis Pharma AG, Basel, Switzerland; Hospital Clinico Universitario de Valencia, Valencia, Spain; Catalan Institute of Oncology, Barcelona, Spain; Highlands Oncology Group, Fayetteville, AZ; Novartis Institutes for BioMedical Research, Cambridge, MA; Novartis Oncology, Paris, France; Oncologisch Centrum AZ-St. Augustinus Oncology, Wilrijk, Belgium; Massachusetts General Hospital, Boston, MA

Introduction: HER2 amplification can activate the phosphatidylinositol-3-kinase (PI3K) pathway in breast cancer. Furthermore, trastuzumab (T) resistance can be associated with loss/deregulation of PTEN, which also causes activation of PI3K pathway signaling. BKM120, a potent orally bioavailable pan-class I PI3K inhibitor, could reverse resistance to T in vitro. Furthermore, administration of BKM120 with T demonstrated synergistic activity in preclinical models. The potential for combining BKM120 with T in heavily pretreated HER2+ metastatic breast cancer (MBC) patients (pts) will be determined in this study to substantiate the hypothesis for future development.

Methods: HER2+ MBC pts resistant to T-containing therapy (progression on or within 4 weeks since last T administration) received treatment in the dose-escalation portion of this multicenter trial. Prior anti-HER2-directed therapies were allowed. The primary objective was to determine the maximum tolerated dose (MTD) of BKM120 in combination with the standard dose of weekly T. A Bayesian logistic regression model with overdose control guided the dose escalation.

Results: Seventeen pts with MBC have been enrolled: 5 at 50 mg/day and 12 at 100 mg/day dose of BKM120. Escalation was conducted up to the MTD level of single agent BKM120, 100 mg/day. Patient characteristics: median age 46 years (range 34–70); most pts were heavily pretreated (reported range of prior chemotherapy lines 1–4). In preliminary results (cut-off date 1st June 2011), 7 pts discontinued treatment. BKM120 in combination with T showed a mean peak drug concentration and half-life similar to single-agent BKM120. T trough levels remained above the single agent efficacy threshold. Only one dose-limiting toxicity (G3 asthenia) was reported at the BKM120 dose of 100 mg/day. The MTD was determined to be 100 mg/day. Reported G3 adverse events were asthenia, altered mood, rash, GGT increase, hypokalemia, and hypersensitivity in 1 pt each. No G4 toxicity has been observed so far. With regards to activity, 2 partial responses (1 confirmed) and 3 occurrences of disease stabilization have been observed.

Conclusions: BKM120 in combination with T in heavily pretreated HER2+ MBC pts with T-resistance has an acceptable safety profile and has shown encouraging preliminary activity. The Phase II portion of the study is ongoing. An updated analysis of efficacy, the potential correlation with PI3K pathway alteration status overlaying HER2 activation, and pharmacodynamics study will be presented.

PD09-04
A Phase Ib, Open-Label, Dose-Escalation Study of the Safety and Pharmacology of the PI3-Kinase Inhibitor GDC-0941 in Combination with Paclitaxel and Bevacizumab in Patients with Locally Recurrent or Metastatic Breast Cancer.
Schiff F, P De Benedictis E, Gendream S, Gianni L, Krop IE, Levy G, Ware J, Wilders H, Winer EP. Catholic University, Leuven, Belgium; Istituto Nazionale dei Tumori, Milan, Italy; Genentech Inc., South San Francisco, CA; Dana-Farber Cancer Institute, Boston, MA

Background: GDC-0941 is a potent and selective oral pan-inhibitor of class I PI3K isoforms that demonstrates single-agent activity in xenograft models1,2,3. Increased phosphorylation of AKT has been observed in breast cancer (BC) cell lines treated with paclitaxel in vitro, suggesting dependence on the PI3K pathway for survival in response to chemotherapy treatment. GDC-0941 increases the antitumor activity of taxanes, associated with increased apoptotic cell death, in multiple BC xenograft models2.

Material and Methods: Patients (pts) with HER2-negative locally recurrent or metastatic BC (MBC) that received no more than 2 prior anti-cancer therapies for MBC (prior paclitaxel and/or bevacizumab permitted) were enrolled in a Phase Ib study (GDC4629g) of paclitaxel and GDC-0941 with and without bevacizumab using a 3+3 dose escalation design to evaluate the safety, tolerability, and PK and PD of the combination. Paclitaxel was given at 90 mg/m² on Days 1, 8 and 15 and bevacizumab, if applicable, at 10 mg/kg on Days 1 and 15 every 28 days. Two dosing schedules of GDC-0941 were examined: GDC-0941 given once-daily on Days 1-21 (“21+7” schedule) or given for 5 consecutive days followed by a 2-day drug holiday (“5+2” schedule), implemented to potentially improve the efficacy and safety of the combination treatment.

Results: We report data from 5 cohorts (25 pts). Sixteen of the 25 pts (64%) are hormone-receptor positive and 12 of 25 patients (48%) received prior treatment with a taxane, (all but one in the neo-adjuvant or adjuvant setting) and only one patient received prior treatment with bevacizumab. Pts in Cohort 1 received GDC-0941 60 mg given 21+7 with paclitaxel in Cycle 1; they were allowed to receive bevacizumab starting in Cycle 2. One DLT of Grade 3 subclavian vein thrombosis (in a pt with an indwelling catheter) was observed at this dose level. The cohort was expanded without any additional DLTs. In Cohorts 2 and 3, GDC-0941 was given 21+7 at 60 mg and 100 mg, respectively, with paclitaxel and bevacizumab starting in Cycle 1. One DLT of Grade 3 subclavian vein thrombosis (in a pt with an indwelling catheter) was observed at this dose level. The cohort was expanded without any additional DLTs. In Cohorts 2 and 3, GDC-0941 was given 21+7 at 60 mg and 100 mg, respectively, with paclitaxel and bevacizumab starting in Cycle 1. In Cohort 4, GDC-0941 was given 5+2 at 165 mg with paclitaxel only. Cohort 5, with 250 mg GDC-0941 given 5+2 with paclitaxel only, is currently under evaluation. The most common drug-related AEs in 22 treated patients are in Table 1. Preliminary PK for GDC-0941, paclitaxel and 6-hydroxy-paclitaxel were similar to historical profiles from previous studies of these molecules. One CR and 9 PRs (ORR 46%) have been observed to date.

PD09-05
SU2C Phase Ib Study of pan-P13K Inhibitor BKM120 Plus Aromatase Inhibitor Letrozole in ER+/HER2- Metastatic Breast Cancer (MBC).
Mayer IA, Balko JM, Kuba MG, Sanders ME, Yap J, Li Y, Winer E, Arteaga CL. Vanderbilt-Ingram Cancer Center, Nashville, TN; Dana Farber Cancer Institute, Boston, MA; MD Anderson Cancer Center, Houston, TX

Background: Experimental evidence and clinical data suggest that PIK3CA mutations (present in approximately 35% of ER+ cancers) are associated with de novo or acquired resistance to antiestrogen therapy. Considering that most breast cancers resistant to antiestrogen therapy retain ER and estrogen sensitivity, treatment of ER+ breast cancers with single-agent PI3K-targeted therapy may be insufficient to inhibit tumor growth.

Materials and Methods: To evaluate safety/tolerability, we initiated a phase Ib clinical trial of letrozole with the pan-P13K inhibitor BKM120 (Novartis) in post-menopausal patients with ER+/HER2– MBC. Letrozole (2.5 mg/d) and BKM120 (100 mg/d) were given on a 28-day cycle. When necessary, BKM120 was reduced to 80 and 60 mg/day. Treatment was continued until unacceptable toxicity or progression of disease. Disease was assessed every 2 months. FDG-PET imaging was performed at 2 weeks to identify changes indicative of pharmacodynamic modulation of PI3K/AKT.

Results: Twenty patients have been accrued; all but 2 patients had previously progressed on an aromatase inhibitor (AI) in the metastatic setting. Median age was 56 years; 85% of patients had metastatic bone disease, 70%, visceral metastases. Twelve patients are still on treatment, 2 of these are currently on BKM120 80 mg/day. Three patients discontinued treatment within 2 months of initiation due to grade 3 transaminitis, grade 2 irritability, and grade 2 hyperglycemia, despite dose reductions and/or optimal treatment. Most common toxicities are summarized in the table below. Transaminase elevation was the only DLT at 100 mg/d BKM120. Of the 12 evaluable patients that completed at least 8 weeks of treatment, 1 had a partial response, 7 had stable disease, and 4 had disease progression (RECIST). So far 3 patients have been on treatment for >4 months. Over 50% of patients had >25% reduction in their peak SUV at the 2-week FDG-PET scan.

Discussion: The letrozole + BKM120 combination is active in patients with ER+/HER2– MBC refractory to previous therapy with an AI. At this time, all patients’ primary diagnostic tumor biopsies and/or metastatic biopsies are being analyzed for the presence of PIK3CA, AKTI, or PTEN mutations and PTEN loss (immunohistochemistry). FDG-PET imaging at 2 weeks appears to be a useful pharmacodynamic biomarker of PI3K pathway inhibition.

Correlation of mutational analysis with clinical benefit will be presented at the meeting. Despite an overall safe side effect profile, an alternative administration schedule of BKM120 with letrozole is planned to enhance tolerability of the combination.

PD09-06
Phase II Trial of RAD001 (Everolimus), an mTOR Inhibitor, with Weekly Cisplatin and Paclitaxel in Patients with HER2-Negative Metastatic Breast Cancer (MBC).
Mayer IA, Means-Powell J, Abramson VG, Shyr Y, Balko JM, Kuba MG, Gharavi HM, Schlabach L, Arteaga CL, Pietenpol JA. Vanderbilt-Ingram Cancer Center; Nashville, TN; Vanderbilt-Ingram Cancer Center Affiliated Network (VICCAN)

Background: In basal-like breast cancers, drugs that either negatively modulate p63 and/or activate p73, such as cisplatin and paclitaxel, promote p73-dependent apoptosis. Further, the serine threonine kinase mTOR negatively regulates p73. Inhibition of mTOR with RAD001 upregulates p73, and results in p73-mediated apoptosis. Therefore, we conducted a phase II trial in patients with HER2-negative MBC to explore safety, tolerability and anti-tumor activity of the combination of paclitaxel, cisplatin and RAD001.

Materials and Methods: We initiated an open-label, phase II multi-institutional study of weekly cisplatin (25 mg/m²), paclitaxel (80 mg/m²) and daily RAD001 (5 mg), given on a 28-day cycle. Treatment was continued until unacceptable toxicity or progression of disease. All toxicities were documented using the NCICTCv.4. Disease was assessed every 2 months.

Results: A total of 55 patients were enrolled. Median age was 55 years; 62% of patients had prior chemotherapy with a median of 3 previous regimens in the metastatic setting. Sixty-three percent of patients had triple-negative disease, 81% patients had visceral disease, and 35% had bone metastases. Twenty-one patients are still on study. The most common toxicities are summarized in the table below. Neutropenia was the main cause for dose reductions, mainly after cycle 3. Only 1 patient developed febrile neutropenia. Of the 44 patients assessed for best response (RECIST) thus far, 11 had partial response, 21 stable disease, 9 disease progression, and 3 were not evaluable. Thirty-eight patients have discontinued treatment so far; 30 due to disease progression, 5 due to toxicity, and 3 withdrew consent. Current median time to progression on the evaluable patients is 6 months.

Discussion: The combination of RAD001, cisplatin and paclitaxel was overall very well tolerated despite cumulative pancytopenia. Significant antitumor activity in this heavily pre-treated patient population was seen. All patients’ primary diagnostic and/or metastatic tumor biopsies are currently being analyzed for the presence of PIK3CA and AKTI mutations, and immunohistochemical expression of p53, p63, p73, and PTEN. Microarrays are being generated to determine whether time to progression is superior in patients with basal-like breast cancers. Microarrays will be mined to identify a pretreatment profile that mirrors a low p63/high p73 gene expression signature. Correlation of mutational analysis and gene signatures with clinical benefit will be presented at the meeting.

PD09-08
Combined Inhibition of mTORC1 with Temsirolimus and HER2 with Neratinib: A Phase I/II Study in Patients with Metastatic HER2-Amplified or Triple-Negative Breast Cancer.

Background: Hyperactivation of the PI3K-AKT-mTOR pathway is a postulated mechanism of resistance to anti-HER2 therapies and has also been described in triple-negative breast tumors. In HER2-amplified (HER2+) laboratory models, inhibition of this pathway induces activation of upstream receptor tyrosine kinases such as HER3. In triple-negative breast cancer (TN), HER1 overexpression has been identified and models show sensitivity to combined HER1 and mTOR inhibition. We hypothesize that dual inhibition of the PI3K pathway, HER1/2, and induced HER3 may be highly effective in patients with HER2+ or TN breast cancer (BC). This phase I/II trial is designed to determine the tolerability and possible efficacy of the mTOR inhibitor temsirolimus (T) plus the HER1/2 inhibitor neratinib (N) in patients with trastuzumab-refractory, HER2+ or TN BC. We will also explore mutational activation of the PI3K pathway in trastuzumab-refractory tumors as it relates to response to the T-N combination.

Methods: The phase I dose-escalation study evaluated T (flat dose IV weekly) plus N (240 mg oral daily) in patients with metastatic HER2+ or TN BC. Cycle length was 4 weeks. Phase I end points included definition of maximum tolerated dose (MTD) and response rate (RR) per RECIST. The phase II study has a Simon two-stage design and evaluates the HER2+ and TN patients separately. Phase II endpoints include progression free survival and duration of response. Response was evaluated radiographically every 8 weeks, toxicity assessed every 2 weeks. All patients underwent biopsy of metastatic disease for biomarker assessment. Activating mutations in PIK3CA were assayed using the Sequenom MassARRAY system. Expression of PTEN was assessed by immunohistochemistry utilizing a published scoring system.

Results: The phase I study enrolled 8 HER2+ patients who received a median of 5 (1-13) cycles of therapy. All patients had received trastuzumab and a median of 5.5 (2-12) prior lines of therapy. Frequent treatment-related grade 2 events were: hyperglycemia (4/8), elevated CPK (3/8), diarrhea (2/8), and rash (2/8). Grade 3 diarrhea was the dose-limiting toxicity. Other grade 3 toxicity was hyperglycemia (1/8); hematologic toxicities were not observed. The MTD of temsirolimus was neratinib is 8 mg IV weekly. Six patients treated at MTD were evaluable for response; 4 patients had PR, 1 had SD for a RR of 67%. PI3K pathway activation, through PIK3CA mutation activation or PTEN loss, was identified in 4/6 tumors analyzed and did not preclude response to temsirolimus and neratinib. Updated results reflecting the phase I/II patients will be reported.

Conclusions: Temsirolimus plus neratinib is active in trastuzumab-refractory HER2+ patients. The phase II study is ongoing and additional efficacy and safety data in both HER2-amplified and triple-negative breast cancer patients will be presented.

PD10-01
Prevalence of Dysfunctional Fanconi Anemia (FA) DNA Repair Pathway in Breast Cancer.
Ramaswamy B, Srividya V, Mullins DA, Carothers S, Young G, Wenrui D, Zhao W, Lustberg M, Leon M, Welslowski R, Layman R, Mrozek E, Shapiro CL, Villalona-Calero M. The Ohio State University, Columbus, OH; The Ohio State University

Purpose: BRCA1/2 deficient breast tumors are highly sensitive to poly-ADP-ribose polymerase inhibitors (PARPi). The Fanconi Anemia (FA) associated gene products along with BRCA 1/2 function in a common pathway that regulates the cellular response to DNA damage, suggesting that tumors with dysfunction of any of the components of FA network would be susceptible to PARPi. Understanding the prevalence of such defects in breast tumors using reproducible methodology will help us target these tumors with novel agents and potentially improve outcomes. Hence we sought to assess the prevalence of FA pathway defect in breast tumors by the absence of nuclear FANCD2 (a pivotal protein in the FA/BRCA pathway which is monoubiquitylated in the nucleus in response to DNA damage) repair foci using a novel immunofluorescence method and correlate this with known molecular markers of breast cancer.

Methods: Using primary tumors obtained from the ongoing PARPi clinical trials (NCT01017640 and NCT01251874) and tumor bank, we evaluated 102 breast tumors for the somatic functionality of the FA pathway (FANCD2 foci formation) by the FA Triple Stain Immunofluorescence (FATSI) test performed in a CLIA-certified laboratory using paraffin embedded tissues. The tissue sections are incubated with a primary antibody cocktail of rabbit polyclonal FANCD2 antibody and a monoclonal anti-Ki67 mouse antibody, followed by co-incubation with a secondary antibody (FITC conjugated to anti-rabbit IgG and Alexafluor 594 donkey anti-mouse), mounted on glass slides in a DAPI containing embedding medium and evaluated by a fluorescence microscope. Absence of nuclear FANCD2 formation in 100 proliferating tumor cells was considered positive for FA defect. Hormone receptor (HR) and Her2 status was compared between the groups using Fisher’s exact test.

Results: A total of 102 primary breast tumors were analyzed for FANCD2 by FATSI test of which 62 were triple negative (TN), 37 were HR positive and 3 were Her2 positive. Of these, 29 tumors (28%) were positive for FA defect with no significant differences among the molecular subtypes (26% in TN vs 32% in HR + vs 33% in Her2+).

Conclusions: We report a novel methodology to efficiently screen archival FFPE tumors for somatic functional defect of FA DNA repair pathway and demonstrated a high prevalence (one-third) in breast tumors irrespective of molecular subtype. We are currently conducting clinical trials with PARPi including patients with tumors that test positive for FA defect to demonstrate if such tumors are sensitive to PARPi.

PD10-02
Sporadic Breast Cancers Show Defects in the BRCA1-BRCA2 Pathway of Homologous Recombination in All Biomarker-Defined Sub-Types of Breast Cancer.
Powell SN, Matter RW, Deliste R, Bindra R, King T, Giri D, Park J. Memorial Sloan-Kettering Cancer Center, New York, NY

Background: Mutation carriers of BRCA1 and BRCA2 are well known to develop early onset breast cancer, with loss of the second
allele occurring in the development of the tumor. However, by array comparative genomic hybridization (aCGH) studies, some sporadic breast cancers have a similar “genetic landscape” as BRCA-mutation carriers, showing large losses and gains across the genome. We have now identified that DNA repair defects involving the BRCA1-BRCA2 pathway can occur in the absence of mutations in either gene and in the absence of a deficiency in either protein.

Methods: Fresh human breast cancer samples were irradiated, ex-vivo, to look for the ability to assemble RAD51 protein macro-complexes or foci. Primary breast cancer specimens were obtained from consented patients with non-metastatic, invasive carcinomas following lumpectomy or mastectomy, without neoadjuvant cytotoxic or hormonal therapy. A single cell suspension was prepared from the tumor, with one half irradiated to 10Gy and the other half mock-treated. After 4h, cells were mounted, fixed on slides, and stained with anti-Rad51, anti-BRCA1, and anti-γH2AX antibodies. At least 200 nuclei were examined and scored using confocal microscopy. A failure to induce RAD51 nuclear foci by 2-fold after ionizing radiation was designated as defective in homologous recombination (HR).

Results: For the 71 patient samples analyzed, we have 14 triple-negative tumors, of which 6 are HR-defective (42.8%); for Her2-amplified tumors, we have 6/19 (31.6%) that are HR-defective and for ER+ tumors 6/38 (15.8%). The overall incidence of HR-defective tumors is 18/71 (25.3%), which is substantially higher than we would have expected.

Known mutation carriers were not included in the study, since these samples are BRCA-HR-defective in all cases we have tested. For the more recently acquired samples, we have undertaken additional tests to characterize the tumors: short-term growth assays in response to mitomycinC to validate that HR-defective tumors are indeed sensitive to cross-linking agents; and, a pilot analysis to study aCGH patterns in HR-defective tumors. The latter studies have compared 6 repair-deficient and 6 repair-proficient tumors using unsupervised cluster analysis of large block deletions or large block copy number increase, which clearly reveal that large block alterations are linked to repair-deficient tumors.

Conclusions: There is a significant incidence of BRCA-HR defective sporadic breast cancers, as determined by RAD51 function in response to ionizing radiation plus genetic landscape alterations using aCGH. The pool of breast cancers that are susceptible to repair targeting strategies is larger than expected and is not readily defined by conventional diagnostic biomarker classification. These findings may account for the failure of the recent phase III study of the addition of iniparib to carboplatin and gemcitabine in triple-negative cancer as only a minority of the tumors will be susceptible to this targeting strategy.

PD10-04
Exploration of the Relationship between Loss of PTEN and BRCA1 Expression in Triple Negative Breast Carcinoma.

Based on the mechanism of action of PARP inhibitors, BRCA1ess breast and ovarian cancers could be defined as the optimal group of tumours to target with such drugs. As the BRCA1ess phenotype is not fully defined at present, a surrogate phenotype of triple negative breast cancer (TNBC) has been proposed. Results of recent clinical trials involving PARP inhibitors in the context of TNBC do not demonstrate a significant improvement in overall survival or progression free survival, partly due to the inaccurate selection of certain tumours. Data from cell culture studies suggests that loss of PTEN expression could be a marker of PARP inhibitor sensitivity.

Materials and Methods
A retrospective study of 160 TNBC resected at Institut Bergonie between 1989 and 2010 was undertaken. Inclusion criteria were: ER & PR immunohistochemical (IHC) negativity (<10% tumour cells positive), non-amplification of HER2 (IHC score 0, 1, or 2 with negative FISH analysis) and an invasive ductal carcinoma resected before chemotherapy. For some familial cases, germline BRCA1 mutation screening had been performed in a diagnostic setting and was accompanied by genetic counselling. PTEN IHC, point mutation and gross rearrangement screening, along with BRCA1 expression and promotor methylation analysis (through real-time PCR and bisulphite treatment, respectively) and 53BP1 IHC were undertaken on this series of TNBC.

Results
Twenty percent of sporadic and familial TNBC demonstrated reduced BRCA1 expression with a greater than 7 fold reduction in expression. Almost half of tumours demonstrated a complete loss of PTEN expression as assessed by IHC, with a deleterious PTEN point mutation identified in 5% of cases. Although a slight correlation is observed between the complete loss of PTEN and a reduction in BRCA1 expression, a complete overlap of these two alterations was not observed; tumours with reduced BRCA1 expression do not always demonstrate complete negativity on PTEN IHC and certain tumours displaying complete negativity on PTEN IHC do not show a reduction in BRCA1 expression. Full immunohistochemical characterization of the tumour series (ER, PR, HER2, AR, CK5/6 & EGFR) together with the results of PTEN, BRCA1 and 53BP1 analyses will be presented.

Conclusion
These results suggest that at present, loss of PTEN expression is not a suitable surrogate marker for tumours with reduced BRCA1 expression. This should be borne in mind for ancillary studies of clinical trials involving PARP inhibitors in the treatment of breast tumours and further investigation is warranted.

Identification of Novel BRCA1 Transcriptional Targets That Promote the Survival of BRCA1-Mutated Estrogen Receptor-α Negative (ER-ve) Breast Tumours.

Lamers E, Haddock P, Cochrane DJ, Gorski JJ, Blayney J, McDyer FA, Mulligan JM, Mullan PB, Couch FJ, Kennedy RD, Harkin PD, Quinn JE. Queen’s University of Belfast, Belfast, Antrim, United Kingdom; Almac Ltd., Craigavon, United Kingdom; Mayo Clinic College of Medicine, Rochester, MN.

Background

The BRCA1 tumour suppressor gene is mutated in the germline of women who are predisposed to developing breast cancer. Gene expression profiling has identified at least five different breast cancer subtypes with BRCA1-mutated breast tumours clustering with triple negative breast cancers. The majority of BRCA1-mutated breast tumours are characterised as being negative for the estrogen receptor-α (ER-α), however, the underlying molecular biology of these tumours has not yet been fully determined. The aim of this study is to identify and characterise novel proliferation-associated BRCA1 target genes that are activated in BRCA1 mutated estrogen receptor negative (ER-ve) breast tumours.

Methods

Gene expression profiling and data analysis was performed on a cohort of 46 FFPE (Formalin Fixed Paraffin Embedded) derived BRCA1 mutated (ER-ve) breast tumours and matched sporadic controls using the Almac Diagnostics Breast DSA research tool. Profiling was also performed on a panel of 15 breast cancer cell lines. Bioinformatics analysis was performed using Oncomine, DAVID and Metacore. High throughput siRNA screening using HiPerFect were performed on the Qiagen Flexiplate siRNA. Validation of gene targets was performed by qRT-PCR and ChIP assay. Clonogenic assays were performed to independently validate the effect of selected target genes on cell survival.

Results

A list of differentially expressed transcripts was derived from the comparison of 23 (ER-ve) BRCA1 mutated breast tumours and 23 matched sporadic controls. A genome-wide ChIP-Chip promoter analysis was also performed in MCF7 breast cancer cells. By overlapping these two datasets, a list of tumour derived BRCA1 promoter bound target genes was identified. Functional analysis of this gene list has identified the main pathways and processes that are deregulated in BRCA1 mutated (ER-ve) breast cancer including: (1) immune response (2) induction of the epithelial to mesenchymal transition (EMT) (3) cell cycle regulation and (4) apoptosis and survival. Hierarchical clustering of these 46 breast tumours and 15 breast cancer cell lines was performed and the BRCA1 mutated (ER-ve) breast cancer cell lines (MDA436 and SUM149) were identified as those that best reflect the biology BRCA1 mutated (ER-ve) tumours. High throughput siRNA screening in these cell lines has identified a set of transcripts that when inhibited have a negative impact on cellular proliferation. Independent validation by qRT-PCR, ChIP assay, western blotting and clonogenic assays have confirmed HE4 (WFDC2) as a novel BRCA1 target gene that provides a growth advantage in BRCA1 mutated (ER-ve) breast cancer cells.

Conclusions

Gene expression profiling of an extensive cohort of BRCA1 mutated (ER-ve) breast tumours and matched sporadic controls has identified a profile of BRCA1 mutated (ER-ve) breast cancer. This list has been further refined to generate a list of BRCA1 promoter bound transcriptional target genes. High throughput siRNA screening has revealed a panel of genes that are implicated in the proliferation of BRCA1 mutated (ER-ve) breast cancer. HE4 has been identified as a novel BRCA1 transcriptional target gene that promotes the survival of BRCA1 mutated (ER-ve) breast tumours.

Loss of the Retinoblastoma Tumor Suppressor (RB) in Triple Negative Breast Cancer Is Associated with a Favorable Prognosis.

Witkiewicz AK, Kline J, Mitchell E, Ertel A, Knudsen ES, Thomas Jefferson University, Philadelphia, PA; Kimmel Cancer Center, Philadelphia, PA

Introduction

The retinoblastoma tumor suppressor gene (RB), initially identified in the pediatric tumor retinoblastoma, has been shown to be functionally inactivated in a variety of other tumor types. RB functions as a key regulator of cell cycle progression and modulates the response to a variety of physiological and clinically relevant stresses. In breast cancer, loss of RB has been shown to have prognostic significance and influence therapeutic response; however, a comprehensive analyses of RB in triple negative breast cancer (TNBC) has not been performed. Although TNBC represents only 15-20% of breast cancers it accounts for approximately half of breast cancer deaths. A subset of patients with TNBC will have a dramatic and durable response to standard chemotherapy. However, currently there are no markers that identify this patient subset. Since RB loss impinges on the response to chemotherapy, the goal of this study was to investigate the impact of RB-status on clinical management of TNBC.

Material and Methods

A cohort of 220 patients diagnosed and treated at Thomas Jefferson University Hospital was included in the study. RB-status was evaluated by immunohistochemistry (IHC) using 3 markers: p16ink4a (MTM Laboratories, Cat #: 9518,1:50 dilution ), Ki67 (AbCam, Cat #: ab16667, 1:600 dilution) and RB (Thermoscientific, Cat #: MS-107-B, 1:50 dilution) through automated image analysis (Aperio). Cases were considered negative for RB when no neoplastic cell nuclei demonstrated labeling in sections in which stromal cells and endothelial cells stained; Ki67 and p16ink4 were scored using established published criteria. Gene expression profiling was performed on 12 cases (6 RB positive and 6 RB negative by IHC) and RB pathway status in these samples was evaluated using an RB-loss signature developed by our group. Parallel analyses of TNBC expression data sets were also employed to define the relationship of the RB pathway with clinical outcome. Overall survival was analyzed using LogRank test and Cox proportional hazard model. Data were analyzed in SAS 9.1 (SAS Institute Inc., Cary, NC, USA).

Results

176 patients had samples that could be scored for RB, p16ink4 and Ki67 expression. 46% (71/176) showed RB loss. RB loss was associated with high p16ink4a expression and high Ki67 proliferation index in 93% (66/71) of samples and correlated with RB loss signature in all but one sample. RB loss and high p16ink4 expression was associated with a longer overall survival in this cohort (p=0.003). In contrast, patients with TNBC showing RB positivity and high p16ink4 had the worse survival (median survival 4 months, 10 year survival 23%). These findings were consistent with gene expression profiling data that indicate specific loss of RB function in TNBC is associated with improved response to chemotherapy and improved survival.

Conclusion

RB loss appears to be a predictor of a favorable clinical outcome in TNBC treated with conventional adjuvant chemotherapy.
PD10-07
microRNA Profiles of Breast Tumors Identifies the miR 17-92 Cluster as a Group of Potentially Essential Oncomirs in Triple-Negative Breast Cancer.
Son BH, Birkbak NJ, Tian R, Iglehart D, Wang ZC, Richardson AL. Dana-Farber Cancer Institute, Boston, MA; Asan Medical Center, Seoul, Korea; Technical University of Denmark, Lyngby, Denmark; Brigham and Women’s Hospital, Harvard Medical School, Boston, MA

Introduction: MicroRNAs (miRNAs) are a class of short non-coding RNAs of about 20-24 nucleotides that act post-transcriptionally to modulate gene expression by sequence-specific base-pairing with target miRNAs. While the function of human miRNA remains largely unknown, certain miRNAs have previously been implicated in cancer development and progression. In this study, we investigate the expression of 734 miRNAs across a cohort of 7 normal breast samples and 104 breast cancer tumors including 70 ER-/PR-/HER2-(triple negative, TN), 15 ER+/PR+, and 19 HER2+.

Methods: We used the novel Nanostring technology to quantify the expression of 734 miRNAs. Unsupervised hierarchical clustering was performed using miRNAs that were detected as expressed in at least one sample. A two-sided Wilcoxon rank sum test was used to identify miRNAs with a significantly differential expression between two sets of samples.

Results: In agreement with previously published results, we found that tumor samples clustered into the luminal and TN subtypes using unsupervised hierarchical clustering on the expressed miRNAs. Interestingly, microRNA expression was similar between HER2 amplified ER+ and HER2 amplified ER-, suggesting a common luminal origin. When we specifically compared luminal (ER+ or HER2+) to TNBC, we found that 50 miRNAs showed significant differential expression. In particular, the miR-17-92 cluster(1) was expressed at significantly higher levels in TN tumors. Within the luminal tumors the miR-17-92 cluster was strongly correlated with proliferation and grade; although miR17-92 was expressed at high level, there was no correlation with proliferation in the TN tumors. miR17-92, which inhibits translation of E2F1(1), is in a regulatory network with myc and E2F to control the balance between proliferation and apoptosis(2). The absence of correlation between miR17-92 and proliferation in the TN tumors suggests disruption of this regulatory network. Indeed, we found a positive correlation between expression of miR17-92 and p16 and inverse correlation with RB across the tumor set. The high p16/low RB expression in TN tumors is consistent with disruption of the RB pathway (3) and suggest these TN tumors may depend on miR17-92 to down-modulate expression of E2F1 which would otherwise induce apoptosis.

Conclusions: Our results show that miRNA expression in breast cancer tumors differs depending on subtype. We also find evidence to suggest subtype-specific miRNA regulation of proliferation and a particular dependency of TN tumors on the miR17-92 cluster for survival.

P1-01-01
A Rat Monoclonal Antibody Against Bone Sialoprotein II Is Active in Preventing and Treating Tumor Growth and Osteolytic Lesions in Nude Rats Induced by MDA-MB-231 Breast Cancer Cells. Berger MR, Zepp M, Armbruster FP. DKFZ, Heidelberg, Germany; Immunndiagnostik Comp., Bensheim, Germany

The SBLING protein bone sialoprotein II (BSPII) has been found implicated in lytic skeletal metastasis. Previous experiments had shown that targeting BSPII by a polyclonal IgY antibody or knock down of the gene’s transcript are instrumental in inhibiting experimental lytic skeletal metastasis. The aim of this study was to investigate the preventive and therapeutic effects of a new rat monoclonal anti BSPII antibody against tumor growth and osteolytic activity of MDA-MB-231 breast cancer cells growing in nude rats. In the preventive arm of this study, rats were pre-treated with the antibody (0 and 10 mg/kg) starting one week before tumor inoculation. In parallel, MDA-MB-231™ cells were incubated with the antibody for one week (0 and 0.5 mg/ml). Following inoculation of 1x10⁶ MDA-MB-231™ breast cancer cells into the femoral artery of 6 male nude rats, respectively, lesions were expected to develop only in the tibia, femur or fibula of the respective hind leg. Their appearance and development were monitored for six weeks by light emission, caused by luciferase mediated metabolism of luciferin. Photon emission was recorded at regular intervals by a Xenogen IVIS 100 imaging system. In the treatment arm of this study, the antibody administration (10 mg/kg/week) started when tumor bearing rats had shown stable tumor growth. Experimental groups of rats received the first treatment either at four (late onset; n = 8) or at two (early onset; n = 6) weeks after tumor cell implantation. Tumor bearing animals were (sham-) treated and followed for up to 8 weeks.

All 6 control rats of the preventive arm showed steady tumor growth. In variance, the rats receiving MDA-MB-231™ cells that had been pre-exposed to the antibody and those rats, which had been pre-treated with the antibody showed clearly reduced light emission as indicator of reduced tumor growth. At 6 weeks after tumor cell inoculation, only 1 of 6 rats was positive for light emission in the group receiving pre-exposed tumor cells (p<0.01), 3 of 6 rats were positive in the group receiving pre-treatment with the antibody (p<0.05), and 1 of 6 rats was positive in the group receiving both, pre-exposed tumor cells as well as pre-treatment with the antibody (p<0.01).

In the treatment arm, all but one untreated tumor bearing rats showed rapid tumor growth accompanied with lytic destruction of femur and tibia of the respective hind leg (18/19; tumor take rate 95%). In contrast, rats treated with the anti-BSP antibody did not show a significant increase in light emission nor a clinical deterioration. In fact, 6 of 8 rats receiving the late onset therapy didn’t show any light emission after 4 to 6 weeks (p = 0.01 versus control) as well as 4 of 6 rats receiving the early onset therapy with the antibody (p < 0.05). Radiological and histological examination confirmed that animals without light emission were free of tumor growth, corresponding to a complete remission.

In conclusion, the rat monoclonal antibody directed against BSP II is a powerful tool in treating experimental skeletal metastasis and warrants further development.

T Cell Is a Key Player in the Establishment of Cancer Associated Pre-Metastatic Bone Disease.
Bonomo A, Monteiro AC, Leal AC, Alves AP, Frusciante T, Braun S, Azevedo RB. Instituto Nacional de Cancer; Rio de Janeiro, Brazil; Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil; Universidade de Brasilia, Brasilia, Brazil

Syngeneic mouse models of malignant diseases have the important advantage of allowing studies to be carried out in immunocompetent animals. In this work, the 4T1(metastatic) and 67NR (non-metastatic) sibling cell lines of mammary mouse carcinomas, syngeneic to BALB/c mouse were used to study tumor specific immune response and its impact on bone disease. By day 11 after tumor injection, in the absence of metastasis, pro-osteoclastogenic cytokines IL17F, TNFα, IL-1β and RANKL were present in the BM of 4T1+ mice in contrast to the virtual absence of these in the BM of 67NR+ animals. More important, imaging studies (histomorphometry and microCT) showed that trabecular bone mass is close to maximum loss (around 50%) already by day 11, in the absence of metastasis. These results support the possibility of T cell involvement in pre-metastatic lesion. Indeed, in vitro, BM T cells from 4T1+ mice, but not from 67NR+, could induce OC differentiation in response to tumor antigens ascertained by TRAP enzymatic activity, morphology and osteolytic disk assay. In vivo transfer experiments showed that T cells from 4T1+ mice (Day 11), when transferred into nude mice produce 3 times more IL17F and 4 times more RANKL than donor 67NR+ T cells. Moreover, trabecular bone at day 14 after transfer of 4T1+ T cells was already 30% that of normal nude mice in contrast to 100% from 67NR+ T cells. Of note is the fact that these activities are achieved in the absence of the metastatic 4T1 tumor in the nude host, but challenged with either 67NR or protein antigen extract. To address the role of T cell derived IL17F and RANKL, T cells from 4T1 bearing mice (day 11) were silenced with shRNA specific for each of these cytokines and transferred into nude mice. Animals were challenged with soluble tumor antigen. Silencing IL17F had no effect over bone loss. However, RANKL silencing completely inhibited osteolytic lesions. Together, these results indicate that RANKL in T cells mediate the osteolytic lesions and that cancer induced bone disease can be metastasis independent. Since osteolytic lesions are believed to be important to feed the tumor with growth factors in a vicious cycle established in the metastatic niche, we asked if T cells could be preparing the pre-metastatic niche. When 4T1 cells are injected into athymic nude mice, bone metastasis is not observed up to day 24, while by day 20 it is already present in euthymic BALB/c animals, indicating that T cells are critical to prepare the seeding soil for tumor cells within the bone. We are currently investigating the role of T cells in the establishment of metastasis at later time points as well as in the primary tumor growth. Our results strongly suggest that tumor cells, according to its metastatic activity, can modulate T cell activity systemically. Moreover, and not less important, we show that cancer induced bone disease starts before metastatic colonization and is mediated by RANKL expressed in tumor specific T cells. We propose that this is the very first step on the establishment of the “vicious cycle” which will allow tumor growth. We believe this work can open new avenues on the prognostic evaluation and treatment of women with breast cancer.

The Cytoxicity of Select Neutrophils in Cancer Patients and the Role of Chemokines in Inducing Neutrophil Cytoxicity.
Comen E, Granot Z, Norton L, Benaza R. Memorial Sloan-Kettering Cancer Center, New York, NY; Memorial Sloan-Kettering Institute, New York, NY

Background: Using murine mammary tumor models, recent research conducted by our laboratory at the Sloan-Kettering Institute indicates that select neutrophils are mobilized by a primary breast tumor and uniquely have the capacity to inhibit metastatic seeding in the lung (Granot Z et al. unpublished). We sought to evaluate the cytotoxic role of select neutrophils in the peripheral blood of breast cancer patients as contrasted with those from women without breast cancer and women with DCIS. In addition, we sought to determine whether the addition of select chemokines to neutrophils from a DCIS patient could induce cytotoxicity.

Methods: Neutrophils were purified from the blood of 21 newly diagnosed pre-operative breast cancer patients without evidence of metastatic disease, 9 healthy female volunteers with no history of any cancer, and 3 patients with newly diagnosed DCIS. Cytotoxicity was evaluated by incubating isolated neutrophils with luciferase labeled MDA-MB-231 cells. Luciferase activity, as a reflection of % cell kill, was measured using a Bio-Tek microplate luminescence reader. Neutrophils from a DCIS patient with low cytotoxicity were then co-cultured with various CC chemokines (CCL2, CCL3 and CCL5) or CXCL chemokines (CXCL1, CXCL12, and CXCL16) at 100ng/ml.

Results: Significant cytotoxicity was notably observed when MDA-MB-231 cells were co-cultured with neutrophils purified from patients with invasive tumors. Pre-operative breast cancer patients (n=21) had a cell kill range of 0-30% (mean = 12.1%), whereas healthy subjects (n=9) had a cell kill range of 0.2-8% (mean = 2.6%), p<0.004. DCIS patients (N=3) had a cell kill range of 3-4% (mean = 2.7%). The addition of select chemokines to neutrophils from a DCIS patient with low cytotoxicity (3.2%) resulted in significant increases in cytotoxicity. Table 1 indicates the relative cytotoxicity percentages from the addition of each chemokine.

Conclusions: To date, this preliminary work is the first to demonstrate the cytotoxic role of select neutrophils in the peripheral blood of breast cancer patients as contrasted with those from women without breast cancer. We further demonstrate the novel induction of neutrophil cytotoxicity by select chemokines. Further studies are needed to evaluate the prognostic and therapeutic role of cytotoxic neutrophils as well as the role of chemokines in neutrophil cytotoxicity.

PI-01-04
Immunological Effects of Bisphosphonates on γδT Cells in Breast Cancer.
Sugie T, Tanaka Y, Toi M, Minato N. Graduate School of Medicine, Kyoto University, Kyoto, Japan

Background: Human γδT cells play an important role in the first-line of defence. Accumulating data demonstrate that γδ T cells recognize nonpeptide antigens such as IPP and HMBPP and activated γδT cells have potent cytotoxic activity against tumor cells. Nitrogen-containing bisphosphonates like zoledronic acid inhibit farnesyl diphosphate synthetase, resulting in the accumulation of upstream metabolites such as IPP. Previous studies on the adoptive transfer of ex-vivo amplified γδ T cells demonstrated the safety and feasibility of γδT cell-based immunotherapy for metastatic cancer. According
to ABCSG-12 clinical trial, zolenderacic acid improved DFS of patients with early-stage breast cancer under adjuvant endocrine therapy. Whereas a precise mechanism remained unclear, it is likely that γδT cells are involved in this anti-tumor effect in breast cancer.

**Materials and Methods:** Peripheral blood mononuclear cells derived from 63 (54 untreated non-metastatic and 9 metastatic) patients with breast cancer were examined for the baseline population of γδT cells and their proliferative responses to zolenderacic acid in vitro. Tumor-infiltrating lymphocytes were isolated from 20 tumor biopsies and 2 pleural effusions. Peripheral blood γδT cells were stimulated with 5 μM zolenderacic acid and cultured in the presence of 100 IU/ml IL-2 for 10 days. Amplified γδ T cells were analyzed for cytokine production and cytotoxic activity.

**Results:** The proportion of γδ (TCRVδ2-bearing) T cells among peripheral blood CD3+ cells was 4.2 ± 5.0%. Although it was equivalent to the previously reported value of 4.3 ± 2.2% in healthy volunteers, 14% (9/63) of patients exhibited an increase in the number of peripheral blood γδT cells at baseline. The level of TCRVδ2 T cells with potent anti-tumor activity was significantly higher than that of TCRVδ1 T cells (4.2± 5.0% vs. 1.5 ± 1.8%, p<0.001), whereas they were present in tumor-infiltrating cells at essentially the same levels (4.4± 9.6% vs. 3.7 ± 9.7%, p=0.434). Percentage of TCRV δ2+ CD3+ cells among amplified γδ T cells in vitro and cytokine (IFN-γ and TNF-α) production by them were significantly proportional to the initial level of TCRVδ2/CD3+ ratio in peripheral blood. Upon treatment with zolenderacic acid, breast cancer cell lines became susceptible to γδ T cells.

**Conclusions:** γδ (TCR Vδ2-bearing) T cells increased in some patients with breast cancer and the TCRVδ2/CD3+ ratio at baseline was correlated with the efficiency of proliferation and cytotoxic activity when treated with zolenderacic acid. Zolenderacic acid efficiently sensitized breast tumor cells to be lyzed by γδ T cells. The present results suggest that γδ T cells stimulated with zolenderacic acid can be utilized for immunotherapy against breast cancer.

**P1-01-05**

**Conditioning by the Tumor Environment Turns Invariant Natural Killer T Cells into Negative Regulators of Anti-Tumor Immunity Elicited by Treatment.**

Pilones KA, Demaria S. NYU School of Medicine, New York, NY

Background: Local suppression in the tumor microenvironment remains an important obstacle to success of immune-based therapy. We have previously shown in the 4T1 model of metastatic breast cancer that combination radiotherapy (RT) to the primary tumor and CTLA-4 blockade can elicit a robust anti-tumor effector response that can inhibit metastases and prolong survival. However, complete cure and long-term survival may only be seen in a small fraction of mice, prompting us to investigate new ways to improve the response elicited by treatment. InNKT cells are known to be powerful regulators of tumor immunity as a result of their ability to rapidly secrete a broad range of cytokines, but the mechanisms regulating their switch from a stimulatory to a regulatory role remain poorly defined. We have previously shown that InNKT cells negatively regulate the response to treatment with RT and CTLA-4 blockade in 4T1 tumor-bearing mice (Clin Cancer Res 15:597, 2009). Here, we test the novel hypothesis that conditioning of InNKT cells to perform this regulatory role occurs within the tumor microenvironment. Specifically, we address whether 4T1 tumor cells, directly or indirectly, promote inNKT cell regulatory phenotype. Methods: For in vitro experiments, 4T1 tumor or LPS-matured bone marrow-derived dendritic cells (BMDC) were loaded with α-galactosylceramide and used to stimulate the NKT DN32.D3 hybridoma cells. In some wells, BMDCs were supplemented with 4T1 conditioned media or loaded with tumor lysates from 4T1 cells. For in vivo experiments, wild-type and InNKT-deficient mice were inoculated s.c with 4T1 cells for enumeration of DCs on immunostained sections.

**Phenotypic profile of DCs within tumor and draining lymph nodes were assessed by flow cytometry. Results: 4T1 cells are positive for CD1d by real-time RT-PCR; surface CD1d were barely detectable by flow cytometry but sufficient to induce activation of DN32.D3 cells when irradiated 4T1 cells were loaded with α-GalCer. BMDC supplemented with conditioned media from untreated or irradiated 4T1 cells, or loaded with tumor lysates from irradiated 4T1 cells were also able to activate DN32.D3 cells, and this effect was partially inhibited by blocking CD1d mAb (1B1) in a dose-dependent manner. In vivo, we found that inNKT-deficient mice showed significantly (p<0.04) higher densities of tumor infiltrating DCs than wild type mice. Moreover, DC in tumor and tumor-draining lymph nodes expressed markers of maturation in the absence but not presence of InNKT cells. Conclusion: Results indicate that a 4T1 derived factor, possibly a lipid antigen that can be presented directly by tumor cells themselves or indirectly by BMDCs, induces activation of InNKT cells in vitro. In vivo, data suggests that inNKT cells downregulate the response to treatment by controlling the population of DC present in the tumor and draining lymph nodes. Since DC are essential for cross-presentation of the tumor antigens released by RT-induced cell death, reduced DC number may impair the activation of anti-tumor T cells. Supported by DOD Postdoctoral Award W81XWH-10-1-1205.

**Mechanisms of Tumor Immune Escape in Triplenegative Breast Cancers (TNBC) with and without Mutated BRCA 1.**

Segerer SE, Kapp M, Hahne JC, Dietl J, Engel J. Medical University of Würzburg, Würzburg, Germany

**Background**

Triplenegative breast cancer (TNBC) is associated with a dismal prognosis, although these tumors are chemo-sensitive. This phenomenon could be at least in part due to tumor immune escape. The current study investigates the host’s immune response to TNBC cells and explores the presence of immunosuppressive factors, such as pAKT expression and infiltration with FoxP3 positive regulatory T-cells (Tregs), in human TNBC samples.

**Material and Methods**

NK-cell induced lysis of tumor cells was evaluated in human breast cancer cell lines MCF-7 (ER/PR pos.), HCC 1937 (triplenegative, BRCA 1 mutated) and HCC 1806 (triplenegative). Expression of pAKT and infiltration with Tregs was determined by immunohistochemistry and evaluated semiquantitatively (0 no expression - 3 strong expression). Control groups consisted of: Fibroadenoma (N=6), prophyliactic mastectomy (BRCA 1 mutated, N=3), ER/PR + breast cancer (N=13). They were compared with triplenegative breast cancers: N=9 BRCA wildtype and N=6 BRCA 1 mutated.

**Results**

At an effector target/target-ratio of 10:1 NK-cell induced lysis in HCC 1937 and HCC 1806 was 2.27 and 4.45 increased, respectively, as compared to MCF 7 cells. No infiltration with Tregs was detected in fibroadenoma and prophyliactic mastectomy samples. Infiltration with FoxP3-positive Tregs was 0.92 +/-0.75 in ER/PR + breast cancers and 2.66 +/-0.5 (p=0.05) in TNBC and 2.16 +/-0.98 (p=0.05) in TNBC with BRCA mutation, respectively. Expression of pAKT was 1.45 +/-1.29 in ER/PR + breast cancers and 1.77 +/-1.20 in TNBC and 2.66 +/-0.51 (p<0.05) TNBC/ with BRCA mutation.
Discussion
TNBC cells stimulated the NK-cell response to a stronger extent than did ER-positive MCF 7 cells mirrored by a more pronounced NK-cell-induced lysis. Thus, the observed stronger infiltration with FoxP3-positive Tregs in TNBC tumor samples could reflect a compensatory mechanism to suppress the host’s immune response. In other tumor entities, such as ovarian cancer infiltration with Tregs is associated with a worse overall survival (1). Thus, the significantly increased infiltration with Tregs, could suggest that the worse prognosis of TNBC is due to tumor immune escape and further investigation of immunomodulatory therapeutic strategies in TNBC could prove fruitful.

(1) Specific recruitment of regulatory T cells in ovarian carcinoma fosters immune privilege and predicts reduced survival.

P1-01-07
ErbB-2 Peptide Vaccination Suppresses Spontaneous Tumorigenesis and Tumor Stem Cell Expansion in MMTV-PyVT Transgenic Mouse.

Park KH, Gil EY, Choi YJ, Kim ST, Cho KR, Seo JH, Lee ES, Kim JS, Disis ML. Korea University College of Medicine, Seoul, Korea; Korea University College of Medicine; University of Washington, Seattle, WA

Immunization targeting ErbB-2 could have considerable therapeutic potential by controlling growth and metastasis of highly aggressive tumor cells in the earlier preclinical and clinical studies. Just a few studies have examined preventive potential of ErbB-2 vaccines in preclinical studies. However, animal model systems used in the previous studies were tumor transplantation or neu-transgenic mouse, which were not relevant to human HER-2 positive breast tumorigenesis. In this study, active immunotherapy against tumor antigen ErbB-2/neu for primary prevention of breast cancer was tested using FVB/N-Tg (MMTV-PyVT) transgenic mice model. Mice were grouped to receive either ErbB-2 peptide vaccine, immune adjuvant only, tetanus toxoid, or PBS every 2 weeks for 3 months and monthly thereafter. The MMTV-PyVT transgenic mice in control groups (PBS, immune adjuvant only, or tetanus toxoid peptide) developed spontaneous mammary adenocarcinomas in 12 to 15 weeks, but vaccination against ErbB-2 strongly suppressed tumor formation by 30 weeks of observation. Further pathologic examination showed complete prevention of tumorigenesis was observed in ErbB-2 vaccinated mice, whereas the mice in control groups developed highly aggressive ErbB-2 overexpressing tumors similar to human breast cancer. The tumor protective effect of peptide vaccination was associated with induction of ErbB-2-specific humoral immune responses as well as T cell responses. Additionally, role of signal through ErbB-2 pathway and the relationship with stemness of cancer cells were determined by Aldefluor assay, mammosphere formation assay using Mouse mammary carcinoma (MMC) cells in vitro, and level of nestin expression determined by Western blot analysis. Further analysis of mammosphere formation capacity of MMC cells using immune sera showed that sera from ErbB2 vaccinated mice had a significant inhibitory effect on mammosphere formation in ErbB2 overexpressing MMC cells. These results suggest that ErbB-2 targeting by cancer vaccination might be useful adjuvant to standard therapy, helping to prevent relapse in patients with ErbB2-overexpressing tumors by suppressing stem/progenitor cell population.

P1-01-08
Expression of Interleukin-15 (IL-15) and the IL-15 Receptor in Human Breast Cancer.

Sanders AJ, Ye L, Wei XQ, Mansel RE, Jiang WG. Cardiff University School of Medicine, Cardiff, Wales, United Kingdom; Cardiff University, Cardiff, Wales, United Kingdom

Introduction: Interleukin-15 (IL-15) is a cytokine that influences activation and proliferation of T-lymphocytes. IL-15 is produced in the body leukocytes such as phagocytes and in many ways has similar immunoregulatory functions to IL-2 including stimulation of NK cells and CD8(+) T cells. It has been suggested that IL-15 may increase the immunity to cancer cells and cancer cell’s response to therapeutic agents. IL-15 has also been shown to be able to inhibit tumour growth in vivo. However, the expression profile of IL-15 and IL-15 receptor (IL-15) in solid tumours including human breast cancer is not clear. The present study investigated the expression profile of both IL-15 and IL-15R in human breast cancer and deduced a clinical and pathological relevance with breast cancer.

Methods: Immunohistochemical methods were used to detect IL-15 and IL-15RA in mammary tissues. IL-15 and IL-15RA transcripts were analysed using real-time quantitative PCR method. Levels of IL-15 and IL-15RA were compared in normal and tumour tissues as well as against tumour staging, nodal status, disease progression and clinical outcome after a 10-year followup.

Results: Both IL-15 and IL-15RA were detectable in mammary tissues and were seen in both epithelial cells and infiltrating cells. Node positive tumours had low levels of IL-15 compared with node negative tumours (21.7±10 vs 103±46, respectively). Late stage tumour also had lower levels of IL-15 (95±43, 31±15, 3.7±2 and 1.3±1.5 for stage I, II, III and IV tumours respectively, p=0.036 and p=0.032, stage-II and Stage-III vs stage-I). Patients with metastatic disease (10.3±3) and patients died of breast cancer related conditions (54.7±25). The disease free survival time for patients with low levels IL-15 was 126 (114-138, 95%CI) months, compared with 139 (131-148) months for those with high levels of IL-15. Despite the reduced expression of IL-15 in aggressive tumours, expression of IL-15 receptor, IL-15RA, did not display a significant change and failed to showed a link with nodal status, tumour staging and clinical outcome.

Conclusions: Interleukin-15, an immunoregulatory cytokine, has an aberrant expression in human breast cancer. Low levels of IL-15, but not IL-15 receptor, is associated with the aggressiveness and disease progression of breast cancer. Together with reported effect of IL-15 on NK cells and other anti-tumour lymphocytes, IL-15 appears to be a useful therapeutic option.

P1-01-09
A Focused Immune Response Targeting the Homotypic Binding Domain of the Carcinoembryonic Antigen Blocks the Establishment of Tumor Foci In Vivo.

Gariepy J, Abdul-Wahid A. University of Toronto, Toronto, ON, Canada; Sunnybrook Research Institute, Toronto, ON, Canada

Background: The carcinoembryonic antigen (CEA) is over-expressed in ~56% of breast cancer biopsies but is absent on normal breast tissues. Clinically, high preoperative serum concentrations of CEA in breast cancer patients correlate with metastasis, treatment failure and poor overall prognosis. More importantly, the homotypic cell adhesion functions of CEA have been associated with cancer progression and tumor metastasis. One approach to prevent the establishment of CEA-dependent metastatic foci in breast cancer patients would thus be to
interfere with the cell adhesion functions of this cell surface antigen. We hypothesize that vaccinating CEA-expressing transgenic (CEA-Tg) mice with a recombinant, altered-self form of the Ig V-like N domain of CEA, involved in homotypic interactions, should result in a focused immune response able to block the CEA-mediated adhesion of murine carcinoma cells expressing CEA (MC38.CEA) and the establishment of metastatic foci in this transgenic mouse model.

Material and Methods: A recombinant form of the CEA N domain was expressed in E. coli, purified and shown in cell-based assays to bind to the Aβ domain of human CEA and to block cell adhesion in CEA-expressing tumor cell lines. CEA-expressing transgenic mice were vaccinated i.p. with the recombinant CEA N domain protein and poly I:C. Resulting serum Ig [IgG1 and IgG2a] as well as cytokine expression levels [IFN-γ, IL-4 and IL10 responses] were measured by ELISA and ELISpot assays. The CEA-expressing MC38 murine tumor cells were implanted s.c. into CEA-Tg mice [hind leg; primary site model; tumor growth within 7 days] or administrated i.v. to generate lung tumor metastases within 60 days or injected i.p. to generate peritoneal tumor nodules within 35 days in unvaccinated animals.

Results: The recombinant folded, deglycosylated N domain of human CEA is perceived as an altered self-antigen by CEA-Tg mice when administered i.p. with poly I:C acting as an adjuvant. The vaccinated mice develop strong IgG1 and IgG2a responses able to kill CEA-expressing human breast cancer cell lines [MCF-7 and MDA-MB231] in vitro by both Antibody-Dependent Cellular Cytotoxicity (ADCC) and Complement-Dependent Cytotoxicity (CDC) mechanisms. The sera of such animals also inhibited cell-cell aggregation mediated by CEA expression. Vaccination of CEA-Tg mice following the establishment of CEA-expressing MC38 murine hind leg tumor mass resulted in a significant delay in tumor growth. More importantly, animals pre-vaccinated with the recombinant CEA N domain did not display lung or peritoneal tumor foci following the i.v. or i.p. injection of CEA-expressing murine tumor cells.

Discussion: A simple vaccination protocol using a recombinant form of the N domain of CEA as an immunogen is sufficient to engender an immune response that can block the development of CEA-expressing tumor foci in the lungs and peritoneal cavity of CEA-Tg mice and destroys human breast cancer cells expressing CEA. These results suggest that mounting a focused antibody response to the N domain of CEA may represent a simple therapeutic strategy to control the establishment of metastatic foci in breast cancer patients expression high levels of the antigen CEA.

Immune Suppression of Regulatory T Cells and M2 Macrophage in Breast Cancer Patients.
Imoto S, Sakemura N, Kamma H, Nakatsuka T. School of Medicine, Kyorin University, Mitaka, Japan; Research Center Organization, National Cancer Center Hospital East, Kashiwa, Japan

Background: Recent multi-disciplinary treatments of breast cancer (BC) could decrease the mortality rate, but successful immune therapy remains uncertain. To explore new strategy of immune therapy of BC, we are investigating about host-tumor immune response in BC patients. Materials and methods: Tumor tissue specimens and peripheral blood mononuclear cells (PBMC) were obtained from early and advanced BC patients. PBMC were also collected from healthy volunteers. Regulatory T (Treg) cells were examined by counting CD4+CD25highCD127low/-cells in PBMC with flow cytometry analysis. Immunohistochemical evaluation of tumor specimens was performed with monoclonal antibodies of HLA-ABC and DR, CD56, CD68, CD83, and CD163. The number of stained cells was analyzed using a semiquantitative ordinal scale ranging from 0 to 3 (0, +, ++, +++). Results: HLA-ABC and DR were stained negative in 44% and 82% of 50 BC cases. When host-tumor immune response were compared between 38 early BC cases and 12 advanced BC cases, numbers of CD68-positive cells significantly increased in peripheral tumor tissues of advanced BC cases than in those of early BC cases (92% versus 53%). CD163-positive tumor cells were also detected more frequently in advanced BC cases than in early BC cases (75% versus 16%). There were no significant differences of distribution of CD4, CD8, CD56, and CD83-positive cells in early and advanced BC cases. Treg cells in PBMC significantly increased in percentage of the population in 37 BC patients than in 21 healthy volunteers (4.2% versus 2.5% of CD4-positive cells at mean value). Interestingly, Treg cells decreased in percentage of the population in 36 postoperative BC patients. Conclusions: Our results suggest that Treg cells render BC patients under immune suppression and M2 macrophage plays an important role of tumor progression. Targeted therapy against M2 macrophage may be a promising strategy of breast cancer.

CD4+CD25highCD127low/- Regulatory T Cells Have Immunosuppressive Function in Patients with Breast Cancer.
Sakemura N, Nakatsugawa M, Ito H, Isaka H, Imi K, Tazaki E, Miyamoto K, Wada N, Imoto S, Nakatsuka T. Graduate School of Medicine, Kyorin University, Mitaka Tokyo, Japan; National Cancer Research Center Hospital East, Kashiwa Chiba, Japan

CD4+CD25highFoxp3+ regulatory T cells play a central role in self-tolerance and suppress antitumor immune response. Recent studies have shown that low levels of the IL-7 receptor (CD127) are expressed on CD4+CD25highFoxp3+ regulatory T cells surfaces and the expression of CD127 is inversely correlated with the suppressive function of CD4+CD25high regulatory T cells. We evaluated the frequency of CD4+CD25highCD127low- T cells in peripheral blood lymphocytes of 72 breast cancer patients and 21 healthy volunteers. The expression of Foxp3 mRNA was inversely correlated with the CD127 expression and correlated with CD25 expression. The frequency of CD4+CD25highCD127low- T cells in breast cancer patents was significantly higher than that of healthy volunteers (p=0.0045). CD4+CD25highCD127low- T cells were increased in hormone receptor negative patients and HER2 positive patients, but no statistical significant was observed in stage progression. In addition, the frequency of CD4+CD25highCD127low- T cells decreased after curative resection in breast cancer patients (p=0.005). CD4+CD25highCD127low- T cells also suppress proliferation of autologous CD4+CD25+ helper T cells and CD8+ cytotoxic T cells in CFSE-based cell proliferation assay. These findings suggest that CD4+CD25highCD127low- T cells a useful marker for regulatory T cells in breast cancer. Circutious peripheral regulatory T cells may participate in immune tolerance to breast carcinoma.

Mesoporous Silicon Particles for the Presentation of Tumor Antigens and Adjuvant for Anti-Cancer Immunity.
Mercez IM, Melendez B, Gu J, Serda RE. Methodist Hospital Research Institute, Houston, TX

Custom-made vaccines based on personalized tumor antigens are realistic options for secondary therapy, with the patient’s excised tumor providing antigens. Overlay in the personalized repertoire of tumor antigens among patients also provides insight into targets for preventative cancer vaccines. Nanotechnology provides carriers for
shielded delivery of antigens and presentation of immunostimulatory molecules. Rapid uptake of particles by phagocytic immune cells and migration to lymphatic tissue for antigen presentation provides opportunities to elicit tumor specific immune responses. Dendritic cells (DC) are the master antigen presenting cells (APC) for efficient processing and presentation of antigens. We have tested the ability of mesoporous silicon particles (pSi) to function as substrates for DC and to activate cells via engagement of surface toll-like receptors (TLR). pSi particles, surface labeled with lipopolysaccharide (LPS) or monophosphoryl lipid (MPL), were presented to bone marrow-derived DC. This resulted in rapid uptake of particles, with an enormous capacity for number of particles internalized per cell. Confocal microscopy studies supported higher uptake of LPS and MPL conjugated as compared to unlabeled pSi. pSi particle uptake into DC was also supported by electron microscopy imaging. TLR ligands induced morphological changes in GM-CSF stimulated cells consistent with maturation towards a DC phenotype. As expected, LPS conjugation to particles resulted in significant toxicity. MPL conjugated pSi showed little or no toxicity to DC and showed improved particle uptake into DC with morphological changes consistent with maturation towards a mature DC phenotype. The impact of cytokine cocktail on DC maturation and its impact on particle uptake were also examined. Flow cytometry analysis supported greater uptake of pSi by DC stimulated with GM-CSF and IL-4 compared to GM-CSF alone, with reduced uptake in the presence of TNF-alpha. Consistent with findings reported by others, addition of TNF-alpha to the cell media also resulted in higher levels of expression of costimulatory molecules by DC, compared to cells stimulated with GM-CSF alone. Thus immature DC are better able to internalize particle-based vaccines, with cytokine or TLR-driven maturation enhancing expression of costimulatory molecules for more effective antigen presentation.

Prognostic Impact of CD8 in Node-Negative Breast Cancer.
Schmidt M, Chen Z, Hellwig B, Böh m D, Lebrecht A, Gebhard S, Gehrmann M, Koelbl H, Hengstler JG. University Hospital, Mainz, Germany; Technical University, Dortmund, Germany; Bayer GmBH, Leverkusen, Germany.

Background: Infiltration of cytotoxic T lymphocytes (CTL) is a common feature in breast cancer. We examined the prognostic impact of CD8 positive CTL in formalin-fixed-paraffin-embedded (FFPE) tissue using immunohistochemistry (IHC) in node-negative breast cancer and validated our findings in previously published cohorts using RNA expression.

Methods: CD8 was evaluated in FFPE tissue of 339 medically untreated node-negative breast cancer patients utilizing IHC. Results were validated utilizing microarray based gene-expression data of four cohorts of medically untreated node-negative breast cancer patients (n=824). Impact of CD8 on metastasis-free survival (MFS) was analyzed with univariate and multivariate Cox regression. Meta-analysis of previously published cohorts was performed using a random effects model. Prognostic significance was examined in the whole cohort and in different molecular subtypes (ER+/HER2-, ER-/HER2-, HER2). Correlation between RNA expression and IHC was analyzed according to Spearman.

Results: Immunohistochemical detection of CD8+ CTL was associated with MFS in univariate (hazard ratio [HR] 0.71, 95% CI 0.51-0.99, P=0.0201) and HER2+ (HR 0.60, 95% CI 0.38-0.97, P=0.037) as well as in multivariate analysis (HR 0.77, 95% CI 0.52-1.14, P=0.1965). Conclusion: CD8 positive CTL have independent prognostic significance in node-negative breast cancer.

P1-01-14
Gene Expression of Immune Mediators within Nipple Aspirate Fluid and Ductal Lavage from Normal and Cancerous Breasts.
Love SM, Ruffell B, Nguyen T, Mills D, Coisson LM. Dr. Susan Love Research Foundation, Santa Monica, CA; University of California-San Francisco, San Francisco, CA.

The majority of breast cancers are thought to initiate in the lining of the 6 to 8 ducts that exit the nipple. Evidence suggests that the presence of nipple aspirate fluid (NAF), and in particular NAF containing atypical epithelial cells, in the ducts is predictive of future breast cancer risk. Although NAF fluid and cells may be representative of a preneoplastic state, use of NAF has not proven to represent a robust indicator for future malignancy. Chronic infiltration of tissues by immune cells predisposes them to future malignancy. Since macrophages can represent up to half of the total cells recovered from NAF, and their presence within malignant breast tumors has predictive value in terms of survival, we hypothesized that changes in the inflammatory microenvironment of breast ducts may foster future malignancy and/or provide an early indicator of future neoplasia. To test this hypothesis, we conducted an exploratory study to investigate gene expression in NAF and ductal lavage fluid. We first used real-time PCR to quantitatively measure mRNA expression of select genes within the cellular milieu of NAF to determine if that microenvironment correlated with a tumor-promoting state. Expression of multiple genes was observed in 15 samples collected from healthy volunteers, with robust expression of myeloid-associated genes including CD14, CD68, CCL3, CSF1 and IL1B observed in the majority of samples. To determine whether similar inflammatory microenvironments were found within each duct, and whether they were comparable to those in NAF-containing ducts, ductal lavage (DL) samples were obtained from 4 different ducts at the same time as NAF collection. Out of 7 volunteers, 4 provided samples allowing comparison between NAF and DL, and between multiple ducts. Analysis of gene expression from these healthy volunteers indicated that gene expression differed between NAF samples and each DL sample. More importantly, unique gene expression was found for each duct sampled, indicating that the immune microenvironment within each duct is distinct from other ducts within the same breast. In order to identify a potential inflammatory gene signature, we then obtained NAF samples from patients with breast cancer that had not received neoadjuvant chemotherapy prior to surgery, from both the cancerous and contralateral breasts. With 4 patients analyzed, no consistent expression difference has thus far been observed, indicating either that the relevant genes have not been identified, or that analysis of inflammatory genes within NAF may not be a predictive method with which to evaluate risk of future malignancy in women that produce NAF. A larger study is warranted to further investigate the significance of inflammatory gene expression in breast ductal fluid.

Do Serum Cytokines Predict Breast Cancer Behavior?
Lush E, Dedert E, Daup M, Dhabhar F, Spiegel D, Tillich J, McMasters K, Sephton SE, Chagpar A. University of Louisville; Duke University Medical Center; Veterans Affairs Medical Center; Stanford University School of Medicine; James Graham Brown Cancer Center; University of Louisville School of Medicine; Yale School of Medicine

Introduction: The role of inflammation in breast cancer development and progression is poorly understood. The potential for serum cytokines to predict breast cancer behavior is an intriguing hypothesis, and data to date, has been conflicting. We sought to determine if serum inflammatory cytokines could predict clinicopathologic factors in breast cancer patients.

Methods: Fifty-seven women with newly diagnosed breast cancer (stage 0-4) were accrued to this IRB-approved study. Serum cytokine levels were obtained in 50 of these women; this was the cohort of interest. All patients underwent surgical therapy, and log serum cytokine levels were correlated to final pathologic results.

Results: The median patient age was 51 (range: 21-79) with a median tumor size was 19.5 mm (range: 2.3-95.0 mm). A variety of cytokines were evaluated. None were found to correlate with tumor size, lymph node status, presence of metastases, tumor grade, or lymphovascular invasion (all p's > .05). While most of the cytokines evaluated did not correlate with hormone receptor status, a significant correlation was seen between serum IFN-gamma and estrogen receptor (p = .011) and progesterone receptor (p = .013) status. No correlation was seen with her-2-neu status (p > .05).

Conclusions: Serum cytokine levels do not seem to correlate with tumor size, lymph node status or grade. However, the strong correlation between IFN-gamma serum levels and hormone receptor status is hypothesis-generating and requires further study.

P1-01-16
Keller K, Boehm DU, Grus FH, Koelbl H. University Medical Center Mainz, Germany

Background:
Noninvasive biomarkers for the early detection of breast cancer are crucial due to the fact that the relapse risk of breast cancer is rising with the time point of its detection. Currently, none of the reported molecular biomarkers is established for the clinical use as a diagnostic tool. Previous proteomics-based studies showed the immunogenicity of breast carcinoma and the following B-cell mediated immune response. As a result, several autoantibodies against tumor proteins were detected in the sera of breast cancer patients. However, these putative biomarkers are still lacking of clinically reliable specificity and sensitivity, even of better discrimination of cancer patients when combining different biomarkers. The search for a new antibody biomarker signature remains very important as a potential cancer detection tool. For further investigations we analyzed the antibody pattern in serum samples of diseased patients and healthy controls after incubation with whole protein extract from a native carcinoma and identified the putative tumor-specific immunoreactive antigens.

Materials and methods:
For our de novo profiling of tumor antigens we used a protein extract from a primary invasive ductal carcinoma. Sera from 20 women, of which 19 were diagnosed with breast carcinoma and one with DCIS (CA), and 20 sera from age-matched healthy donors (CTRL) were obtained and pooled separately. For optimal separation of tumor antigens a two-dimensional sodium dodecylsulfate gel electrophoresis (2D SDS-PAGE) was applied. Following immunoblots with each serum pool were performed and the immunospecific reactions visualized with a horseradish peroxidase-conjugated anti-IgG antibody. The relevant tumor antigens were identified via Matrix-Assisted Laser Desorption Ionization Time of Flight Mass Spectrometry (MALDI TOF-TOF MS).

Discussion:
We identified over 10 tumor antigens which reacted with the corresponding autoantibodies in CA or CTRL approach, showing again the complexity of immune response. Besides of already described breast carcinoma related antigens like alpha enolase, which showed immune reaction also with the healthy serum pool, we identified several potential antigens of interest like peroxiredoxin 6 which showed a strong immune response only after the incubation with cancer sera.

P1-02-01
c-Jun N-Terminal Kinase 1 (JNK1) Inhibits Tumor Growth and Metastasis by Downregulating Epithelial to Mesenchymal Transition (EMT) and Stem Cell-Related Genes.
Ehbelt ND, Van Den Berg CL. The University of Texas, Austin, TX

Murine and human mammary cancers often show dysregulation of important signaling pathways including the canonical Wingless-iNtegrated (Wnt) and avian ERythroBlastosis oncogene B (ErbB) pathways. Transgenic expression of Wnt ligands causes transformation of normal mammary cells in mice, and Wnt10b is frequently upregulated in human breast cancers. Overexpression of ErbB ligands and amplification of receptors have also been implicated in human breast cancer. JNK1 is a tumor suppressor in the skin and intestinal epithelium, and JNKs are known to integrate ErbB and Wnt pathways as well as others to control cell growth and differentiation. In a murine mammary cancer model where 4T1.2 cells were injected into the mammary gland, reducing JNK1 levels by expressing shRNA (shJNK1) resulted in increased tumor growth and lung metastasis compared to mice injected with control vector-(pSM2) expressing cells. A microarray analysis comparing gene expression between shJNK1 and control tumors revealed 2 and 2.5-fold increases in the ErbB pathway genes Nrg3 and ETV5, 2-fold increases in the Wnt genes Bcl-9 and Wnt10a, and a 1.6-fold increase in the EMT gene Twist1. RT-PCR analysis of in vitro grown 4T1.2 cell lines transfected with shJNK1 confirmed increased expression of Bcl-9 and ETV5, as well as the ETV5 target Cox-2. ErbB2 protein was also overexpressed. The shJNK1 cells showed upregulation of pERK in response to Herregulin1 (an ErbB2/3 ligand) and Fibroblast Growth Factor (FGF) 1, which further amplifies canonical Wnt signaling. In a p53-/- tumor model, ETV5, Bcl-9, and Cox-2 were still upregulated in jnk1-/- compared to wildtype tumor cells, indicating this effect is p53-independent. In the normal mammary gland, a 4-fold increase in ETV5 and a 5-fold increase in Twist1 were found in jnk1-/- mice.
compared to wildtype, further indicating that this effect is dependent on JNK1 alone. The ErbB and Wnt pathways are known to upregulate EMT and stem-cell related genes, however, the involvement of JNK1 in these effects is a novel hypothesis. Thus far, our data suggest that JNK1 deficiency targets these oncogenic pathways to contribute to a more aggressive tumor phenotype due to heightened EMT and “stem-cellness”. Further studies using cell sorting and differentiation assays will determine whether normal jnk1−/- glands contain a higher fraction of stem cells than wildtype glands. Inhibition of EMT genes and/or ETV5 in the p53−/−,jnk1−/- cancer cells will determine whether the tumor growth or metastasis phenotypes are dependent on these genes. EMT and stem-cell genes are frequently expressed in human breast cancer subtypes that exhibit low survival rates, and EMT is known to be linked to increased metastasis. Some of these sub-types, such as claudin-low tumors, currently have no molecularly-targeted treatments, therefore it is important to determine what proteins critically contribute to these phenotypes so that efficient and effective treatments can be developed.

P1-02-02
Zoledronic Acid Reverses the Epithelial-Mesenchymal Transition While Inhibiting the Tumor Initiating Cell Population of Highly Tumorigenic Breast Cancer Cell Lines.
Schech AJ, Gilani RA, Kazi AA, Brodie AH. University of Maryland, Baltimore, Baltimore, MD

Breast cancer remains the second leading cause of cancer related death amongst women in the United States. This is largely due to metastasis of cancer cells from the primary tumor to other parts of the body, and to the putative cancer stem cell population. Both are driven by the epithelial-mesenchymal transition (EMT), a cellular process whereby cancer cells of epithelial origin lose their epithelial characteristics and acquire a mesenchymal phenotype. Cells which undergo EMT tend to be motile and invasive, and therefore can metastasize to other parts of the body. EMT has also been implicated in the generation of cells expressing the cancer stem cell phenotype. As metastatic disease and the cancer stem cell are difficult to eliminate, more effective therapy is required. Zoledronic acid, originally indicated for use in the treatment of osteoporosis, has been reported to inhibit the growth of breast cancer cells. The mechanism of this effect however has yet to be determined. In preliminary data studies, treatment with zoledronic acid was found to reduce activation of nuclear factor kappa-b, an established regulator of EMT. These findings suggest that treatment with zoledronic acid may reverse EMT in breast cancer cells, driving them to express a more epithelial phenotype. To test this hypothesis, the highly metastatic, triple negative breast cancer cell lines MDA-MB-231 and Hs578t, which largely express mesenchymal proteins, were used to measure cell viability and changes in protein and mRNA expression following treatment with zoledronic acid. Dose response analysis for inhibition of cell viability showed an IC50 of approximately 2µM in the Hs578t and 6 µM in the MDA-MB-231 cell line. Zoledronic acid treated cells displayed a decreased mesenchymal phenotype, as evidenced by reduced expression of mesenchymal markers N-cadherin (75% reduction, p<0.0076; 65% reduction, p=0.005) and TWIST (67% reduction, p=0.08; 64% reduction, p=0.009) in MDA-MB-231 and Hs578t cells, respectively. This was accompanied by a subsequent increase in epithelial phenotype as evidenced by increased expression of epithelial marker E-cadherin (223% increase, p<0.006) in MDA-MB-231 cells. To further elucidate the effects on the mesenchymal and epithelial phenotypes of these cells, surface expression of CD24 and CD44 was measured by flow cytometry. While vehicle treated samples of both cell lines stained positive for CD44 and negative for CD24, zoledronic acid treatment decreased CD44 expression. As both increased the ratio of surface expression of CD44hi/CD24lo and mammosphere formation are characteristics of the breast cancer stem cell, effects of zoledronic acid on this subpopulation in Hs578t cells were determined. Cells pretreated with zoledronic acid were seeded under mammosphere conditions and allowed to propagate for 7 days. Zoledronic acid treated cells formed significantly fewer mammospheres (86% reduction, p<0.041), while the ones that formed were smaller in size. These findings suggest that zoledronic acid is able to reverse the epithelial mesenchymal transition, which may reduce the tumor initiating capacity of highly metastatic cells.

P1-02-03
The Reciprocal Roles of E-Cadherin and ZEB1 Demonstrate the Mesenchymal-Epithelial Transition as a Primary Characteristic of Inflammatory Breast Cancer.
Cha K, Boley KM, Luo AZ, Ye Z, Wright MC, Freiter EM, Robertson FM. The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Inflammatory breast cancer (IBC) is a rare but very aggressive form of breast cancer. IBC is characterized by nests of tightly aggregated cells, defined as tumor emboli, that exhibit characteristics of cancer stem cells (CSCs). IBC tumor emboli express E-cadherin which is required to maintain their integrity and our recent evidence demonstrates that expression of E-cadherin by tumor emboli is associated with lack of ZEB1 expression, a transcriptional repressor of E-cadherin. This is at odds with the current hypothesis that metastatic progression is associated with the process of epithelial mesenchymal transition (EMT), with loss of E-cadherin and gain of transcription factors including ZEB1, acquisition of CSC characteristics and enhanced invasive capabilities.

Materials and Methods: shRNA knockdown and over-expression methods, real time PCR arrays, western blotting, and in vivo assays to evaluate proliferation, invasion, growth in soft agar and clonogenicity and in vivo animal studies were used.

Results: Expression of E-cadherin was reduced by shRNA and ZEB1 was expressed in SUM149 IBC tumor cells. Numerous EMT-related genes were upregulated with loss of E-cadherin and gain of ZEB1, including N-cadherin and vimentin. However, there were marginal differences in the in vitro parameters of proliferation, Matrigel invasion and anchorage independent growth in soft agar between SUM149-shEcad or SUM149-ZEB1 clones and their respective vector control cells. The loss of E-cadherin and gain of ZEB1 altered the morphology of SUM149 cells when cultured under low adherence conditions permissive for the enrichment of CSC, exhibiting a reversion in grape-like morphology to more well defined spheres, which was accompanied by increased clonogenicity in both SUM149-shEcad and SUM149-ZEB1 cells. The loss of E-cadherin and the gain of ZEB1 significantly inhibited tumor growth of cells injected in the mammary fat pad of NOD.Cg-PkdcreloxP129+Il2rgtm1Wjl/SzJ mice. Tumor volume at 56 days for E-cadherin vector control cells was 771.9 mm3 +/- 185.6 compared to shEcadherin tumors, which was 13.6 mm3 +/- 7.2. Tumor volume of ZEB1 expressing tumors, which was 346.1 mm3 +/- 96 compared to volume of ZEB1 expressing tumors, which was 21.5 mm3 +/- 7.2.

Conclusions: E-cadherin with lack of ZEB1 expression in IBC is consistent with a mesenchymal-epithelial transition (MET), consistent with the retention of the epithelial phenotype while maintaining a program of rapid metastasis and colonization of lymph nodes and distant organ sites. Furthermore, we demonstrate that the E-cadherin-ZEB1 axis is critical for the in
vivo growth of IBC tumor cells. Although SUM149 cells are fully capable of undergoing an EMT process, which is under negative regulation by E-cadherin, the process of EMT does not drive in vivo tumor growth in IBC.

**Estrogen Receptor beta Inhibits Breast Cancer EMT by Regulating the Expression of miR-200.**

Thomas C, Gayani R, Nikols F, Hao R, Katchy A, McCollum C, Williams C, Bondesson M, Krishnamurthy S, Esteva F, Gustafsson J-A. University of Houston; University of Texas MD Anderson Cancer Center

Estrogen receptor beta (ERβ) mediates the effects of estrogens in a variety of human tissues and regulates cellular processes involved in initiation and progression of breast cancer such as cell proliferation and migration. Clinical studies produced contradictory data regarding the role for ERβ in prognosis of metastatic breast cancer and the molecular mechanism through which ERβ influences cell migration and invasion has not been fully elucidated. Here we show that induction of ERβ expression inhibits epithelial to mesenchymal transition (EMT) in metastatic breast cancer cells. This correlates with an ERβ-mediated induction in the expression of the epithelial marker E-cadherin and downregulation of its transcriptional repressors ZEB1 and SIP1. ERβ alters the expression of ZEB1 and SIP1 by inducing the expression of the miR-200a, miR200b and miR-429. Downregulation of these miRNAs in ERβ-expressing cells resulted in decreased cell-cell contact and decline of E-cadherin levels. In addition, ERβ was found to inhibit the invasiveness of metastatic breast cancer cells in a zebrafish xenotransplantation model. We are now examining breast cancer specimens derived from ductal carcinomas and metaplastic breast cancers to see whether ERβ levels decline in the mesenchymal regions and ERβ expression is correlated with epithelial markers. These data propose a crucial role for ERβ in the regulation of EMT and in prognosis of invasive and metastatic breast cancer.

**Invasive Lobular Carcinoma – A Luminal Breast Cancer Histotype Enriched for Epithelial-to-Mesenchymal Transition Features.**

Metzger O, Singhal SK, Michiels S, Ignatiadis M, Bertucci F, Galant C, Larsimont D, Salgado R, Veys I, Fumagalli D, Saini KS, Piccart M, Sotiriou C. Institut Jules Bordet, Université Libre de Bruxelles, Brussels, Belgium; Institut Paoli-Calmettes, Marseille, France; Cliniques Universitaires Saint Luc, Brussels, Belgium

Background: Invasive lobular carcinoma (ILC) represent the second most common breast cancer (BC) histotype, but little information remains a statistically significant prognostic factor for ILC. ILC tumors were enriched with an EMT phenotype, which is not observed among IDC luminals. Of interest IGF signaling, which is known to be associated with poor prognosis in ER-positive BC, added prognostic value in this population which may open new therapeutic avenues for ILC.

Conclusions: ILC is mainly composed of luminal tumors and a minority of HER2-positive tumors. Similarly to IDC, proliferation remains a statistically significant prognostic factor for ILC. ILC tumors were enriched with an EMT phenotype, which is not observed among IDC luminals. Of interest IGF signaling, which is known to be associated with poor prognosis in ER-positive BC, added prognostic value in this population which may open new therapeutic avenues for ILC.

**P1-02-06**

**Silencing of IGF-1R Has Paradoxic Effects in Triple Negative Breast Cancer Phenotypes.**

Talaijarro-Smith LD, Oberlick EM, Liu T, Eggers C, Kline ER, Nagaraju GC, Marcus A, O’Regan R. Winship Cancer Institute at Emory University, Atlanta, GA; Grady Memorial Hospital, Atlanta, GA

Background: Triple negative (TN) breast cancers are a heterogeneous group of breast cancers with a poor prognosis in part due to a lack of effective targeted agents. Insulin-like growth factor-1 receptor (IGF-1R) has been shown to play a role in breast cancer cell proliferation, adhesion, invasion, and migration and is overexpressed in more than a third of TN breast tumors. We hypothesized that IGF-1R could be a therapeutic target for a subset of TN breast cancers. Methods: We evaluated the effects of IGF-1R silencing on the metastatic properties of TN breast cancer cells by knock down in two morphologically distinct TN breast cancer cell lines using shRNA lentiviral techniques. Reverse-transcription polymerase chain reaction (RT-PCR) and immunoblotting were used to detect mRNA and protein expression levels, respectively, of IGF-1R signaling molecules. Anchorage-dependent growth and Matrigel chamber assays were performed to assess the effects of IGF-1R silencing on colony formation and invasion of TN breast cancer cells, respectively; wound-healing and spheroid migration were also performed to assess the effects of IGF-1R inhibition on TN breast cancer cell motility. Results: Stably transfected mesenchymal MDA-MB-231 TN cells showed effective downregulation of IGF-1R protein expression, which resulted in mesenchymal-to-epithelial transition (MET), confirmed by
upregulation of the epithelial marker E-cadherin and downregulation of the mesenchymal marker vimentin. Importantly, this MET resulted in reduced colony formation (p<0.0042) and cell motility and dramatically reduced invasion (p<0.0001). Conversely, silencing of IGF-1R in epithelial MDA-MB-468 TN cells induced epithelial-to-mesenchymal transition (EMT), confirmed by downregulation of E-cadherin and upregulation of vimentin expression, with resultant increased colony formation (p<0.006), cell motility, and invasion (p<0.0001). Conclusion: Collectively, these results demonstrate a paradoxical effect of targeting IGF-1R in TN breast cancers of mesenchymal and epithelial origin. Targeting IGF-1R in TN breast cancers with a mesenchymal phenotype decreases invasion and metastatic potential. In contrast, targeting IGF-1R in TN breast cancers with an epithelial phenotype could have potentially detrimental effects. Our data suggest that IGF-1R inhibition should be explored as a therapeutic modality in TN breast cancers with a mesenchymal phenotype.

P1-02-07 Epithelial-Mesenchymal Transition Correlated with Serum Cytokine Profiling in Breast Cancer Patients.
Giordano A, Cohen EN, Anfossi S, Gao H, Lee B-N, Mego M, Sanda T, Valero V, Alvarez RH, Cristofanilli M, De Placido S, Horta obese GN, Woodward W, Ueno NT, Reuben JM. The University of Texas MD Anderson Cancer Center, Houston, TX; University Federico II of Naples, Naples, Italy; Fox Chase Cancer Center, Philadelphia, PA; National Cancer Institute, Bratislava, Slovakia (Slovak Republic)

Background: Inflammation contributes to the increased invasiveness and poor prognosis in breast cancer (BC) patients. Specifically, the expression of the proinflammatory cytokines interleukin-6 (IL-6), tumor necrosis factor alpha (TNFα) and interleukin-1 (IL-1) have all been linked to increased invasiveness and poor prognosis. Interestingly, the increased invasiveness was associated with an increase in the acquisition of markers of epithelial-mesenchymal transition (EMT). Therefore, we determined whether the levels of circulating proinflammatory cytokines (IL-1, IL-6, TNFα) and anti-inflammatory cytokines (IL10) were correlated with the induction of EMT transcription factors (TFs), Snail1, Zeb1, Twist1, in breast cancer patients.

Materials and Methods: From two laboratory-based ongoing studies at the MD Anderson Cancer Center, 41 BC patients were assessed for EMT-TFs in circulating CD45-ve cells (EMT-CTCs) and for serum proinflammatory cytokines before starting any treatment. 32 of 41 patients assessed for EMT had metastatic BC. EMT-CTCs were detected by qRT-PCR for the EMT-TFs Snail1, Zeb1 and Twist1 (Mego 2011; PMID 21387303) and serum cytokines were measured by Luminex bead array assay (MILLIPLEX™ MAP Human Cytokine/Chemokine Panel). Cytokine serum concentrations were compared with the median cytokine levels of healthy donors (HD). We examined the association of serum cytokines above the median HD levels and the presence of EMT-CTCs by non-parametric Mann-Whitney test with a statistical significance for p<.05.

Results: Of the 41 patients assessed for both serum cytokines and EMT-CTCs, 14 (34%) were positive for at least one EMT-TF, including 3 of 9 (33%) patients with no-metastatic BC and 11 of 32 (34%) patients with metastatic BC. We found that serum levels of IL1a, IL2, TGFα, and TNFβ in patients that were above the median levels of HD sera were higher in patients with EMT-CTCs in the blood (higher IL1a concentration in patients with over expression of Snail1, Zeb1, and Twist1; IL2 with Zeb1; TGFα with Snail1; TNFβ with Zeb1, and Twist1). Further, the higher ratio of proinflammatory/anti-inflammatory cytokines, was associated with the presence of at least one EMT-TF, e.g., IL8/IL10 (p=.005) and TNFα/IL10 (p=.037).

Discussion: Patients with proinflammatory cytokine (IL1a, IL2, TGFα, and TNFβ) levels above the median levels of HD or who had a predominantly proinflammatory cytokine profile were more likely to have at least one EMT-TF in their blood. These data are consistent with the hypothesis that proinflammatory cytokines promote EMT, which may be involved in tumor aggressiveness and disease progression.

P1-02-08 Modulation of EMT by Targeting E-Cadherin Restores Radiation Sensitivity in Human Breast Cancer Cells.
Munshi A, Yuan Y, Liu J, Meyn RE. University of Oklahoma Health Sciences Center, Oklahoma City, OK; Baylor College of Medicine, Houston, TX; The University of Texas M.D. Anderson Cancer Center, Houston, TX

E-cadherin is the major adhesion protein associated with epithelial cells and loss of its expression is diagnostic of the epithelial to mesenchymal transition (EMT). Findings from our laboratory, suggest that EMT, detected as the loss of E-cadherin expression, may regulate tumor cell radioresistance, i.e. cells that have undergone EMT are relatively radioresistant compared to the lines that have retained the epithelial phenotype, which typically are relatively radiosensitive. To definitively test this hypothesis we compared expression levels of E-cadherin and other EMT related markers in ER-a negative (MDA-MB-231 and Hs578t) and ER-a positive (MCF-7) human breast cancer cells. We observed that many ER-a negative lines, were also E-cadherin negative, and the ER-a positive lines were positive for E-cadherin expression. Clonogenic cell survival assays showed that the cell lines expressing estrogen receptor (MCF-7) and had high expression of E-cadherin, were also more sensitive to increasing doses of radiation. Treatment of MCF-7 cells with 100nM siRNA to E-cadherin for 72 hrs made the cells more resistant to radiation with the surviving fraction changing from 42.3% in control cells to 56.4% in siRNA treated cells. In contrast, ER negative cells (MDA-MB-231 and Hs578t) had no detectable expression of E-cadherin and were more radioresistant. We transfected MDA-MB-231 and Hs578t cells with a CDH1-expression vector and isolated stable clones, which were then tested for radiosensitivity. Cells transfected with the backbone vector (pCMV) served as controls. Restoring E-cadherin expression radiosensitized both, MDA-MB-231 and Hs578t cells, compared to the control vector cell line, suggesting that restoration of E-cadherin expression in mesenchymal-like cells produces a radiosensitizing effect. These observations suggest that ER-a signaling might regulate E-cadherin and implied that this regulation might influence EMT and radioresistance. Overall, our results suggest that the EMT status of breast cancer cells governs their response to radiation. A detailed investigation of the mechanism is ongoing.

P1-02-09 Epigenetics-Regulated microRNAs Related with Epithelial-Mesenchymal Transition of Breast Cancer Cells.
Sato F, Ito T, Tsuchiya S, Kawaguchi-Sakita N, Shimizu K, Tsujimoto G, Toi M. Graduate School of Medicine, Kyoto University, Kyoto, Japan; Graduate School of Pharmaceutical Sciences, Kyoto University, Kyoto, Japan

Background: Epithelial-mesenchymal transition (EMT) is a program in which biological cells change morphologically and functionally from an epithelial phenotype to a mesenchymal phenotype. The EMT is involved in the process of cancer metastasis. On the other hand, accumulated evidence showed epigenetics and microRNA plays
important roles in breast cancer. However, to date, biological networks between epigenetics and microRNAs regarding EMT remains largely unclear. Thus, the aim of this study is to identify epigenetics-regulated microRNAs related with EMT of breast cancer.

Materials / Methods and Results: MicroRNA expression profiles of 11 breast cancer cell lines (8 epithelial-phenotype (E-type) cells and 3 mesenchymal-phenotype (M-type) cells) were obtained by microarray method. Unsupervised clustering analysis showed that E- and M-type breast cancer cells had different microRNA expression profiles. On the other hand, we obtained a genomewide methylation status of these breast cancer cell lines by a MeDIP-seq method. An integrated in silico analysis identified microRNAs which microRNA and DNA methylation were inversely correlated. All of miR-200b/a/429 cluster members were listed in top5 differentially expressed miRs between E- and M-type cells, and also in top 5 epigenetics-regulated microRNAs. In the further study, we focused upon the miR-200b/a/429 cluster. A COBRA assay revealed that promoter regions of miR-200b/a/429 cluster in M-type breast cancer cells were more frequently methylated than that in E-type cells (65.1% vs 6.8%, p<0.0001, respectively). The methylation levels were inversely associated with miR-200b/a/429 cluster expression (Taqman assay, p<0.01). In addition, demethylating treatment using 5-aza-dC unmasked miR-200b/a/429 expression in M-typed breast cancer cell lines. Taken together, the finding indicated that the expression of miR-200b/a/429 cluster is epigenetically regulated. Next, we investigated an effect of the miR-200b/a/429 cluster upon cell motility as a function of the EMT. A transfection of exogenous miR-200b/429 inhibited 24% of cell migration ability (Transwell assay). Utilizing microRNA target prediction algorithm, we identified fibronectin as a target gene of miR-200b/429. Utilizing several prediction algorithms for microRNA target genes, we identified fibronectin as a target gene of miR-200b/429. A luciferase-based reporter assay demonstrated that miR-200b/429 were directly associated with fibronectin-3'UTR and repressed 21% (p<0.0001) of the reporter gene expression post-transcriptionally. Conclusion: The promoter hypermethylation of miR-200b cluster is associated with epithelial-mesenchymal transition, and stimulates cell motility by upregulating fibronectin expression in mesenchymal-phenotype breast cancer cells.

P1-02-10
Vimentin Expression; as a Prognostic Factor and a Possible Molecular Target of Triple Negative Breast Cancer.

Yamashita N, Tokunaga E, Kitao H, Hisamatsu Y, Akiyoshi S, Saeki H, Oki E, Ohga T, Kakeji Y, Maehara Y. Kyushu University, Fukuoka, Japan

BACKGROUND: Triple negative breast cancer (TNBC), characterized by absence of estrogen receptor (ER), progesterone receptor (PR) and human epidermal growth factor receptor 2 (HER2), is typically associated with aggressive tumor phenotype and poor prognosis. TNBC is also considered highly heterogeneous disease. Since TNBC lacks efficient therapeutic target, it is generally treated with non-specific cytotoxic agents. A better understanding of molecular and histopathological features of TNBC is of great importance, in order to develop a new therapeutic strategy and to improve the prognosis of TNBC. TNBC has many similarities with basal-like breast cancer (BLBC), and is also associated with stemness and BRCA-ness. In addition, recent studies suggest links between TNBC and epithelial-mesenchymal transition (EMT). To identify prognostic biomarkers and novel therapeutic targets, we investigated the expression of the factors associated with EMT in TNBC.

MATERIALS and METHODS: Sporadic invasive breast cancer specimens were obtained from 659 Japanese patients who underwent surgery in our department between 1994 and 2010, and 90(14%) cases were diagnosed as TNBC. The E-cadherin and vimentin mRNA expression was evaluated by quantitative RT-PCR. The E-cadherin, vimentin, CK5/6 and epidermal growth factor receptor (EGFR) protein expression was assessed by immunohistochemistry. In this study, we defined TNBC with positive expression of CK5/6 and/or EGFR as BLBC, and TNBC with low expression of E-cadherin and positive expression of vimentin as EMT-type.

RESULTS: Compared with non-TNBC cases, E-cadherin mRNA expression was significantly lower in TNBC cases (p=0.0012). Immunohistochemically, E-cadherin expression was significantly lower (p=0.0001) and vimentin expression was significantly higher (p=0.0049) in TNBC cases. Vimentin expression was associated with younger age (<50 years old, p=0.021), high nuclear grade (p=0.017) and high Ki67 expression (p<0.001) in TNBC. Among the patients with TNBC, vimentin expression was significantly associated with poor prognosis, in terms of disease free survival (p=0.0059) and overall survival (p=0.013). Multivariate analysis showed that vimentin expression was an independent prognostic factor for both disease free survival (p=0.017) and overall survival (p=0.012). Among TNBC cases, 52(63%) cases were BLBCs and 15(18%) cases were EMT-type. Among BLBC patients, vimentin expression was also associated with significantly shorter disease free survival (p=0.0058) and overall survival (p=0.0057). The patients with both BLBC and EMT-type features showed especially poor prognosis (p=0.05).

CONCLUSION: These findings suggest that elevated expression of vimentin attributes to the aggressive phenotype in TNBC patients. Vimentin expression might be useful as a molecular marker for prognosis of TNBC, and vimentin may represent a novel therapeutic target of TNBC.

P1-02-11
The BCL2 Antagonist of Death, BAD Is Down-Regulated in Breast Cancer and Inhibits Cancer Cell Invasion.

Cekanova M, Fernando R, Wimalasena J. University of Tennessee, Knoxville; TN; NIH, NCI, Bethesda, MD

Background

Recent clinical evidence suggest that expression of BCL2 and its antagonist BAD are good prognosticators for survival in breast cancer patients. BAD protein was previously shown by us to inhibit cyclin D1 expression and c-Jun activation, both may enhance invasiveness of tumor cells(Fernando et al JBC 07). However, the role of BAD and other BCL2 family proteins in invasion/metastasis of breast cancer is poorly characterized.

Methods

By immunohistochemistry nuclear and cytoplasmic staining of several proteins including BAD in normal epithelial was compared to that of cancer cells in human specimens . Western blotting and ELISA methods were used to compare BAD overexpressing MCF-7 breast cancer cells with control cells for the expression of variety of signaling molecules, proteins that take part in metastasis and invasion and ability of cells to invade was measured. PCR was used to measure mRNA levels and reporter constructs utilized for transcriptional factor activity studies.

Results

Grade II breast cancer specimens express less total and phosphorylated forms of BAD in nuclei and cytoplasm compared to normals. BAD expression decreased Sp1, β-catenin and STAT proteins, which may increase cyclin D1 in vitro. BAD inhibited activation of the CRE and
AP1 elements, and phosphorylation of BAD on S112 and S136 is required for this activity. BAD inhibited the Ras/MEK/ERK pathway and JNK, which may underlie inactivation of c-Jun. BAD, like BCL2, may decrease metastasis, therefore, ability of BAD to modulate the expression of metastasis-related proteins were measured and MMP10, VEGF, SNAIL, CXCR4, E-cadherin, and TIMP2 were regulated by BAD with a concomitant reduction in cell invasion.

Conclusion

Higher expression of BAD in breast cancer and a role in metastasis and proliferation suggests that BAD is a valuable diagnostic marker in breast cancer and a multi-functional protein. Further given the overwhelming clinical evidence that BCL2 prolongs survival, a reevaluation of the role of BCL2 family proteins in metastasis is urgently required.

P1-03-01

ECM Stiffness and Breast Tumor Histology and Treatment Phenotype.
Acerbi I, Au A, Chen Y-Y, Park C, Hwang S, Weaver V. Center for Bioengineering and Tissue Regeneration, University of California, San Francisco, San Francisco, CA; Carol Buck Breast Cancer Center, University of California San Francisco, San Francisco, CA; University of California San Francisco, San Francisco, CA; Cancer Stem Cells May Explain the Effectiveness of Dose-Dense Chemotherapy.

The Norton-Simon Hypothesis and Cancer Stem Cells: How Cancer Stem Cells May Explain the Effectiveness of Dose-Dense Chemotherapy.

The Norton-Simon Hypothesis and Cancer Stem Cells: How Cancer Stem Cells May Explain the Effectiveness of Dose-Dense Chemotherapy.

Materials and Methods: To evaluate TICs response to chemotherapy, mice with human breast tumor xenograft lines BCM-2665a and BCM-2147 were treated with vehicle, 10-, or 33-mg/kg docetaxel, and then tumors were collected for TIC assays and molecular analysis at both 48 and 72h after treatment. Using Affymetrix gene expression microarrays and reverse phase protein array (RPPA) analysis with 119 different validated antibodies, we identified pathways involved in regulation of TICs.

Results: According to flow cytometric analysis for TIC markers and mammosphere (MS) formation efficiency, BCM-2665 TICs were reduced by docetaxel treatment compared to vehicle-treated at 48h post 10 mg/kg docetaxel (4-fold decrease) and 48 and 72h post 33 mg/kg docetaxel compared to control (14- and 2-fold decrease, respectively). Although the BCM-2147 TICs did not significantly decrease at any time points or doses tested, they were clearly induced at 72h post-treatment compared to control. Additionally, BCM-2665 TICs were increased within 72h post 10 mg/kg docetaxel, indicating that these time points are ideal for chemotherapy. BCM-2147 TICs did not significantly decrease at any time points or doses tested, and then tumors were collected for TIC assays and molecular analysis at both 48 and 72h after treatment. Using Affymetrix gene expression microarrays and reverse phase protein array (RPPA) analysis with 119 different validated antibodies, we identified pathways involved in regulation of TICs.

Discussion: These in vivo studies and showed that there was a significant increase in ECM stiffness as the tissues transitioned from normal to an invasive lesion with the highest stiffness being located at the tumor edge (~2-4 folds greater). Intriguingly, we observed that ER positive tumors were substantially stiffer than ER positive tumors (50% increase in upper 10-percentile) and that there were tracks of ECM stiffness that correlated with oriented parallel collagen fibers and ECM birefringence. Moreover, we quantified a significant decrease in ECM stiffness following treatment (40% lower) with the most striking reduction in ECM tension being noted in ER negative patient tissues who demonstrated the most robust response. This study should lead to a deeper understanding of the nature of breast cancer stroma and its role in tumor phenotype and response to therapy.
findings are consistent with the Norton-Simon Hypothesis in that chemotherapy regimens given more frequently may in fact eliminate TICs, thereby explaining the proven increased effectiveness of dose-dense chemotherapy. Based on when TICs became chemoresistant, we are comparing dose-dense treatment (4 mg/kg docetaxel every 3 days) to a traditional single dose of 32 mg/kg, in an effort to eliminate the tumor cells that cause tumor recurrence. Furthermore, our analysis of gene expression at both the RNA and protein level implicated the immune cells as TICs inducers. Since our immunocompromised mice lack T- and B- cells but have active macrophages, macrophages are indicated as inducers of TICs. We are focusing our current efforts at identifying how immune cells activate TICs and thus enhance tumorigenesis.

P1-03-03
Adaptive Exploitation of Stromal Cell Metabolism by Tumor Cells.
Patel B, Rattigan Y, Ackerstaff E, Koutcher J, Sukenick G, Glod J, Banerjee D. Cancer Institute of New Jersey - University of Medicine and Dentistry of New Jersey; Johns Hopkins University; Memorial Sloan-Kettering Cancer Center

Tumor cells secrete cytokines to recruit and activate stromal cells in the tumor milieu leading to reciprocal paracrine support of tumor growth by stroma-derived growth factors. This is an important means by which tumors adapt their microenvironment to facilitate their growth. Indeed, breast cancer development and metastatic progression is highly dependent on stromal support, particularly from carcinoma associated fibroblasts (CAFs). As a result of aerobic glycolysis, tumor cells produce and secrete high levels of lactate, thought to be a toxic byproduct that needs to be extruded into the tumor milieu. Using CAFs generated by prolonged exposure to tumor conditioned medium, we have investigated the role that lactate may play in CAF-mediated support of tumor growth. In addition to extruding lactate as a byproduct of glycolysis, we suggest that tumor cells secrete it to recruit and subsequently exploit stromal cells to recycle lactate into utilisable metabolites, such as pyruvate, to fulfill metabolic demands of tumor cells. Our hypothesis is that lactate secreted by tumor cells is taken up by stromal cells and converted to metabolites critical for tumor growth and progression. Our studies indicate that (i) MDA-MB-231 breast cancer cells secrete significantly higher levels of lactate (3-fold more) under hypoxia, and that (ii) lactate recruits mesenchymal stem cells, the precursors of CAFs, towards tumor cells by activating signaling pathways to enhance migration. Lactate is transported by a family of proteins termed monocarboxylate transporters (MCTs); cells take up lactate via MCT1 and efflux it via MCT4. Expectedly, MDA-MB-231 breast carcinoma cells display low expression of MCT1 while exhibiting high expression of MCT4. However, CAFs show high expression of MCT1 while displaying low expression of MCT4, indicating that lactate extruded by the tumor cells is taken up by stromal cells. Our investigation further revealed that expression of lactate dehydrogenase B and pyruvate dehydrogenase are induced upon lactate exposure in CAFs, supporting the contention that the lactate taken up by stromal cells is metabolized. This implies that CAFs may be less glycolytic than MDA-MB-231s. Indeed the expression of pyruvate kinase isoform 2 (PKM2), which positively correlates with glycolysis, is greater in MDA-MB-231s than in CAFs, while CAFs express significantly more PKM1, the isoform that correlates with a more oxidative metabolic state. Finally, 13C NMR spectroscopic analyses indicate that 13C-lactate is indeed metabolized via the TCA cycle in stromal cells, further supporting our hypothesis. Thus, stromal fibroblasts in the tumor microenvironment have the capacity to take up tumor-secreted lactate and use it as an energy source. To our knowledge this is the first in vitro model system demonstrating tumor/stroma metabolic coupling by which tumor cells exploit stromal cells.

A better understanding of the molecular mechanisms governing metabolic cooperation within the tumor milieu will potentially identify new targets for therapeutic intervention.

P1-03-04
Cashas-Hernandez P, Roman-Perez E, Mani S, Troester MA. School of Medicine, UNC, Chapel Hill, NC; Gillings School of Public Health, UNC, Chapel Hill, NC; UNC Hospitals, Chapel Hill, NC; University of Texas MD Anderson Cancer Center, Houston, TX

Non-neoplastic tissues adjacent to tumor is known to influence the progression of the disease. We and others found that there are two types of microenvironment, one of these highly expresses genes associated with epithelial-to-mesenchymal transition (EMT). Tumor adjacent microenvironment (TAME) with wound responses have been observed in >90% of tumor-adjacent tissues, but EMT- characteristics seems to be less common and are observed in less than half of all patients. Our data suggest that the patients with EMT-TAME have worse breast cancer outcome, particularly among estrogen receptor positive patients. Thus, understanding the molecular cross talk between tumor cells and adjacent cells located in the TAME with EMT properties may identify targetable pathways that play a important role in breast cancer progression. Toward this end, we developed an in-vitro model system that can be used to probe paracrine signaling between cancer cells and adjacent cells undergoing EMT. We hypothesized that the presence of EMT signals in the TAME will alter the gene expression and phenotype of epithelial cells. We further hypothesized that the interactions between cancer cells and their TAME would be subtype dependent. Using cell line models of luminal and basal-like breast cancer, we performed cocultures with cancer cells and cell line models of EMT. The latter cell lines were HMLE cells transduced with either Snail or Twist, representing an intermediate state between an epithelial and a fully mesenchymal phenotype. This coculture system allows the study of heterotypic interactions between cancers and TAME cells with EMT characteristics. Gene expression, proliferation, migration, anchorage independent growth and cytokine production of different breast cancer and non-neoplastic cell lines were evaluated. We observed that coculture with models of EMT microenvironments altered the behavior of epithelial cells and that the gene expression changes were relevant to in-vivo in public datasets, showing correlations with both subtype and outcome. Cocultured cells acquired more migratory behavior and reduced expression of cellular adhesion genes, while simultaneously increasing anchorage independent growth and production of cytokines such as IL-6 and IL-8. Furthermore, we observed different response by luminal and basal-like breast cancer cells to the coculture condition, suggesting that the tumor-TAME interactions occur in a tumor subtype dependent fashion. These results reiterate the importance of the surrounding environment on cancer cell phenotypes and document that paracrine interactions with cells undergoing EMT may increase the aggressiveness of some cancers. Identification of specific signaling pathways that define interactions between specific breast cancer subtypes and their microenvironments
will lead to new insights regarding tumor biology and identify potential pathway-specific biomarkers and/or targets for prognosis and treatment of breast cancer.

P1-03-05
Fibrocystic Changes Have Different Age-Dependent Patterns in Benign, In Situ, and Invasive Breast Cancer Patients.
Bekhash A, Kovatchi AJ, Chen Y, Hooke JA, Kvecher L, Mural RJ, Shrider CD, Hu H. Windber Research Institute, Windber, PA; Walter Reed Army Medical Center, Washington, DC; MDR Global Systems LLC, Windber, PA

Background: Fibrocystic changes (FCCs) have been known to develop in the aging process. Breast cancers in younger and elderly women are known to have different characteristics. Less is known about alterations in the microenvironment for disease development in middle-aged women who undergo menopausal changes. The Walter Reed Army Medical Center, through the Clinical Breast Care Project, has enrolled over 2000 subjects undergoing a biopsy; all the pathology was reviewed by a single pathologist. These subjects provide an opportunity to study the age-dependent pattern of FCC across benign, in situ (IS) and invasive breast carcinoma (IBC) patient populations.

Methods: Subjects were enrolled following IRB-approved protocols. A total of 2060 subjects were identified for this study, including 1226 benign/atypical, 193 IS, and 641 IBC patients. Patients were divided into three age groups: <=45 years, 46-65 years, and >66 years. Chi-Square test in the SAS was used for statistical analysis across the age groups for the occurrence of FCCs. For IS and IBC patients, additional analysis was performed on high grade (grade 3) and non-high grade (grades 1 and 2) combined cancers. For IS, grade analysis was performed on ductal carcinoma (DCIS).

Results: As shown in the Table, FCC occurrence rate is significantly lower in younger patients in the benign population. In the IBC population, this rate is significantly higher in middle-aged patients. This higher rate is significant in the non-high grade patients but disappears in the high grade patients. In the IS population, the same trend exists that the FCC rate is higher in middle-aged patients. This trend is retained in non-high grade DCIS but again lost in high grade DCIS.

Discussion: The observation that FCC increases with age in the benign population, but is bell-shaped in IBC and IS populations, supports a hypothesis that physiological changes in the middle-aged women may alter the microenvironment for disease development. The observation that the bell-shaped pattern is due to non-high grade DCIS but not due to high-grade DCIS suggests that changes in the microenvironment contribute to breast disease development.

P1-03-06
Fibroadenomatoid Changes Have a Higher Occurrence Rate in Middle-Aged Benign Breast Disease Patients with the Trend Retained in Cancer Patients.
Bekhash A, Hooke JA, Chen Y, Kovatchi AJ, Kvecher L, Mural RJ, Shrider CD, Hu H. Windber Research Institute, Windber, PA; Walter Reed Army Medical Center, Washington, DC; MDR Global Systems LLC, Windber, PA

Background: Fibroadenoma (FA) is a common benign breast lesion known to have a high incidence rate in younger women. There are controversial reports whether FA elevates the risk of developing breast cancers. In clinical practice, FA may be surgically removed due to multiple reasons making it complicated to study its impact on the development of breast cancers that have a higher incidence rate in older women. Fibroadenomatoid change (FAC), also known as fibroadenomatous hyperplasia, is an uncommon lesion with histologic features similar to that of FA but lacking well-defined borders and usually discovered incidentally on breast biopsy specimens. FAC is not surgically targeted. The Walter Reed Army Medical Center, through the Clinical Breast Care Project, has enrolled over 2000 subjects undergoing a biopsy; all the pathology was reviewed by a single pathologist. These subjects provide an opportunity to study the age-dependent pattern of FAC in different patient populations.

Methods: Subjects were enrolled following IRB-approved protocols with data collected through two comprehensive questionnaires, a Core Questionnaire and a Pathology Checklist. A total of 1942 female subjects were identified for this study, including 1135 benign/atypical, 192 in situ, and 637 invasive cancer patients. Patients were divided into three age groups: <=45 years, 46-65 years, and >66 years. Chi-Square test in the SAS was used for statistical analysis.

Results: As shown in the table, FA occurrence rate decreases significantly with increasing age in benign disease patients. FAC, on the other hand, shows a significantly higher occurrence rate in middle-aged patients with benign findings, and this trend is retained in the invasive or in situ cancer populations. FAC rate is also significantly higher in patients with cancer (invasive, or invasive and in situ combined) compared to benign patients in each age group with p-values ranging from 0.0001 to 0.019 (not shown).

Discussion: Our preliminary results suggest that FAC occurs more often in middle-aged patients. It’s significantly lower occurrence in patients with benign findings may be partially explained by the fact that breast cancer patients undergo more extensive surgeries, thus providing more breast tissue for pathologic evaluation. Otherwise, the increased FAC rate may suggest its role as a risk factor for cancer development. Since FAC may be considered a miniature FA that is not surgically targeted, it may be used as a window for the study of FA on its impact in cancer development. Further study needs to be performed to explain why FA and FAC have different age-dependent patterns and whether FA or FAC is a risk factor for breast cancer development.

P1-03-07
Subtype-Specific Gene Expression Signatures in Peritumoral
Non-Neoplastic Breast Tissue.

Williams T, Roman-Perez E, Rein JL, Amos KD, Troester MA. University of North Carolina-Chapel Hill, Chapel Hill, NC

Tumors and histologically normal-tissue adjacent to cancer share many biological features with healing wounds. We previously described that the majority of cancer-adjacent normal (CN) tissues show activation of wound response gene expression signatures. However, CN tissue also shows considerable heterogeneity across patients. Therefore, to characterize interindividual variation in CN tissues, we performed unsupervised clustering on gene expression data from women with invasive breast cancer or ductal carcinoma in situ of the breast. Two distinct classes of CN tissue were identified, one of which showed gene expression consistent with epithelial-to-mesenchymal transition (EMT), a process that is well known to be activated in healing wounds. Activation of this signature was present in ~40% of cancer-adjacent normal specimens and it was also correlated with poor outcome among ER-positive patients. We next hypothesized that gene expression changes in cancer-adjacent normal tissue would be associated with breast cancer subtype and/or estrogen receptor status. To test this, we performed supervised analysis to identify subtype-associated gene expression profiles in CN. We observed that more aggressive tumor subtypes had distinct gene expression profiles in the adjacent normal tissue in supervised analysis. Specifically, Basal-like and luminal B tumors were characterized by reduced expression of claudins and cell adhesion genes, while also exhibiting higher expression of transcription factors associated with migration. These characteristic changes were validated in independent datasets by evaluating the ability of these signatures to predict subtype. It is possible to predict tumor subtype using just adjacent normal gene expression. Thus, our findings show that cancer-adjacent tissue may have value in identifying tumor subtype for cases where tumors are too small to allow genomic analyses. Furthermore, genomic field effects may have clinical implications if, as our data suggests, subtypes with higher local recurrence rates (e.g. basal-like and luminal B breast cancers) have widespread genomic alterations, even in non-neoplastic tissue. Widespread genomic changes may indicate a need for mastectomy rather than breast conserving therapy. Ongoing work is (1) assessing these signatures in association with relapse outcomes in the Polish Women’s Breast Cancer Study, where more than 10 years of follow up data have been accrued on more than 200 patients, and (2) using co-culture models systems to study paracrine communication between breast cancer cells and stroma according to breast cancer subtypes.

P1-03-08

Adipose Tissue in Breast Cancer: Not an Idle Bystander but an Active Participant in Breast Cancer Progression.

Background:

Adipose tissue is a dynamic organ that secretes a plethora of molecules called adipokines. In breast cancer we find a unique situation were adipokines play an important role. Thus, we hypothesize that adipocyte-derived factors influence breast cancer progression. Materials and methods:

Adipose tissue was collected from breast cancer patients undergoing a mastectomy. After macroscopic removal of blood vessels and connective tissue, the adipose tissue was carefully cut into 2-3mm3 pieces and were incubated in specific adipose-tissue culture medium. After 24h, the medium was collected and the quality was checked by determining the concentration of total proteins, leptin, adiponectin, TNFalpha and triglycerides. This conditioned medium of adipose tissue (CM AT) was used for in vitro experimentation with MCF-7 breast cancer cells.

Results:

Effect of AT on morphology and aggregation: when MCF-7 cells are grown in a culture flask, they tend to form round compact islands. Under influence of CM AT, the islands form sharp edges, the cells in an island can be counted individually and they show scattering. Importantly, despite the major changes in cellular morphology, CM AT removal rescued the compact island formation of MCF-7 cells. In the slow aggregation assay, cells treated with CM AT (and a subtherapeutic concentration of a neutralizing E-cadherin antibody) lost the ability to form compact aggregates. Furthermore, MCF-7 spheroids placed inside adipose tissue showed massive reorganization into an irregularly shaped mass.

Effect of AT on proliferation: starting from an equal number of cells and counting them every 2 days, it became clear that MCF-7 cells with CM AT had a higher rate of proliferation than MCF-7 cells in control medium. This stimulation of proliferation was confirmed by cell cycle analysis which revealed a doubling of cells in the G2/M phase, and western blot which showed an upregulation of cyclin A and cyclin E, both positive regulators of the cell cycle.

Effect of AT on invasion: a 24h collagen type I invasion assay revealed invasive characteristics of MCF-7 cells treated with CM AT while MCF-7 cells in control conditions are round and non-invasive. In contrast, a transwell collagen test over 14 days was not able to show MCF-7 cells invading the collagen gel under influence of CM AT. However, the growth pattern of MCF-7 cells on the collagen gel was clearly disorganised when compared with the control situation.

Conclusion:

These findings suggest that adipose tissue-derived factors exert a dramatic selective force on patterning, invasion and growth of MCF-7 breast cancer cells. Unraveling the mechanism behind these observations may provide vital information regarding the link between obesity and poor prognosis in postmenopausal breast cancer.

P1-03-09

Significance of FAP, SMA and CD31 Expression in the Stroma of Breast Cancer.

Tchou J, Satija C, Zhang P, Bi Y, Davuluri R, Chen H, Majumdar R, Mies C, Herlyn M, Pure E. Perelman School of Medicine at University of Pennsylvania, Philadelphia, PA; Perelman School of Medicine at University of Pennsylvania; Wistar Institute, Philadelphia

Breast cancer stroma heterogeneity has been demonstrated in various gene expression profile analyses. Whether there is any association between stroma heterogeneity and the molecular phenotype of breast cancer has yet to be established. Therefore, we performed immunohistochemical analyses (IHC) to evaluate the expression of the following stromal cell markers (fibroblast activation protein (FAP), smooth muscle actin (SMA), and CD31, an endothelial cell marker) in tumor tissues from a contemporary cohort of 52 patients comprising of all four molecular subtypes (luminal A (n=25); luminal B (n=2); Her2-neu (+) (n=5); and basal (n=20)). We hypothesize that stroma heterogeneity as reflected by the proportion of stromal cells staining (+) for FAP and SMA may correlate with their molecular epithelial phenotype. Furthermore, studying the distribution of these stromal cell markers in IHC sections may evaluate their spatial relationship.
with tumor cells, immune cells, and tumor microvasculature which may have strategic significance within the tumor/microenvironment.

Clinical characteristics of study cohort and stromal cell marker distribution in breast cancer tissue stratified by molecular subtypes

As shown in Table 1, FAP is a more robust stromal cell marker staining 85±14% of stromal cells compared to SMA which stains only 28±29% of stromal cells (p<0.05). However, the distribution of FAP, SMA and microvessel density appears to be similar in all four subtypes. Multivariate analyses to correlate molecular subtype, tumor grade, tumor size, the no. of (+) nodes, and age with the % stromal cells staining (+) for FAP, SMA and CD31 yielded a significant correlation between the intensity of FAP(+) cells with tumor size, tumor grade, and the no. of positive nodes (p=0.00134, 0.0044, and 0.01141 respectively). We conclude that 1) stroma heterogeneity on IHC does not differ significantly across molecular subtypes; 2) FAP is a robust stromal cell marker; and 3) a higher FAP expression intensity on IHC may correlate with poor prognosis. Recent reports on the role of FAP in promoting tumor growth plus the abundance of FAP expression in breast cancer stroma underscore a significant role of FAP in breast cancer.

P1-04-01
The Mechanism of Anti-Breast Cancer TICs Effect of Pyrvinium Pamoate Is through WNT/beta-Catenin Signaling.
Xu W, Debeb B, de Lacerda A, Li L, Larson R, Reuben J, Ueno N, Woodward W. UT MD Anderson Cancer Center, Houston, TX

We have previously shown that pyrvinium pamoate can decrease breast cancer TICs in vitro and shrink the tumor size in vivo. Although pyrvinium pamoate has been shown to target beta-catenin through activating CK-1alpha in a vitro model, the mechanism of its anti-breast cancer TICs effect is unknown. Herein, we use a constitutively active WNT/beta-catenin signaling construct EBETAP (ref) to determine if the anti-TIC effect of pyrvinium pamoate is through WNT/beta-catenin signaling. Using aldefluor expression and mammosphere formation efficiency as TIC surrogate assays, we found that TICs of SUM-159 transfected with EBETAP construct are resistant to pyrvinium pamoate treatment compared to control cells. Moreover, microarray analysis reveals a series of genes and signaling downstream of WNT-beta-catenin were down-regulated in SUM-159 cells treated with pyrvinium pamoate. In summary, mechanism of anti-breast cancer TICs effect of pyrvinium pamoate is through WNT/beta-catenin signaling.

In Vitro Qualification and Quantification of Murine Mammary Stem/Progenitor Cells.
Dong Q, Wang D, Bandyopadhyay A, Liu Z, Yu L, Gao H, Moncada K, Huang C, Walter CA, Sun L-Z. University of Texas Health Science Center, San Antonio, TX; Wenzhou Medical College, Wenzhou, China

Increasing evidence suggest that tumors with a cell origin of more basal or stem-like sources are often highly metastatic and associated with poor prognosis. Identification of the cell of origin thus has important implications for development of new preventive and therapeutic approaches. To identifying the cells of origin of various breast cancers, understanding the normal cellular hierarchy within the breast tissue is an important prerequisite. However, current understanding of normal mammmary stem/progenitor cell is limited due to the lack of a robust in vitro assay. The newly developed cell surface markers (CD24+CD49dim+) can only be used for low percent of enrichment. The only gold standard assay for functional evaluation of stem cell property is the in vivo transplantation of cleared mammary fat pad assay, yet this assay is expensive, time consuming, and requires highly trained skills, and thus cannot be used routinely for experiments. The goal of our study is thus to develop a robust in vitro assay to qualify and quantify murine mammary stem/progenitor cells. Our rationale lies on our recent findings of in vitro study of different fractions of murine stem/progenitor cells. When we use isolated primary epithelial cells for in vitro mammosphere formation, we found that stem cell enriched fraction and progenitor cell enriched fraction both formed very small mammospheres (≤ 50 µm) and these spheres appear to be of clonal origin (one cell gives rise to one sphere). When we plated these small spheres into 3D extracellular matrix for colony formation, however, they gave rise to two distinct structures: stem-enriched fraction generated predominately solid structure while progenitor-enriched fraction is dominated by hollow structures. Previous studies have linked the solid structure to the basal/myoepithelial lineage and the hollow structure to the luminal lineage. We thus suspected that the small mammospheres derived from the stem or progenitor enriched fractions could be originated from single stem or progenitor cell, and the number of spheres could indicate the number of original stem/progenitor cells within these enriched fractions. Subsequent in vivo transplantation with single sphere or single solid structure cultured in 3D extracellular matrix derived from green fluorescent protein transgenic mice proved that single sphere or 3D solid structure can repopulate the gland-free mammary fat pad. To conclude, the in vitro mammosphere formation in combination with subsequent differentiation in 3D extracellular matrix can be used as a robust in vitro assay for qualification and quantification of murine mammary stem/progenitor cells. This in vitro assay will greatly facilitate our understanding of genes regulate stem cell self-renewal, proliferation, differentiation as well as mechanisms keeping them at quiescent state within the niche.

P1-04-03
The Effect of Survivin Downregulation on Radiosensitization of Breast Cancer Cell Lines Grown under Adherent and Stem Cell Promoting Culture Conditions.
Debeb BG, Larson R, Xu W, Lacerda L, Reuben JM, Buchholz TA, Ueno NT, Woodward WA, Morgan Welsh Inflammatory Breast Cancer Clinic and Research Group, The University of Texas M.D. Anderson Cancer Center, Houston, TX

Survivin, the smallest member of the inhibitor of apoptosis protein (IAP) family, is a bifunctional protein that has been implicated in both...
control of cell division and inhibition of apoptosis. Survivin has been shown to be involved in radiation resistance of various cancer types and its expression is increased by sublethal doses of irradiation in both differentiated and cancer stem cell (CSC) population. However, it is unknown whether suppression of survivin radiosensitizes the CSC population or diminishes its self renewal ability. Herein, we cloned the survivin dominant-negative mutant lacking a phosphorylation site (T34A) (Mesri et al., 2001 JCI) into the lentiviral LeGo vectors and assessed mammosphere formation and radiosensitization in MCF7, SUM149 and SUM159 cell lines grown under adherent or stem cell promoting conditions. We found an induction of survivin by western blotting in the dominant negative mutant (T34A)-transfected cell lines. Moreover, we observed a higher than two-fold increase in the Sub-G1 population as well as an increased Caspase 3 activity in the T34A-transfected SUM149 and SUM159 cells compared to control cells indicating an anti-apoptotic function of survivin. We also found that T34A-transfected cells showed a 1.5 to 2-fold decrease in the number of mammospheres compared to the control-transfected cells. Furthermore, T34A-transfected cells showed radiosensitization in adherent cells from SUM149 and SUM159 cells but no effect was observed in MCF7 cells. However, no radiosensitization was observed in stem cell promoting culture conditions with increasing doses of radiation in all tested cell lines. This indicates that the widely used standard clonogenic assays do not optimally select anti-CSC agents and that targeted therapies should be specifically tested for their activity against the CSC population. Further functional endpoint studies will be conducted to validate the in vitro findings.

P1-04-04
Focal Adhesion Kinase Plays a Major Role in the Regulation of Human Ductal Carcinoma In Situ (DCIS) Stem Cell Activity.
Williams KE, Bundre NJ, Farnie G. University of Manchester, Paterson Institute for Cancer Research, Manchester, United Kingdom; University Hospital of South Manchester, Manchester, United Kingdom

Focal Adhesion Kinase (FAK) is a non-receptor tyrosine kinase that has been implicated in the regulation of normal mammary stem cells and cancer stem cells (CSCs) within mouse models. FAK is frequently overexpressed in human breast cancers but its role in human CSCs is not known. We aimed to investigate the role of FAK in human ductal carcinoma in situ (DCIS) stem cells (SCs). We have used PF573228 to inhibit FAK activity in SUM225 (HER2-overexpressing) and MCF10DCIS.com (HER2-normal) DCIS cell lines. PF573228 inhibits the autophosphorylation of FAK at tyrosine 397 causing inactivation. Western blot analysis confirmed PF573228 (0.1-5µM) caused a dose dependent inhibition of FAK activity in both cell lines. The in vitro mammosphere colony assay was used to measure CSC activity in both DCIS cell lines and primary DCIS samples (n=5) (LREC/01/012). Mammosphere-forming efficiency (MFE) was calculated as percentage colony formation (>60µm) in the presence or absence of PF573228 (0.1-5µM). MFE was reduced in both the SUM225 cell line (p=0.02) and in the MCF10DCIS.com cell line (p=0.04) by PF573228 at a dose concentration of ≥0.1µM (see Table 1). PF573228 (1µM) also reduced mammosphere formation in human primary DCIS cells (n=5) by 18.1±5.75% when compared to control (p=0.03).

Table One Shows the Primary Generation Mammosphere Forming Efficiency (MFE) in the DCIS cell lines.

To measure the effect of PF573228 on DCIS SC self-renewal capacity we performed secondary generation mammosphere colony assays. Primary generation mammamospheres that had been treated with PF573228 (0.1-5µM) were dissociated into a single cell suspension and reseeded out into mammosphere culture conditions with no additional PF573228. The mammosphere regeneration ratio (MRR) was calculated as the proportion of secondary mammamospheres formed relative to the number of primary mammamospheres. MRR was reduced in both the SUM225 (p=0.005) and MCF10DCIS.com (p=0.001) cell lines after treatment with ≥0.5µM or ≥1.0µM PF573228 respectively (see Table 2). Preliminary data in human primary DCIS cells (n=1) also shows a reduction in MRR, from 0.56 to 0.14 with 0.5µM PF573228. These results suggest that CSC self-renewal capacity is reduced by FAK inhibition.

Table Two Shows the Secondary Generation Mammosphere Regeneration Ratio (MRR) in the DCIS cell lines.

We conclude that FAK signalling is important in human DCIS SC activity measured by mammosphere growth and regeneration. Targeting FAK in the treatment of DCIS may reduce disease recurrence and improve patient outcome.

P1-04-05
Honig A, Diessner J, Dietl J, Wischniessen J. University of Wuerzburg, Wuerzburg, Germany

Trastuzumab (Herceptin®) has significantly improved the overall survival of patients with HER2-positive breast cancer. The efficacy of this treatment depends significantly on antibody-dependent cell mediated cytotoxicity (ADCC). However, while trastuzumab can direct NK cells towards tumor cells and thereby promote tumor cell lysis, spheroid-forming tumor-initiating cells are largely spared. Consequently, populations of surviving cells showed greatly enhanced clonogenicity in vitro and tumorigenicity in vivo. Low HER2 levels and reduced expression of activating NK cell ligands provide likely explanations for the escape of these cells from HER2-directed NK cell-dependent therapies. Moreover, recent data show that unproductive interactions between immune cells and cancer cells can induce a process called “epithelial-to-mesenchymal transition” (EMT) which enables previously differentiated cancer cells to acquire stem cell-like properties as evidenced by a CD44hi/CD24low breast cancer stem cell signature and aldehyde dehydrogenase positivity. We thus investigated whether new HER2-specific antibodies could enhance NK-cell mediated target cell lysis or inhibit the induction of tumor stem cells. The antibody pertuzumab also binds to the HER2-receptor. It inhibits homo- and heterodimerization of the HER2 receptor with HER3 receptors. We were able to show that the combination of trastuzumab and pertuzumab leads to increased antibody-binding on breast cancer cells and breast cancer stem cells, resulting in enhanced ADCC. This correlates with the clinically observed synergy between trastuzumab and pertuzumab as observed for example in the...
Neosphere trial, a neoadjuvant study for HER2-positive breast cancer. Trastuzumab emtansine (T-DM1) is an antibody-drug conjugate which combines trastuzumab with the tubulin inhibitor maytansine. Interestingly, treatment with T-DM1 largely prevented the NK cell-dependent induction of the EMT markers Twist and Snail and the characteristic downregulation of E-cadherin. Thus, T-DM1 apparently interferes with EMT and may hence prevent the re-induction of the stem cell phenotype. In line with the presumed effect against cancer stem cells, T-DM1 significantly attenuated the clonogenic potential of FACS-sorted trastuzumab-unresponsive cancer stem cells. Accordingly, our data show that these new therapeutics may be more effective against cancer stem cells and thereby promise a more sustained treatment of HER2-positive breast cancer.

P1-04-06
Ionizing Radiation Reprograms Non-Tumorigenic Cancer Cells into Cancer Stem Cells.
Chann L, Vlasi E, Lorenza DD, Dekmezian C, Pajonk F. University of California, Los Angeles, CA
Breast cancers are thought to be organized hierarchically with a small number of breast cancer stem cells (BCSCs) able to re-grow a tumor while their progeny lack this feature. BCSCs in breast cancer have been found to be relatively resistant to radiation and several groups reported enrichment for BCSCs when breast cancers are subjected to classical anticancer treatment. Differentiation of BCSCs is thought to be unidirectional but an alternative model assumes that stemness can be obtained by clonal evolution. In this study, we quantified the number of BCSCs surviving after radiation treatment. We compared the number of surviving BCSCs to the expected number and found an increase in BCSCs after irradiation that could not be explained by current models. We propose that radiation induces a BCSC phenotype in previously non-BCSCs and show that this transition is Notch-dependent and coincided with up-regulation of the transcription factors Oct4, Sox-2, Nanog, and Klf4.

P1-04-07
Poly (ADP-Ribose) Polymerase-1 (PARP-1) Is Overexpressed in Human Breast Cancer Stem Cells: Results from a Proteomic-Based Approach.
Gilabert M, Ginestier C, Audebert S, Pophillat M, Toirnon Y, Birnbaum D, Borg J-P, Charafe-Jauffret E, Gonçalves A. Institut Paoli-Calmettes, Marseille, France; U981 INSERM, Marseille, France; Université de la Méditerranée, Marseille, France; Centre d’Immunologie Marseille-Luminy, Marseille, France
Introduction: Cancer stem cells (CSC) have been increasingly recognized as playing a major role in various fields of breast tumor biology including carcinogenesis, metastasis and resistance to cytotoxic drugs and radiotherapy. Identification of protein biomarkers associated with breast CSC may help understanding CSC biology as well as identifying novel diagnostics and specific therapeutic targets. 2-D Fluorescence Difference Gel Electrophoresis (2-D DIGE) is a method that labels protein samples with fluorescent dyes before 2-D electrophoresis, enabling accurate analysis of differences in protein abundance between samples. Methods: Using flow cytometry-based ALDEFLUOR assay (ALD), we isolated CSC-enriched (ALD-positive) and non CSC-enriched (ALD-negative) cell populations of MDA-MB-453, a human breast cancer cell line. Total proteins were extracted from both fractions using urea-based buffer and subjected to 2D-DIGE. Differentially expressed spots were excised, proteins were gel-extracted, digested and identified using MALDI-TOF MS (Ultraflex, Brucker Daltonics, Billerica, USA).

Results: 2D-DIGE revealed differential expression of various protein spots between ALD-positive and ALD-negative MDA-MB-453 cells. MALDI-TOF MS analysis allowed identification of 11 differentially expressed proteins, among which 7 were down-regulated and 4 were up-regulated in ALD-positive MDA-MB-453 cells, including Poly (ADP-ribose) polymerase-1 (PARP-1). Overexpression of PARP-1 in MDA-MB-453 cells was further confirmed by western blot using specific monoclonal antibody and such an observation was extended to 4 additional human breast cancer cell lines including HCC1937, MDA-MB-436, SUM149 and SUM159. These 5 human breast cancer cells were found to display a limited short-term sensitivity (within the micromolar range) to olaparib, a specific PARP-1 inhibitor. However, a negative correlation was found between the level of overexpression and the ability of olaparib to inhibit the growth of ALD-positive cells. Conclusion: A proteomic-based approach revealed that PARP-1 was up-regulated in ALD-positive, CSC-enriched from various human breast cancer cell lines. Such an overexpression may contribute to clinical resistance to PARP-inhibitors.

P1-04-08
Distribution of ALDH1 Positive Stem Cells in Benign Mammary Tissue from Women with and without Breast Cancer.
Isfoss BL, Holmqvist B, Alm P, Olsson H. Telemark Hospital, Skien, Norway; Lund University, Lund, Sweden
Background and Aims. ALDH1 in female breast tissue has been linked to stem cells, but little is known about the benign cellular organisation in situ. We investigated the distibution of ALDH1 immunoreactive (ALDH1+) cells in histomorphologically benign breast tissue from 28 women with or without breast cancer.

Methods and Results. ALDH1+ cells were detected in benign tissue of women age 20 - 72, located most commonly within the luminal and intermediate ductular levels and in the stroma. ALDH1+ cell populations and Ki-67+ cell populations were present in separate ductules, both cell types rarely showing epithelial differentiation. ALDH1+ cells were non-reactive to Ki-67 and oestrogen receptor. Stromal round/oval ALDH1+ non-leukocyte cells in both age groups expressed contractile protein. There was a lower concentration of luminal and intermediate ductular ALDH1+ cells in post-menopausal women than pre-menopausal women, lower in cancer than non-cancer patients, and higher in women on exogenous hormones.

Conclusions. The study provides further evidence for the stem cell character of ALDH1+ cells, here in benign breast tissue of cancer and non-cancer women throughout non-lactating adult life, and contributes evidence of benign stromal ALDH1+ cells. The distribution of ductular ALDH1+ stem cells appears to be influenced by hormonal status.

Biphasic Effects of Docetaxel and Hedgehog Signaling Antagonists on Breast Cancer Tumor-Initiating Cells In Vivo.
Zhang X, Moraes RC, Landis MM, Wu M-F, Hilsenbeck SG, Cairo MM, Tofigar R, Chang JC, Lewis MT. Baylor College of Medicine, Houston, TX; Karolinska Institutet, Novum, Sweden
Recent data suggest the existence of a subset of breast cancer cells variously termed cancer stem cells, tumor-initiating, or tumor-propagating cells, that are capable of self-renewal and of regenerating tumors upon transplantation that are biologically consistent with the tumor of origin. These cells appear to be intrinsically resistant
RESULTS: Our results show that PELP1 uniquely recognizes histones modified by arginine dimethylation, arginine citrullination and lysine dimethylation. Phosphorylation of residues adjacent to a methyl modification affects the ability of PELP1 to recognize histone methylation. Using various deletions of PELP1 peptides, we have found that PELP1 acts as a module for recognition of a specific histone modification through the carboxyl-terminal glutamic acid rich region. Reporter gene assays showed that PELP1 functionally interacts with arginine methyltransferases including CARM1 and PRMT6, both shown to be dysregulated in human cancers, and synergistically enhances ER-transactivation. Chromatin immunoprecipitation assays revealed that PELP1 has the potential to alter histone H3 arginine methylation status at ER target gene promoters. PELP1 knockdown via PELP1-siRNA liposomes using xenograft based assays resulted in decreased arginine dimethylation with concomitant reduction in tumor volume.

Conclusions: Our findings suggest that PELP1 is a reader of histone methyl modifications and deregulation of PELP1 may have implications on tumor proliferation via epigenetic alterations at ER target promoter. Targeting these epigenetic alterations through inhibition of PELP1 and the arginine methyltransferases could be a promising cancer therapeutic. This study was funded by CPRIT pre-doctoral fellowship grant and Komen KG090447.

P1-05-02
Epigenetic Regulation by Alcohol Reactivates Estrogen Receptor alpha in Estrogen Receptor alpha-Negative Cells.

Wong AW, Nunez N. University of Texas at Austin, Austin, TX

Introduction: Alcohol consumption is an established risk factor for breast cancer development and contributes to mammary tumorigenesis through the regulation of estrogen receptor alpha (ERα) expression. Previously, we reported that alcohol consumption in the MMTV- neu ERα-negative mouse model of human breast cancer resulted in significantly increased ERα expression compared to non-alcohol consuming mice. Thus, our results indicated that alcohol consumption led to reexpression of ERα in an ERα-negative mouse model. Several lines of evidence suggest that ERα expression in ERα-negative cancer cells is inhibited through epigenetic mechanisms. In this study, we examine the role of alcohol on ERα reactivation through changes in histone modifications, DNA methylation, and recruitment of transcriptional regulation complexes on the ERα promoter, in vitro. Methods: ERα-negative MDA-MB-231 human breast cancer cells were treated with 0.1%, 0.2% and 0.5% v/v ethanol in culture media for 24 h. Chromatin immunoprecipitation (ChIP) assays were used to examine the enrichment of active and inactive markers of chromatin on the ERα promoter following alcohol treatment. DNA methylation at three ERα promoter CpG dinucleotide sites was assessed following alcohol treatment using methyl-sensitive restriction enzyme (MSRE)-qPCR. ChIP assays are used to determine the binding of the transcriptional regulation complexes, pRB2/p130-E2F4/5-HDAC1-SUV39H1-MSRE-qPCR, to the ERα promoter following alcohol treatment. MCF-7 human breast cancer cells served as an ERα-positive control.

Results: We report that histone modifications were affected by alcohol treatment in a dose-dependent manner. Enrichment levels of all five chromatin markers tested, which includes markers of active and inactive transcription, were significantly altered as a result of alcohol treatment (p<0.05). We also found significantly decreased DNA methylation at three ERα promoter CpG sites as a result of alcohol treatment (p<0.05). Experiments testing the recruitment of the
transcriptional regulation complexes, pRb2/p130-E2F4/5-HDAC1-SUV39H1-p300 and pRb2/p130-E2F4/5-HDAC1-SUV39H1-DNMT1, are currently ongoing. Discussion: ERα expression has been linked to mammary carcinogenesis and clinical outcome in breast cancer patients. However, approximately one out of three breast cancers lack ERα expression at the time of diagnosis and many breast cancers lose ERα expression during the course of tumor progression. Thus, understanding the regulation of ERα expression in breast cancer cells is critical and results from this study will facilitate the development of novel therapeutic strategies and treatment options for hormone-resistant breast cancer.

Relationship between Polycomb Repressive Complex EZH2/CBX7, Large Non-Coding RNA ANRIL and Stem Cells Biomarkers in Triple Negative Breast Carcinomas: Important Role in Carcinogenesis through an Epigenetic Silencing Process and New Clues for Targeted Therapies.

Background: Epigenetic deregulation and carcinogenesis are intimately connected and gene silencing is a major consequence of epigenetic modifications. Polycomb group proteins (PcG) play important roles by inhibiting chromatin remodeling and transcription, silencing tumor suppressor genes, regulating stem cells and interconnecting with Wnt/beta-catenin, TGF-beta and Sonic-Hedgehog pathways. EZH2 is a transcriptional repressor and acts mainly as an oncogenic silencer gene involved in cell cycle regulation. Large non coding RNA are major regulators of oncogenic and oncosuppressive pathways at epigenetic, transcriptional and post-transcriptional levels. Recent studies have showed that (i) EZH2 overexpression is associated with cancer progression and acquisition of stem cell properties and (ii) disruption of ANRIL/CBX7 interactions repress the INK4b/ARF/INK4a locus. The aim of the study was to analyze PRC complexes, large non-coding RNA ANRIL and downstream signaling targets in triple negative breast carcinomas (TNC).

Design: By using real time quantitative RT-PCR in a series of 432 invasive breast ductal carcinomas (IDC), we quantified gene expression levels of the large non coding RNA ANRIL, PcG (EZH2, CBX7, SUZ12), stem cells markers (ALDH1, CD133, ASCL1) and oncosuppressor genes (p15, p16 and p19). Immunohistochemistry (IHC) was performed using EZH2, CBX7, ALDH1 and b-catenin Abs. We compared mRNA expression levels and IHC intensity score in TNC with non TNC and normal breast parenchyma.

Results: EZH2 overexpression was respectively found by RT-PCR and IHC in the TNC subgroup of IDC. We observed variable mRNA expression levels of SUZ12, CBX7, ANRIL, ALDH1, CD133, ASCL1, p15, p16 and p19. IHC showed EZH2 and CBX7 nuclear staining. Mutual positive correlations were found between EZH2, CBX7, ALDH1, ASCL1 and CCND1 (p<0.05). Conclusion: Polycomb EZH2/CBX7 and the large non coding RNA ANRIL are epigenetic transcriptional repressors overexpressed in the TNC subgroup of IDC. Their implication in the process of gene silencing (p16, p15, p19), activation of oncogenic pathways (Wnt, TGFβ) and tumor stem cells self-renewal may explain several hallmarks of TNC and open new avenues to target this aggressive subgroup.

P1-05-04
Distinct Patterns of Promoter CpG Island Methylation of Breast Cancer Subtype Are Associated with Different Stem Cell Phenotype.
Park SY, Kwon HJ, Choi Y, Lee HE, Kim S-W, Kim JH, Kim IA, Jung N, Cho N-Y, Kang GH. Seoul National University Bundang Hospital; Seoul National University Hospital; Cancer Research Institute, Seoul National University

Background: Although DNA methylation profiles in breast cancer have been connected to breast cancer molecular subtype, there have been no studies of the association of DNA methylation with stem cell phenotype. This study was designed to evaluate promoter CpG island methylation of 15 genes with regard to breast cancer subtype and to investigate whether the patterns of CpG island methylation in each subtype are associated with cancer stem cell phenotype represented by CD44+/CD24- or ALDH1 expression.

Methods: We performed MethyLight analysis for the methylation status of 15 promoter CpG island loci involved in breast cancer progression (APC, DLEC1, GRIN2B, GSTP1, HOXA1, HOXA10, IGF2, MT1G, RARB, RASSF1A, RUNX3, SCD3, SUZ12, TMEM124, and TMEFF2) and determined cancer stem cell phenotype by CD44+/CD24- and ALDH1+ immunohistochemistry in 36 luminal A, 33 luminal B, 30 luminal-HER2, 40 HER2 enriched, and 40 basal-like subtypes of breast cancer.

Results: The number of CpG island loci methylated was significantly different among subtypes and it was highest in luminal-HER2 subtype and lowest in basal-like subtype. Methylation frequencies and levels in 12 out of the 15 genes were significantly different among all subtypes and basal-like subtype showed significantly lower methylation frequencies and levels in nine genes, compared to luminal A, luminal B, HER2 enriched, and luminal-HER2 subtypes. CD44+/CD24- or ALDH1+ putative stem cell populations were most enriched in basal-like subtype. The methylation of promoter CpG islands was significantly lower in CD44+/CD24- cell (+) tumors, compared to CD44+/CD24- cell (-) tumors, and even within the basal-like subtype, ALDH1 (+) tumors also had significantly lower methylation, compared to ALDH1 (-) tumors.

Conclusions: Our findings showed that promoter CpG island methylation was significantly different according to breast cancer subtype and stem cell phenotype of tumor, suggesting that breast cancers have different methylation patterns according to molecular subtypes and it is associated with stem cell phenotypes of the tumor.

P1-05-05
Patani N, Jiang WG, Newbold RF, Mokbel K. The London Breast Institute, The Princess Grace Hospital, London, United Kingdom; University Department of Surgery, Cardiff University School of Medicine, Cardiff, United Kingdom; Brunel Institute of Cancer Genetics and Pharmacogenomics, Brunel University, London, United Kingdom

Background: Gene expression is stringently controlled under physiological conditions by epigenetic mechanisms, including the specific methylation of cytosine residues within CpG dinucleotides and orchestrated adjustments in the histone dependent organisation of chromatin. The organisation of DNA within the chromatin template depends upon highly conserved histone proteins, the properties of which continue to exceed the simplistic packaging role originally assigned to them. Histone modifier enzymes impart a dynamic histone code and specific permutations have significant implications for
chromatin topology and the functional configuration of promoters. This study follows our initial report describing potential tumour suppressor function associated with the histone methyltransferase SETD2 in human breast cancer. The objective was to evaluate the expression profiles of sixteen additional histone modifier genes in women with primary operable breast cancer within a well annotated cohort with extended follow-up.

Methods: Primary breast cancer tissues (n=127) and adjacent benign/normal tissues (n=33) underwent RNA extraction and reverse transcription. The transcript levels of histone modifier genes were evaluated using real-time quantitative PCR, these included: histone acetyltransferases (CREBBP), Class 1 (HDAC1 and HDAC2), II (HDAC5) and III (SIRT1) histone deacetylases and histone methyltransferases (SUVR9H1 and SUVR9H2) amongst others. Transcript levels were analysed against a range of clinico-pathological variables, including: tumour size, grade, nodal involvement, histological subtype, receptor status, TNM stage, Nottingham Prognostic Index, disease free and overall survival over a 10 year follow-up period.

Results: Transcript levels of the histone modifier genes in breast cancer tissues differed significantly from non-malignant samples (HDAC5, HDAC1, KDM4A and KDM6A). Amongst breast cancers, significant differences in transcript levels were associated with established pathological parameters and prognostic indices: tumour grade (KAT5, HDAC1, KDM4A, SUVR9H1 and KDM6A), receptor status (KAT5, SMYD3 and KDM1A), histological type (KAT5, KDM5C, MYST1, KDM4A and MLL), TNM stage (SUVR9H1, KAT2B, KDM1A, KDM4A, KDM5C, MYST1, HDAC5 and KAT5), Nottingham Prognostic Index (KDM5C, MLL, MYST1 and SMYD3), disease free survival (SUVR9H1, SMYD3, HDAC5, KDM6A, HDAC1, KDM1A, KDM4A, MYST1, KDM5C, KAT5 and MLL) and overall survival (MYST1). Interestingly, significant correlations were also identified between the differential expression profiles of particular histone modifying genes.

Conclusion: The expression profiles of histone modifier genes differ significantly between breast cancer tissues and normal/benign samples. Particular expression profiles in breast cancer are significantly associated with established pathological parameters, prognostic indices, disease free and overall survival. The biological significance and clinical relevance of altered expression of specific histone modifier genes and particular permutations of misexpression remain to be fully elucidated and further study is warranted. Epigenetic signatures derived from histone modifier genes may offer utility as biomarkers and histone modifier enzymes have potential for targeted therapeutic strategies.

Hypermethylation 14-3-3- Sigma Promoter as a Biomarker to Screening for Metastasis and Potential Prognostic Factor in Breast Cancer Patients.

Martinez-Galan J, Torres-Torres B, Gonzalez-Vicente A, Ruiz-Vazmediano J, Delgado-Perez JR. Hospital Universitario Virgen de las Nieves, Granada, Spain; Centro de Investigaciones Biomédicas, Granada, Spain

Background: 14-3-3sigma is an epithelial marker whose expression is induced by DNA damage through a p53-dependent pathway. 14-3-3sigma functions sequesters cyclin B1-CDC2 complexes outside the nucleus and thereby contributes to a G2 arrest. Epigenetic silencing by CpG methylation, p53 inactivation, and proteasome-dependent proteolysis leads to loss of 14-3-3sigma and is often observed in precancerous lesions and likely to be causally linked to the onset of cancer.

Objective: To correlation methylation levels of promoter 14-3-3 sigma with association prognostic factors in breast cancer and their correlation with phenotype luminal.

Material and Methods: This is a prospective study we quantified methylation levels of promoter 14-3-3 sigma gene in 107 women with breast cancer and 108 control subjects by Real Time QMS-PCR SYBR green (methylation-specific PCR) and analyzed association with prognostics factor in breast cancer.

Results: Median age was 58 years (32-88); 69% were postmenopausal women. Nodal involvement N0; 63%,N1;30%,N2;7%, tumor size (T1;58%,T2;35%,T3;4%,T4;4%) and grade G1;20%,G2;37%,G3;30%). Significant differences between breast cancer patients (pts) and healthy controls in relative serum levels of methylation gene promoters 14-3-3s (p=0.0047) were detected. Presence of methylated 14-3-3-σ in serum of breast cancer patients was associated with T3-4 stage (OMS) (p<0.05) and nodal positive status (p<0.05). With a median follow up 6 years we saw more probability of developing distant metastasis in patients with methylation 14-3-3 sigma (p<0.05).

Conclusions: Hypermethylation of the 14-3-3 sigma promoter is an early and frequent event in breast neoplastic transformation, leading to the suggestion that silencing of 14-3-3 sigma may be an important event in tumor progression and particularly in breast carcinogenesis. This study identifies the presence of variations in global levels of methylation promoters genes in patients breast cancer with different phenotype classes and shows that these differences have clinical significance. Perhaps in the detection of CpG methylation of 14-3-3sigma may be used for diagnostic and prognostic purposes.

Correlation between Gene Variants in CYP19 (Aromatase) and TCL1A with Disease and Tolerability Endpoints in the ATAC Trial.

Rae JM, Sestak I, Henry NL, Drury S, Hayes DF, Thibert JN, Lopez-Knowles E, Salter J, Pineda S, Cuzick J, Dowsett M. University of Michigan, Ann Arbor, MI; Queen Mary University, London, United Kingdom; Royal Marsden Hospital, London, United Kingdom; Breakthrough Breast Cancer Research Centre, London, United Kingdom

Aim: To assess whether candidate polymorphisms in CYP19 (aromatase) and TCL1A were associated with recurrence, musculoskeletal symptoms (MSKs) or hot-flushes in primary estrogen receptor-positive breast cancer in postmenopausal women treated with tamoxifen or anastrozole.

Background. Recently, variants rs10459592 and rs4775936 in CYP19 (aromatase) and TCL1A were associated with recurrence, MSKs or hot-flushes in primary estrogen receptor-positive breast cancer in postmenopausal women treated with tamoxifen or anastrozole.

Methods: This is a prospective randomized double-blind placebo-controlled trial that compared the adjuvant use of anastrozole versus tamoxifen for 5 years. The trial’s detailed efficacy and safety data, long term (10-year) follow-up and high event rate make it an ideal setting for pharmacogenetic single nucleotide polymorphism (SNP)
validation studies. Here we report our findings testing for correlations with 3 SNPs in CYP19 and TCL1A with clinical outcomes including any disease recurrence, distant recurrence, MSKs, and hot-flushes. 

Methods: Genotypes were determined using ABI Taqman assays without knowledge of the patient’s treatment assignment or outcomes. Hazard ratios (HR) and corresponding 95% confidence intervals (CI) were estimated by the proportional hazards regression model and were adjusted for: age, tumor size, grade, and nodal status (for survival analyses) and age, hormone replacement therapy, body mass index, and smoking (for toxicity analyses).

Results: 807 patients were genotyped for CYP19 SNPs rs10459592 and rs4775936 and 842 for TCL1A SNP rs11849538. The rs10459592 genotype frequencies were 16.6% Wt/Wt, 51.5% Wt/Vt, and 32% Vt/Vt. There was a trend towards decreased recurrence in Vt/Vt and Vt/Wt compared to Wt/Wt (HR=0.77 [0.50-1.22] and 0.68 [0.42-1.09], p[ trend]=0.1), similar for both anastrozole- and tamoxifen-treated patients and also similar for distant recurrence. For the same SNP, there was a trend toward more MSKs in Vt/Vt and Vt/Wt compared to Wt/Wt (HR=1.22 [0.80-1.88] and 1.47 [0.94-2.36], p[ trend]=0.08), primarily due to the effect in the tamoxifen cohort (HR=1.88 [0.89-3.99], p[ trend]=0.1). The rs4775936 genotype frequencies were 26.0% Wt/Wt, 52.1% Wt/Vt and 21.9% Vt/Vt. Trends in the same direction as those for rs10459592 were found with rs4775936, albeit less significant. The TCL1A genotype frequencies were 77.5% Wt/Wt, 20% Wt/Vt and 2.5% Vt/Vt. No association was observed between TCL1A genotypes and recurrences or MSKs, however, the small number of Vt/Vt patients on tamoxifen had greater incidence of hot flushes (HR=1.99 [0.9-3.91], p=0.09).

Conclusion: These data do not support an association between the TCL1A 3’ variant and AI-induced MSKs independent of severity. Our data do support the CYP19 SNP rs10459592 and the loosely linked rs4775936, which previously were associated with letrozole efficacy, as probably being associated with better disease outcome on anastrozole and tamoxifen and with worse drug side effects. The degree of association requires definition in further data sets.

P1-06-03 Predictive Value of HER2, Topoisomerase-II (Topo-II) and Tissue Inhibitor of Metalloproteinases (TIMP-1) for Efficacy of Taxane-Based Chemotherapy in Intermediate Risk Breast Cancer – Results from the EC-Doc Trial.

Gluz O, Eber R, Kates R, Kreipe H, Bartels A, Liedike C, Pelz E, Huober J, Kuhn W, Nitz U, Hartmann A, Harbeck N, Brünnner N. West German Study Group, Moenchengladbach, Germany; University Hospital Erlangen, Erlangen, Germany; Medizinische Hochschule Hannover, Hannover, Germany; University Copenhagen, Copenhagen, Denmark; University Hospital Muenster, Muenster, Germany; Pathology Practice, Viersen, Germany; Ummern University Hospital Tuebingen, Tuebingen, Germany; Kantnnonhospital St. Gallen, St. Gallen, Switzerland; University Hospital Bonn, Bonn, Germany; University Hospital Cologne, Cologne, Germany

Background:

Despite extensive research, there is still no consensus on optimal predictors for use of taxane-based chemotherapy (cht) in early breast cancer. Some studies have revealed HER2 as a significant predictive marker for efficacy of taxanes and anthracyclines. TIMP-1 and Topo-II are reported to be predictive for anthracycline efficacy. In our previous reports, both Ki-67>20% and central G3 status emerged as significant predictors for taxane benefit. We have now compared HER2 and Topo-II (as protein expression and gene amplification) and TIMP-1 immunoreactivity as well as factor combinations (HT (HER2/TIMP-1) and 2T (Topo-II/TIMP-1)) regarding their predictive value for benefit from taxane-based cht.

Methods: The EC-Doc trial randomized 1950 patients with 1-3 positive LN to 6x CEF/CMF vs. 4xE-4xD. Significantly better DFS and OS favoring EC-Doc have been previously reported (Nitz et al., SABCS 2008). Protein expression and gene amplification data as well central histology/grade were available for 772 patients. Survival analysis was performed using Cox proportional hazards and Kaplan-Meier statistics. Analysis of HER2 survival impact status was prospectively planned.

Results: The entire and the investigated study populations did not differ regarding baseline characteristics. After median follow up of 64 months, both DFS (5y 90% vs. 80%, p=0.006) and OS (5y 95% vs. 92%, p=0.022) rates significantly favored EC-Doc vs. CEF in this cohort as well. HER2 over-expression (3+ and/or FISH≥2.0) was reported in 158 tumors (20%), Topo-II aberration (deletion or amplification) was reported in 78 (49.4%) HER2+ and in 83 (13.6%) HER2-negative tumors; 496 tumors were classified as TIMP-1 immunoreactive (65.2%). None of these factors were significantly prognostic for EFS in this collective. Regarding DFS, EC-Doc was strongly superior to FEC in HER2+ tumors (HR=0.29, 95%CI: 0.12-0.7, p=0.006) but not in HER2- tumors (p=0.18). In Topo-II aberrated tumors, the benefit of EC-Doc was remarkably strong (HR=0.28, 95% CI: 0.11-0.69, p=0.006), whereas the benefit was not significant in Topo-II normal tumors (p=0.16), which comprise more than ¾ of the total. In contrast, Topo-II protein overexpression (>10%) was not associated with a stronger benefit in either subgroup. The superiority of EC-Doc to FEC was significant in the larger group of TIMP-1 immunoreactive tumors (HR=0.57, p=0.025) but not in TIMP-1 negative tumors (p=0.14), similar behavior was seen in “HT” and “2T” subgroups (significance with HR about 0.5 in the “+” subgroups).

In a multivariate model for DFS including age, tumor size, Ki-67, central grade, HR, HER2, Topo-II aberration, TIMP-1 status, therapy and interactions of all these factors with therapy arm, the only significant therapy interaction was that of (high) Ki-67 (HR=0.76, 95% CI: 0.59-0.98, p=0.03); significant main effects in this model were age, central grade, and Ki-67.

Conclusions: These data suggest predictive significance for Topo-II aberration, TIMP immunoreactivity and HER2 over-expression as well as a multivariate predictive significance of high Ki-67 for enhanced benefit of taxane-based cht.

Martin M, Rodríguez-Lescure A, Stijlemans IJ, Munárriz B, Ruiz-Borrego M, Davis C, Crespo C, Rodríguez CA, Ebbert MTW, Álvarez I, Furió V, Bastien RRL, Garcia AM, Cheang MC, Palacios J, Ellis MJ, Carrasco E, Casas MI, Caballero R, Perou CM, Bernard PS. Hospital General Universitario Gregorio Marañón, Madrid, Spain; Hospital Universitario de Elche, Elche, Spain; University of Utah Health Sciences Center/Huntsman Cancer Institute, Salt Lake City, UT; Hospital Universitario La Fe, Valencia, Spain; Hospital Universitario Virgen del Rocio, Sevilla, Spain; Hospital Universitario Ramón y Cajal, Madrid, Spain; Hospital Clínico Universitario de Salamanca, Salamanca, Spain; The ARUP Institute for Clinical and Experimental Pathology, Salt Lake City, UT; Hospital de Donostia, San Sebastián, Spain; Hospital Clínico Universitario San Carlos, Madrid, Spain; University of North Carolina at Chapel Hill; Washington University in St Louis, St Louis; Spanish Breast Cancer Research Group, GEICAM, San Sebastián de los Reyes, Madrid, Spain

BACKGROUND
Predictive factors of survival benefit from taxane over non-taxane based adjuvant chemotherapy regimens are needed. Recent studies have suggested that “intrinsic” breast cancer subtypes may differ in their responsiveness to specific chemotherapeutics. Tumor samples from GEICAM 9906 study (Randomized Phase 3 Trial of Fluorouracil, Epirubicin, and Cyclophosphamide Alone [FEC] or FEC Followed by Paclitaxel [FEC-P]) for Early Breast Cancer, JNCI 100:805, 2008) were gene expression profiled using the RT-qPCR PAM50 clinical test in order to identify potential predictive markers of taxane clinical benefit.

METHODS
793 formalin-fixed paraffin-embedded tumors were studied and classified into intrinsic subtypes (Luminal A & B, HER2-enriched, Basal-like, and Normal) using the PAM50 test. The assay also provided gene expression scores for the standard protein biomarkers usually measured by immunohistochemistry (ESR1/ER, PGR/PR, and ERBB2/HER2) and a meta-gene score for proliferation (proliferation signature) and for a luminal gene signature. Intrinsic subtypes, individual genes, or meta-genes were correlated with disease-free survival (DFS). Multivariable Cox regression analyses were performed to determine the significance of the interaction between treatment and intrinsic subtypes, single genes and meta-genes, adjusting for standard clinicopathological factors.

RESULTS
A 8.7 years follow-up update of GEICAM 9906 trial confirmed a statistically significant advantage of FEC-P over FEC in terms of DFS (p=0.016) and OS (p=0.013). Exploratory analyses for prognostic factors showed that treatment arm (p=0.016), tumor size (p=0.0001), type of surgery (p=0.003), tumor grade (p=0.001), nodal status (p=0.0001), intrinsic subtypes (p=0.0001), ERBB2 (p=0.031), PGR (p=0.0001), Luminal meta-gene (p=0.006) and Proliferation meta-gene (p=0.0001) were associated with DFS. A Cox multivariable analysis using the backward and forward method showed that only the treatment arm (P=0.052), tumor size (p=0.0003), nodal status (p=0.001), intrinsic subtypes (p=0.045) and Proliferation (p=0.008) were prognostic for DFS. Concerning predictive factors, exploratory analyses were performed and interaction tests were calculated. Theses analyses showed that FEC-P was superior to FEC in low PGR expression (HR= 0.68, p=0.034) and not in high PGR group (HR=0.83, p=0.245); interaction test p=0.358. Similarly, FEC-P was superior in low ERBB2 expression (HR=0.67; p=0.005) and not in the high ERBB2 group (HR=0.92, P=0.707); interaction test p=0.256. Interestingly, superiority of FEC-P was observed for the low Proliferation Signature group (HR=0.58, p=0.006) in contrast to the high proliferation group (HR=0.93, p=0.633); the interaction test showed an almost statistical significant difference (p=0.069). The FEC-P arm showed improved outcome in all genomic intrinsic subtypes, although no subtype alone reached statistical significance.

CONCLUSION
Our study suggests that the PAM50 proliferation signature could be predictive of benefit for adding weekly paclitaxel to the adjuvant chemotherapy FEC regimen. These results need further validation in an independent study.

The Importance of CXCL10 and CXCR3-A in Breast Cancer.
Hilborn E, Sivik T, Kot A, Forander T, Skoog L, Nordenskjöld B, Stål O, Jansson A. Faculty of Health Sciences, Linköping, Sweden; Karolinska Institutet

Background: CXCL10 is a chemokine with chemo attractant properties which signals through G protein-coupled receptor CXCR3. At least two reported isoforms exists; CXCR3-A and CXCR3-B. CXCL10 is involved in the recruitment of leukocytes, immune modulation and angiogenesis. In animal models CXCL10 inhibits tumour growth, metastase formation and inhibits angiogenesis. The receptors have opposite features; CXCR3-A mediates proliferative or anti-apoptotic response and CXCR3-B mediates growth inhibition and apoptosis in response to ligand binding. The aim of this study was to investigate the role of CXCL10 and CXCR3-A as prognostic or tamoxifen treatment predictive factors in breast cancer.

Material and Methods: A randomized tamoxifen trial comprising 1,780 breast cancer patients was conducted in Stockholm, Sweden, 1976-1990. All patients had lymph node negative primary breast cancer and were postmenopausal at the time of diagnosis. The patients were randomized to tamoxifen or no endocrine treatment. We analyzed the protein expression of CXCL10 and the receptor CXCR3A with immunohistochemistry using tissue microarrays, which were constructed from paraffin blocks originating from 912 patients. CXCL10 and CXCR3A could be scored in 793 (87%) and 735 (81%), respectively.

Results: High expression of CXCL10 was associated with significant benefit of tamoxifen treatment concerning local recurrence and breast cancer survival (P=0.02 and P=0.008). For patients with high CXCL10 expression, tamoxifen decreased the risk concerning local recurrence (rate ratio (RR) = 0.56, 95% C.I. 0.33-0.97, P=0.0029) and breast cancer survival (RR 0.6 95% C.I. 0.39-0.97, P=0.023). High expression of CXCR3-A was associated with significant benefit of tamoxifen treatment concerning total recurrence and breast cancer survival (P=0.00001 and P=0.004, respectively). For patients with high CXCR3-A expression, tamoxifen decreased the risk of total recurrence (RR 0.54 95% C.I. 0.35-0.83, P=0.005) and breast cancer survival (RR 0.49 95% C.I. 0.35-0.89, P=0.00003). On the opposite, in the cohort of patients with no endocrine treatment and high CXCR3-A expression, there was an increased risk of total recurrence (P=0.003).
Conclusions: This study indicates that high expression of CXCL10 can be used as predictive markers for tamoxifen treatment. Further, high expression of CXCR3-A is related to bad prognosis and predicts tamoxifen treatment in breast cancer patients. This needs to be further evaluated.

P1-06-07
TIMP-1 in Combination with HER2 and TOP2A for Prediction of Benefit from Adjuvant Anthracyclines in High Risk Breast Cancer Patients.
Hertel PB, Tu D, Ejlersen B, Jensen M-B, Balslev E, Jiang S, O’Malley FP, Pritchard Ki, Shepherd LE, Bartels A, Brünner N, Nielsen TO. Faculty of Life Sciences, Univ of Copenhagen, Copenhagen, Denmark; National Cancer Institute of Canada, Kingston, ON, Canada; Rigshospitalet, Copenhagen, Denmark; Danish Breast Cancer Cooperative Group, Copenhagen, Denmark; Herlev Hospital, Herlev, Copenhagen, Denmark; Mount Sinai Hospital, Toronto, ON, Canada; University of Toronto, Toronto, ON, Canada; BCCA - Vancouver Cancer Centre, Vancouver, BC, Canada

Purpose: HER2 amplification, TOP2A aberrations and absence of TIMP-1 (Tissue Inhibitor of Metalloproteinase-1) expression in breast carcinomas have been associated with incremental benefit from anthracycline-containing adjuvant chemotherapy in several reports. In the DBCG 89D trial, we demonstrated that the predictive value of these markers improved when they were combined in a profile and the present study was undertaken to validate these findings in NCIC CTG MA.5, a similar but independent clinical trial.

Design: TIMP-1 was examined by immunohistochemistry in archival tumor tissue from 403 of 716 premenopausal high-risk patients with known HER2 and TOP2A status who were randomized to CEF or CMF in the MA.5 trial. Patients were classified according to 2 predefined marker profiles – the HT profile (HER2,TIMP-1) and the 2T profile (TOP2A, TIMP-1) and the statistical analyses were performed as closely as possible to the analytical approach used previously in the MA.5 trial and when analysing the biomarker profiles in the DBCG 89D trial.

Results: 98 (24%) patients had no TIMP-1 staining of tumor cells, 27% were HER2 amplified, and 18% were TOP2A aberrant. 44% of patients were classified as HT responsive (HER2-positive and/or TIMP-1 negative) and 37% as 2T responsive (TOP2A aberrant and/or TIMP-1 negative). There was no heterogeneity in treatment effect of CEF versus CMF according to TIMP-1. In HT responsive patients, CEF was superior to CMF with improved RFS (adjusted HR, 0.64; 95% CI, 0.42 to 0.98) and a borderline-significant improvement in OS (adjusted HR, 0.66; 95% CI, 0.42 to 1.04). A significant HT profile versus treatment interaction was detected for OS (P=0.03). In 2T responsive patients, CEF was superior to CMF with borderline significant improvement in RFS (adjusted HR, 0.67; 95% CI, 0.43 to 1.03), and with improvement in OS (adjusted HR, 0.58; 95% CI, 0.36 to 0.93). A significant 2T profile versus treatment interaction was detected for OS (P=0.01).

Conclusion: In the MA.5 trial, we have validated the HT and 2T profiles as predictors of incremental benefit from anthracycline-containing chemotherapy. The proportion of patients categorized as anthracycline responsive increases from 18-27% when using individual markers to 37-44% when combining TIMP-1 with either HER2 or TOP2A. Patients with responsive profiles had a 34-42% relative reduction in mortality when treated with CEF. In contrast, patients with non-responsive profiles (56-63% of patients) had no incremental benefit from CEF compared with CMF. All 3 biomarkers are easily applied in the pathology lab and as such could be used in daily clinical practice to select patients for anthracycline or non-anthracycline containing adjuvant chemotherapy.

P1-06-08
Effect of Treatment Emergent Symptoms on Relapse Free Survival: NCIC CTG MA.12 a Randomized Placebo-Controlled Trial of Tamoxifen after Adjuvant Chemotherapy in Pre-Menopausal Women in Early Breast Cancer.
Chapman J-AW, Shepherd LE, Le Maitre A, Pritchard Ki, Graham BC, Gelmon KA, Bramwell VH. NCIC Clinical Trials Group, Queen’s University, Kingston, ON, Canada; University of Toronto, Toronto, ON, Canada; BCCA - Vancouver Cancer Centre, Vancouver, BC, Canada; Tom Baker Cancer Centre, Calgary, AB, Canada

Background: Evidence from the ATAC trial that vasomotor or joint symptomatology by 3 months is associated with reduced recurrence after 3 months led to an interest in examining this phenomenon in other aromatase inhibitor trials. We examined here whether there is such an association in the context of a placebo-controlled tamoxifen therapy trial.

Methods: NCIC CTG MA.12 is a randomized placebo-controlled trial of tamoxifen (TAM) after adjuvant chemotherapy for pre-menopausal women with early breast cancer. Eligible patients were included if they received some protocol therapy, were alive and disease-free at 3 months: 1.) without prior grade 3/4 vasomotor or joint symptoms (N=293; only 3 patients had prior grade 1/2 vasomotor or joint symptoms); separately, 2.) all patients with/without prior vasomotor or joint symptoms (N=631). Vasomotor symptom at 3 months was adverse reporting of any grade of hot flashes and/or sweating, while joint symptom was any adverse event reporting of pain – joint, pain – muscle, pain – bone, arthritis, joint – function, or musculoskeletal – other. Exact Fisher tests were used to examine associations between baseline patient and tumour characteristics, treatment arm, and the development of symptomatology. Univariate testing of effect of symptomatology on relapse-free survival (RFS) was with a stratified Cox model, and multivariate was with stratified step-wise forward Cox modeling.

Results: MA.12 accrued 672 patients, and the median follow-up for this investigation was 9.7 years. Excluding patients with prior vasomotor or joint symptoms, 27.3% of 293 patients reported vasomotor or joint symptoms by three months, all of which was vasomotor. Meanwhile, 20.8% of all 631 patients had symptomatology by 3 months: 19.2% reported vasomotor alone, 1.1% joint alone, and 0.5% both. With no prior symptoms, 23.4% on placebo (P) and 31.7% on TAM developed symptomatology; age was the only baseline factor with significant differences at 3 months (p=0.01), with under 40 years 18% of women on TAM and 8% on P, and 50 or older, 21% on TAM and 14% on P being symptomatic. For all patients, 20.1% on P and 21.4% on TAM reported symptomatology by 3 months, and there was weak evidence that those >50 on TAM had more symptoms (p=0.06). Vasomotor and joint symptoms did not exhibit significant univariate or multivariate effects on RFS (without prior symptoms, respectively, p=0.98 and p=0.90; for all patients, p=0.99 and p=0.93).

Discussion: We did not observe any association of vasomotor or joint symptoms by 3 months and relapse-free survival after 3 months in the MA.12 placebo-controlled trial of tamoxifen therapy in pre-menopausal women. This mirrors the results we observed in our MA.27 trial of exemestane versus anastrozole in postmenopausal women, and points to the simple metric of early symptomatology not being a universal predictor of reduced relapse.
P1-06-09
Patient-Specific Integrative Pathway Analysis Using PARADIGM Identifies Key Activities in I-SPY 1 Breast Cancer Patients (CALGB 150007/150012; ACRIN 6657).
Wolf DM, You C, Benz S, Vaske C, Stuart J, Roy R, Oshen A, Boudreau A, Haussler D, Gray J, Spellman P, Davis S, Hylton N, Van ‘t Veer L, Esserman L. University of California, San Francisco; University of California, Santa Cruz; Oregon Health & Science University; I-SPY 1 Trial Investigators

Background: A major challenge in interpreting high-throughput multianalyte genomic data sets such as those produced by the ISPY clinical trials is data integration and interpretation within the context of biologically relevant pathways. To address this need, the data analysis tool PARADIGM (Pathway Recognition Algorithm using Data Integration on Genomic Models) was developed to infer the activities of genetic pathways by integrating any number of functional genomic data sets for a given patient sample into a pathway activity profile.

Methods: We used PARADIGM to integrate gene expression (Agilent 44K) and DNA copy number data (AFFY 22K and 330K MIP) from 133 ISPY-1 patients into pathway component activity levels for approximately 1400 curated signal transduction, transcriptional and metabolic pathways superimposed onto a single non-redundant “SuperPathway”. These pathway activities then become the substrate for statistical analyses to identify pathways characterizing different breast cancer subtypes, as well as those associated with recurrence and response to neoadjuvant chemotherapy within breast cancer subgroups. To identify subtype-specific pathway activities, we used ANOVA for initial feature filtering followed by Tukey analysis with Benjamini Hochberg multiple testing correction. For other binary outcome comparisons we used Mann-Whitney (2-sample Wilcoxon) analysis. PARADIGM results were corroborated with pathway enrichment analysis and filtered for significance.

Results: In agreement with breast cancer cell line and other prior studies, basal-like and triple negative cancers are dominated by upregulation of the FOXM1 and MYC/Max subnetworks and downregulation of the FOXA1/ER signal transduction pathway, the converse of the activity pattern seen in luminal breast cancers. These and other subtype associations pass stringent multiple testing corrected significance tests. Though an association study of recurrence over the entire patient cohort mostly yields pathways characteristic of basal-like tumors, alternative pathway associations emerge when subtypes are analyzed individually for outcome and significance tests are relaxed to include features that pass un-corrected Wilcoxon significance tests and also generate highly significant pathway enrichment scores. Subtype-specific drivers of recurrence and chemoresistance supported by this level of evidence include ALK1/2 (TGFβ-BMP) and p53 effector signaling for basal and Syndecan-1 and c-MYC for luminals. Chemo-sensitivity pathways, assessed by association with pCR and RCB1, appear to be subtype-specific as well, with HDAC class 1 signaling, LRP6-Wnt, and IRE1α chaperones dominating basal-like cancers and c-MYB activity dominating Her2+ cancers, whereas chemo-sensitivity of HR+/Her2- cancers though rare appears to be driven by the DNA damage axis (BRCA1/BARD1).

Conclusion: These and other similar analyses suggest that patients with TN or basal-like disease might benefit from the addition of ALK1 pathway inhibitors to treatment, whereas high risk HR+ patients might benefit from Syndecan-1 inhibitors. C-MYC/MAX inhibitors might benefit all high risk patients.

P1-06-10
Lobular Breast Cancer and NAC: Combined Results from the NKI and I-SPY 1 Trial.
Mukhtar RA, Lips E, Wesseling J, Livasy C, Yau C, Berry D, van’t Veer L, Carey LA, Esserman LJ, Rodenhuis S, I-SPY Investigators, Hwang ES. UCSF; Netherlands Cancer Institute; University of North Carolina, Chapel Hill; MD Anderson

Background
The benefits of neoadjuvant chemotherapy (NAC) in breast cancer are twofold: allowing breast conservation surgery, and assessment of response. Having pathologic complete response (pCR) predicts improved outcomes. Many have suggested that invasive lobular cancers (ILC) do not respond to NAC as well as invasive ductal cancers (IDC), and recommend against offering NAC in such cases. We previously investigated differences in the response to NAC in ILC and IDC in the I-SPY 1 Trial, and now present findings from a joint analysis with the Netherlands Cancer Institute (NKI).

Methods
We combined datasets comprising 676 patients (221 from I-SPY, 455 from NKI) enrolled in NAC trials. Eligible patients had palpable tumors ≥ 3 cm, and underwent serial biopsies, microarray analysis (Agilent 44K for I-SPY and Illumina 6v3 for NKI), and MRI imaging. ILC versus IDC histology was assigned by pathologic appearance, and ILCs were tested for e-cadherin expression and centrally reviewed by a breast pathologist at each site. We performed multivariate logistic regression analyses to assess differences in pCR. We compared intrinsic subtypes, prognostic gene signature expression, and MRI phenotypes.

Results
There were 75 ILC and 601 IDC cases. ILCs had lower risk features and were more likely hormone receptor + (Table 1) but there was substantial heterogeneity and many ILC had high risk features. There were fewer T2 (33% versus 48%) but more T3 tumors (59% versus 37%) among the ILCs. Nearly 10% of ILC cases had the basal intrinsic subtype; 22% expressed the activated wound healing signature, and 56% had a high risk 70-gene prognostic signature. While pCR rate was lower in ILCs, adjustment for low risk features showed lobular histology was not an independent predictor of pCR. ILC was less likely to present as a solid mass. 85% of ILC were e-cadherin negative.

Cancer Res; 71(24 Suppl.) December 15, 2011
Conclusions

This combined analysis suggests that the decreased response to NAC in ILC is due to the association between ILC and low risk features. ILC in a clinically high risk setting has a higher proportion of high risk biology in spite of lobular histology. Lobular histology alone should not be used to exclude patients from NAC trials or treatment.

P1-06-11

Comparison of Community and Central Her2 Assessment on Outcome of Neoadjuvant Chemotherapy in the I-SPY Trial.

DeMichele A, Vau C, Zhu J, Wuhufkuhle J, Lenburg M, Buxton M, Davis S, Mies C, Livasy C, Chin K, Gray J, Carey L, Esserman L, Petricoin E. Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA; University of California, San Francisco, CA; George Mason University, Fairfax, VA; University of California, Santa Cruz, CA; Carolina HealthCare System, Charlotte, NC; Oregon Health Sciences University, Portland, OR; The University of North Carolina at Chapel Hill, Chapel Hill, NC; University of Pennsylvania, Philadelphia, PA

Background: Her-2/neu overexpression, by immunohistochemistry (IHC) or fluorescence in-situ hybridization (FISH), is highly correlated with response to trastuzumab and these are currently the gold-standard, FDA-cleared testing methods for assigning treatment to Her-2-directed therapies. However, substantial variability has been documented between community and central laboratory IHC and FISH testing. Biologically, Her-2 overexpression may reflect increased gene copy number, gene expression and/or protein production, and these can be measured by other platforms, including comparative genomic hybridization (CGH), expression arrays and quantitative protein assays, respectively. We sought to determine the degree to which community IHC/FISH results differed from centrally-assessed IHC, FISH, and other assessment platforms within the I-SPY Trial and whether response to neoadjuvant chemotherapy (NAC) differed by platform.

Methods: The I-SPY Trial enrolled 237 women 2002-06 with invasive breast tumors at least 3 cm in clinical/radiographic size who subsequently underwent anthracycline/taxane NAC, serial core biopsies and imaging. Pathologic complete response (pCR) was determined at time of surgery and 3-year follow up has been reached. Trastuzumab was given to Her2+ patients at physician discretion, based upon community IHC/FISH results, and became more widespread after 2005. Central I-SPY laboratories determined Her2 copy number by MIP array, gene expression by Affymetrix and Agilent arrays, and Her2 protein by reverse-phase protein array (RPMA). Unsupervised clustering algorithms were used to evaluate expression patterns. Composite variables were constructed for DNA, RNA and protein positivity as well as for community and central IHC/FISH. Platforms were compared and Kaplan-Meier curves were constructed to compare outcomes by platform.

Results: 222 women were evaluable, though not all patients had results for all platforms. Community composite IHC/FISH was positive in 64/214 (30%) but only 41 of these (64%) were confirmed by central IHC/FISH and 4 additional cases were centrally positive despite negative community testing. Concordance was high among centrally-assessed Her2 platforms, but was lower between community IHC/protein and central RNA (90%), DNA (91%) and protein (91%). Among patients receiving trastuzumab (n=36), the pCR rate was ~50% regardless of Her2-assessment platform; in contrast, those not receiving trastuzumab had pCR rates below 30%. Among the 64 patients deemed Her2+ by community IHC/FISH, 30 (48%) had pCR and 15 (25%) have had distant relapse. Five distant relapses have occurred despite pCR; all received trastuzumab, all were Her2 positive by multiple central platforms and 3/5 were ER-positive. Sites of distant relapse included brain, bone and viscera; only 1 of 5 had isolated brain relapse.

Conclusions: Community IHC/FISH testing for Her2 expression in the I-SPY Trial overcalled Her2 positivity compared to central testing while central results were highly concordant among DNA, RNA and protein platforms. Despite the high rate of community “false positives”, relapse after pCR occurred only in central Her2 “true positives,” exclusively among those receiving trastuzumab, and was rarely isolated to CNS sanctuary sites.

P1-06-12

Circulating Tumor Cells (CTC) Monitoring during Phase II Study with Lapatinib (L) and Capecitabine (C) in Patients with Brain Metastases from HER2-Positive (+) Metastatic Breast Cancer (MBC) before Whole Brain Radiotherapy (WBR): LANDSCAPE Study.

Pierga J-Y, Cropet C, Tresca P, Dalenc F, Romieu G, Campone M, Mahier Ait-Oukhatar C, Le Rhun E, Gonçalves A, Lebeurteur M, Domont J, Gutierrez M, Curé H, Ferrero J-M, Labbe-Devilliers C, Bidard F-C, Bachelot T, Institut Curie & Universite Paris Descartes, Paris, France; Centre Léon Bérard, Lyon, France; Institut Claudius Regaud, Toulouse, France; Centre Val d’Aurelle, Montpellier, France; Institut de Cancérologie de l’Ouest, Nantes, France; R&D Unicancer; Paris, France; Centre Oscar Lambret, Lille, France; Institut Paoli Calmettes, Marseille, France; Centre Henri Becquerel, Rouen, France; Institut Gustave Roussy, Villejuif, France; Institut Curie - Hôpital René Huguenin, Saint-Cloud, France; Institut Jean Godinot, Reims, France; Centre Antoine Lacassagne, Nice, France

Background: Decrease of CTC level during treatment in MBC has been reported as an independent prognostic and predictive factor of patients’ outcome. Monitoring CTC in addition to clinical response criteria is currently evaluated in early clinical trials in various cancer types. We sought to evaluate the clinical interest of peripheral blood CTC for patients included in the LANDSCAPE study which assessed the efficacy of upfront systemic treatment with L+C for newly diagnosed brain metastasis.

Methods: This analysis is a preplanned secondary endpoint of the LANDSCAPE study. Eligible pts had HER2+ MBC with BM not previously treated with WBR, C or L. Pts received L1250 mg/day and C2000 mg/m²/day, days 1-14, every 21 days. The primary endpoint was a centrally assessed CNS objective response (CNS-OR) defined as a ≥50% volumetric reduction of CNS lesions in the absence of increasing steroid use, progressive neurologic symptoms or progressive extra-CNS disease. CTC were detected in 7.5 ml of blood using the CellSearchSystem™, combining EpCAM immunomagnetic selection (IMS) followed by anti-cytokeratin (A45B/B3) fluorescently staining for CTC at baseline and at day (D) 21, before cycle 2.

Results: From 04/2009 to 08/2010, 45 pts were enrolled, 41 were evaluable for CTC at baseline and 38 at D21. Median age was 56 (range 35 to 79). PS was >1 only in 2 pts. At baseline, 20/41 (48.8%) pts had ≥1 CTC and 9 (22%) ≥5 CTC (range 1-301, median 3). CTC were detected in pts with (18/37) or without disease outside SNC (2/6) (p=0.63). At a median follow-up of 10 months (range 2.9-16.5), median TTP was 6.0 months [95% CI 4.9; 7.4] vs. 4.3 [2.8; 5.9] months for pts without and with CTC at baseline respectively (p=0.14). After 21 days of treatment, a disappearance of CTC was observed in 11pts (31%). At D21, only 7 (18.4%) pts had ≥1 CTC and 3 (8%) ≥ 5 CTC (p=0.006, D21 vs. baseline). In 43 evaluable pts, CNS-OR rate was 67% (95%CI 51-81), with a median time
from inclusion to response of 1.8 month. Absence of CTC was not correlated with CNS-OR rate at baseline (17/21 (81%) vs. 11/19 (58%), NS). Strikingly, remaining positivity for CTC at D 21 (≥ 1CTC) was correlated with a poor response rate in CNS: 2/6 (33.3%) vs. 25/31 (80.6%) in pts with 0 CTC, p=0.03.

**Conclusions:** Early decrease (at D 21) in CTC level is correlated with a high response rate in newly diagnosed BM to L + C and underlines the predictive value of this blood marker in MBC pts even for brain metastasis. Longer follow-up is needed to assess its prognostic value under antiHER2 targeted therapy.

### P1-06-13

**An Amplicon-Driven Aromatase Inhibitor Response (ADAIR) Signature Provides an Orthogonal Risk Classifier for ER+ Breast Cancer.**

**Background:** Many gene signatures have been proposed to predict outcomes for estrogen receptor positive (ER+) breast cancer; most are solely based on mRNA expression data without integration of genomic aberrations that are the primary drivers of disease. We coupled gene expression and copy number variation data to improve the current generation of prognostic algorithms.

**Methods:** mRNA expression based discovery was conducted in 167 patients with low (<10%) or high (>10%) levels of Ki67 after neoadjuvant aromatase inhibition. Genes that were significant in SAM analysis (q ≤0.05) were used if significantly correlated (P≤0.05) with copy number gains detected by aCGH. Interrogation for association with relapse-free survival (RFS) (P≤0.05) in a large public microarray dataset produced an Amplicon-Driven Aromatase Inhibitor Response (ADAIR) signature. Each gene was subject to rigorous independent validation in public microarray datasets and by NanoString on archival tumor RNA accrued from patients treated with adjuvant tamoxifen (UBC-TAM) that were previously profiled for PAM50 subtyping and risk of relapse (RO). The associations between clinicopathological outcomes and management of breast cancer (BC).

**Results:** A 54-gene ADAIR signature of 27 FR(favorable response) and 27 UR(unfavorable response) genes was chosen based on statistical and genomic information. 80% of the ADAIR genes were univariately prognostic for RFS in UBC-TAM. The multigene-based ADAIR risk classifier of endocrine sensitive, intermediate and insensitive categories were prognostic for relapse in the combined public data (p=2.72e-08) and UBC-TAM (p=1.51e-08). Multivariable survival analysis showed that ADAIR was independently prognostic from standard clinical variables. The ADAIR risk classifier was highly concordant with the PAM50-gene based intrinsic subtype and ROR using subtype information (ROR-S) in all datasets in the analysis (for ROR-S, p=3.50e-44 in combined public data and p=2.16e-47 in UBC-TAM). ADAIR significantly stratified the patients in the medium ROR subtype risk group (p=0.007 in public cohort, p=0.005 in TAM), suggesting clinical utility. Pathway analysis indicated that the FR gene signature was enriched for cell survival genes, while UR genes were largely cell cycle related. Two major TFs, E2F1 and GABPB1 were predicted to regulate 22 and 13 signature genes. Amplification/overexpression of E2F1 regulated genes characterizes the UR signature. In contrast, the FR signature down regulates the transcriptional repressor GABPB1, resulting in upregulated NFKB1 possibly mediating a survival response.

**Conclusions:** These data suggest that current gene expression signatures can be improved upon through the inclusion of genes whose over-expression is linked to the gene copy number gains typical of the ER+ breast cancer genome. Functionally, tumors sensitive to estrogen deprivation are associated with genes that promote cell survival, whereas resistant tumors are associated with genes that drive estrogen independent cell cycle progression. This study underscores the profound differences in the transcriptome of estrogen-dependent and independent breast cancer beyond the patterns identified by the established classifiers.

### P1-06-14

**Topoisomerase II alpha (Top2a) Protein Expression Is a Predictor for Response to Anthracycline-Based Chemotherapy (ATC-CT): Is It Due to Gene Amplification, HER2-Coamplification or a Summation of Pathways Leading to This Highly Proliferative Phenotype?**

Abdel-Fatah TMA, Lambros MB, Vatcheva R, Ball G, Dickinson PD, Moseley P, Green AR, Ellis IO, Reis-Filho JS, Chan S. Nottingham University City Hospital, NHS Trust, Nottingham, Nottinghamshire, United Kingdom; The Institute of Cancer Research, London, United Kingdom; School of Molecular Medical Science, Nottingham University, Nottingham, Nottingham Trent University, Nottingham, United Kingdom

**Background:** The evaluation of Top2a protein may be clinically more useful than gene alterations as a predictive marker for ATC-CT. In this study we assessed the association between gene copy number, gene and protein expressions of both TOP2A and HER2, and their effect on clinicopathological outcomes and management of breast cancer (BC).

**Methods:** 1- To study the response to anthracycline based chemotherapy (ATC-CT): The associations between clinical outcomes and both gene copy number changes (using in-situ hybridization; CISH) and protein expression (using immunohistochemistry) were studied in the neoadjuvant and adjuvant settings: a) 250 locally advanced primary BC treated with Neoadjuvant ATC-CT with or without Taxane followed by surgery (S) + radiotherapy (RT); pathological complete response (pCR) was used as the primary end point (PEP), b) 245 BC in which all patients were treated with S + RT followed by Adjuvant ATC-CT; progression free survival (PFS) was used as PEP (i) 145 primary BC overexpressing HER-2 treated with S+ RT followed by sequential adjuvant ATC-CT+ trastuzumab; PFS was used as PEP.

2- To study the clinic-pathological association of TOP2A alterations, we evaluated TOP2A alterations detected by CISH and IHC in an unselected series of 1650 consecutive cases of primary BC who treated with S + RT and received adjuvant CMF and/or endocrine therapies according to Nottingham prognostic index and ER status. 3- To study in details the molecular alterations of TOP2A/HER2, in 171 unselected series of primary BC, we evaluated a) gene copy number changes using both high resolution oligo array CGH and CISH, b) mRNA expression using Agilent gene expression array and c) protein expression using IHC. We analysed 48,000 gene transcripts using Artificial Neural Networks (ANN) and pathway analysis to identify genes and biological pathways that related to TOP2A gene alterations.

**Results:**

1) In the ATC-CT neoadjuvant series, the pCR rate was 32/115 (28%) in tumours expressing high levels of Topo2A, compared to 5/74 (7%) in tumours expressing low levels of Topo2A (p=0.0001).
In multivariate analysis, Top2A overexpression was an independent predictor for pCR (HR 5.1, CI 95%; 1.4-18.4, p<0.001).

2) Top2A overexpression was strongly associated with mitotic index, histological grade, KIF2C, loss of p53 function and the absence of both BRCA1 and ATM inactivation (p<0.0001).

3) ANN and pathway analysis revealed that Top2A-strongly correlated genes are involved in: mitotic cell cycle regulation especially M phase and cell division (AURKB, KIF2C, BRIC5, ASPM, CCNA2, BUB1, FBX05, PTG1, CDC5, CDC3, CDC8), Kinesin and microtubules regulator genes (KIF2C, KIF11, KIF14, KIF20A, KIF23, and KIFC1), and metastases (BRIC5, BUB1B, CCNA2, CCNE, PRGG1, PRM2, STMN1).

Conclusions: Top2A protein expression is an independent predictor for pCR after ACT-CT treatment. The high response rate of Top2A protein overexpression supports the theory that Top2a protein is a direct target of ATC-CT in these highly proliferative tumour cells. Furthermore, evaluation of Top2A protein may lead to a clinically useful test.

P1-06-15
A Genomic Predictor Developed from Breast Cancer Cell Lines Predicts Both Disease-Free Survival and Overall Survival in Breast Cancer Patients Treated with Doxorubicin and Cyclophosphamide: A Collaborative Project of the NSABP and Precision Therapeutics.

Background: A cell line-derived multigene predictor of tumor response to doxorubicin + cyclophosphamide (MGP-AC) has been shown to predict the pathological complete response (pCR) in breast cancer patients from the National Surgical Adjuvant Breast and Bowel Project (NSABP) Protocol B-27. However, a cell line-derived MPG for doxorubicin + cyclophosphamide + docetaxel (MGP-ACT) was not predictive in patients from B-27. The purpose of this study was to further assess the performance of these predictors on disease-free survival (DFS) and overall survival (OS) in the same patient populations.

Methods: NSABP B-27 was a 3-arm trial of 2411 early-stage breast cancer patients randomized to receive 4 cycles of preoperative doxorubicin+cyclophosphamide (AC) or 4 cycles of AC followed by 4 cycles of docetaxel either pre-op (AC+T) or post-op (AC→T). MGPs for AC and ACT were developed based on the in vitro assay and microarray genomic profiles of 40 breast cancer cell lines. A higher MGP score indicates lower chemoresponse sensitivity.

Results: 322 patients with available microarray data were included for this analysis (103 treated with AC, 102 with AC+T, and 117 with AC→T). For patients treated with AC, a higher MGP-AC score was significantly associated with increased risk of disease progression (standardized hazard ratio [HR] SD set to 1=1.48, 95% confidence interval [CI]=1.02-2.15, p=0.043) or death (standardized HR=1.66, 95% CI=1.06-2.62, p=0.028) after adjusting for clinical covariates (ER status, clinical tumor size, lymph node status, and age). The addition of MGP-AC to the clinical model improved the accuracy in predicting five-year DFS: the area under the ROC curve improved from 63% to 72%. For patients treated with AC+T or AC→T, MGP-ACT was not predictive of either DFS (standardized HR=1.03, 95% CI=0.78-1.37, p=0.818) or OS (standardized HR=1.05, 95% CI=0.73-1.51, p=0.8).

Conclusions: A cell line-derived MGP for AC that was predictive of pCR was also predictive of DFS and OS in breast cancer patients treated with neoadjuvant AC. The MGP for ACT, which was not predictive for pCR, was not predictive of either DFS or OS in patients who received docetaxel after AC. The B-27 study was funded by NCI PHS grants U10-CA-37377, U10-CA-69974, U10-CA-12027, U10-CA-69651, and U24-CA-114732, and received additional support from sanofi-aventis.

P1-06-16
BRCA2 Mutation Carriers Respond Poorly to Conventional Anthracyclins/Taxanes-Based Neo-Adjuvant Chemotherapy.

Raphael J. Caron O, Rimareix F, Spielmann M, Al Ghazlan A, Mathieu M-C, Delalogue S. Institut Gustave Roussy, Villejuif, France

Background: BRCA2 carriers typically develop luminal B-type breast cancers. Their exact sensitivity to conventional chemotherapy remains unclear. Promising drugs such as parp inhibitors are currently being developed in this indication. We attempted to evaluate pathological response rates of BRCA2 carriers in current the routine setting.

Patients and methods: We screened our database of all patients seen at our genetic clinic over the past 15 years who were completely tested for BRCA1 and BRCA2 mutation and had received primary anthracyclines/taxanes-based chemotherapy (6-8 cycles) for invasive breast cancer as primary care. The pathological responses of pts who tested positive for BRCA2 were compared to those of BRCA1 and BRCA2-negative patients who had been diagnosed with luminal breast cancer (ER-positive, Her2-negative).

Results: Among 155 BRCA2-carriers and 503 wild-type patients, 24 BRCA2 pts and 58 pts with luminal B-type breast cancer have received primary standard anthracyclin/taxane-based chemotherapy. Median age was 38 for both populations. Median tumor size was 45 and 40 mm respectively among carriers and WT pts. 60% of BRCA2 and 100% of WT luminal B pts had ER-positive disease. A pathological complete response occurred in 18% of BRCA2 carriers and of 39% of luminal B Wt-pts. 65% of BRCA2 and 51% of WT-pts pts remained node-negative.

Conclusion: Deleterious germline mutations of BRCA2 are associated with a low probability of complete pathological response and a high risk of axillary invasion after conventional primary chemotherapy. Alternative treatments are highly expected.

P1-06-17
A New Pathological Response Index (PRI) for Neoadjuvant Chemotherapy Accurately Predicts Clinical Outcomes of Locally Advanced Breast Cancers (LAPBC).

Abde-Fatah TMA, Mosley P, Lee A, Balls G, Ellis IO, Chan S. Nottingham University City Hospital, Nottingham, Nottinghamshire, United Kingdom; Nottingham University, Nottingham, United Kingdom; The Institute of Cancer Research, London; Nottingham Trent University

Pathological complete response (pCR) after neoadjuvant chemotherapy predicts overall survival that is independent of treatment regimen. However, pCR is not a perfect surrogate for overall survival, given that a significant number of patients who did not achieve pCR also have a good prognosis and a small number of patients with pCR still develop recurrences. Furthermore, residual cancer cells after neoadjuvant therapy includes a wide range of responses from near pCR to complete resistance.

In this study we performed a comprehensive pathological assessment
for 245 surgical specimens of LAPBC, treated at a single institution, removed after receiving neoadjuvant anthracycline combination chemotherapy only (n=152) or with Taxane (n=93) with median follow up 42 months. Progression free survival (PFS) was used as the study endpoint. For comparison, residual cancer burden (RCB) was calculated using web calculator at www.mdanderson.org/breast_BCR. A multivariate Cox regression model revealed that size of the residual invasive carcinoma (OR; 3.2, CI 95%; 1.6-6.1, p=0.001), presence of lympho-vascular invasion (OR; 2.4, CI 95%; 1.3-4.3, p=0.004), absence of any pathological evidence of response at the site of the primary tumour or axillary lymph nodes after CT (OR; 3.2, CI 95%; 2.2-8.0, p=0.00001) and presence of at least one apical lymph node metastases (OR; 4.2, CI 95%; 1.5-6.8, p=0.003) at surgery were significantly associated with shorter PFS. These results were used to develop a pathological response index (PRI) from which 5 prognostic subgroups with distinct clinical outcomes were identified.

Patients with PRI-PG1 (n=110; 49%) had a good clinical outcomes in both ER+ (3-year PFS; 91%) and ER- tumours (3-year PFS; 84%). Moreover, patients with PRI-PG1 who did not show pCR (n=69) had equivalent overall and PFS as those with PRI-PG1 who achieved pCR (n=41); p=NS. Patients with PRI-PG2-5, had a 5 fold increase in the risk of progression compared to those with PRI-PG1 (HR; 5.2, CI 95%; 2.9-9.6, p=0.0001). ER+ patients with PRI-PG3-5 (25% of ER+ cases) had shorter 3-year PFS 30%) compared to those ER+ with PRI PG1-2 (91%) despite treatment with adjuvant hormonal therapy (HR=6.5, CI 95%; 2.8-14.7, p=0.0001). Similarly, HER2 positive patients with PRI- PG3-5 (20% of HER2+ patients) showed very rapid progression within < 3 years (PFS; 10%) vs. those with PRI-PG1-2 (PFS; 82%) despite trastuzumab treatment (HR=8.4; CI 95%; 2.8-25.0, p=0.0001).

In conclusion, a pathological response index including size of residual tumour, post chemotherapy lymph node pathological stage, lympho-vascular invasion and any evidence of fibrotic/response reaction following neoadjuvant chemotherapy may accurately predict the chance of disease progression, identify a greater proportion of patients (>twice as many as pCR) who could potentially benefit from the neoadjuvant chemotherapy and may be able to spared further adjuvant therapy. Furthermore this new PRI may help to improve the sensitivity of pathological response as a study end-point for predicting tumours response to a given neoadjuvant regimen and enable biological markers to be studied in a good prognostic group in addition to pCR.

P1-06-18
Loss of E-Cadherin Expression in Clinical Breast Cancer Is Associated with an Adverse Outcome on Tamoxifen.
Hiscox S, Rakha E, Smith C, Farrow L, Gandahara S, Green A, Ellis I, Barrett-Lee P, Nicholson R, Geer J, Cardiff University, Cardiff, Wales, United Kingdom; Nottingham University Hospital, Nottingham, United Kingdom; Velindre Hospital, Cardiff, Wales, United Kingdom

Background: Despite the benefits provided by tamoxifen, not all ER+ patients respond to endocrine therapy and a substantial number of patients who initially respond ultimately relapse whilst on therapy, with endocrine resistance associated with poorer survival. The ability to identify biomarkers predictive of outcome on endocrine treatment would enable more effective stratification of patients most likely to benefit from such measures. Previously, we reported that tamoxifen is able to promote the development of a highly aggressive phenotype in ER+, HER2- endocrine-sensitive breast cancer cells in vitro that have been depleted of the intercellular adhesion molecule, E-cadherin. Here we have investigated the clinical relevance of these observations by examining the association between E-cadherin protein expression and clinical outcome in a series of primary early stage (Stage I-IIIA) invasive ductal carcinomas of the breast.

Material and Methods: A series of 794 ER+ breast cancer tissues of known E-cadherin immunohistochemical status (Rakha EA et al (2005) Histopathol 46(6)) were available for this study and comprised both patients who had received tamoxifen for 5 years (n=345) or who had had no endocrine treatment (n=449). E-cadherin was further assessed in a group of ER-negative, tamoxifen-treated primary breast cancers (n=93) as an internal control. The median E-cadherin H-score staining was 120 (range 0 to 300).

Results: Kaplan-Meier survival analysis revealed a significant association between reduced E-cadherin expression (< median) and overall survival (OS) in the tamoxifen-treated group at 20 years (p=0.04; Hazard Ratio [HR]=1.51, 95% CI:1.01-2.26) however this relationship was much stronger at 5 years (p=0.02; HR=2.00, 95% CI:1.10-3.65). In the ER+, tamoxifen-untreated tumours, a relationship was observed at 60 months only. Reduced E-cadherin also correlated with metastasis (regional and distant, p=0.01; HR=1.90, 95%CI:1.12-3.24) but only within the tamoxifen-treated group and only within the first 5 years, reflecting the time during which patients would have received tamoxifen. In the ER+, tamoxifen-treated cohort, no adverse impact of reduced E cadherin on these parameters was observed. Subgroup analysis of tamoxifen-treated patients revealed that the association between E-cadherin loss and adverse outcome was apparent in both HER2+ (n=39) and HER2- (n=302) cohorts. However, the association was more significant within the HER2+ group (p=0.02 for OS; HR=3.45, 95% CI:1.08-11.07) (p=0.03 for regional and distant metastasis; HR=2.78, 95%CI:1.02-7.57). These data support our in vitro observations that suppression of E-cadherin within in ER+ HER2+ breast cancer cell lines results in a significant gain in migration and invasion in response to tamoxifen.

Discussion: These results are supportive of our hypothesis that low or absent E-cadherin expression in ER+, ductal breast cancer treated with tamoxifen predicts poor survival, particularly within the ER+, HER2+ phenotype. Of note, the presence of tamoxifen appears to be required for this event, suggesting that there is a patient cohort where other systemic endocrine therapy should be considered. E-cadherin represents a biomarker able to discriminate such cases.

P1-06-19
Absence or Low Levels of c-JunNH2- Terminal Protein Kinase (JNK) Mitogen Activated Protein Kinase (MAPK) Is Related to a Luminal B Subtype and an Impaired Survival in Patients with an ER Positive Breast Cancer Treated with Adjuvant Tamoxifen.
Linderholm BK, Sanchez-Chavez B, Hellborg H, Johansson UM, Lewensohn R, Viktorsson K, Kanter L. Institution of Oncology, Sahlgrenska University Hospital, Gothenburg, Sweden; Institution of Oncology and Pathology, Karolinska Institute, Stockholm, Sweden; Institution of Pathology, Herlev, Denmark

Background: Resistance to endocrine therapy is a clinical problem and is not explained by lack or loss of the oestrogen receptor (ER). Up-regulation of several receptor tyrosine kinases have been correlated to diminished effect of endocrine treatment. More contradictory are the role of downstream mitogen activated protein kinases (MAPK’s).

Patients and Methods: We performed a tissue micro array (TMA) on patients that originate from an earlier presented population of 404 patients with a steroid receptor positive BC subjected to tamoxifen as only adjuvant systemic treatment. Material from 120 patients was available for the TMA. JNK, p38 and ERK was determined by use of immunohistochemistry and scored 0, +1, +2, +3. Patients were
grouped into two categories for statistical analyses. Results: Absence or low JNK was statistically significantly correlated with HER2+ (p = 0.018), a Luminal B like subtype (ER+, high proliferation rate and/or HER2+) (p = 0.007), shorter relapse-free (p = 0.0494) and breast cancer corrected survival (p = 0.0458). High ERK was more frequent among no node-negative patients (p = 0.00469) and more frequent in relapse-free patients; RFS (p = 0.225); BCCS (p = 0.0705). High expression of p38 was associated with p38 previously determined by ELISA (p = 0.085) and HER2+ (p = 0.094), however not reaching statistical significance. High p38 was related to increased relapses within the first years but the difference vanished with longer follow-up time; RFS (p = 0.486) and BCCS (p = 0.589). JNK remained as an independent marker of RFS in a Cox proportional multivariate analysis (HR = 2.19; 95% CI = 1.14-11.41; p = 0.029), together with nodal status (HR = 3.6; 95% CI = 1.44-8.81; p = 0.006) and histological grade (HR = 3.1; 95% CI = 1.29-7.56; p = 0.011). Discussion: Our data on ERK and p38 is concordant with results from previous published studies. Two studies have shown ERK expression, determined by IHC to be correlated with “good prognosis features” as smaller tumour size, absence of nodal metastasis, lower proliferation and a favourable outcome after adjuvant tamoxifen (Svensson et al. 2005, Bergqvist et al. 2006). Higher p38 determined by use of an ELISA has been suggested as a marker of early relapses i.e. intrinsic resistance, although methodological problems must be taken into account (Linderholm et al. 2011). By use of IHC we could confirm that patients with higher expression of p38 actually had significantly more relapses within early follow-up. JNK was the MAPK with the most pronounced effect on survival. Absent or low expression was significantly correlated with an impaired survival in both uni- and multivariate analyses, a finding to our very best knowledge not described before. Low JNK was actually found more frequently in patients with a HER2 positive or Luminal B like BC (ER+, high proliferation rate or HER2+). Conclusions: Our results suggest that MAPK’s can be evaluated by IHC on TMA’s. Absence/low JNK was significantly correlated with an impaired survival and a Luminal B like subtype. Confirming studies in large preferable randomised patient populations are warranted.

P1-06-20
Response to Neo-Adjuvant Chemotherapy and Outcomes for I-SPY 1 Patients Stratified by the 70-Gene Prognosis Signature (MammaPrint) and Molecular Subtyping (BluePrint).
Gluck S, de Snoo F, Tian S, Glax A, van ’t Veer L. Miller School of Medicine, University of Miami, Miami, FL; Agenda, Amsterdam, Netherlands; HDFC Cancer Center, UCSF, San Francisco, CA

Background
Classification of breast cancers into molecular subtypes may be important for the proper selection of therapy for patients as tumors with seemingly similar biology can have strikingly different clinical outcomes. We analyzed response to neo-adjuvant chemotherapy as a function of molecular subtypes and show patient survival from the multi-center neo adjuvant trial, I-SPY 1 (CALGB 150007/150012; ACRIN 6657). Previous analyses had shown that breast cancer subtypes as identified by immunohistochemistry or molecular analyses, have distinct clinical outcome (Esserman, ASCO 2009). Here, we analyze how the 70-gene signature (MammaPrint) together with an 80-gene molecular subtyping profile (BluePrint=Basal-type, Luminal-type, ERBB2-type; de Snoo, ASCO, 2010 and manuscript under review) can sub-classify patients.

Materials
This study was carried out on genomics data of core needle biopsies from 149 out of 221 patients enrolled in the I-SPY 1 trial, a multi-center trial designed to identify predictive markers of pathological complete response (pCR) and disease-free survival (DFS) in women with locally advanced breast cancer (3 cm or greater). All women received neoadjuvant Doxorubicin & Cytoxan followed by paclitaxel chemotherapy. The 70-gene and the subtyping signatures, Basal, Luminal and ERBB2-type were determined on 44K Agilent arrays available through the I-SPY 1 data portal (Esserman, ASCO, 2009 and manuscript under review).

Results
The 70-gene signature classified 9% of patients (13/149) as Low Risk, of whom one patient was ERBB2-type, and the other 12 were Luminal-type. None of these patients experienced a pCR. The remaining 136 were classified as 70-gene High Risk (91%), of whom 47% were classified as Luminal-type with a pCR rate of 13%, 41% were Basal-type with a pCR rate of 34%, and 12% were ERBB2-type with a pCR rate of 56%.

Patients with BluePrint Basal-type tumors had a 5-year DFS of 61%; ERBB2-type had a 5-year DFS of 78%; 70-gene High Risk/Luminal-type had a 5-year DFS of 73% and 70-gene Low Risk/Luminal-type showed 5-year DFS of 100%.

The molecular subtype classification shows significant association to clinically assessed receptor status. However, clinically assessed HER2+ patients were distributed across all molecular subtypes, where ER+HER+ are predominantly classified as Luminal-type.

Conclusion
This study was performed with the I-SPY 1 dataset, which provides a platform to compare, contrast & combine marker signatures to tailor therapy. We show how combining BluePrint, with MammaPrint risk-classification can detect specific groups of patients who are at high risk of recurrence and who would have a higher likelihood to benefit from chemotherapy. Furthermore, MammaPrint Low Risk patients do not benefit from neo-adjuvant therapy, though have excellent survival rates, suggesting that the Low Risk Luminal-type patients could be managed conservatively.

P1-06-21
Relationship between Body Mass Index and Preoperative Treatment Response to Aromatase Inhibitor Exemestane in Postmenopausal Patients with Primary Breast Cancer.
Takada M, Saji S, Masuda N, Kuroi K, Sato N, Taket H, Yamamoto Y, Ohno S, Yamashita H, Hisamatsu K, Argi K, Iwata H, Ueno T, Sasano H, Toi M. Graduate School of Medicine, Kyoto University, Japan; Saitama Medical University, International Medical Center, Japan; Osaka National Hospital, Japan; Tokyo Metropolitan Cancer and Infectious Diseases Center, Komagome Hospital, Japan; Niigata Cancer Center Hospital, Japan; Saitama Cancer Center, Japan; Kumamoto University, Japan; National Kyushu Cancer Center, Japan; Nagoya City University Hospital, Japan; Hiroshima City Asa Hospital, Japan; National Shikoku Cancer Center, Japan; Aichi Cancer Center Hospital, Japan; Tohoku University Hospital and School of Medicine, Japan

Background:
Some studies have shown that high body mass index (BMI) is associated with inferior outcome after adjuvant therapy with non-stereoidal aromatase inhibitor, anastrozole in breast cancer patients. We aimed to investigate predictive effect of BMI on clinical response to neoadjuvant therapy with steroidal aromatase inhibitor, exemestane in postmenopausal patients with primary breast cancer.

Patients and methods:
The study group consisted of 109 patients from the JFMC 34-0601 neoadjuvant endocrine therapy trial in which postmenopausal patients...
with estrogen receptor (ER)-positive primary breast cancer were administered exemestane (25 mg/day) for 24 weeks before surgery. Patients were categorized into three groups according to BMI: low (BMI < 22 kg/m²), intermediate (22 ≤ BMI < 25 kg/m²) and high (BMI ≥ 25 kg/m²). Statistical analyses were performed to explore the predictive effect of BMI on clinical response using a multivariable logistic regression model.

Results:
Higher BMI correlated with positive progesterone receptor status (p < 0.01) and low Ki-67 index (p = 0.03). Objective response rates (ORR) were 21.7% in low BMI, 56.0% in intermediate BMI and 60.6% in high BMI, respectively (p = 0.01). In a multivariate analysis, only low BMI was an independent negative predictor of clinical response.

Conclusion:
Low BMI was associated with a decreased ORR to neoadjuvant endocrine therapy with exemestane. Our results may suggest that the predictive effect of BMI varies according to the type of aromatase inhibitor and objective outcome.

P1-06-22
Identification of Biomarkers in Breast Cancer for Prediction of Response to PARP Inhibitor Olaparib.

Background: Poly (ADP-ribose) polymerase (PARP) is an enzyme involved in DNA repair. PARP inhibitors operate on the principle of synthetic lethality in conjunction with DNA damaging agents, and are likely to be useful for treatment of BRCA-mutated and triple negative breast cancers exhibiting ‘BRCA-ness’ or other signs of DNA repair deficiency. Multiple PARP inhibitors have been developed, such as Olaparib (AstraZeneca), BSI-201 (Sanofi-Aventis) and ABT-888 (Abbott Laboratories). Though some clinical trials have shown drugs in this class to be promising, not all results have been positive. As PARP inhibitors differ in mechanism of action, dosing interval and toxicities, trial results seem to depend on the specific combination of PARP inhibitor and patient population. To understand why some studies succeeded and others failed and to guide new clinical trials in patient selection, there is an urgent need for biomarker identification, both for PARP inhibitors in general and for the specific idiosyncratic mechanisms of each drug.

Material and Methods: Thirty-three in vitro breast cancer cell lines were administered the PARP inhibitor Olaparib, with sensitivity to the compound summarized as the dose necessary to kill 50% of each culture. mRNA expression (Affymetrix U133A, Exon 1.0ST array) and transcriptome sequence (Illumina GAII) were available for 22/33 cell lines, among which 9 were sensitive and 13 resistant. To obtain robust predictive markers that are minimally dependent on the specific PARP inhibitor and expression platform, a bottom-up approach was opted for, restricted to genes in the major DNA repair pathways. Logistic regression with forward selection was used to determine the most important markers, further reduced based on consistency across platforms. The weighted voting algorithm was used to build the final predictor. Eight U133A data sets with number of tumor samples varying from 61 to 289 were subsequently used to verify prevalence and to identify the subpopulations that are likely to respond according to the predictor. To verify cross-platform generalizability, the signature was additionally tested in 430 TCGA samples with custom Agilent 244K gene expression.

Results: For the development of a genomic signature that might work for multiple PARP inhibitors and expression platforms, prior knowledge of DNA repair pathways was incorporated and stringent criteria for marker inclusion were applied using three different platforms. Eight genes fulfilled the criteria, of which 5 were resistance markers and 3 sensitivity markers. When testing the 8-gene signature in eight U133A data sets, 40-48% of patients were predicted to be responsive to Olaparib. In addition, well-known markers (ER, PR, ERBB2, KRT5/17) were examined in patients expressing the 8-gene sensitivity signature. A higher percentage of these patients were ERBB2-negative and did overexpress KRT5/17, indicative for the basal subtype. Prevalence and relationship with these markers were confirmed in 430 samples on a distinct platform (Agilent).

Conclusion: Cell line exposure to Olaparib has yielded an 8-gene predictor of sensitivity. This signature was observed in a substantial fraction of primary breast tumors predicted to benefit from Olaparib.

Sprecher E, Lezon-Geyda K, Sarkar S, Bossuyt V, Narayaan M, Kumar A, Krop I, Winer E, Tuck D, Kleinstein S, Harris L, Yale University, New Haven, CT; Yale University; Beckman Coulter; Stony Brook University Hospital, Stony Brook, NY; Dana-Farber Cancer Institute, Boston, MA

Introduction: Trastuzumab is a targeted therapy against the HER2 cell surface receptor and has greatly improved prognosis for HER2+ breast cancer patients. Despite decades of research, the mechanism of action of T remains unclear and mechanisms of resistance have not been adequately defined. We sought to determine if models of response and resistance in vitro could identify biomarkers in vivo in HER2+ early breast cancer.

Methods: BT474 and UACC812 cell lines were treated with 10ug/ml T for 0 and 24 hours. Fresh tumor core biopsies were taken at a 2 week timepoint after a single dose of T (8mg/m2) from 80 HER2-overexpressing, early breast cancer patients enrolled on a clinical trial of T>T+C. Nucleic acids were extracted using Qiagen AllPrep and were analyzed with Illumina HT12v3 Beadchip arrays. All arrays were processed at the Yale Center for Genome Analysis (West Haven, CT). Clinical response at surgery was defined as pathologic complete response (pCR), objective response (CR+PR=OR) and non-response (SD+PD=NOR) by RECIST criteria. Gene expression was analyzed in Bioconductor using LIMMA analysis. Pathway analysis was performed using the DAVID bioinformatics resource.

Results: We identified gene expression signatures of T response and resistance in HER2+ breast cancer cell lines across 24-hour exposure to trastuzumab. 180-genes changed significantly in a T-sensitive HER2+ cell line (BT474) and 58 genes changed significantly across treatment in a T-resistant HER2+ cell line (UACC812). We applied these signatures to gene expression profiles from early stage HER2+ breast tumors treated with a single dose of T. The BT474 T-responsive signature was enriched among the changes in expression across treatment for responsive patients. The expression change for the BT474 signature genes was also able to partially cluster responsive and resistant breast tumors by outcome. A subset of the UACC812 T-resistance signature was also enriched in the differential between responsive and resistant tumors prior to T treatment.
Pathway analysis based on the direction of change of genes in pCR and sensitive (BT474) cell lines found gland development/differentiation (enrichment score=4.5), DNA synthesis (ES=4.0), chaperone (ES=2.8) and transcriptional machinery (ES=2.2) to be coordinately downregulated in both sensitive cell lines and tumors. This suggests that the downregulation of differentiation pathways seen in our ‘pCR signature’ (Harris et al: AACR 2011) is not an epiphenomenon of cell loss. There were no significant pathways upregulated in both sensitive tumors and cell lines, however discordant genes were enriched in chromatin regulation pathways (ES=4.1). Of note, our previous findings of amplicon gene downregulation in pCR tumors, yet upregulation in cell lines points to a novel mechanism of chromatin modulation heretofor undiscovered in response to T.

Conclusions: These results demonstrate the value of iterative study of in vitro and in vivo response mechanisms in HER2 cell lines and tumors, and the importance of brief exposure studies in understanding the mechanism of response to T, and other targeted therapies.

**P1-06-24**

**Nuclear Localization of Stat5a Predicts Response to Antiestrogen Therapy and Prognosis of Clinical Breast Cancer Outcome.**

Peck AR, Witkiewicz AK, Liu C, Klimowicz AC, Stringer GA, Pequignot E, Freydin B, Yang N, Tran TH, Rosenberg AL, Hooke JA, Kovatch AJ, Shriver CD, Rimm DL, Magliocco AM, Hyslop T, Rau H. Thomas Jefferson University, Philadelphia, PA; Tom Baker Cancer Center, Calgary, AB, Canada; Walter Reed Army Medical Center, Washington, DC; MDR Global Systems, LLC, Windber, PA; Yale University School of Medicine, New Haven, CT

Nuclear-localized and tyrosine-phosphorylated Stat5 has been reported as a favorable prognostic marker and predictor of response to antiestrogen therapy in breast cancer. Phospho-Stat5 antibodies do not distinguish between phosphorylated Stat5a and the closely related Stat5b, but Stat5a is considered more critical for normal mammary development than Stat5b. The purpose of this study was to determine whether levels of nuclear-localized Stat5a protein (Nuc-Stat5a) were prognostic of clinical outcome or predictive of antiestrogen response. Stat5a was detected by traditional diaminobenzidine-chromogen immunohistochemistry (IHC) and pathologist scoring or by quantitative immunofluorescence in five archival cohorts of breast cancer. Levels of nuclear-localized Stat5a (Nuc-Stat5a) were evaluated by pathologist scoring of whole tissue sections detected by IHC or automated quantitative analysis (AQUA) of immunofluorescently-labeled tissue microarrays. Levels of Nuc-Stat5a were reduced in invasive breast cancer tissues and lymph node metastases compared to normal tissue and ductal carcinoma in situ when quantified by AQUA (Material I; n=180). Tissues from patients not treated with adjuvant therapy or treated with antiestrogen monotherapy were analyzed according to Nuc-Stat5a status for breast cancer-specific survival (CSS) and time to recurrence (TTR) using univariate and multivariate statistical models, adjusting for clinical features including tumor grade, size, lymph node and ER, PR and Her2 status. In two prognostic cohorts of node-negative breast cancer patients, low expression of Nuc-Stat5a detected by standard IHC (Material II; n=223) or quantitative analysis (Material III; n=198), was prognostic of poor breast cancer outcome as measured by univariate and multivariate CSS (Material II/III) and TTR (Material II). CSS and TTR analysis of two independent materials of tumors from patients treated with antiestrogen monotherapy and analyzed by standard IHC (Material IV; n=73) or quantitative immunofluorescence (Material V; n=97) indicated that patients whose tumors expressed low levels of Nuc-Stat5a were at a greater than 4-fold risk of antiestrogen therapy failure when adjusted for hormone receptor status and clinical features (multivariate CSS: Material IV HR=4.3 (1.2,15.6), p=0.03; Material V HR=5.0 (1.87,13.06), p=0.001). In conclusion, loss of Nuc-Stat5a is a promising independent marker of poor breast cancer prognosis in node-negative, non-adjuvant treated breast cancer patients. Additionally, Nuc-Stat5a may be a useful clinical tool to predict tumor response to antiestrogen therapy.

**P1-06-25**

**Changes in FDG PET SUV Correlates with Ki-67 Following 2 Weeks of Aromatase Inhibitor Therapy in ER+ Early Stage Breast Cancer, a Pilot Imaging Study.**

Gadi VK, Kurland BF, Specht JM, Rodler E, Korde LA, Peterson LM, Schubert EK, Chai X, Mankoff DA, Linden HM. University of Washington, Seattle, WA; Fred Hutchinson Cancer Research Center, Seattle, WA

**Background:** In estrogen receptor positive (ER+) tumors, a low proliferative index (Ki-67) two weeks into endocrine therapy predicts response. FDG PET non-invasively measures tumor sites in vivo. The pre-operative window is an opportunity to assess impact of systemic therapies. We tested associations between FDG PET standardized uptake value (SUV) and Ki-67 after two weeks of aromatase inhibitor (AI) therapy in newly diagnosed, postmenopausal women.

**Methods:** Postmenopausal patients with clinical stage I-II ER+ HER2 primary tumors underwent a 9-35 day “run-in” of AI monotherapy prior to definitive surgery. FDG PET was performed before AI therapy, and 1-5 days before surgery. Ki-67 was measured in baseline core biopsy and surgical specimens.

**Results:** To date, 18 patients (median age 59) have been enrolled of whom 14 patients have undergone serial FDG PET imaging with 12 completed assessment of Ki-67 in surgical samples including one who had no residual invasive carcinoma. The majority harbored ductal carcinomas (n=16) with 10/18 having histologic grade ≥ 2. The median number of days exposed to AI was 18 (range, 9-35). Baseline SUV ranged from 1.8 to 10.9 (median 2.5), and post run-in SUV (7-34 days later) ranged from 1.0 to 10.7 (median 2.5). A median 14% decrease in SUV was observed between paired FDG PET studies (range, 44% decline to 13% increase). Five of 12 patients’ index lesion FDG SUV declined by 20% or more; all also had Ki-67 ≤5% at surgery. An additional 5 patients with Ki-67 ≤5% at surgery had percentage change in FDG PET SUV of 0% to 17% decline. Results will be updated as accrual is ongoing.

**Conclusions:** Substantial changes in FDG PET SUV in the breast tumor were appreciated early in AI therapy. SUV declined or was stable in all but one patient of 14, and all patients with ≤20% decrease in SUV had a low ≤5% Ki-67 at surgery. Serial PET is a promising measure of early response to therapy.
P1-06-26
The EndoPredict Score Is a Response Predictor for Neoadjuvant Chemotherapy in ER-Positive, HER2-Negative Breast Cancer.
Brase JC, Gehrmann MC, Petry C, Weber KE, Schmidt M, Köhl H, Brauch H, Schwab M, Müller V, Jänicke F, Rody A, Kaufmann M, Filipits M, Gnant M, Denkert C, Loibl S, von Minckwitz G, Kronenwett R. Sividon Diagnostics, Cologne, Germany; Bayer Technology Services GmbH, Leverkusen, Germany; University of Mainz, Germany; Dr. Margaretre Fischer-Bosch Institute of Clinical Pharmacology Stuttgart and University Tübingen, Germany; University Medical Center Hamburg-Eppendorf, Germany; J.W. Goethe University, Frankfurt, Germany; Medical University of Vienna, Austria; Charité - University of Berlin, Germany; German Breast Group, Neu-Isernburg, Germany

Background:
The EndoPredict (EP) score is a multigene classifier to predict the likelihood of distant recurrence in ER-positive, HER2-negative breast cancer patients treated with adjuvant endocrine therapy. Two large randomized phase III trials involving endocrine therapy only (n > 1700) demonstrated additional prognostic information of the EP score independent from clinicopathological parameters by classifying 49% as low risk. However, the predictive role of the EP is not clear. Therefore, we examined whether the EP Score also predicts sensitivity towards neoadjuvant chemotherapy in ER-positive, HER2-negative breast cancer patients.

Methods:
Four publicly available gene expression data sets (Affymetrix HG-U133A) were retrieved from the gene expression omnibus (GEO) data repository. All analyzed breast cancer patients were treated with anthracycline or taxane/anthracycline-based neoadjuvant chemotherapy. Microarray cel files were MAS5 normalized with a global scaling procedure and a target intensity of 500. The analysis was restricted to ER-positive, HER2-negative breast cancer patients according to pre-specified cut-off levels for the respective ESR1/ERBB2 Affymetrix probesets. The EP score was calculated and patients were classified as having low or high risk according to the pre-specified validated cut-off value. Pathological complete response (pCR) - defined as no residual invasive cancer in the breast or lymph nodes - was used as the primary endpoint for the assessment of treatment response.

Results:
The EP Score was examined in 221 ER-positive, HER2-negative breast cancer patients treated with neoadjuvant therapy. Among the 221 patients, 61 tumors (27.6%) were classified as EP-low-risk, whereas 160 tumors (72.4%) were EP-high-risk. Only one of the EP-low-risk tumors achieved a pCR after neoadjuvant therapy, whereas 24 of the 25 pCR events were classified as EP high risk. The sensitivity of the EP score was 96% and the negative predictive value 98% with an area under the receiver operating characteristic curve of 0.73.

Conclusions:
The EP Score is a predictor of chemosensitivity in the neoadjuvant setting. The test correctly identified all but one of the patients achieving a pCR suggesting that the benefit of cytotoxic chemotherapy is limited to the EP high risk group.

P1-07-01
Comparison of Four HER2 Testing Methods in the Detection of HER2-Positive Breast Cancer: Results from the FinHer Study Cohort.
Huang W, Wirtz R, Weidler J, Lie Y, Sherwood T, Leinonen M, Bono P, Isola J, Kellokumpu-Lehtinen P-L, Joensuu H. Monogram Biosciences Inc., So. San Francisco, CA; STRATIFYER Molecular Pathology GmbH, Cologne, Germany; Pharma, Turku, Finland; Helsinki University Central Hospital, Helsinki, Finland; Institute of Medical Technology, University of Tampere and Tampere University Hospital, Tampere, Finland; Tampere University Hospital, Tampere, Finland

Background: Accurate assessment of the HER2 status is essential for identifying patients who may benefit from HER2 targeted therapy. The current methods, immunohistochemistry (IHC) and in situ hybridization (ISH), determine HER2 status semi-quantitatively as positive (+), equivocal (+/-) and negative (-) with predefined cutoff values. Recent studies have suggested that current HER2 cutoffs may not be optimal for all clinical settings of HER2 targeted therapy. In a small subset of adjuvant NCCTG N9831 patients confirmed as HER2-normal by round-robins of HER2 testing, trastuzumab benefit was observed (Perez et al, SABCS 2010). Quantification of HER2 as continuous variable may enable a more accurate optimization of HER2 cutoffs for various HER2 targeted therapies. In this study, we measured continuous HER2 protein expression by the HERmark™ assay and continuous mRNA expression by quantitative real time polymerase chain reaction (qPCR), and compared these results with central IHC and central chromogenic in situ hybridization (CISH) results of FinHer.

Methods: Total HER2 protein expression (H2T) was quantified using the HERmark assay as previously described (Huang et al. Am J Clin Pathol 2010;134:303). HER2 mRNA expression (H2N) was measured by qPCR as previously published (Noske et al. Br Cancer Res Treat 2011;126:109). The results of H2T and H2N as continuous variables and as predefined categories were compared with central CISH results from FinHer (Joensuu et al, N Engl J Med 2006;354), and central IHC retesting.

Results: H2T in 899 evaluable samples described a continuum of 0.4 to 721.2 (relative HERmark unit); while H2N in 915 evaluable samples showed a continuum of 31.4 to 42.8 (delta-Ct). Significant correlation between H2T and H2N as continuous variable was found (R² = 0.56, Pc < .0001). Paired method comparison was performed for samples with valid results in any two of the four testing methods. Overall concordance of H2T and H2N with predefined categories (+, +/-, -) was 81%, and concordance of (+) and (-) subsets was 95% when (+/-) cases (H2T 11%; H2N 6%) were excluded. Overall concordance of central IHC and H2T categories (+, +/-, -) was 75%, and concordance of (+) and (-) subsets was 96% when (+/-) cases (IHC 16%; H2T 11%) were excluded. Overall concordance of IHC and H2N categories (+, +/-, -) was 84%, and concordance of (+) and (-) subsets was 99% when (+/-) cases (IHC 16%; H2N 6%) were excluded. Concordance of central CISH (+, -) with H2T and H2N categories (+, -) was 89% and 91%, respectively, when (+/-) cases were excluded from H2T (13%) and H2N (8%), respectively.

Conclusions: All four methods identified HER2-positive breast cancers. The discordance rate between the methods tested was approximately 10 to 20% despite careful delineation of cancerous tissue in the sample and analysis of adjacent tumor sections. No combination of assays could be identified with concordance rate >95% when the equivocal subsets were included in comparisons. Exclusion of the equivocal subsets (about 10% of samples) yielded
Discordance between Central and Local Laboratory HER2 Testing from a Large HER2-Negative Population in VIRGO, a Metastatic Breast Cancer Registry.

Vogel CL, Bloom K, Burris H, Gralow JR, Mayer M, Pegram M, Rugo HS, Swain SM, Yardley DA, Chau M, Lalla D, Brummer MG, Kaufman PA. Sylvester Comprehensive Center at Deersfield, Miller School of Medicine, University of Miami, Miami, FL; Clariant, Inc., Aliso Viejo, CA; Sarah Cannon Research Institute, Nashville, TN; Tennessee Oncology, PLLC, Nashville, TN; University of Washington Medical Oncology, Seattle Cancer Care Alliance, Seattle, WA; Patient Advocate, New York, NY; University of California San Francisco Comprehensive Cancer Center, San Francisco, CA; Washington Cancer Institute, Washington Hospital Center, Washington, DC; Genentech, Inc., South San Francisco, CA; Norris Cotton Cancer Center; Dartmouth-Hitchcock Medical Center, Lebanon, NH

Background: HER2 overexpression is associated with unfavorable prognosis and is reported in 18–25% of breast cancers (BC). HER2 testing is often performed using immunohistochemistry (IHC) or fluorescence in situ hybridization (FISH). Because of the significant benefit of HER2-directed therapies, it is critical to accurately identify women whose tumors are HER2+. Reports have noted discordance between HER2+ test results from local vs. reference labs in patients with HER2+ BC evaluated for trastuzumab-based clinical trials. There are little published data on central testing of BC found to be negative locally.

Patients and Methods: VIRGO is an observational cohort of N=1,287 women with primarily HER2-negative metastatic BC. An optional tissue collection substudy was conducted, and 776 patients were included in the primary analysis. Central testing was performed at 2 reference labs and tumors were deemed HER2+ if IHC 3+ and/or FISH positive (HER2:CEP17 ratio ≥2.0). Tumors with unknown/missing local HER2 status (n=68) were excluded from primary analyses. Number of patients potentially affected based on BC incidences from the American Cancer Society (ACS) 2011 estimates and the World Health Organization (WHO) 2008 report were calculated. Testing on the remaining HER2-negative cohort is in process.

Results: Central retesting has been performed on tumor samples from n=373 patients to date. HER2-negative locally evaluable tumors (n=301), n=4 HER2-negative locally with no evaluable tumor, and HER2 unknown (n=68). A total of 301 unique patient samples were included in the primary analysis. Of these, 15 (4.98% [95% CI (2.7%, 7.9%)]) were found to be HER2+ by central testing (Table). Based on sensitivity analyses assuming all 68 tumors with unknown HER2 status to be negative locally, 4.07% (15/369) would be centrally HER2+. Of the 15 HER2+ tumors, 4 tumors tested positive centrally by both IHC and FISH; 6 IHC positive/FISH negative; and 5 FISH positive/IHC negative. 14/15 tumors were tested centrally by only one testing methodology, and 11/15 were determined to be HER2+ centrally based on the testing methodology not performed locally. Investigators for all 15 patients have been notified of central HER2 testing results.

Conclusion: Based on ACS estimates of 232,620 new cases of invasive BC diagnosed in the US in 2011 (assuming 80% testing HER2-negative); a discordance rate of 4.5% equates to 7,444–9,305 patients’ tumors diagnosed as HER2+ by central testing. Based on WHO global BC incidence estimates, 44,274–55,342 patients could be impacted worldwide as reported in this study. Inaccurate HER2 testing has significant clinical impact, both in denying appropriate treatment or leading to inappropriate use of HER2-targeted therapies. This study suggests testing by both IHC and FISH may be of benefit to accurately identify HER2 status, consistent with the Herceptin® USPI.
moderate effects that appear less critical to measurement accuracy than the issue of tumor heterogeneity. We identified 4 proteins which show a significant change with increasing time to formalin fixation and should allow construction of a TQI for assessment of pre-analytic antigenic degradation.

P1-07-04
Gene Expression Module Biomarkers To Stratify Multiple Clinical and Therapeutic Endpoints for Universal Breast Cancer Companion Diagnostic.

Gene expression patterns are increasingly capable of stratifying patients based on prognosis and response to therapy. Given the limited availability of sample tissue, however, it is not feasible to run many tests, suggesting the need for a universal companion diagnostic assay that is informative with respect to multiple clinical and therapeutic endpoints. Key challenges are identification of appropriate gene expression biomarkers, translation of biomarkers to clinical assays, and development of reliable gene expression profiling of formalin-fixed clinical specimens. Here, we describe a meta-analysis approach that identifies novel biomarker modules that results in multiple clinical and therapeutic read-outs.

A co-expression meta-analysis of 5,339 breast tumors from 56 microarray datasets identified highly co-expressed sets of genes (modules) across multiple datasets. These module based biomarkers were tested for their ability to associate with prognostic and predictive targets in published datasets. In addition, each module was reduced from 10 – 1,000 genes to the top performing 2-3 genes based on the degree of co-expression across the meta-analysis and validation by quantitative PCR in an independent panel of FFPE tumor samples. This study demonstrates that a single 96 gene qPCR test utilizing multiple module biomarkers is not only capable of stratifying patients by standard histopathological parameters (ER, PR and Her2), but also stratifies by other diverse elements of the disease (cell lineage, dysregulated core biological functions, factors of cell growth, underlying genomic aberrations and the tumor microenvironment). Taken together, these biological variables represent the major biological diversity present within the breast cancer population. A series of retrospective analyses demonstrated that different single module and combinations of modules were capable of predicting a variety of clinical endpoints, including 5-year survival, neoadjuvant chemotherapy response in ER-patients and targeted therapy response in model systems. The molecular heterogeneity of breast cancer can be summarized by discrete gene expression modules that individually represent distinct biological pathways, and that collectively can be represented by as few as 96 genes. These breast cancer modules, together with outlier genes, allow for summarization of the entire transcriptional program and provide a universal assay with broad application to companion diagnostics development.

P1-07-05
HER2 Status Resolution in FISH and IHC “Double Equivocal” Breast Carcinomas by Quantitative Real-Time PCR.
Portier BP, Wang Z, Downs-Kelly E, Budd GT, Lanigan C, Tubbs RR. Cleveland Clinic, Cleveland, OH; Taussig Cancer Center; Cleveland Clinic, Cleveland, OH

Background:
Clinical testing for HER2 amplification/over-expression is performed by immunohistochemistry (IHC) and/or fluorescence in situ hybridization (FISH) as outlined by the ASCO/CAP guidelines. Although these guidelines standardize testing and reporting, in a subset of patients, HER2 is equivocal by both IHC and FISH (“Double Equivocal”). These double equivocal patients represent a clinically problematic sub-group that currently lack standardized management guidelines. In this study, we utilize Quantitative Real-Time PCR (Q-RT-PCR) to resolve HER2 status in invasive breast cancers that could not be resolved via IHC and FISH testing.

Material and Methods:
FISH for HER2 was performed on 2259 invasive breast carcinomas from 1/2008 to 12/2010. In accordance with ASCO/CAP, all equivocal HER2 FISH cases were reflex tested by IHC. In double equivocal cases, RNA extraction was performed following macro-dissection using High Pure RNA Paraffin Kit (Roche Applied Biosciences, Indianapolis, IN). Q-RT-PCR was carried out using TaqMan® RNA-to-CT™ 1-Step Kit with primers and probes for HER2, B2M, and GAPDH (Applied Biosystems, Foster City, CA). Q-RT-PCR results were expressed as the relative quantification of HER2 vs. two control genes, all normalized against calibrator RNA from the MCF7 cell line. Cut off for Q-RT-PCR HER2 overexpression was set using ROC curve analysis (MedCalc, Belgium).

Results:
In our cohort of 2259 patients, 124 (5.5%) had an equivocal HER2 result by primary FISH testing. Reflex HER2 testing by IHC was unable to resolve the HER2 status in 35 (1.5%) patients. Detection of HER2 overexpression by Q-RT-PCR was validated using 50 FISH confirmed amplified and 50 non-amplified cases. Q-RT-PCR performed on these 2 control populations generated two non-overlapping populations and ROC curve analysis using a cut off value of 7.0 showed 100% sensitivity and specificity in detection of HER2 overexpression. Application of Q-RT-PCR in the double equivocal sub-group resulted in resolution of HER2 status in all cases, 8 HER2 positive (test value ranging from 7.12 – 15.37) and 14 HER2 negative (test value ranging from 1.05 – 6.92).

Conclusion:
Application of Q-RT-PCR for HER2 represents a viable approach to resolve HER2 status in cases that fail classification by both FISH and IHC. Q-RT-PCR combines the precision and high sensitivity of real-time PCR with the morphological specificity of histological evaluation and ultimately allows definitive HER2 classification at the time of initial diagnosis. This knowledge of HER2 status at the time of diagnosis allows for comprehensive neoadjuvant treatment although, additional studies correlating response to anti-HER2 therapy and HER2 status by Q-RT-PCR are warranted.
PI-07-06

High Concordance of Protein (by IHC), Gene (by FISH; HER-2 Only) and Microarray Readout (by TargetPrint) of ER/PR/HER2: Results from the MINDACT Trial.

Viale G, Bogaerts J, van 't Veer L, Rutgers E, Piccart M, de Snoo F, Engelen K, Russo L, Dell’Orto P, Glas A, Cardoso F. On Behalf of the TRANSBIG Consortium & the MINDACT Investigators. European Institute of Oncology, Milan, Italy; European Organisation of Research and Treatment of Cancer; Brussels, Belgium; Netherlands Cancer Institute, Amsterdam, Netherlands; Institute Jules Bordet, Brussels, Belgium; AgendiaNV, Amsterdam, Netherlands; Champalimaud Cancer Center, Lisboa, Portugal

Background

Previously, the micro-array readout of ER, PR and HER2 by TargetPrint was shown to be strongly correlated with high quality immunohistochemistry (IHC)/FISH assessment, especially for ER and HER2. Concordance rates were 93% (k=0.79) for ER; 83% (k=0.65) for PR and 96% for HER2 (k=0.88) in 636 patients (Roepman et al., Clin Cancer Res, 2009). This study analysis was undertaken to further determine the correlation of microarray readout with IHC/FISH assessment both locally and centrally determined in the first 800 pts enrolled in the MINDACT trial. This work is essential to determine the quality of biological data in the two risk assessment methods used in MINDACT based upon which adjuvant chemotherapy decision is made, in order to exclude bias.

Methods

ER/PR/HER2 IHC assessment was performed on the first 800 primary breast cancers (BC) of pts enrolled in the MINDACT study. The assessment was performed locally at each center (n=800) and by central review at the laboratory of the European Institute of Oncology (n=626). A tumor was classified positive for ER and PR when 1% of tumor cells showed positive staining. HER2 IHC status was scored as 0, 1+, 2+ or 3+. A score of 3+ was considered positive. In 2+ cases FISH was performed to assess final HER2 status. Gene expression data for ER, PR and HER2 were obtained by TargetPrint stratified based upon which adjuvant chemotherapy decision is made, in order to exclude bias.

Results

Comparison of local assessment (IHC & FISH for HER2) with central review indicated highly similar results for receptor readout with a concordance of 98% (k=0.90) for ER; and 96% for HER2 (k=0.80) and slightly lower for PR (90% (k=0.72)). Comparison of central assessment (IHC & FISH for HER2) with micro array readout by TargetPrint indicated highly similar results for receptor readout with a concordance of 97% (k=0.88) for ER and 95% for HER2 (k=0.76). For PR the concordance was lower but still quite acceptable (85% (k=0.62)).

Conclusion

Local and centrally assessed ER, PR and HER2 status in the first 800 MINDACT patient samples indicate a high level of quality for pathology in the local participating hospitals. These results exclude any bias induced by a lower quality of “traditional” pathology results as compared to the centrally assessed MammaPrint, both used for risk assessment and adjuvant chemotherapy decision in the MINDACT trial. The microarray-based assessment of ER, PR and HER2 gives results comparable to IHC & FISH and provides an objective and quantitative assessment of tumor receptor status. These results indicate that TargetPrint can serve as a second pathology assessment for locally assessed parameters, especially since TargetPrint is part of a multi-profile platform for breast cancer treatment management. This work was funded by the Breast Cancer Research Foundation and the EU Framework Program VI.

PI-07-07

Assessing Two Methods of Meta-Analysis in Studies of Patients with Breast Cancer: Individual Patient Data-Based (IPD) Versus Literature Based Abstracted Data (AD) in 5 Meta-Analyses Including over 28,000 Patients. Are There Results Differences of Concern?

Gralla RJ, Bria E, Raptopoulos H, Sperduti I, Giannarelli D, Cognetti F. Hofstra North Shore - LIJ School of Medicine, Lake Success, NY; Regina Elena National Cancer Institute, Rome, Italy

Background: Meta-analyses are widely used to provide high level evidence to resolve controversies. Differences of opinion continue concerning the two most frequently used methods (IPD and AD) and their roles in providing reliable recommendations for Evidence-Based Medicine. Some regard the IPD method as being more accurate, yet it is time-consuming, expensive, and can be troubled by getting data from all investigators. We tested whether overall conclusions would differ between the two methods when using the same studies for comparison. To overcome limitations related to simple correlation analysis, and: 1) to weigh the agreement between these 2 approaches (Bland-Altman [BA], Lancet 1986), and 2) to evaluate the eventual predictive role of the data coming from AD over IPD, an analysis with multiple methods was performed.

Methods: 5 meta-analyses in breast cancer examining 9 outcomes which had been subjected to IPD meta-analysis were selected. Literature-based AD meta-analyses were then conducted. Hazard Ratios (HR) and Risk Ratios (RRs) with 95% confidence intervals (CI) were extracted or derived from original meta-analyses. At least 90% of patients’ reports were required for the IPD analysis. Methods agreement was analyzed according to the BA method, as differences or ratios, and a comparison with the Variance-Ratio test (F-test), and the Concordance Correlation Coefficient (CCC) was done. Correlations between IPD/AD-ratios were estimated using a linear regression model with Pearson (r) and R² coefficients (parametric) and Spearman’s Rho/Kendall’s Tau coefficient (non-parametric), to derive a predictive estimation on IPD when adopting AD. MedCalc® Software was used.

Results: 9 outcomes in 5 meta-analyses (28,358 patients) were analyzed, as seen in the table.

Graphical comparison between the deviation from the ‘line of identity’ identified with the B-A method did not show meaningful differences between AD and IPD (mean difference -0.01535, 95% CI -0.0315, 0.0008; mean ratio 0.9816, 95% CI 0.9625, 1.0008). No significant difference in the Variance (F-test 1.01, p=0.98), and a high concordance (CCC 0.9775, 95% CI 0.91, 0.99) were found. A highly significant correlation by both parametric and non-parametric tests allowed derivation of a linear regression equation able to predict estimation IPD results from AD data; R² = 0.97, p<0.001.

Conclusions: When analyzing the results of studies (AD) or patient results from those same studies (IDP) we found: 1) No significant or
meaningful differences between the 2 meta-analysis methods; and 2) Data from the AD analyses are able to predict those from IPD, without significant risk of overestimation.

**P1-07-08**

Background: Genomic grade (GG) is a 97-gene signature which improves the accuracy and prognostic value of histological grade (HG) in invasive breast cancer (IBC) (Sotiriou JNCI 2006). It is particularly useful in stratifying HG2 tumors into GG-1 (low grade) and GG-3 (high grade) tumors. In order to extend the applicability of GG on routinely-used formalin-fixed-paraffin-embedded (FFPE) samples, the original microarray MapQuant Dx® signature was converted into a RQ-PCR assay (PCR-GG). The study aimed at validating the grading classification performance of the newly developed PCR-GG test.

Methods: Subsets of genes derived from the original GG were selected by testing their grading classification and prognostic performances using different classifiers on 15 independent public microarray data sets. 25 most-performing genes were quantified by RQ-PCR using a TaqMan assay on a training set consisting of 91 early IBC cases graded acc. to the Elston-Ellis recommendations, and classification performance of various combinations assessed.

Analytical performance of the final reduced signature was assessed on 4 samples (5 RNA extractions and 3 RQ-PCR per sample) and used to define a 95% CI around the GG-1/GG-3 cut-off. Cases with a PCR-GG score falling into the 95% CI were considered “Equivocal” (Eq). Concordance with the MapQuant Dx® GG was assessed on 44 paired FFPE/frozen samples of the training set. Grade classification performance of the PCR-GG test was evaluated on an independent validation set of 396 FFPE samples retrieved from the Department of Pathology (2004 to 2010) of Institut Jules Bordet (Brussels, Be). FFPE samples from early invasive, NO, ER+, HER2-, ductal or lobular BC containing ≥30% inv. tumor cells were selected. Classification performance was evaluated on the whole cohort and by histological subtype.

Results: The PCR-GG signature is based on the expression of 6 reporter and 3 reference genes. Most of the genes are overexpressed in grade 3 tumors and those associated with proliferation. The 9-gene PCR-GG showed a high concordance with the original GG microarray test (95%). 388 eligible cases were available for validation. 336 samples contained ≥30% inv. tumor cells and 322 were successfully amplified, corresponding to a 96% technical success rate. The HG1, HG2 and HG3 distribution in the validation cohort were 27%, 55% and 18% resp. PCR-GG reclassified 84% of all tumors (Table 1) with an overall concordance of 90% (92% HG1/GG-1 concordance and 88% HG3/GG-3). 82% of HG2 tumors were reclassified into 74% GG-1 and 26% GG-3. Overall concordance was 91% in the Ductal subset (comprising 84% of all cases) and 89% in the Lobular subset.

Conclusion: The newly developed PCR-GG test composed of 9 genes will open its use in routine clinical practice.

**P1-07-09**

Estrogen Receptor (ER) mRNA and ER-Related Gene Expression in Breast Cancers That Are 1%-10% ER-Positive by Immunohistochemistry.

Iwamoto T, Booser D, Valero V, Murray JL, Koening K, Esteva FJ, Ueno NT, Zhang J, Shi W, Qi Y, Matsuoka J, Hortobagyi GN, Hatzis C, Symmans WF, Paszti E, The University of Texas MD Anderson Cancer Center, TX; Okayama University, Okayama, Japan; Nivera Biosciences Inc, MA

Purpose: Our goal was to examine whether borderline estrogen receptor (ER)-positive cancers, defined as 1-10% positivity by immunohistochemistry (IHC), show the same global gene expression pattern and high ESR1 mRNA expression as ER-positive cancers or are more similar to ER-negative cancers.

Patients and methods: ER status was determined by IHC in 465 primary breast cancers and with Affymetrix U133A gene chip (ESR1 mRNA gene expression: Probe set = 205255_at). We compared expressions of ESR1 mRNA and a 106-probe set ER-associated gene signature score between ER-negative (n=183), 1-9% (n=25), exactly 10% (n=6), and > 10% ER-positive (n=251) cancers. We also assessed the molecular class of the borderline ER-positive cases using the PAM-50 classifier.

Results: Among the 1-9%, 10% and > 10% IHC positive cases, 24%, 67% and 92% were also ER-positive by ESR1 mRNA expression. The average ESR1 expression was significantly higher in the > 10% IHC-positive cohorts compared to the 1-9% or completely negative cases but in these latter two cohorts ER expression was similarly low. The average ER gene signature scores were similar for the ER-negative and 1-9% IHC-positive cases, but significantly lower than in > 10% ER-positive cases. None of the 1-9% ER-positive cases were classified as Luminal A, 2 were Luminal B and 12 were Basal-like. Among the 10% ER-positive cases, 2 were Luminal A and 1 was Luminal B. Conclusion: Overall, 24% of the 1-9% and 67% of the 10% ER-positive cancers show ESR1 mRNA levels and gene signatures that are consistent with ER-positive, potentially endocrine sensitive tumors.

Validation of a Diagnostic Molecular Signature (EHT Dxl4) on Fine-Needle Aspirate Samples from Breast Tumors.

Delaloge S, André F, Fehlbaum P, Sol O, Vielh P, Institut Gustave Roussy, Villejuif, France; Exonhit, Paris, France

Background: A 1228-probeset molecular classifier (EHT Dxl4) able to discriminate benign breast lesions from breast adenocarcinoma with a 96% performance was previously identified in a panel of 71 fine-needle aspirate (FNA) samples of nodular breast lesions collected at Institut Gustave Roussy (IGR). The microarray which enabled the signature identification was based on the genomewide RNA analysis using the ExonHit’s SpliceArray™ technology. The objective of the current study was to validate the performance of the EHT Dxl4 molecular classifier on an independent cohort of FNA samples stored at the Centre de Ressources Biologiques at IGR.

Patients and methods: The samples were collected from women undergoing investigations for suspicious nodular breast lesions classified by ICDR ACR 4 or 5 on mammogram and/or ultrasonography. The morphological cytological analysis of FNA samples classified the
lesions as either benign, malignant or indeterminate. All samples were associated with a definite clinico-pathological diagnosis of the breast lesions. The first part of the study aims at confirming the sensitivity, specificity and overall performance of EHT Dx14 among lesions clearly classified by morphological cytology. The second part aims at establishing its performance among lesions with indeterminate cytological results.

Results: In the first part of the study, the EHT Dx14 transcriptomic signature was applied on a set of 94 FNA consecutive samples categorized as benign (n=47) or adenocarcinoma (n=47) on cytology. The benign/malignant status of the lesions was confirmed by subsequent investigations or follow-up. Results of EHT DX-14 assessment of the samples were respectively 97.9% (95%CI: [88.7%-99.9%]) for sensitivity and 91.5% (95%CI: [79.6%-97.6%]) for specificity. Results on indeterminate FNA samples are being investigated in the second part of the study.

Conclusion: This study did confirm the high performance of EHT Dx14 signature in identifying malignant from benign breast lesions in clinically suspect lesions. EHT Dx14 may provide adequate biological diagnosis in the absence of capability of morphological evaluation.

P1-07-11
Consistency and Control in Clinical Assay Technology over Time: The Oncotype DX Recurrence Score and Assessment of Single Gene Expression Levels.

Background: ASCO® and CAP have recently highlighted the importance of consistency and control in clinical assay technology. To date the Oncotype DX® Recurrence Score® (RS) has been ordered to assist in individualized treatment decision making in over 200,000 estrogen receptor positive, early stage breast cancer patients. The assay quantifies gene expression using RT-PCR from fixed paraffin embedded tissue (FPET) and employs a large number of controls and calibrators to enhance precision and reproducibility. Over 6 years of data on the assay presents an opportunity to explore consistency over time in the RS and quantitative single gene levels (ER, PR, HER2).

Methods: All tumors successfully analyzed in the Genomic Health Laboratory from 1/1/05-3/31/11 were included. Descriptive statistics for the RS, the average reference gene expression level, and expression levels for quantitative single genes were obtained for each calendar year. This was done for the entire data set as well as for subgroups defined by histological tumor type. The associations by year between HER2 and GRB7, ER and HER2, and ER and PR expression levels were explored including scatterplots and summary statistics.

Results: There were a total of 207,691 breast cancer cases, and the number in each calendar year increased over time as shown in the Table. In general the median age increased slightly over time, as did the proportion of patients in the low RS Risk Group. There was no systematic change over time in the average reference gene expression level, or in the expression levels for the individual genes ER, PR or HER2 during the period from 2008 to 2011 when individual gene testing was provided as part of the Oncotype DX assay report. The relationships between HER2 and GRB7, ER and HER2, and ER and PR remained consistent over time.

Conclusions: Active monitoring of the Oncotype DX assay as mandated by ASCO/CAP shows a high degree of consistency in results for both the multigene Recurrence Score and the quantitative single gene results. These results and the approaches used for monitoring consistency are relevant to other institutions in their efforts to maintain and improve assay quality control.

P1-07-12
Assessment of Real World HER2 Status by Immunohistochemistry (IHC) and Fluorescence In Situ Hybridization (FISH) in Breast Cancers: Comparison with HERMark®, a Validated Quantitative Measure of HER2 Protein Expression.

Huang W, Paquet A, Sivaraman S, Pesano R, Goodman L, Sherwood T, Lie Y, Hickey J, Walworth C, Haddad M, Anderson S, Bates M, Weidler J. Monogram Biosciences Inc., South San Francisco, CA; Incyte Corporation, Wilmington, DE; Quest Diagnostics Nichols Institute, San Juan Capistrano, CA; Affymetrix, Santa Clara, CA; Gilead Sciences, Inc, Foster City, CA; Cepheid, Sunnyvale, CA

Background: Accurate assessment of the HER2 status is critical in determining appropriate therapy for patients with invasive breast cancer. ASCO/CAP HER2 testing guidelines caution that up to 20% of routine HER2 testing by IHC/FISH may be unreliable (Wolff et al. JCO 2007:25:118). The HERMark assay is a novel quantitative HER2 protein measurement for determining HER2 status in breast cancer. Central HER2 testing showed high concordance (96-98%) with HERMark for positive and negative categories when equivocal subsets were excluded (Huang et al. Am J Clin Pathol 2010; 134:303; Joesuus et al. 2008 SABCS, abstract 2071). In this study, we examined concordance between HERMark and routine HER2 testing by IHC and FISH from “real world” formalin-fixed, paraffin-embedded (FFPE) breast cancers submitted commercially for HERMark testing.

Methods: 717 HERMark results on FFPE breast cancers tested from 2008 to 2010 and corresponding HER2 IHC/FISH results were reviewed. The IHC and FISH results, per pathology reports submitted at the time of HERMark testing, were compared to HERMark categorical (negative, equivocal, positive) results.

Results: 590 (419) samples had IHC (FISH) and HERMark results available. Of these cases, 92% (94%) were either negative or equivocal by IHC (FISH). The HERMark testing reported 33% HERMark positive, 33% HERMark equivocal and 34% HERMark negative. Comparisons of HER2 status by IHC and FISH vs. HERMark are detailed in Table 1.

Table 1: Comparison of HERMark with HER2 IHC and FISH.

Conclusions: Active monitoring of the Oncotype DX assay as mandated by ASCO/CAP shows a high degree of consistency in results for both the multigene Recurrence Score and the quantitative single gene results. These results and the approaches used for monitoring consistency are relevant to other institutions in their efforts to maintain and improve assay quality control.
Central HER2 FISH retesting of these samples will be performed and compared with HERmark results to further evaluate the discordance observed in this analysis.

Efficiency of a Laboratory Developed HER2 FISH Test on Circulating Tumor Cells.  
Mayer JA, Pham T, Wong KL, Scoggin J, Sales EV, Clarin T, Pircher TJ, Mikolajczyk SD, Cotter PD, Bischoff FZ. Biocept Inc, San Diego, CA

INTRODUCTION: Most circulating tumor cell (CTC) platforms rely on EpCAM for capture and cytokeratin (CK) for detection. However, an important population of cells that are CK-negative (i.e. cells with epithelial-mesenchymal transition (EMT) phenotype) will be missed. We report a new strategy to efficiently isolate a more heterogeneous population of CTCs using an antibody cocktail.

METHODS: In the first prospective study, blood (20 mL) was collected from 89 patients diagnosed with various late stage metastatic/recurrent cancers (breast, CRC, lung, prostate) following IRB approval. PBMCs were incubated with either EpCAM alone or a mixture of 10 capture antibodies to target both epithelial and mesenchymal cells. CTCs were subsequently captured in the OncoCEE™ channels and detected with cytokeratin (CK) and CD45. A second prospective IRB approved study involving 54 patients diagnosed with late stage metastatic/recurrent breast cancer was performed using similar detection strategies (CK cocktail mixture and anti-CD45) with the addition of HER2 FISH to determine amplification status among captured CK+/CD45- and CK-/CD45- cells.

RESULTS: In the first study, overall detection of CK+ cells was 83% with EpCAM alone and 93% with antibody cocktail. In addition, a median of 0.4 CK+ cells/mL and 1.0 CK+ cells/mL was observed using EpCAM and antibody cocktail, respectively. In the second study, CK+/CD45- cells were detected in 43 of 54 cases (80%). Among the 43 cases in which CK+/CD45- cells were detected, high concordance (93%) in HER2 status between primary tumor and CTCs was observed with HER2 amplification noted in both CK+/CD45- (50%) and CK-/CD45- (50%) cells.

CONCLUSIONS: We have developed a novel and robust method for CTC enumeration that utilizes a cocktail of antibodies for the detection of a heterogeneous (CK+ and CK-) population of CTCs. Our findings suggest an important population of CK- cells is being missed by current stain criteria in breast cancer patients. Data also demonstrate that recovery of CTCs from peripheral blood using the OncoCEE™ platform is efficient and suitable for FISH-based laboratory testing.

Quantum Dot-Labelled Antibodies To Assess HER2 Expression In Breast Cancer.  
Zona S, Blackburn E, Hojijaleslami AS, Brown IR, Gullick WJ. University of Kent, Canterbury, Kent, United Kingdom

Background: The Human Epidermal Growth Factor Receptor 2 (HER2) is overexpressed in 18-20% of breast cancers. Herceptin is an effective drug for the treatment of breast cancers expressing high levels of HER2. It is well known that there is a correlation between levels of HER2 expression and response to Herceptin. However a proportion of patients selected for Herceptin treatment do not respond to the drug. The accuracy of the assessment of HER2 levels in breast cancer is therefore important to predict patients’ response to Herceptin therapy. The current techniques in clinical use for the assessment of HER2 are immunohistochemistry (IHC) and fluorescence in situ hybridization (FISH); however both IHC and FISH have several limitations which may result in patient misclassification. A more accurate technique, which can quantify HER2 levels more precisely, could help to improve clinical diagnosis, prediction of prognosis and allow more accurate select individual patients for particular drug therapies.

Materials and Methods: We employed QDs labelled antibodies, laser scanning confocal microscopy and image segmentation techniques to quantify HER2 expression in cases of formalin fixed paraffin embedded breast cancers. Quantum dots (QDs) are a new class of fluorochromes made of semiconductor nanocrystal which have several useful properties for quantitative image analysis. In order to validate the system we used a breast cancer HER2-IHC control tissue array with negative, low, moderate and strong expressing cases, and a tissue microarray containing 60 samples of formalin fixed paraffin embedded breast cancer sections, previously examined by IHC and scored semi-quantitatively (0-3+). We then applied this system to quantify HER2 expression a tissue microarray containing 150 primary breast cancers scored as 3+ by IHC from patients treated with Herceptin.

Results: We first demonstrated that the QD system could reliably detect HER2 expression in IHC 3+ cases. A comparison of immunofluorescent staining with conventional immunohistochemistry showed that QDs give more linear and scalable measurements of receptor levels. We also quantified HER2 within a set of 150 breast cancers scored as 3+ by IHC, and we found that HER2 is expressed at very different levels, ranging over fifty fold between individual (IHC3+) cases. We currently are evaluating the correlation between HER2 receptor levels, measured by QDs, and patient’s response to Herceptin.

Conclusion: QDs and image analysis can produce a more precise measurement of HER2 levels of expression than IHC. This should help to improve clinical diagnosis, prognosis, identify specific treatments for individual patients and reduce costs associated with Herceptin treatment. This technology may be applied to study other members of the EGF family in breast cancers or more widely as a quantitative measurement of biomarkers in tumours.

P1-07-15  
The Reliability of Ki-67 Expression Assessment Using Core Needle Biopsy and Surgical Specimens of Invasive Breast Cancer: Can Ki-67 Change Predict Benefits of Preoperative Endocrine Therapy?  
Mizuno Y, Takayanagi H, Sato K. Tokyo-West Tokushukai Hospital, Akishima-City, Tokyo, Japan

Background: The use of Ki-67 change as a predictive marker in breast cancer has been widely investigated in patients treated with preoperative endocrine therapy. It has been assumed that Ki-67 expression determined using core needle biopsy and surgical specimens of invasive breast cancer is concordant. Many studies have suggested the concordance of the results obtained using core needle biopsy and surgical specimens for expression of the estrogen receptor (ER), progesterone receptor (PgR), and human epidermal growth factor receptor type2 (HER2) status in early-stage breast cancer. However, there was few study to compare Ki-67 expression in the core needle biopsy and surgical specimens. We conducted a retrospective study of Ki-67 expression assessment between the two types of specimens to answer this question.

Methods: A total of 269 patients underwent primary operations for early-stage breast cancer at Tokyo-West Tokushukai Hospital from August 2008 to May 2011. Among these patients, 169 patients who received core needle biopsy prior to operation were enrolled.
Patients with ductal carcinoma in situ and those with neoadjuvant chemotherapy were excluded. A cutoff value of 20% was used for Ki-67-positive criteria. We also examined ER, PgR, and HER2 expression and compared it with Ki-67 expression. Statistical significance for concordance rates between the two types of specimens was evaluated by Wilcoxon t-test. To evaluate the consequence of formalin and genetic heterogeneity, parameters such as operative method and tumor size were analyzed by χ² analysis.

**Results:** The concordance rate between the two types of specimens for Ki-67 expression was 76%, and this was significantly lower than that for ER expression, which was 96%. The concordance rates for PgR and HER2 expression were 88% and 91%, respectively, and they were not significantly different from the rate for Ki-67 expression. 45 patients (34.6%) had received mastectomy in the Ki-67 concordant group, and 14 patients (34.1%) in the discordant group. 55 patients (42.0%) showed T2 tumor size in the concordant group, 13 patients (31.7%) in the discordant group. No significant differences of parameters such as operative method (mastectomy vs breast conserving surgery) and tumor size (T1 vs T2) were observed between the two patient groups.

**Conclusion:** The reliability of Ki-67 concordance rate assessment using core needle biopsy specimens was significantly lower than that of ER expression. A standard pathological assessment of Ki-67 expression might be needed for the possible use of Ki-67 as a predictive marker for preoperative endocrine therapy.

**Number Needed To Count: A Novel Model for Ki67 Assessment in Breast Cancer.**

**Background:** Tumor proliferation assessed by Ki67 is frequently used as a prognostic and above all treatment predictive marker in breast cancer where a decrease in Ki67 expression, following neo-adjuvant therapy, may be interpreted as a reliable treatment effect. Previous studies have indicated that the optimal number of tumor cells needed to count may vary from case to case. The standard error of the estimated proportion will decrease with increasing number of tumor cells counted (n), but a dilution bias will affect the estimate in cases with few tumor cells within a hotspot area. Hence, a large n is appropriate in Ki67-homogeneous hotspot areas and inappropriate, at least for small hotspots, in case of heterogeneity. Further, a chosen cut-off value has implications for the choice of n. A low n may be sufficient for extreme proportions, but the closer the true unknown proportion is to the cut-off, the larger n will be required. The lack of consensus concerning Ki67 assessment may jeopardize the comparison of research results. Hence, a standardized counting model is warranted.

**Material and Methods:**

Exact two-sided confidence intervals for proportions based on the binomial distribution were used to derive rejection regions for sequential testing of the null hypothesis that the fraction of Ki67-positive cells is equal to the chosen cut-off (20% in this study). A lower limit of 50 counted tumor cells to get a reasonably stable estimate and an upper limit of 400 tumor cells to prevent extreme dilution bias for small hotspots, were applied. Briefly, the counting strategy can be explained as follows: Locate a hotspot and count 50 tumor cells. If the Ki67 estimate belongs to the upper or lower rejection region, stop counting. If not, count another 10 tumor cells and perform a new hypothesis test. Proceed until either the null hypothesis has been rejected or the upper limit of 400 has been reached. Simulation was used to determine that a nominal significance level of α=0.01 for each test will keep the overall probability of falsely rejecting the null hypothesis fixed at 0.05. The novel counting strategy was compared to static counting of 200 tumor cells using 100 Ki67-stained breast cancer samples.

**Results:** The median number of tumor cells needed to count to determine Ki67-status was 100 and the average 175. The rejection region was reached immediately after 50 tumor cells counted for 32 samples with Ki67-levels far from the cut-off, whereas counting 400 tumor cells was insufficient for classification in another 18 samples. In samples classified as highly proliferative (>20%), the mean Ki67-estimate was 49% using the counting model compared to 42% using a fixed denominator of 200 tumor cells. The largest absolute difference between the two estimates for these 32 samples was 23% - from 42% (model) to 19% (static), thus more than a factor two and a dilution effect leading to changed Ki67-status.

**Conclusions:** Estimation of the fraction of Ki67-positive tumor cells using a fixed denominator may be inadequate – especially for small hotspots. We hereby propose a strategy for tumor cell count optimization that hopefully will contribute to standardization of the counting practice for tumor proliferation assessed by Ki67.

**Multiplex Plasma Biomarkers Associated with Bone Metastasis from Breast Cancer.**

**Background:** Over two-thirds of breast cancer patients who relapse will develop bone metastasis, and there are currently no effective biomarkers to predict for this event. Multiplex immunoassay technology for 60 bone metastasis-associated biomarkers was conducted on pretreatment plasma from 40 patients enrolled in a 2nd-line phase III hormone therapy trial of metastatic breast cancer, to discover effective circulating biomarkers predictive of bone metastasis.

**Methods:** Pretreatment EDTA plasma from 20 patients with bone metastasis, and 20 patients with non-bone metastasis from the letrozole-megace 2nd-line phase III hormone therapy trial of metastatic breast cancer was evaluated using Searchlight multiplex immunoassay technology (Aushon Biosciences, Billerica, MA) on 60 biomarkers custom-selected for known association with bone metastasis. Multiplex data analysis for maximal discrimination of bone metastasis vs. no bone metastasis cohorts was performed by two independent statisticians: one evaluated the predictive capacity of individual biomarkers as well as two-marker combinations constructed by Monte Carlo optimization using Metropolis algorithm (MMC), and the other used a machine learning technique called hybrid bootstrapped RLDA + PCA (regularized linear discriminant analysis with principal component analysis, with dimensionality reduction used in the bootstrapping procedure).

**Results:** One of the 60 analytes (IL-17) was undetectable at the 1.6 pg/ml lower limit of detection, and was not included in the multiplex statistical analyses. Of the remaining 59 analytes, MMC multiplex analysis yielded 9 biomarkers that predicted for bone metastasis, whereas RLDA + PCA multiplex analysis yielded 20 predictive biomarkers. Common to both analyses, which were limited in this
small 40 patient study, were 5 biomarkers, with varying functions including growth factors, cytokines, inflammatory factors, protease inhibitors, and cell adhesion molecules.

Conclusions: Multiplex analysis of 60 biomarkers custom-selected for known association with breast cancer metastasis to bone yielded 5 pretreatment plasma biomarkers classified as predictive of bone metastasis by 2 different multiplex statistical analysis methods. Evaluation of these biomarkers is now warranted in a larger validation cohort of breast cancer patients with and without bone metastasis.

P1-07-18
Expanding an Online Tool for Genome-Wide Validation of Survival-Associated Biomarkers in Breast and Ovarian Cancer Using Microarray Data of 3,862 Patients.

Gyorffy B, Laneczky A, Szallasi Z. Semmelweis University, Budapest, Hungary; Harvard Medical School, Boston

The pre-clinical validation of prognostic gene candidates in large independent patient cohorts is a pre-requisite for the development of robust biomarkers. We earlier implemented an online tool to assess the prognostic or predictive value of the expression levels of all microarray quantified genes in breast cancer patients. In present study, we further expanded our database, added additional analytical options and implemented the tool for ovarian cancer patients. The database was set up using gene expression data and survival information of breast and ovarian cancer patients downloaded from GEO and TCGA (Affymetrix HGU133A, HGU133A 2.0 and HGU133+2 microarrays). After quality control and normalization only probes present on all three Affymetrix platforms were retained (n=22,277). Patients can be stratified into the various robust subtypes either by histology or by various gene expression profiling based methods. To analyze the prognostic value of the selected gene in the various cohorts the patients are divided into two groups according to the median expression of the gene. A Kaplan-Meier survival plot is generated and significance is computed. All together 2,472 breast cancer patients and 1,390 ovarian cancer patients were entered into the database. These groups can be compared using relapse free survival (n=2,414 in breast cancer and 1,090 in ovarian cancer), or overall survival (n=463 and n=1,290). Follow-up threshold has been implemented to exclude long-term effects. The combination of several probe sets can be employed to assess the mean of their expression as a multigene predictor of survival and therapy efficiency. In summary, we expanded our global online biomarker validation platform to mine all available microarray data to assess the prognostic power of 22,277 genes in 2,472 breast and 1,390 ovarian cancer patients. The tool can be accessed online at: www.kmplot.com/breast and www.kmplot.com/dev/ovar.

P1-07-19
Analysis of HER2-Status in Breast Cancer by Mass Spectrometry in Archival, Formalin-Fixed Tissues.

Sanders M, Sprung R, Ham A, Sanchez V, Manning S, Arteaga C, Liebler D. Vanderbilt University Medical Center, Nashville, TN

HER2 (ERBB2) is overexpressed in about 25% of breast cancers and predicts clinical benefit from trastuzumab, as well as response to anthracycline-based chemotherapy. Fluorescence in situ hybridization (FISH) to detect HER2 gene copy number and immunohistochemistry (IHC) to detect HER2 protein levels are approved by the FDA to identify HER2-positive (H2) tumors. However, the 2007 ASCO/CAP report concluded that approximately 20% of HER2 testing may be inaccurate. Further, the available data did not clearly demonstrate clear superiority of either IHC or FISH as a predictor of benefit from anti-HER2 therapy. Discordance between these methods is as high as 5%. Thus, novel complementary quantitative methods for interrogating HER2 expression in tumors are needed.

Targeted protein analysis by multiple reaction monitoring mass spectrometry (MRM-MS) offers a powerful approach to configure assays for specific proteins without using antibodies. Our studies using this platform have demonstrated applicability to formalin-fixed, paraffin-embedded (FFPE) specimens. In the current studies, we used this approach to measure signals from two tryptic peptides specific to HER2, one each from the extracellular and intracellular domains, selected from among 28 candidates based on their signal intensity and sharpness of their chromatographic profiles. Preliminary studies with a HER2-overexpressing BT474 xenograft in mice demonstrated quantitation and detected previously reported HER2 ectodomain shedding. Subsequent analysis of FFPE tissue from five H2 and five triple-negative (TN) tumors yielded measurement of at least 1 femtomole of receptor for H2 tumors and less than 0.2 femtomole of receptor for TN tumors per microgram of digest analyzed. If we assume 200 picograms of protein per cell, the results suggest 110.00 to 468,000 receptors per cell in the H2 tumors and only 2,000 to 14,000 receptors per cell in the TN tumors. Despite significant biological variability in receptor levels measured among the specimens of each type, a clear separation of the H2 and TN tumors was achieved based on the peptide quantitation. This preliminary study demonstrates the potential of MRM-MS in FFPE tissue to provide an alternate approach to IHC-based protein analysis. MRM-MS offers the potential for more, accurate and robust HER2 quantification in clinical breast cancer tissues. The next phase of this work will encompass a larger sample set, including tumors with equivocal and negative FISH and/or IHC test results. Correlation with response to anti-Her2 therapy will be performed in samples with available follow-up data.

P1-07-20
Consistent High False Negative Rate of HER2 qRT-PCR of Oncotype DX® in Comparison to ASCO/CAP Recommended Combined IHC/FISH Method.

Dubbs DJ, Bhargava R. Magee-Womens Hospital of UPMC, Pittsburgh, PA

Background

In our prior multi-institutional study of 843 cases we have shown a high false negative rate for HER2 testing by the oncoTYPE DX® RT-PCR method, (ODX) compared to our combined FISH and IHC approach [J Clin Oncol 29: 2011 (suppl; abstr 603)]. This study is part of an ongoing quality assurance study, comparing HER2 test results by FISH/IHC and the ODX.

Methods

From July 2010 till April, 2011, all patients who had either positive or equivocal HER2 results (on core biopsy) at Magee-Womens Hospital (MWH) by combined IHC/FISH, and who also had the ODX ordered (on resection specimen) by an oncologist, were reviewed for positive concordance of HER2 results. All tissues were fixed and FISH/IHC was reported according to ASCO/CAP HER2 guidelines. The core biopsy HER2 positive results were also confirmed positive on the same tissue block that was tested by ODX.

Results

Of the total 234 cases, there were 21 cases that were either classified as positive (n=8) or equivocal (n=13) by combined IHC/FISH approach at MWH. Of the 8 MWH+ cases, 4 showed 3+ IHC score and these were also positive by ODX. The remainder 4 MWH+ cases were IHC 2+, and unequivocally amplified by FISH. These 4 cases were
either equivocal (2 cases) or negative (2 cases) by ODX. Thirteen cases reported as equivocal by MWH FISH, were all reported as negative by ODX. Of the 213 MWH negative cases, 212 were also negative by ODX (percent negative agreement of >99%) and one case was called equivocal. If all equivocal cases are excluded, then percent positive agreement (PPA) between IHC/FISH and ODX is 67% (4/6). If “equivocal” cases are considered as “negative”, then PPA is 50% (4/8). If “equivocal” cases are considered as “positive”, then PPA is only 29% (6/21).

Conclusions
(1) Similar to our prior study [J Clin Oncol 29: 2011 (suppl; abstr 603)], there is a consistent poor percent positive agreement for HER2 testing between FDA cleared FISH/IHC methods and ODX, and these results cast serious doubt on the robustness/reliability of ODX results for HER2. (2) There should be serious concern raised over the reliability of the other multiplex IHC product results of ODX, and likely, the ODX recurrence score for an individual patient, as this sensitivity data suggests inadequate tissue microdissection, or issues with the ODX test platform. (3) Clinicians need to be aware that HER2 results of ODX are not reliable for patients who are equivocal or amplified by FDA approved methods, and only FDA approved methods should guide treatment decisions.

P1-07-21
Analysis of Molecular Markers by Immunohistochemistry (IHC) Method on Formalin Fixed Paraffin Embedded (FFPE) Tissues Could Predict Shorter Recurrence Free Survival (RFS) and Overall Survival (OS) among Patients Who Have Received Adjuvant Chemotherapy for Early Breast Cancer.
Moe M, Gee J, Finlay P, Mansel R, Adams R, Singleton Hospital, Swansea, United Kingdom; Velindre Hospital and Cardiff University, Cardiff, United Kingdom; Cardiff University, Cardiff, United Kingdom

Background: Various molecular markers assessed by IHC (ER, PR, HER2) and gene expression profiling (e.g. Oncotype Dx) have been developed as prognostic and predictive tools for breast cancer. Gene profiling is said to be superior to IHC but at a considerable cost with limited availability. IHC is relatively inexpensive and more readily available. If early breast cancer patients who are going to relapse within 5 years of curative surgery despite adjuvant chemotherapy could be identified by IHC on FFPE tissue alternative adjuvant therapies could be explored. In this context, we here evaluate IHC for expression of a panel of molecular markers implicated in: growth signalling pathways (ER, PR, HER2, EGFR, CD71, Ki67, MCM2), cell survival (Bcl-2, Bag 1), angiogenesis (PDGFrA) and cell cycle progression (Aurora A, MCM2). Of note, this study includes markers of breast cancer molecular subtype (ER, PR, HER2, Ki67, EGFR, also CK5/6) and several proteins encoded by genes in the Oncotype Dx test (ER, PR, HER2, Ki67, Bcl2, Bag1 and CD68).

Materials and Method: 72 cases (R) relapsing within 5 years of curative surgery, 72 controls (C), relapse free > 5 years were identified from the hospital records. All patients had adjuvant chemotherapy. Controls were matched to cases by Adjuvant! recurrence risk (ARR). Optimised IHC was performed on FFPE TMA slides using a Ventana autostainer. Protein expression was evaluated on digitalised images (Mirax scanner). Survival analysis by molecular markers expression and also 5 molecular subtypes, Luminal A (LA = ER/PR+, HER2−, Ki67−), Luminal B (LB = ER/PR+, HER2/Ki67+), HER2 enriched (H = ER−, PR−, HER2+), Core Basal (CB = ER−, PR−, HER2−, CK5/6/EGFR−) and 5-negative (5N = negative for ER, PR, HER2, EGFR, CK5/6), were performed. SPSS 16v. was used for statistical analysis.

Findings: All but four cases had died at the time of analysis. Four controls developed relapse at 83.8, 90.6, 107.7, 127.6 months respectively. Two controls died from non-breast cancer causes. Median follow-up for the controls group (ie. mOS) was 104.9 mo (72.8 - 164.4). For cases, mRFS and mOS were 23.2 (4.5 - 59.9) and 39.7 (8.1 - 129.7). mRFS and mOS for HER2 molecular subtypes were: Subtype LA = not yet & not yet; LB = 58.1 & 86.1; CB = 15.4 & 30.4; H = 28 & 55.9; 5N = 19.9 & 26 (p < 0.0001 & <0.0001 by Log rank test). Better RFS and OS were found for positive Bcl2 (p = 0.036 & 0.058) and MCM2 (p = 0.022 & 0.048), negative Aurora A (p = 0.01 & 0.001) and PDGFRA (p = 0.07 & 0.086) expressions. For this study cohort there was no correlation between ARR and survival outcome or molecular subtypes. Result of ongoing multivariate analysis and correlation between survival and CD68, CD71 and Bag 1 expressions will be presented in the conference.

Discussion: Subtypes CB & 5N, negative Bcl-2 & MCM2, positive Aurora A & PDGFRA expression as measured by IHC were predictive of poor RFS and OS. While these findings need to be verified in an independent cohort, IHC profiles nevertheless have potential to stratify different risk groups for clinical trials and effective adjuvant treatments.

P1-07-22
A Venezuelan Study of Breast Cancer Estrogen Receptor, Progesterone Receptor and HER2 Receptor Expression by the Standard Method, Immunohistochemistry (IHC), Compared to a New Method, Quantitative Reverse Transcription Polymerase Chain Reaction (RT-PCR).
Marin C-EM, Ramirez AC, Baehner FL, Yoshizawa C, Acosta MM. Fundacion BADAN; Caracas, Miranda, Venezuela; Genomic Health, Redwood City, CA

Background: Assessment of ER, PR and HER2 is of significant importance in breast cancer diagnosis and treatment. We have performed the first large assessment of central IHC for ER, PR and HER2 by a South American (Caracas, Venezuela) Central Lab to Central Lab RT-PCR by Oncotype DX®.

Design: Breast cancer specimens from the Fundación BADAN were evaluated by IHC for ER (clone 1D5), PR (clone 636) using 1% staining for positivity using ASCO/CAP guidelines and HER2 (clone A0485) using ASCO/CAP guidelines of 3+ in ≥30%. Standardized quantitative RT-PCR analysis for ER and PR used Oncotype DX with the pre-defined cutoffs of 6.5 units and 5.5 units for positivity, respectively. For HER2 the standard pre-defined cutoffs were used: positive ≥11.5 units, equivocal >10.7–<11.5 units, and negative ≤10.7 units. For HER2 concordance analysis the equivocal range was excluded from both assays according to ASCO/CAP Guidelines (Wolff et al, 2006). For all quantitative RT-PCR assessments the reference normalized expression measurements ranged from 0 to 15, where each 1-unit increase reflects about a 2-fold increase in RNA.

Result: Evaluable data was obtained in 96 pts for ER, 95 pts for PR (1 patient assessment unavailable) and 89 pts for HER2 (7 patient assessments unavailable). Two-by-two tables (below) compare IHC versus RT-PCR for ER, PR and HER2. The overall concordance for ER between IHC and RT-PCR was 94% (Kappa 0.467; 95% CI 0.307, 0.628); for PR between IHC and RT-PCR was 92% (Kappa 0.668; 95% CI 0.457, 0.878); and for HER2 between IHC and RT-PCR was 97% (Kappa = 0.649; 95% CI 0.280, 1.000). Three IHC 2+ cases and 4 equivocal cases by Oncotype DX were excluded from Concordance and Kappa statistics.

Conclusion: RT-PCR by Oncotype DX for ER, PR and HER2 status is useful for active monitoring of IHC assays as mandated by ASCO/
CAP guidelines. There is a high degree of overall concordance between central IHC performed in South America (Caracas, Venezuela) and central RT-PCR for ER, PR and HER2 status.

### P1-07-23

**Absolute Quantification of Estrogen Receptor alpha in Breast Cancer.**

Britton D, Scott G, Russell C, Held J, Ward M, Benz C, Pike I. Proteome Sciences Plc, London, United Kingdom; Buck Institute, Novato, CA

Estrogen receptor alpha (ER) is the first biomarker to have been clinically validated as a predictor of cancer therapy response. Measurements of tumor ER expression were based on radiolabeled ligand binding to receptor present in tumor lysates. Despite substantial tissue requirement, lack of specificity for ER isoforms (alpha versus beta) or receptor integrity, quantitative determination of tumor ER content (fmol/mg total protein) was possible. Introduction of anti-ER antibodies later permitted immunohistochemical (IHC) evaluation of ER expression. IHC determination of ER status in newly diagnosed breast cancer is now a standard of care. While these IHC assays have been shown to be as predictive of endocrine responsiveness as ligand binding assays, they remain semi-quantitative at best reporting tumor ER status either categorically (e.g. + or -) or as a numeric score which is subjective and lacks a linear relationship with endocrine responsiveness. Thus the lack of precision for quantifying ER as a predictive biomarker is one of the most important unresolved issues in breast cancer. We are working to develop a proteomic liquid chromatography-mass spectrometry (LC-MS) assay to help resolve this issue. Samples included recombinant ER (rER), immunoprecipitated (IP) rER, and IP ER from MCF7 cells. ER was digested with trypsin, lyophilised and solubilised in 5 femto-mol/ microliter (100 μl) heavy peptide internal standard mix. ER peptides were resolved by LC (100 μl/minute) and detected by selected reaction monitoring MS. The area under the total ion chromatogram for each peptide was used to quantify the amount of analyte present in each sample as a single point reference to the signal of the heavy peptide spike. An 11 point calibration curve (0.1-1000 fmol on column (o/c)) of light peptides with each point in the curve spiked with 100 fmol heavy peptide was also produced to determine assay characteristics such as limits of detection (LOD), limits of quantification (LOQ), linearity, accuracy and precision. Three ER peptides were selected for quantification as they gave the greatest LOD, LOQ, linearity as well as reasonable intra- and inter-assay precision following multiple digestions of rER (intra = 3 digestions in 1 day; inter = 9 digestions over 3 weeks).

Following IP of ER from four replicates MCF7 cell lysates (1mg/ ml total protein) and measurement of ion intensities of the three ER peptides the mean concentration of ER was calculated to be 52 fmol (S.D of 7.5 fmol; n=4) per mg of total cell lysate after normalising for IP efficiency. We continue to develop the method to improve sensitivity and normalise for variability in IP and digestion. With the inclusion of reference peptides to known ER phosphorylation sites we are also in the process of quantifying ER phosphorylation. We aim to accurately determine ER concentration and phosphorylation status in tumor lysates and assess how these correlate with responsiveness to antiestrogen therapies.

---

**Quantitative and Immunohistochemical Detection of Breast Cancer Cells in Blood Samples.**

Andergassen U, Zebisch M, Kölbl AC, Schindelbeck C, Jäger B, Hepp P, Janni W, Jeschke U, Friese K, Rack BJ. Ludwig-Maximilians-University Muenchen, Munich, Bayern, Germany; Heinrich-Heine-University Düsseldorf; Duesseldorf, NRW, Germany; Klinikum Traunstein, Traunstein, Bayern, Germany

**Background**

Disseminated tumor cells (DTCs) in bone marrow and circulating tumor cells (CTCs) in blood are found in patients with epithelial carcinomas (breast cancer) and are often correlated with poor prognosis of the disease. In current models circulating tumor cells (CTCs) dissolved from the primary tumor are thought to be responsible for the occurrence of metastases. However, the detection of CTCs is still a technical challenge. In this study, two methods for tumor cell detection of patients’ samples are presented (Real-Time-PCR and immunohisto-chemical staining). Both are simple and known methods with a high sensitivity and a spread marker panel.

**Materials and Methods**

For the implementation of both methods, different breast cancer cell lines have been used (Cama-1, MCF-7; ZR-75-1). For Real-Time-PCR, blood samples of a healthy donors were spiked with different cell counts (0, 10, 100, 1000, 10.000 and 100.000) per ml blood sample. Total RNA was isolated from the samples, reversely transcribed into cDNA and used for TaqMan Real-Time-PCR reaction with probes against CK8, 18 and 19, while 18s was used as reference. Relative Quantification Curves were drawn by Microsoft® Excel®. For immunohistochemical staining, cytospins were prepared from spiked blood samples, fixed with acetone, air dried and stained with antibodies against Her2- and Thomsen-Friedenreich-Antigen (CD176). In a second staining step fluorescently labelled secondary antibodies were applied. Nuclei were counterstained with DAPI, TF-Antigen was stained by Cy2 and Her2-Antigen by Cy3. The staining was controlled and documented by an epifluorescence microscope.

**Results**

The curve of Relative Quantification for MCF-7 and ZR-75-1 cells shows an increasing slope starting from 1000 cells. For the Cama-1 cell line this trend is already seen from 10-100 cells. In ZR-75-1 all three genes analysed reveal this trend, whereas in Cama-1 and MCF-7 cells a strong increase in Relative Quantification is especially seen for CK8 and 18. In the immunohistochemical staining, the cells were considered as tumour cells if they showed staining with the antibody-combinations used. Stained cells were counted and recovery rates were determined. For ZR-75-1, 17 of 30 cells which were spiked in the blood samples were recovered. For MCF-7, 18 cells were found in average, and for Cama-1 23 cells were located per slide. The recovery rates calculated from these numbers are 56,6% and 60,0% for ZR-75-1 and MCF-7, for Cama-1 the recovery rate reaches 76,6%. Conclusion It seems that Cama-1 cells are a better model than MCF-7 and ZR-75-1 for Real-Time PCR quantification of mamma carcinoma.
tumor cells in blood samples. MCF-7 and ZR-75-1 cells tend to react more likely immunologically with blood cells of the donor (agglutination between blood cells and cancer cells). The Cama-1 cell line shows also advantages in the detection of tumor cells using immunohistochemical staining. Therefore it will be necessary to test both methods on patient samples to proof their benefit.

**PI-08-01**

**Survival in Metastatic Breast Cancer (MBC): No Evidence for Improved Survival Following Distant Recurrence after Adjuvant Chemotherapy.**

Tevaarwerk AJ, Gray R, Schneider BP, Smith ML, Wagner LI, Miller KD, Sparano JA. University of Wisconsin-Carbone Cancer Center; Indiana University-Simon Cancer Center; Northwestern University, Chicago, IL; Dana-Farber Cancer Institute; Research Advocacy Network; Albert Einstein University-Montefiore Medical Center

Population-based studies have suggested improved survival for patients diagnosed with MBC in recent years, presumably due to the availability of new and more effective therapies (Chia et al. Cancer 2007; Dawood et al. JCO, 2008). The objective of this analysis was to determine if survival improved for patients who participated in Eastern Cooperative Oncology Group (ECOG) adjuvant trials and later developed MBC.

**Methods:** Adjuvant trials coordinated by the ECOG that accrued patients between 1978 and 2002 were reviewed (n=12), which included followup until 2010. Cytotoxic and biologic agents approved for MBC during this time included paclitaxel (1994), capetcitabine and trastuzumab (1998), docetaxel and gemcitabine (2004), lapatinib and ixabepilone (2007), and bevacizumab (2008). Survival following distant recurrence was estimated for 4 time periods ranging from 6-10 years, and adjusted for baseline covariates in a Cox proportional hazards model. Because distant relapse free interval (DRFI) was the covariate most strongly associated with survival after recurrence, and the potential for “gap time” bias this could introduce, logrank tests for other covariates and estimates of effects were computed stratified on DRFI (0-3, >3-6, > 6 years). HER2 status was not routinely available and thus not included.

**Results:** The 12 trials included 14,752 patients (93% received adjuvant chemotherapy); 3711 (25.2%) developed distant recurrence. Median survival after distant recurrence was 20 months; the estimated 5 and 10-year survival rates were 16.3% and 6.1%, respectively. Median survival by time period is shown in the table, stratified by DRFI. Median survival did not significantly change over time by DRFI (≤3 years, p=0.15; >3 yr, p=0.57). In a Cox proportional hazards model, factors associated with inferior survival after adjusting for other covariates included shorter DRFI (<3 years vs. 3-6 years - hazard ratio [HR] 1.60, p<0.001, and > 6 years vs. < 3 years - HR 2.23, p <0.001), ER-negative disease (HR 1.30, p<0.001), PR-negative disease (HR 1.36, P=0.0001), number of positive axillary nodes at diagnosis (1-3 vs. 0 nodes - HR 1.28, 4-9 vs. 0 nodes - HR 1.51, > 9 vs. 0 nodes - HR 1.51, p=0.0001), and black vs. white race (HR 1.29, p=0.0003), but not age at recurrence (p=0.15). When the year of recurrence was added to the Cox proportional hazards model using the intervals shown in the table below, it was not significantly associated with survival. Results were similar when 1978-2010 was assessed by 5-6 year intervals.

**Conclusions:** In contrast to reports from population-based studies, we do not observe any improvement in survival over time for patients who develop distant recurrence after adjuvant chemotherapy. There remains a critical unmet need for new therapies for MBC, especially for those who recur after adjuvant chemotherapy.

**PI-08-02**

**Pre-Diagnosis Body Mass Index and Breast Cancer Prognosis and Survival: Report from the after Breast Cancer Pooling Project.**

Kwan ML, Chen WY, Weltzien E, Beasley JM, Lu W, Nechuta SJ, Quesenberry CP, Pierce JP, Shu XO, Caan BJ. Kaiser Permanente Division of Research; Brigham and Women’s Hospital and Harvard Medical School; Fred Hutchinson Cancer Research Center; Shanghai Institute of Preventive Medicine; Vanderbilt University; University of California, San Diego

Background: A large body of evidence dating back over 30 years suggests that obese women have poorer survival after a breast cancer (BC) diagnosis compared to non-obese women. Despite most studies supporting an association of elevated risk of overall mortality with obesity, the relationship of obesity with risk of BC recurrence, BC mortality and non-BC mortality remains unclear. Furthermore, reports suggest that the association of BMI with BC outcomes may be U or J shaped, prompting the necessity of examining underweight and more severely obese women as independent groups. We conducted a pooled investigation of pre-diagnosis BMI and BC recurrence and survival using data from the After Breast Cancer Pooling Project (ABCPP).

Materials and Methods: The ABCPP includes 14,950 BC survivors from four prospective cohorts (three US and one Shanghai, China) diagnosed from 1990-2006 with invasive primary AJCC Stage I-III BC at ages 20-83 years. A random effects meta-analysis was conducted to assess heterogeneity across studies and poolability of data. Delayed entry Cox proportional hazards models were used to estimate hazard ratios (HR) and 95% confidence intervals (CI) for the associations of pre-diagnosis BMI (underweight <18.5 kg/m², normal 18.5-<25 kg/m², overweight 25-30 kg/m², obese ≥30 kg/m²) with BC recurrence, BC death, non-BC death, and overall death, adjusted for age at diagnosis, stage, race/ethnicity, menopausal status, hormone receptor status, number of positive lymph nodes, treatment, smoking history, and comorbidity (diabetes, hypertension, and/or CVD). Subgroup analyses further divided the obesity group into obese (30-<35 kg/m²), severely obese (35-<40 kg/m²), and morbidly obese (≥40 kg/m²) categories.

**Results:** No heterogeneity in effect estimates by study was found. 2104 deaths (1416 BC-related) and 2320 recurrences were observed after a mean (SD) of 7.66 (3.95) years of follow-up. Both underweight and obese women had a statistically significant increased risk of overall death compared to normal-weight women (underweight HR=1.69; 95% CI: 1.25, 2.28 and obese HR=1.74; 95% CI: 1.36, 2.22; p for non-linear association=0.01). Similar associations were found for non-BC death. Obese but not underweight was associated with increased risk of BC death (HR=1.17; 95% CI: 1.01, 1.36) and recurrence (HR=1.11; 95% CI: 0.98, 1.26). When examining finer obesity categories, the morbidly obese women had the greatest risk for all outcomes (overall death HR=1.90; 95% CI: 1.48, 2.45; non-BC death HR= 3.27; 95% CI: 2.25, 4.77; BC death HR = 1.47; 95% CI: 1.05, 2.06; recurrence HR = 1.27; 95% CI: 0.95, 1.71). No effect modification was observed by menopausal status, hormone receptor status, chemotherapy, and smoking. In all analyses, overweight women had similar risk of outcomes compared to normal-weight women.

**Discussion:** In this large pooling study of nearly 15,000 BC survivors, we found that the association between BMI and BC outcomes,
specifically overall death and non-BC death, was U shaped with both underweight and obese women at greatest risk. Morbidly obese women were at even greater risk compared to other obesity groups. Maintaining a healthy weight throughout adult life may be beneficial for BC prognosis and survival.

**P1-08-03**

**Huge Improvement in Relapse-Free Breast Cancer Survival over the Last 25 Years.**

Geurts SME, van Dijck JAAM, de Vegt F, Paquay Y, Siesling S, Verbeek ALM, Tjan-Heijnen VCG. Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; Hospital Bernhoven, Oss, Netherlands; Comprehensive Cancer Centre, Netherlands; Maastricht University Medical Centre, Maastricht, Netherlands

**Introduction** The purpose of this study was to evaluate the dwindling risk of relapse in breast cancer patients treated with curative intent since the 1970s.

**Patients and methods** 8570 women diagnosed with invasive breast cancer in 2003 or 2004 were compared with 307 consecutively diagnosed patients with invasive breast cancer between 1972 and 1986 in the Netherlands. Five-year overall survival and 5-year risk of relapse, i.e., second primary breast cancer, locoregional recurrence or distant metastasis, were calculated using the Kaplan-Meier method. Multivariable Cox-proportional hazards modelling was applied to correct the period-specific risk of relapse for tumour size, lymph node involvement and age at diagnosis.

**Results** Median (range) age at diagnosis was 52 years (27-82 years) in 1972-1986 and 58 years (20-96 years) in 2003-2004. Patients diagnosed in 1972-1986 had a larger tumour size and similar nodal involvement as compared to patients diagnosed in 2003-2004. In 2003-2004 more women were treated with breast conserving surgery, chemotherapy, and hormonal therapy as compared to 1972-1986. The 5-year overall survival rate increased from 71% (95% CI: 65% - 76%) in the period 1972-1986 to 85% (95% CI: 84% - 85%) in the years 2003-2004. Five-year risk of any relapse decreased from 37% to 16% across the calendar years (table 1). This decrease was observed for the risk of locoregional recurrence and the risk of distant metastasis (table 1). Risk of second primary breast cancer was similar for both periods of diagnosis (table 1). After adjustment for tumour size, nodal status and age at diagnosis the decrease in risk of relapse remained significant for patients diagnosed in 2003-2004 compared to 1972-1986 (HR= 0.5, 95% CI: 0.4 - 0.6).

**Conclusion** Over the last decades, the risk of breast cancer relapse has tremendously decreased, also after adjustment for tumour stage and age at diagnosis. The improved prognosis can be explained by the more often administered and intensified systemic treatment procedures and, further, by an earlier detection. The similar nodal stage probably resulted from stage migration caused by a more thorough performed lymph node staging in 2003-2004 compared to 1972-1986.

**Obesity, Adjuvant Therapy, and Survival Outcomes in Early-Stage Breast Cancer.**

Jiralerspong S, Wang T, Rimawi MF, Nangia JR, Schiff R, Giordano SH, Pollak MN, Chenault CC, Osborne CK, Hilsenbeck SG. Baylor College of Medicine, Houston, TX; M.D. Anderson Cancer Center, Houston, TX; McGill University, Montreal, Canada

**BACKGROUND:** Obesity has risen to epidemic proportions and is associated with worse breast cancer (BC) prognosis in most studies. However, the effects of obesity according to adjuvant therapy choice are largely unknown. To address this issue, we examined the relationship between body mass index (BMI), adjuvant therapy, and survival outcomes in a large cohort of early-stage BC patients.

**METHODS:** We retrospectively studied patients from the Baylor Breast Center Tumor Bank treated from 1970-1995. Patients were divided into 3 BMI classes: normal/underweight (N, BMI<25), overweight (Ov, BMI 25-30), obese (Ob, BMI≥30); and 4 treatment groups: no adjuvant therapy, chemotherapy (mainly CMF), endocrine therapy (mainly tamoxifen), both chemo- and endocrine therapy. Time-to-recurrence (TTR), disease-free survival (DFS) and overall survival (OS) were estimated by the Kaplan-Meier method and compared among groups via the log-rank test. Multivariate analysis was conducted via Cox proportional hazards models.

**RESULTS:** There were 4,368 patients. Median age was 58. 74% were postmenopausal. 72% had stage I-II disease, 28% stage III. 76% were estrogen receptor (ER)-positive, 24% ER-negative. Patients distributed into BMI classes as follows: N 48%, Ov 30%, Ob 22%. Higher BMI was associated with postmenopausal status and increasing age, tumor size, positive lymph nodes, and stage, as well as a higher likelihood of receiving treatment. Median follow-up was 5 years. Kaplan-Meier analysis showed that TTR was significantly shorter in the Ov and Ob groups as compared to the N group (p=0.019), due to distant (p=0.001) rather than local (p=0.970) recurrences. DFS was also significantly worse in the Ov and Ob groups (p=0.002), as was OS (p=0.001). The Table shows the hazard ratios for the various survival outcomes after adjustment for age, tumor size, nodal status, and treatment groups. For all patients, TTR, DFS, and OS were significantly worse in the Ob vs. N groups. TTR and DFS were significantly worse in the chemo treated Ob vs. N groups. DFS and OS were significantly better in the endo treated Ov vs. N groups.

**DISCUSSION:** In this large cohort of BC patients, survival outcomes (TTR, DFS, OS) were significantly worse in the obese group. This remained true after adjustment for multiple factors. Obesity was associated with worse survival outcomes in the chemo treated (CMF) group. Overweight was associated with postmenopausal status and increasing age, tumor size, positive lymph nodes, and stage, as well as a higher likelihood of receiving treatment. Median follow-up was 5 years. Kaplan-Meier analysis showed that TTR was significantly shorter in the Ov and Ob groups as compared to the N group (p=0.019), due to distant (p=0.001) rather than local (p=0.970) recurrences. DFS was also significantly worse in the Ov and Ob groups (p=0.002), as was OS (p=0.001). The Table shows the hazard ratios for the various survival outcomes after adjustment for age, tumor size, nodal status, and treatment groups. For all patients, TTR, DFS, and OS were significantly worse in the Ob vs. N groups. TTR and DFS were significantly worse in the chemo treated Ob vs. N groups. DFS and OS were significantly better in the endo treated Ov vs. N groups.
P1-08-05
Age and Survival in Women with Early Stage Breast Cancer: An Analysis Controlling for Tumor Subtype.
Partridge AH, Hughes ME, Ottesen R, Wong Y-N, Edge SB, Theriault RL, Blayney DW, Niland JC, Winer EP, Weeks JC, Tamimi RM. Dana-Farber Cancer Institute, Boston, MA; City of Hope, Duarte, CA; Fox Chase Cancer Center, Philadelphia, PA; Roswell Park Cancer Institute, Buffalo, NY; University of Texas MD Anderson Cancer Center, Houston, TX; Stanford Cancer Center, Palo Alto, CA; Brigham and Women’s Hospital, Boston, MA

Background: Previous research has suggested that young age at diagnosis is an independent risk factor for breast cancer recurrence and death in women with early stage breast cancer. However, young women are more likely to have aggressive subtypes of breast cancer. No prior studies have adequately controlled for tumor phenotype, including HER-2/neu (HER2) status, in particular. Recent evidence has suggested that the prognostic effect of young age varies by tumor subtype.

Methods: We examined data from women with newly diagnosed Stage I-3 breast cancer presenting to one of 8 NCCN centers between January 2000 and December 2007. Multivariate Cox proportional hazards models were used to assess the relationship between age and breast cancer specific survival, controlling for known prognostic factors and treatment. In addition, we conducted stratified analyses by estrogen receptor (ER) and HER2 status.

Results: 19,633 women with Stage I-3 breast cancer eligible for analysis including 2,177 (11%) who were age 40 years or younger at diagnosis. Younger women were more likely to be non-white or Hispanic, more educated, employed, and to have higher stage, high grade, ER-negative, progesterone receptor (PR) negative, and HER2-positive disease, and treated with chemotherapy and trastuzumab (all variables P< 0.0001 by Chi-Square test). 5-year survival among younger women was 94.1% (95% Confidence Interval [CI] 92.9-95.3) and 96.3% (95% CI 95.9-96.6) for older women. In a multivariate Cox proportional hazards model controlling for sociodemographic, disease, and treatment characteristics, women age <40 or younger at diagnosis had increased mortality compared to older women (Hazard Ratio [HR] 1.26, 95% CI 1.02-1.56). In stratified analyses, age 40 or less was associated with increased mortality among women with ER-positive disease (HR 1.44, 95% CI 1.01-2.05), but was not among those with ER-negative disease (HR 1.15, 95% CI 0.85-1.55). Younger age was associated with a statistically significant increase in mortality among women with HER2-negative disease (HR 1.29, 95% CI 1.00-1.68), but this difference did not reach statistical significance among those with HER2-positive disease (HR 1.30, 95% CI 0.82-2.09).

Conclusions: The effect of age on short-term survival of women with early breast cancer appears to vary by breast cancer subtype, particularly ER status. Further research to elucidate differences in breast cancer biology and efficacy of therapy within tumor types by age is warranted.

P1-08-06
Breast Cancer among Patients with Diabetes, Obesity and Abnormal Blood Lipids – A Population-Based Register Study in Sweden.
Olsson H, Attner B, Landin Olsson M, Lithman T, Noreen D. Clinical Sciences, Lund University, Lund, Sweden

Objective: To study how the incidence of breast cancer is related to diabetes, obesity or abnormal blood lipids.

Methods: Diagnosis of diabetes, obesity or abnormal blood lipids was studied 0-10 years prior to the diagnosis of cancer in 2724 cases of cancer and in 20542 controls matched regarding age, sex and domicile in a population based material. Diagnoses were obtained by using out and inpatient population based registries. Also the use of glargine and metformin was studied in relation to cancer risk in diabetic patients using the national pharmacy prescription registry. Conditional logistic regression was used for the analyses.

Results: Diabetes was significantly more common prior to diagnosis in patients with breast cancer with diabetes diagnosed 0-4 years prior to the cancer diagnosis. The findings remained after adjusting for obesity and high blood lipids. Obesity was significantly more common in patients with breast cancer above the age of 60 years in those where obesity was diagnosed close to the diagnosis of cancer. High blood lipids were significantly less common in patients with breast cancer close to diagnosis.

Glarigine use was associated with a doubled risk 2.88 (1.15-6.64) and metformin use with a lower risk of cancer in diabetic patients 0.92 (0.82-1.09).

Analysis Controlling for Tumor Subtype.

Breast Cancer Diagnosis and Chemotherapy Initiation: A SEER-Medicare Analysis.
Rugo H, Taylor D, Sanon M, Clements K, Balu S, Faria C, Teitelbaum A. University of California San Francisco; OptumInsight; Eisai Inc.

Objective: Use SEER-Medicare data to identify US women with metastatic breast cancer (MBC) treated (tx) with chemotherapy (CTX) and evaluate survival.

Methods: Key inclusion criteria were women diagnosed (dx) with breast cancer (BC) in 2001-2005 with 1) Medicare enrollment 12 mo prior to dx through follow-up (2008) or death; 2) an indication of tx with CTX at any time after initial BC diagnosis (any stage). Dx of MBC between 2001-2006. MBC dx date was defined as the initial BC dx date if the patient had “distant” disease at entry into SEER or the date of first appearance of secondary malignancy in claims data (ICD9 codes 197.0-198.1, 198.3-198.7, 198.82-198.89) during follow up, at least 2 mo after initial dx. CTX date was defined as the date of first receipt of a CTX agent commonly used to treat BC after the MBC date. Data on oral medications (e.g., most hormone therapies, capcitabine) were not available. Kaplan-Meier survival analyses were performed to describe survival after MBC dx (patients were censored at end of follow-up). Survival was assessed both from the date of MBC and receipt of first intravenous (IV) chemo. Subgroup analyses were performed based on age, type of MBC dx and estrogen receptor (ER) status.
Results: Patient demographics and survival are shown in the table.

Conclusions: Despite recent advances in treatment options, median survival following a dx of MBC is less than two years, and is approximately 16 months after start of IV CTX. Survival is shorter for patients who develop MBC after an initial breast cancer dx compared to those with MBC at diagnosis, and for those with ER-negative tumors. In order to improve clinical outcomes, it is critical to pursue a better understanding of tumor biology and appropriate use of new agents.

P1-08-08
Higher Prediagnostic Serum 25-Hydroxyvitamin D is Associated with Substantially Lower Incidence of Breast Cancer: Prospective Study.
Mohr SB, Gorham ED, Garland CF, Grant WB, Baggerly L. University of California San Diego, La Jolla, CA; Sunlight and Nutrition Research Center, San Francisco, CA; GrassrootsHealth, San Diego, CA

Background: Recent studies have found lower risk of breast cancer in women with higher serum concentrations of 25-hydroxyvitamin D (25(OH)D), with few exceptions. To help resolve remaining differences, a nested case-control study was conducted.

Material and Methods: Serum was provided by the Department of Defense Serum Repository for 600 new cases of breast cancer and 600 controls individually matched on age ±6 months; date blood was drawn ±2 days; and active-duty status; and were analyzed for 25(OH)D (25[OH]D), with few exceptions. To help resolve remaining differences, a nested case-control study was conducted.

Results: Race-adjusted odds ratios for breast cancer, from lowest to highest quintile, from lowest to highest, were 11, 18, 24, 30 and 42 ng/ml. The trend was similar after adjustment for race. The serum 25(OH)D concentration was high (42 ng/ml) had approximately 2-3 times lower risk of breast cancer in the lowest and highest 25(OH)D quintiles was significant.

Discussion: Consistent with previous research, women whose serum 25(OH)D concentration was high (42 ng/ml) had approximately half the risk of breast cancer as those whose serum 25(OH)D was low (11 ng/ml). The trend was similar after adjustment for race. The favorable association of serum 25(OH)D with risk of breast cancer apparently was strongest during the final few doublings of the tumor mass preceding diagnosis in this population. (An alternative, far less likely, interpretation, is that the tumor mass might adversely influence 25(OH)D concentration). A serum 25(OH)D concentration of 42 ng/ml can be achieved with vitamin D, intake of 4000 IU/day. This is the safe daily upper level intake of the National Academy of Sciences-Institute of Medicine (NAS-IOM December 2010 monograph). While further research would be beneficial, such intake should be recommended as a useful tool for prevention of breast cancer. Serum 25(OH)D should be monitored on a routine basis, when feasible, to ensure that at least 40 ng/ml is maintained throughout the year, and 150 ng/ml is not exceeded. This hygienic measure could prevent approximately 50% of breast cancer in the US. (The views expressed in this abstract are those of the authors and do not represent positions of the Department of the Navy, Department of the Army, the Department of Defense or the US Government.)

P1-08-09
Increased Mortality in Swedish Women Diagnosed with Breast Cancer during and Shortly after Pregnancy.
Johansson ALV, Andersson TM-L, Cnattingius S, Hsieh C-C, Lambe M. Karolinska Institutet, Stockholm, Sweden; University of Massachusetts Medical School, Worcester; Regional Oncologic Center, Uppsala, Sweden

Background: The incidence of pregnancy-associated breast cancer (PABC), i.e. breast cancer diagnosed during pregnancy or within two years after delivery, is increasing in Sweden. Results from epidemiological studies suggest that women with PABC have worse prognosis than women of same age and no recent birth. We studied the mortality in women with PABC, compared to women with a diagnosis of breast cancer not close to pregnancy, and in relation to when the PABC diagnosis occurred (during pregnancy, different postpartum periods). We also studied whether mortality varied over time since diagnosis.

Materials and Methods: We used data from the Swedish National Cancer Register to identify all women diagnosed with breast cancer between ages 15-44 years during 1963-2002 (n=15,729). The study cohort was linked to the Multi-Generation Register to obtain information on childbirths and when they occurred. We estimated mortality rates among women with and without PABC, and subdivided by time of detection among PABC patients (PABC during pregnancy, or during months 1-3, 4-6, 7-12, 13-18, 19-24 after delivery). Hazard ratios (HR) with 95% confidence intervals (CI) were estimated using the novel method of flexible parametric survival models. These models use splines to model the baseline hazard rate, and are able to pick up more subtle time-dependent effects than the more commonly used piecewise splitting of the timescale (for example in Poisson regression).

Results: Women with PABC had higher mortality than women diagnosed at the same age and calendar period and with no recent birth. In women with PABC (n=1,110), 46% died during follow-up, compared to 34% of the non-PABC patients (n=14,611). The mortality in both groups peaked at around two years after diagnosis, with the highest peak occurring in women diagnosed 4-6 months after delivery (HR=3.8, 95% CI 2.4-5.9). Also, among women diagnosed during pregnancy the mortality was higher compared to women diagnosed further away from delivery. An increased mortality among women with PABC remained up to 10 years after diagnosis.

Discussion: Women with PABC had a poorer prognosis compared to women with breast cancer and no recent birth. The worse prognosis may be due to diagnostic delays or tumour promoting hormonal boosts or changes in the tumour micro-environment post-partum. Taken together, our findings indicate that women with PABC represent...
a high-risk group of young breast cancer patients that may require special management. Also, by applying novel statistical methods we were able to detect time dependent effects in that the elevated mortality associated with PABC varied by timing of diagnosis and time since diagnosis.

**Invasive Lobular Breast Cancer – No Increased Risk of Contralateral Disease.**

Langlands F, Morgen K, Kearins O, Burns R, Dowdell D. The General Infirmary at Leeds, Leeds, United Kingdom; The University of Birmingham, Birmingham, United Kingdom; Level 6, Besley Wing (Institute of Oncology), Leeds, United Kingdom; St James University Hospital, Leeds, United Kingdom

**Background:** Invasive lobular carcinoma (ILC) is the second most common type of breast cancer accounting for up to 14% of invasive breast cancers. Worldwide the incidence of breast cancer is increasing each year. Large population based studies using the Surveillance, Epidemiology, and End results (SEER) data have shown that the incidence of ILC has increased from 1977 to 1995. ILC has historically been thought to be associated with an increased risk of developing contralateral breast cancer and this belief may, in part, be responsible for the increasing trend towards contralateral prophylactic mastectomy.

**Methods:** All female patients diagnosed with breast cancer during the time period 1998-2003 were identified from two large cancer registries, Northern and Yorkshire Cancer Registry and Information Service (NYCIRS) and West Midlands Cancer Intelligence Unit (WMCIU). All patients diagnosed with either Infiltrating duct(adeno) carcinoma, microinvasive ductal carcinoma, infiltrating ductular carcinoma (all classified as ‘ductal’) or lobular (adenocarcinoma were included. Patients with a mixed type of breast cancer were excluded from the analysis. Follow-up was complete until October 2010. Data were compiled for diagnosed contralateral breast cancer of any histological type.

**Results:** Of the 32,735 patients with invasive ductal cancer 898 (2.74%) developed a contralateral breast cancer. In comparison 166 (3.1%) of 5397 patients with lobular breast cancer developed a contralateral breast cancer. The median time to first contralateral event was equivalent for both morphologies (ductal 40 months and lobular 39 months).

**Conclusion:** This study suggests that there is no increased risk for developing a contralateral breast cancer in patients diagnosed with an invasive lobular breast cancer.

**P1-08-11**

**Differences in Recurrence Dynamics between Lobular and Ductal Invasive Breast Cancer.**

Siesling S, Kwast ABG, Grandjean I, Ho V, van der Sangen MJC, Menke-Pluymer MBE, Tjan-Heijnen VCG. Comprehensive Cancer Centre the Netherlands, Utrecht, Netherlands; Catharina Hospital, Eindhoven, Netherlands; Erasmus Medical Centre, Rotterdam, Netherlands; Maastricht University Medical Centre, Maastricht, Netherlands

**Introduction:** Many studies investigated disease free survival after breast cancer treatment. A few studies focused on patterns of recurrence risk over time. However, they ignored the impact of histology. This study aimed to determine differences in recurrence dynamics on population-based data between patients with a ductal breast cancer (DBC) and lobular breast cancer (LBC).

**Methods:** All surgically treated women diagnosed in 2003-2004 with invasive DBC or LBC, with no distant metastases or second primary breast cancer were selected from the Netherlands Cancer Registry. The recurrence patterns were studied using the life-table method to estimate the hazard rate for the first recurrence with the worst prognosis (locoregional (LRR) or distant metastases), that is, the conditional probability of manifesting recurrence in a time interval, given that the patient is clinically free of any recurrence at the beginning of the interval. The wilcoxon test was used to determine differences in recurrence patterns between DBC and LBC.

**Results:** Of 16,231 women identified, 87% had DBC and 13% LBC. LRR was found in 4% of the DBC and in 3% of the LBC patients, whereas metastases were found in 11% and 10% of patients, respectively. Notably, in DBC patients a peak in recurrence rate was seen between 1-2 years after diagnosis, both for LRR and distant metastases. On the other hand, in LBC patients the recurrence pattern did not show major peaks: after 2 years the curve revealed an almost steady level for LRR and distant metastases. This recurrence pattern was significantly different (P<0.001). Moreover, the influence of age, stage and treatment on recurrence differed between DBC and LBC. We also noticed a difference in localization of metastasis.

**Conclusion:** Our study showed an overall equal number of recurrences after DBC and LBC, but with a totally different recurrence pattern, which could have implications on follow-up of the patients.

**P1-08-12**

**Hormonal Therapy Compliance and Mortality in Metastatic Breast Cancer.**

Barron TI, Kennedy MJ, Sharp L, Bennett K. Trinity College, University of Dublin, Dublin, Ireland; St James’s Hospital and Trinity College Dublin, Dublin, Ireland; National Cancer Registry Ireland, Cork, Ireland

**Methods:** A retrospective analysis was conducted using linked pharmacy claims and cancer registry data from the population-based National Cancer Registry Ireland (NCRI). Women with stage IV breast cancer at initial diagnosis (2004-2006), who received HTx as 1st line treatment for ≥90 days were identified (tamoxifen, toremifene, fulvestrant, anastrozole, letrozole, exemestane). Compliance was calculated over the time that patients remained on HTx i.e. from the date of treatment initiation to the earliest of either HTx discontinuation or end of follow up (31/12/07, 3 years or death). Patients discontinuing HTx were assigned their compliance rate at this time for the remainder of follow-up. In the primary analysis Cox proportional hazard models with late entry at 90 days post HTx initiation and time varying compliance (defined dichotomously as: low < 80%, high ≥ 80%), were used to estimate hazard ratios (HR) and 95% confidence intervals (CI) for all-cause and breast cancer specific mortality. Secondary analyses of (a) time to treatment discontinuation and (b) compliance in the first 90 days of treatment were conducted. All models were adjusted for age, tumor grade, number/site of metastases, estrogen, progesterone and human epidermal growth factor 2 receptor status.

**Results:** 359 women with stage IV breast cancer at diagnosis were identified. Of these, 151 received HTx as 1st line treatment. Median HTx compliance was 84.8%, (range 19.4%-100%; interquartile range 75.5%-100%). Demographic, tumor and treatment characteristics were similar between low (n=51) and high (n=100) compliance groups. The number and distribution of metastatic sites at diagnosis was also similar (low/high compliance: bone only 70.6%/70.0%, lung only 17.6%/18.0%, liver only 11.8%/14.0%, brain only 0.0%/0.0%, other 13.7%/17.0%, multiple sites 15.7%/18.0%). Compliance rates for both compliance groups increased marginally over time.
Unadjusted all-cause mortality rates were 143 and 359 deaths/1000 woman years for low and high compliance respectively. Low compliance was associated with a 90% increased risk of all-cause (HR 1.90; 95%CI 1.06, 3.41) and breast cancer specific (HR 1.91; 95%CI 1.03, 3.55) mortality. In the secondary analyses low compliance was associated with a shorter time to HTx discontinuation (HR 1.97; 95%CI 1.01, 3.84). Low compliance within the first 90 days of treatment was associated with non-significantly increased mortality (all-cause HR 1.57; 95%CI 0.88, 2.80; breast cancer specific HR 1.58; 95%CI 0.85, 2.93).

Discussion: This study demonstrates, for the first time to our knowledge, a significant association between low HTx compliance and increased mortality in patients with MBC. In addition, the observed association between compliance and treatment duration is consistent with a reduced time to disease progression in low compliance patients. The findings do not appear to be related to either the burden of metastatic disease at diagnosis or to increasing disease severity causing lower compliance over time. These results suggest that the development and evaluation of effective interventions to support HTx compliance in patients with MBC is warranted.

**P1-08-13**

**Determinants of Risk, Characteristics and Prognosis of Breast Cancer Occurring after Hodgkin Lymphoma.**

**Background**

Several studies have evaluated the excess of breast cancer (BC) risk after Hodgkin lymphoma (HL) but none has reported of all the aspects of BC occurring after HL including determinants of risk, comparison with other BC profile, treatment and outcome. This is the aim of our study.

**Patients and Methods**

We used data from the Surveillance, Epidemiology and End Results (SEER) Programme of the National Cancer Institute. To assess the risk and determinants of BC after HL we included all 9’620 women with first primary HL diagnosed between 1973 and 2007 and calculated age and period standardized incidence ratio (SIR) of BC as compared with general population. We also compared tumour characteristics and treatment between BC after HL (n=316) vs. all other first primary BC occurring during the same period (n=450’413) by logistic regression. Finally, we compared breast cancer specific mortality between the two groups by Cox model.

**Results**

Overall, HL patients had an increased risk of developing BC (SIR: 2.4, 95% confidence interval [CI]: 2.2-2.7); the risk decreased with increasing age at HL, and disappeared when HIV occurred after 50 years. BC risk was the same among those treated with or without radiotherapy until 15 years after HL and then an excess appeared in the irradiated group and persisted over 30 years after diagnosis of HL. Compared with other BC, BC after HL occurred at younger age (Adjusted odds ratio [OR] for age 40-59 vs. < 40 years 0.25, 95%CI: 0.20-0.33), was diagnosed at an early stage (OR for regional extension vs. localized 0.63, 95% CI: 0.42-0.89), expressed less frequently hormone receptors (OR for negative vs. positive status: 1.34, 95%CI: 0.99-1.81), was located more frequently in external quadrants (OR for internal vs. external: 0.61, 95%CI: 0.42-0.89), and received less frequently radiotherapy (OR for use vs. non use: 0.30, 95%CI: 0.22-0.42). The last two results were limited to patients who had received radiotherapy for HL. BC after HL presented higher breast cancer mortality (Hazard ratio: 1.36, 95%CI: 1.05-1.76) after adjustment for patients, tumour and treatment characteristics.

**Conclusion**

This study provides valuable results on various aspects of BC occurring after HL. In particular, we found earlier stage at diagnosis of BC probably linked to higher surveillance, more aggressive tumours probably due to iatrogenic effect of HL treatment, more frequent occurrence in outer quadrants less protected during mantel radiation. Also, this study confirms the poorer prognostic of those BC not explained by differences in patient, tumour or treatment characteristics.

**P1-08-14**

**Arsenic Methylation Is Associated with Breast Cancer Risk in Northern Mexico.**

López-Carrillo L, Hernández-Ramirez U, Torres-Sánchez L, Gandolfi JA, Ornelas-Aguirre JM, Cebrián ME. Mexico National Institute of Public Health, Cuernavaca, Morelos, Mexico; University of Arizona, Tucson, AZ; Hospital de Especialidades. Instituto Mexicano del Seguro Socia, Cd. Obregón, Sonora, Mexico; Centro de Investigación y Estudios Avanzados (Cinvestav), Mexico, DF, Mexico

**Background:** Arsenic (iAs) exposure has been associated with several types of cancer. However, most studies to date have not yet implicated iAs as a cofactor for breast cancer (BC). BC incidence and mortality are 3-fold higher in Northern Mexico (NM) than in the rest of the country. iAs levels in drinking water are a source of concern since they have been above international standards. We hypothesized that iAs exposure and individual Arsenic-methylation ability are potential cofactors for BC risk.

**Material and Methods:** We investigated 840 BC incident cases and 973 controls from a population-based case-control study performed in NM. Women were directly interviewed about dietary and reproductive BC covariables. iAs metabolites in urine were determined by HPLC/ICP-MS. Methylation capacity was assessed by calculating the percentage of iAs species and primary [MMA(V)/(As(III)+As(V)) (PMI) and secondary [DMA(V)/MMA(V)] methylation indexes (SMI).

**Results:** The range of total urinary Arsenic was 0.4-303.9 ug/L. Most women (91%) had values above 30 ugAs/L. %MMA(V) was significantly higher in BC cases while %DMA(V) was significantly lower. PMI was positively associated with BC (OR T3 vs T1=1.47; CI95%=1.17-1.84; p for trend=0.001), while SMI was negatively associated (OR T3 vs T1=0.54; CI95%=0.42-0.68; p for trend=0.001).

**Discussion:** As exposure may pose a risk for BC, particularly in women with higher capacity to methylate iAs to MMA(V) and lower capacity to further methylate MMA(V) to DMA(V). This is consistent with studies indicating that the proportion of MMA(V) in urine was positively associated whereas that of DMA(V) was inversely associated with the risk of skin, bladder and lung cancer. Further research is needed about the temporal relationships between disease and methylation capacity and the presence of potential association modifiers, including environmental and genetic factors involved in one carbon metabolism.
PI-08-15
Pattern of Cardiac Monitoring and a Risk of Trastuzumab Associated-Cardiac Dysfunction in a Clinical Practice: A Population Based Study.
Lee-Ying R, Ubhi C, Roberts S, Lim H, Bhatt H, Gesy K, Ahmed S. University of Saskatchewan, Saskatoon, SK, Canada; University of Saskatchewan; Saskatchewan Cancer Agency

Background: Adjuvant trastuzumab therapy (ATT) in women with early-stage HER2+ breast cancer has been associated with significant reduction in the disease recurrence and mortality. Cardiac dysfunction (CD) is a known serious adverse effect of ATT. Although periodic cardiac monitoring is recommended during ATT, little is known about pattern of cardiac monitoring and incidence of CD in a clinical setting. The study aimed to determine extent of cardiac monitoring and rate of CD during ATT and to identify factors correlated with CD.

Methods: Medical records of women with localized HER2+ breast cancer diagnosed between the years 2005-2007 in the province of Saskatchewan were reviewed. Women with advanced or recurrent disease or if they were treated in the setting of an adjuvant trastuzumab trial were excluded. A logistic regression analysis was performed to determine various clinical variables correlated with CD.

Results: A total 116 eligible women with median age of 54 yrs (range: 27-74) and median BMI of 27 (range: 14-47) were identified. 40% had a cardiac risk factor & 30% were premenopausal. 51% had node positive & 53% had HER2+ breast cancer. 92% received anthracycline-based chemotherapy and 23% received sequential ATT. Of 62 patients with ER/PR+ breast cancer, 61% received adjuvant aromatase inhibitors. Baseline cardiac assessment was performed in 93% women, 98% women underwent periodic cardiac monitoring during ATT, 55% had monitoring performed at the interval of 3-4 months & 82% women had monitoring performed at the interval of 3-6 months. Mean baseline cardiac ejection fraction (EF%) prior to the commencement of chemotherapy and ATT were 65% & 63.9% respectively (p<0.05). CD was observed in 32 (28%) women and only 4% were asymptomatic. Trastuzumab was interrupted in 34%, and was discontinued in 20% women. Of 32 women with CD, 59% were referred to a cardiologist and 53% were treated with medication. CD was reversible in 84% cases. On multivariate analysis adjuvant aromatase inhibitor therapy was significantly correlated with cardiac dysfunction (Odds ratio 6.9 [95% CI: 1.4-33.0]). During the follow up period 18% women developed recurrent disease and 16% were died.

Conclusions: Our results confirm high compliance with cardiac monitoring, though not as frequently as recommended in the clinical trial setting. Overall the rate of symptomatic decline in cardiac function was similar to the rate reported in the clinical trials, however, a relatively higher incidence of asymptomatic decline in the left ventricle EF% was noted. Among various variables examined, adjuvant aromatase inhibitor therapy was associated with an increased risk of CD.

PI-08-16
Benign Breast Disease (BBD) and Breast Cancer in African American Women.
Fehmi RA, Cote M, Ruterbusch J, Alosh B, Bandypadhyay S, Albashiti B, Frost MH, Hartmann LC, Vieszcher DW. Wayne State University/Karmanos Cancer Institute/DMC, Detroit, MI; Wayne State University/Karmanos Cancer Institute, Detroit, MI; Mayo Clinic Cancer Center, Rochester, MN

African American (AA) women have higher mortality rates from breast cancer (BrCa) and are diagnosed at younger ages than their Caucasian counterparts. Women who have had a benign breast biopsy are at increased risk of the disease, although less is known about the risk of BrCa associated with benign breast disease in AA women. We examined 1428 breast biopsies from AA women which occurred from 1997-2000 and assessed various pathologic markers including: apocrine metaplasia, ductal hyperplasia including atypia, evidence of cysts, duct ectasia, fibrosis, intra-ductal papilloma, sclerosing adenosis, columnar alteration, and involution (atrophy). These women were followed for later BrCa through the Metropolitan Detroit Cancer Surveillance System, part of the Surveillance, Epidemiology and End Results (SEER) program through 2008. Women who developed BrCa were compared to those in the cohort who did not, and to other AA women with BrCa in the SEER registry. AA women in our study were also compared to Caucasian women in the Mayo Clinic cohort. Differences in variables were assessed by chi-squared tests and 95% confidence intervals. Of the 1428 biopsies, 52 (3.6%) subsequent incident breast cancers were reported in SEER. The mean age at diagnosis was 59, and the mean time from biopsy to BrCa diagnosis was 6.1 years. Individuals with atypical ductal hyperplasia at biopsy were more likely to develop breast cancer (n=7, 13.5%, p<0.01). No other pathologic variables were associated with increased risk. Women in our cohort with breast cancer did not differ from AA in the SEER database with respect to age at diagnosis, stage at diagnosis, or receptor positivity. Compared to the Caucasian women in the Mayo Clinic BBD cohort, AA women in our study were younger at biopsy (p<0.01), but had similar percentages of involution and atypia (p=0.50 and 0.15, respectively). Our preliminary findings among a relatively small group of AA women with prior benign breast biopsies and incident breast cancers suggest that results from the Mayo Cohort study are likely to apply to AA populations.

PI-08-17
Pregnancy-Associated Breast Cancer Does Not Have a Worse Outcome in the 4912 Women with Breast Cancer of the AMAZONA Project.
Liedke PER, Szymonifka J, Simon SD, Barrios CH, Bines J, Finkelstein D, Goss PE. Massachusetts General Hospital, Boston, MA; Universidade Federal de São Paulo (UNIFESP), São Paulo, Brazil; Pontificia Universidade Católica do RS (PUCRS), Porto Alegre, Rio Grande do Sul, Brazil; Instituto Nacional do Cancer (INCA), Rio de Janeiro, Brazil; Brazilian Breast Cancer Study Group (GBECAM), São Paulo, Brazil

Introduction: Pregnancy traditionally is considered a protective factor for breast cancer. Recent data suggests that pregnancy-associated breast cancer (PABC), a distinct biologic variant possibly related to breast involution, can occur up to 10 years post-partum and may carry a worse prognosis than that of age matched sporadic or nulliparous breast cancer. The Amazona project is a retrospective cohort of 4,912 Brazilian women with breast cancer that has previously reported on worse outcomes of patients according to type of institution where treatment was received (San Antonio 2009 abstr. 306). We have assessed the outcomes of PABC in the Amazona cohort.

Objectives: 1- To identify whether women who were diagnosed with breast cancer up to 10 years after their first pregnancy had worse disease free survival (DFS) and overall survival (OS) than nulliparous women (NW); 2- to assess if age at first pregnancy is related to age of breast cancer diagnosis and worse DFS or OS; 3- to assess whether number of pregnancies is associated with worse DFS or OS; 4- to assess whether time from first pregnancy to diagnosis or age of first pregnancy are associated with histological grade, clinical stage or tumor expression of ER, PR, and HER2.
Methods: We analyzed 4836 women for whom parous history was available, in respect to DFS, OS, tumor clinical stage, histological grade, expression of ER, PR and HER2, according to age of first pregnancy, diagnosis up to 5 and 10 years after first pregnancy, and number of pregnancies, using up to 10 years as controls. Analysis of DFS and OS was done by Cox regression modeling adjusted for institution type, stage, ER, PR, HER2 and grade.

Results: Our cohort had 1996 nulliparous women and 2840 parous women. The median follow up was 28 months and there were 318 deaths and 735 recurrences. We did not find any correlation between PABC with DFS (5 year interval HR 1.15, 95%CI 0.43-3.07; 10 year interval HR 1.01, 95%CI 0.57-1.81) or OS (5 year interval HR 1.88, 95%CI 0.6-5.94; 10 year interval HR 0.5, 95%CI 0.73-3.09), nor was there a correlation between age at first pregnancy with age of breast cancer diagnosis. We also did not see any difference between age of first pregnancy and DFS or OS.

Women with 3 or more pregnancies had worse OS (HR 0.71, 95%CI 0.54-0.93) but not worse DFS (HR 0.93, 95%CI 0.76-1.13).Tumors diagnosed within 5 or 10 years from first pregnancy did not differ by grade, ER, PR, HER2, and clinical stage from those of NW. Women who had their first pregnancy after age 20 tended to have more ER+ tumor (OR 1.99, 95%CI 1.40-2.65), PR positive tumor (OR 1.40, 95%CI 1.06-1.87), and HER2 positive tumor (OR 1.85, 95%CI 1.22-2.79) tumors than NW.

Conclusions: In this large cohort of breast cancer patients from the diverse geographic and socioeconomic spectrum of Brazil we did not find any association between PABC or age of first pregnancy to DFS or OS. The association with worse OS but not DFS of women with 3 or more pregnancies might be due to confounding factors. PABC was not associated with worse clinical prognostic factors. Women who had their first pregnancy after age 20 were more likely to have ER+, PR+ and HER2+ tumors than nulliparous patients.

P1-08-18
Aspirin Exposure and Nodal Status at Diagnosis in Women with Stage I-III Breast Cancer.
Barron T, Sharp L, Bennett K, Visvanathan K. Trinity College, University of Dublin, Dublin, Ireland; National Cancer Registry Ireland, Cork, Ireland; Johns Hopkins School of Public Health, Baltimore, MD

Background: The recent Nurses’ Health Study reported an association between aspirin use and a reduction in breast cancer (BC) recurrence and BC-specific mortality. It has been suggested based on preclinical data that these effects may be due to the inhibition of tumor invasion and metastasis by aspirin. To test this hypothesis we examined the association between aspirin exposure prior to BC diagnosis and nodal involvement at diagnosis.

Methods: A retrospective analysis was conducted using linked pharmacy claims and cancer registry data from the National Cancer Registry Ireland. Women with an incident diagnosis of stage I-III BC between 2001-2006 and no prior invasive cancer were included. Women with a prescription for aspirin at any time in the year prior to diagnosis were defined as exposed. Multivariate logistic regression was used to estimate odds ratios (OR) and 95% confidence intervals (CI) for (a) N0 disease; (b) N1 disease (c) N1/2/3 disease at diagnosis in aspirin exposed (overall exposure & exposure quartiles by duration of use) versus unexposed women. All analyses were adjusted for age, tumor size/grade, ER, PR and HER2 receptor status. Analyses were repeated including women with stage IV BC at diagnosis. Survival analyses are ongoing.

Results: 4212 women with stage I-III BC at diagnosis were identified. 1086 (25.8%) had a supply of aspirin available to them in the year prior to diagnosis (median dose 75mg, interquartile range 75mg, 75mg). Women taking aspirin were older than those who did not (74.3 yrs/64.4 yrs p<0.05). There was no difference in tumor sizes, grade, ER, PR or HER2 receptor status between exposed and unexposed women. In the multivariate logistic regression analysis aspirin exposure was associated with significantly increased odds of an N0 tumor (Table 1; OR 1.27 95%CI 1.09, 1.48) and significantly decreased odds of an N1 or N1/2/3 tumor. Additionally, women taking aspirin for >95% of the year prior to diagnosis had the highest odds of an N0 tumor (Table1; OR 1.50 95%CI 1.14, 1.97 ). There was no difference in the odds of an N0 tumor for women taking aspirin for <40% of the prior year (OR 1.01 95%CI 0.78, 1.31). Inclusion of stage IV BC (n=789) in the analysis did not significantly alter these results.

Parity Interferes with the Effect of Age at Diagnosis on the Frequency Breast Cancers Are Triple-Negative.

Background: Epidemiologic studies show an age related decrease in the frequency of TN breast cancer, < 51 years at diagnosis. We compared the frequency of TN breast cancers between parous (N = 1271) and nulliparous (N = 312) women in three age categories (21 to 30 yrs, 31 to 40 yrs and 41 to 50 yrs). For statistical analysis we used a logistic regression model.

Results: Our cohort had 1996 nulliparous women and 2840 parous women. The median follow up was 28 months and there were 318 deaths and 735 recurrences. We did not find any association between PABC or age of first pregnancy to DFS or OS. The association with worse OS but not DFS of women with 3 or more pregnancies might be due to confounding factors. PABC was not associated with worse clinical prognostic factors. Women who had their first pregnancy after age 20 were more likely to have ER+, PR+ and HER2+ tumors than nulliparous patients.

**Demographic and Clinical Characteristics of Metastatic Breast Cancer Patients and Biomarker-Based Prevalence in the UK, Germany, France, Spain and Italy (EU-5).**

**Ganguli A, DeKoven M, Bonthapally V, Lee WC, Ray S. Abbott Laboratories, Abbott Park, IL; IMS Consulting Group, Alexandria, VA**

**Background:** Much peer-reviewed literature focuses on metastatic breast cancer (mBC) treatment regimens. However, research around mBC patients' demographic/clinical characteristics across Europe is limited. This study compared such mBC characteristics as well as biomarker-based prevalence across the EU-5.

**Methods:** IMS LifeLink™ Oncology Analyzer (OA) database, based upon practicing oncologist surveys, was used to identify mBC patients aged ≥18 between 01/2005-06/2010. The study investigated the distribution of mBC population based on age, biomarker, comorbidities and stage at diagnosis. This study also estimated the proportion of patients, and sites of metastasis, by lines of drug therapies (LOT).

**Results:** A total of 186,640 mBC patients were identified - Germany (30.2%), France (22.4%), UK (21.2%), Italy (17.7%) and Spain (8.4%). The majority of patients were aged 61-70yrs (24%-32%), except in Spain (22.3% aged 71-80yrs). Proportion of mBC patients with ≥1 co-morbid condition were highest in Germany (36.3%), followed by Spain (32.8%), UK (31.5%), Italy (27.6%) and France (20.1%), with diabetes (12.9-23.9%) and cardiac dysfunction (5.2-21.7%) being most prevalent. The distribution of mBC patients by biomarker status was 53.9% HER-/HR+, 17.8% HER+/HR+, 11.1% HER+/HR- and 17.2% triple negative, and was similar amongst the EU5 countries. The top three metastatic sites were bone (54.4%), lung (36.0%) and liver (32.7%), with proportion of bone metastasis increasing from 1st LOT (38.1%) to 4th LOT (69.6%). Almost 50% of the mBC patients were diagnosed at Stage IV, 14% at Stage III, 26% at Stage II and 6% at Stage I. Of all mBC patients, 93% received 1st LOT, 31% received 2nd LOT, 27% received 3rd LOT and 6.8% received 4th LOT.

**Conclusion:** In the EU-5, mBC patients were primarily elderly and HER-/HR+. The burden of bone metastasis was higher in later LOTs. Following the 1st LOT, fewer patients moved to subsequent LOTs. Following the 1st LOT, fewer patients moved to subsequent LOTs. The international BCAC has recently accepted to validate our UZ Leuven findings.

**Treatment Patterns and Clinical Outcomes in Elderly Patients with HER2-Positive Metastatic Breast Cancer from the registHER Observational Study.**

**Kaufman PA, Brafsky AM, Mayer M, Rugo HS, Tripathy D, Ulicickas Yood M, Feng S, Wang LI, Brammer MG, Yardley DA. Norris Cotton Cancer Center, Dartmouth-Hitchcock Medical Center, Lebanon, NH; University of Pittsburgh Cancer Center, Pittsburgh, PA; Patient Advocate, New York, NY; University of California San Francisco Comprehensive Cancer Center, San Francisco, CA; University of Southern California/Norris Comprehensive Cancer Center, Los Angeles, CA; EpiSource, LLC; Boston, MA; Boston University School of Medicine, Boston, MA; Genentech, Inc., South San Francisco, CA; Sarah Cannon Research Institute, Nashville, TN; Tennessee Oncology, PLLC, Nashville, TN**

**Background:** Data are lacking regarding treatment patterns and outcomes in elderly patients (pts) with HER2-positive (HER2+) metastatic breast cancer (MBC).

**Methods:** registHER is a large, observational cohort of pts with HER2+ MBC diagnosed within 6 months of enrollment. Pts (N=1,001) were followed until death, disenrollment, or June 2009 (median follow-up 27 months). In these analyses, pts were stratified into three groups based on age at MBC diagnosis: younger (<65 years), older (65-74 years), elderly (≥75 years). For Progression Free Survival (PFS) and Overall Survival (OS) analyses of 1st-line trastuzumab (T) vs. no T, older and elderly pts were combined due to small number of events in elderly. Hierarchical multivariate analyses were adjusted for baseline characteristics and treatments.

**Results:** ER/PR status was similar across age groups (Table 1). Elderly pts with HER2+ MBC had higher rates of underlying cardiovascular disease (CVD) than younger or older pts. In pts receiving T-based 1st-line treatment, elderly pts were less likely to receive chemotherapy (C), and more likely to receive T alone or combined with hormone therapy (HT). Central nervous system (CNS) events decreased with increasing age. In T-treated pts, incidence of left ventricular dysfunction (grade ≥3) was higher in elderly pts (20.1%) than in younger (21.4% [2.8%]) or older pts (21.4% [1.5%]). Across age groups, unadjusted median PFS (months) was significantly higher for pts treated with T in 1st-line than those who were not (<65 years T: 11.0; <65 years no T: 3.4; ≥65 years T: 11.7; ≥65 years no T: 4.8). In pts <65 years, unadjusted median OS (months) was significantly higher in T-treated pts: in pts ≥65 years, median OS was similar (<65 years T: 40.4, <65 years no T: 25.9; ≥65 years T: 31.2, ≥65 years no T: 28.5). In multivariate analyses, T in 1st-line was associated with significant improvement in PFS across age (Table 2). In OS, significant improvement was observed for pts <65 years; results were suggestive for pts ≥65 years.

**Conclusions:** Elderly pts (≥75 years) with HER2+ MBC in registHER had higher rates of underlying CVD than younger counterparts and received less aggressive treatment, including less 1st-line T. These population-based, real-world data suggest improved PFS with T as 1st-line therapy across all age groups.

**Characteristics of De Novo Stage IV Breast Cancer Presentation and Comparison with Stage IV Disease Relapse after Adjuvant Therapy.**

**Background:** We hypothesized that patients diagnosed with stage IV breast cancer at presentation may have different disease characteristics than patients who develop relapsed stage IV disease after adjuvant therapy. To examine potential differences, we analyzed a prospectively collected data set for patients diagnosed at the Markey Cancer Center starting from the beginning of 2007 to date.

**Methods:** Out of 1089 patients, we identified 76 patients (7%) who presented with de novo stage IV disease and 40 patients (4%) who experienced systemic disease relapse after initial adjuvant therapy. We compared key variables between the two groups including patient age, tumor size, grade, estrogen receptor (ER) status, progesterone receptor (PgR) status, HER2, and sites of metastatic disease involvement. Statistical significance was determined using the Chi-square test, Fisher’s exact test, two-sample t-test, or Wilcoxon’s rank sum test as appropriate.

**Results:** Patients with de novo stage IV breast cancer were more likely to be older (median age 58.5 years, Range 28-88) than women with relapsed stage IV breast cancer (median age 53 years, Range 28-77), and this difference was statistically significant (p = 0.039). As compared to the group with relapsed disease, breast cancer presenting with de novo stage IV disease was more likely to be Grade 1/2 (43% vs. 18.4%, p=0.032), ER positive (69.7% vs. 47.5%, p = 0.019), and PgR positive (56.6% vs. 32.5%, p = 0.0136). Interestingly, de novo stage IV breast cancer was more likely to be HER2 positive than in patients with relapsed disease (27.5% vs. 10.26%, p=0.035). When available patient data prior to 2007 was included in the analysis, we observed no significant difference in the frequency of HER2 expression between the de novo and relapsed groups (27.4% vs. 19.4%, p = 0.26). In comparing sites of metastatic disease involvement, the de novo stage IV patient group was more likely to have bone metastasis than the relapsed disease patient group (68.4% vs. 35%, p = 0.0006). There were no significant differences in the frequency of other metastatic sites involved, including brain, liver, and lung.

**Conclusions:** In this breast cancer patient cohort, there was a relatively high percentage of women presenting with stage IV disease, likely reflecting the underserved nature of this patient population. Women with de novo stage IV breast cancer were more likely to be older, have ER/PgR positive disease, and have bone metastasis as the primary site of involvement. These characteristics may reflect delay in initial presentation rather than a biologically more aggressive disease phenotype. The higher relative frequency of HER2 positive cancer in the de novo stage IV patient group is likely related to the impact of adjuvant trastuzumab use on reducing the risk of relapse in HER2 positive breast cancer.

**P1-08-24**

**Clinical and Pathologic Characteristics of Diabetic Breast Cancer Patients in a Tertiary Care Safety Net Hospital.**

Loch MM, Eapen A, Ross AA, Rosenberg C, Blanchard RA. Boston University Medical Center, Boston, MA; Boston University, Boston, MA

**Background:** Recent studies have indicated an increased risk of breast cancer in women with diabetes, and an increase in disease specific mortality in patients with diabetes and breast cancer. Clinical and pathologic features of diabetic women with breast cancer have not been described. We examine tumor characteristics in diabetic women in our ethnically diverse tertiary care hospital that may help explain the increased mortality seen in diabetic women diagnosed with breast cancer.

**Methods:** We expanded a pre-existing database to include all women diagnosed with breast cancer from 1998-2011. From the electronic medical record we documented age, body mass index (BMI), place of birth, self-identified race/ethnicity, date of diagnosis, T, N, M stage, grade, ER, PR, HER2 expression, presence of diabetes (DM) or thyroid disease at diagnosis, recurrence and treatment data including neoadjuvant, surgical, adjuvant and radiation therapy and adequacy of treatment. We determined associations using contingency tables and multivariable logistic regression.

**Results:** 480 cases were identified. Patients were racially diverse: 35% white [W], 41% black [B], 14% Hispanic and 10% other. 23% had DM, 47% were obese (body mass index [BMI] >30). Age in DM vs. non-DM were 63.327 vs. 57.729 (p = < 0.0001) and BMI in DM vs. non-DM were 32.749 vs. 29.433 (p = 0.001). When exploring odds ratios (OR) of different tumor subtypes, none were statistically significant when controlling for age and BMI. The OR calculated were as follows: Triple negative 1.00 (confidence interval [CI]: 0.6-1.666, p = 0.9996), ER+ 1.063 (CI: 0.89-1.226, p = 0.7877), PR+ 1.005 (CI: 0.76-1.506, p = 0.9811), HER2+ 1.011 (CI: 0.78-1.768, p = 0.8535), recurrence: 1.090 (CI: 0.63-1.837, p = 0.7558). There were no significant interactions with DM and T, N stage when controlling for age and BMI. T stage: p=0.692, N stage : p=0.7349 and recurrence p=0.5469 on recurrence controlling for age, BMI and grade: p=0.5462. There was no significant association between grade in DM vs. no DM with rates of grade in DM as follows: grade 1: 10.81%, grade 2: 49.55%, grade 3: 39.64% and in non-DM grade 1: 13.55%, grade 2: 45.8% and grade 3: 40.65%. Mean score difference p=0.7588

**Conclusions:** We did not find significant differences in our DM women compared with non-DM women when evaluating tumor subtype, T stage, N stage, grade or recurrence. In our patient population these factors do not play a role in the increased cause specific mortality in DM patients with breast cancer. Other factors must play a role in this and should be explored further.

**P1-08-25**

**Breast Cancer Burden, Risks and Outcomes in Latin America.**

Justo NA, Wilking NE, Jönsson B. OptumInsight, Stockholm, Sweden; Karolinska Institutet, Stockholm, Sweden; Stockholm School of Economics, Stockholm, Sweden

**BACKGROUND:** Breast cancer (BC) burden and care vary substantially across Latin America (LA). Aim: To provide an overview of the epidemiology, outcomes and countries’ risk profiles in LA to identify opportunities for improvement.

**METHODS:** Review of literature (PubMed, LILACS, SCIELO), public databases (Globocan 2002 & 2008, CEPALSTAT, DIRAC, PAHO, WHO/YS, etc) and conference presentations (ASCO, ISPOR). Local experts & patient organizations were surveyed. Current
Age is the main risk factor; while the association of education and wealth with BC occurrence is less significant. Reproductive and lifestyle-related risk factors, proven at a patient level, were not significant at a country-aggregate level and the specialized literature indicates that the evidence on associations between BC and diet is inconclusive.

### Discussion
LA’s considerable variation embedded within per-country averages may be masking underlying causality. Though, it can be inferred that there is no one-suit-all prevention campaign and policies aimed at reducing the risk of developing BC will succeed as long as they are properly targeted and tailored for different needs. Early diagnosis and population-wide access to treatment following policies aimed at reducing the risk of developing BC will succeed with a minimum 2.0-fold change of expression, 119 probes from 106 genes were differentially expressed, with 35 genes expressed at significantly higher levels and 71 at significantly lower levels in tumors from obese women compared to those from healthy-weight patients. Hierarchical clustering using these 119 probes reliably partitioned all samples as healthy-weight or obese. Genes differentially expressed include lower expression of several members of the histone cluster 1 family, APOD and IGF1, and higher expression of FABP7, members of the major histocompatibility complex and LTF in tumors from obese women.

### Conclusions
Invasive breast tumors from obese women are genetically different from those of healthy-weight women. Altered gene expression may affect tumor cell proliferation and survival, contributing to aggressive phenotypes and altered immune response. These underlying molecular differences may contribute to the less favorable prognosis observed in obese women with breast cancer.

### P1-09-02
**HDL-Cholesterol and Low-Penetration Gene CYP17 rs2486758 Influence Daily Estrogen Levels. The EBBA-I Study.**

**Iversen A, Thune I, McTiernan A, Makar KW, Wilsgaard T, Ellison PT, Jasienska G, Flote V, Poole E, Furberg A-S. University of Tromso, Tromso, Norway; Oslo University Hospital, Oslo, Norway; Fred Hutchinson Cancer Research Center, Seattle, WA; Harvard University, Cambridge, MA; Medical College, Krakow, Poland; Channing Laboratory, Boston, MA; University Hospital of North Norway, Tromso, Norway.**

**Objectives:** The low-penetration gene CYP17 encodes cytochrome P450 enzymes, catalysts in the endogenous estrogen biosynthesis. Low levels of high-density lipoprotein cholesterol (HDL-C) have been associated with increased estrogen level1, increased breast cancer risk and poor breast cancer prognosis2. However, the relationship between CYP17 and metabolic profile including HDL-C levels, and estradiol levels remains unclear. Thus, we hypothesize that gene-environment interactions between eight SNPs on CYP17 and metabolic profile including HDL-cholesterol, may influence the levels of biologically active 17β-estradiol of importance of breast cancer development.

**Material and methods:** The Norwegian Energy Balance and Breast cancer Aspects Study (EBBA-I) includes 203 healthy women (25-35 years) that underwent clinical examinations, blood sampling for metabolic profiling in serum and DNA extraction from whole blood, and daily saliva sampling throughout an entire menstrual cycle. Daily saliva levels of 17b-estradiol were measured by radioimmunoassay at the Reproductive Ecology Laboratory, Harvard University, USA. Tagging SNPs (rs1004467, rs743575, rs4919687, rs37811286, rs3824755, rs10786712, rs743572, rs2486758) representing CYP17 variability in the Caucasian population were selected using MAF > 5% and r2 = 0.80. The polymorphisms were genotyped at the Molecular Epidemiology Laboratory, Fred Hutchinson Cancer Research Center, USA. A clustered metabolic risk score was defined based on WHO criteria for the metabolic syndrome. Multivariable linear and generalized estimating equation regression models were used to study the associations.

**Risk factor Correlation Coefficient**

- Births women under 30: -0.485, 0.131
- Age at childbearing: 0.378, 0.252
- Fertility rate: -0.309, 0.355
- Overweight & obesity (fem): 0.219, 0.518
- Alcohol consumption (fem): 0.112, 0.791
- GDP per Capita: 0.688, 0.019
- Education (fem): 0.607, 0.051
- Mean Age (fem): 0.846, 0.801
Result: Women with at least one variant allele of the CYP17 rs2486758 combined with the highest metabolic risk score (i.e., upper tertile), had 53% higher levels of daily salivary 17β-estradiol throughout the entire menstrual cycle compared with all other women (P < 0.001). Among women in the upper tertile of metabolic risk score, those with the variant allele had 43% higher levels of daily salivary 17β-estradiol (P = 0.002). Similarly, the combination of having the variant allele and serum total cholesterol/HDL-C ratio in the upper tertile was associated with 43% higher levels of daily salivary 17β-estradiol, compared with all other women (P = 0.005), and 34% higher levels of daily salivary 17β-estradiol, compared with the women with common allele in the upper tertile (P = 0.038).

Conclusion: Our results suggest that a polymorphism in CYP17 (rs2486758) may represent a strong genetic predisposition to increased endogenous estrogen levels in women with an unfavourable metabolic profile and a high total cholesterol/HDL-C ratio. Thus, total cholesterol/HDL-C ratio may be a clinical biomarker for breast cancer development in these subsets of women.

Prevalence of Germline TP53 Mutations in Young Women with HER2-Positive Breast Cancer.

Dick MG, Masciari S, Miron A, Miron P, Foley K, Gelman R, Dillon DA, Richardson AL, Verselis SJ, Lypas G, Krop JE, Garber JE. Dana Farber Cancer Institute, Boston, MA; Brigham and Women’s Hospital, Boston, MA

Background: Li Fraumeni syndrome is a rare inherited cancer susceptibility condition associated with germline mutations in the TP53 gene, in which breast cancer (BC) is the most frequent tumor. The prevalence of TP53 mutations in population-based series of very young onset BC (<30 years at diagnosis) ranges from <1% to approximately 7% 

Results: We identified 347 women with invasive HER2 positive BC diagnosed at age < 50 years using the Clinical Operations and Research Information System (CORIS) at the Dana Farber Cancer Institute. Information on age at diagnosis, histology, hormone receptor and HER2 status as well as personal and family cancer history was confirmed from medical records. 129 patients were excluded for various reasons, including a cancer diagnosis prior to the BC and a documented BRCA1/2 mutation. A combination of Exon Grouping Analysis (EGAN) and Sanger sequencing for detection of TP53 mutations in exons 2-11 including surrounding intronic sequence was performed on 218 germline DNA samples. Multiplex Ligation-dependent Probe Amplification (MLPA) analysis for the detection of TP53 deletions or duplications is ongoing.

Results: A germline TP53 mutation was identified in 4 women diagnosed at age < 50 years (1.8%, 95%CI 0.5-4.6). At BC diagnosis, they were 23, 32, 44 and 50 years. Two BC were ER+/PR+, HER2+ and 2 were ER-/PR-, HER2+. Estimate of prevalence of germline TP53 mutations by age at BC diagnosis are: age ≤ 35, 2/41 (4.9%, 95%CI 0.6-16.6), and age ≤ 45 3/168 (1.8%, 95%CI 0.4-5.1). Among the women with germline TP53 mutations, 2 met the Chompret criteria and none the classic LFS criteria.

Discussion: TP53 mutations were identified in a cohort of women with HER2+ BC at young age. As expected, the frequency is higher in younger women, but mutations were seen in all age groups that were evaluated. None of these women met classic LFS criteria by family history. Consideration of TP53 testing should be given to women diagnosed below age 35 who are negative for BRCA1/2 mutations regardless of family history. Analysis of other series will be helpful in reaching more stable estimates of the prevalence of mutation carriers among patients with HER2+ BC at young age.

Sueta A, Ito H, Iwata H, Hosono S, Watanabe M, Iwase H, Tajima K, Tanaka H, Matsuo K. Aichi Cancer Center Research, Nagoya, Japan; Kumamoto University Graduate School of Medical Science, Kumamoto, Japan; Aichi Cancer Center Central Hospital, Nagoya, Japan; Nagoya University Graduate School of Medicine, Nagoya, Japan

Objective Genome-wide association studies (GWASs) have identified genetic variants associated with breast cancer. Most GWASs to data were conducted in women with European background and the extent to which these variants contribute as predictors of breast cancer among Japanese population is unknown.

Methods We analyzed 24 genetic variants that have been identified in previous GWASs and conducted a case-control study with 697 cases and age- and menopausal status- matched 1394 controls in the framework of the Hospital-based Epidemiologic Study at Aichi Cancer Center (HERPACC). All subjects were asked to provide information on lifestyle factors and blood samples for genetic studies. We fit conditional regression models with genetic variants and conventional risk factors including age, age at menarche, menopausal status, current body-mass-index, age at first live birth, regular exercise, family history of breast cancer, and referral pattern to our hospital. In addition, we created a polygenetic risk score, using the single nucleotide polymorphisms (SNPs) with statistically significant association with the breast cancer risk to measure the cumulative effect of multiple genetic risk variants. Furthermore, we evaluated the prediction model that included conventional risk factors by comparing with and without the genetic risk score, using c statistic.

Results Eleven SNPs (FGFR2-rs2981579, rs2981578, rs1219648, rs2402094, rs2981582, TOX3/TNRC9-rs8051542, rs3803662, LOC643714-rs4784227, C6orf97-rs2046210, 8q24-rs13281615, SLC4A7-rs4973768) revealed significant associations with breast cancer among Japanese population is unknown.

Discussion Among women with at least one variant allele of the CYP17 rs2486758 combined with the highest metabolic risk score (i.e., upper tertile), had 53% higher levels of daily salivary 17β-estradiol throughout the entire menstrual cycle compared with all other women (P < 0.001). Among women in the upper tertile of metabolic risk score, those with the variant allele had 43% higher levels of daily salivary 17β-estradiol (P = 0.002). Similarly, the combination of having the variant allele and serum total cholesterol/HDL-C ratio in the upper tertile was associated with 43% higher levels of daily salivary 17β-estradiol, compared with all other women (P = 0.005), and 34% higher levels of daily salivary 17β-estradiol, compared with the women with common allele in the upper tertile (P = 0.038).

Conclusion: Our results suggest that a polymorphism in CYP17 (rs2486758) may represent a strong genetic predisposition to increased endogenous estrogen levels in women with an unfavourable metabolic profile and a high total cholesterol/HDL-C ratio. Thus, total cholesterol/HDL-C ratio may be a clinical biomarker for breast cancer development in these subsets of women.

References
women with scores of 4-5, 6-7, 8-9 and 10 or more were 1.33 (95% confidence interval, 1.00 - 1.80), 1.71 (1.26 - 2.30), 3.01 (1.97 - 4.58) and 8.69 (2.74 - 27.5), respectively (P<0.001). The ORs for premenopausal women with the corresponding risk scores were 1.71 (1.12 - 2.63), 1.79 (1.15 - 2.78), 3.70 (1.98 - 6.93), and 14.0 (3.30 - 59.5), respectively, and those for postmenopausal women with the corresponding risk scores were 1.09 (0.72 - 1.66), 1.71 (1.12 - 2.61), 2.60 (1.44 - 4.71), 3.75 (0.57 - 24.4), respectively, compared to those with scores of 3 or less (each P<0.001). The c statistic for a model including the genetic risk score in addition to the conventional risk factors was 0.633, whereas 0.602 without it (P<0.001). Population-attributable fraction of the risk score was 33.8%.

**Conclusion** we identified a genetic predictor of breast cancer in a Japanese population. A risk model including genetic risk score may be useful to distinguish women at high-risk of breast cancer from those at low-risk, particularly in the context of targeted prevention.

**A 3'UTR Functional Variant in BRCA1: A Predictor of Poor Outcome in Breast Cancer.**

Dorairaj JJ, Miller N, Newell J, Kerin MJ, Weidhaas JB. National University of Ireland, Galway, Ireland; Yale University, New Haven, CT

**Background:** MicroRNAs (miRNAs) are class of gene regulators which exert their effects through binding with partial complementarity to sequences in the 3' untranslated region (3'UTR) of the target mRNA. Single nucleotide polymorphisms (SNPs) in the 3'UTR of target mRNA have the potential to disrupt or create new illegitimate miRNA targets and have been associated with cancer predisposition as well as tumor biology. An association between rs8176318 and risk for familial breast and ovarian cancer as well as risk for triple negative breast cancer in African American women has previously been established. We aimed to evaluate the phenotypic effect of rs8176318 in a west of Ireland breast cancer cohort, and also its role as a biomarker of prognosis.

**Methods:** DNA from 727 unselected breast cancer cases and 387 controls were extracted from whole blood and genotyped for rs8176318 in the 3'UTR of the BRCA1 oncogene. The association with disease specific parameters and outcome were evaluated.

**Results:** Overall, there was a significant difference in the distribution of the three genotypes between cases and controls (p=0.035). The dominant variant model was predictive of breast cancer (OR=1.4, 95% CI 1.1-1.8). Fifty-two percent of breast cancer cases had the variant, with similar prevalence between subtypes: Luminal A (279 [54%] of 519 cases), Luminal B (37 [43%] of 85 cases), HER2 (21 [53%] of 40 cases) and triple negative breast cancer (41 [49%] of 83 cases). Comparing the prevalence of the variant within respective subtypes with controls however, Luminal A breast cancer was most strongly associated with rs8176318 (OR=1.5, 95%CI 1.1-1.9). The variant was not significantly associated with disease free survival (DFS) in all cancer cases (Log-rank test=0.084). However, rs8176318 was predictive of a poorer DFS (Log-rank test=0.041) in Luminal A patients with a 10-year DFS of 54% (95% CI 0.4-0.7) and 77% (95% CI 0.7-0.9) for the variant versus the non-variant, respectively. In addition, patients with Stage IV disease had a 6-fold increased risk of carrying the variant (p=0.035), with 17 (73%) of 23 patients with metastasis at presentation positive for the variant compared to 324 (50%) of 642 patients without metastasis (p=0.034). Luminal A patients with Stage IV disease had a 13-fold risk of carrying the variant (p=0.043) in regression analysis, controlling for all other clinicopathological variables. Similarly, the variant was associated with distant metastasis in Luminal A patients, with 11 (92%) of 12 patients with metastasis positive for the variant compared to 242 (52%) of 463 patients without metastasis (p=0.028).

**Conclusion:** These findings suggest that rs8176318, a variant in the 3'UTR of BRCA1, is a genetic marker for modest breast cancer risk but aggressive tumor biology in breast cancer, and highlights the need for further clinical and biological evaluation of such markers.

**Single Nucleotide Polymorphisms in the BRMS1 and SIPA1 Metastasis Suppressor Genes as Prognostic Markers in Breast Cancer Patients.**

Roberts MR, Hong C-C, Edge SB, Yao S, Nesline M, Ambrosone CB. Roswell Park Cancer Institute, Buffalo, NY

**Introduction:** Single nucleotide polymorphisms (SNPs) in the metastasis suppressors BRMS1 and SIPA1 may affect metastatic efficiency. BRMS1 affects apoptosis, colonization, cell adhesion, and invasive potential. Loss of BRMS1 expression has been correlated with younger age at diagnosis and reduced survival time in patients with progesterone-receptor (PR) negative, HER2-positive tumors. SIPA1 affects extracellular matrix gene expression and cell adhesion, and while SNPs have been associated with node positive, estrogen-receptor (ER)/PR negative tumors, evidence for a relationship with survival has been conflicting. Identifying SNPs that affect risk of recurrence and survival may improve the ascertainment of patients who require aggressive adjuvant therapy following a diagnosis of breast cancer. We evaluated associations between seven BRMS1 and SIPA1 SNPs and recurrence and survival in patients with primary breast cancer.

**Methods:** We identified 1,015 incident breast cancer patients who received surgery at Roswell Park Cancer Institute (RPCI) and participated in the DataBank and BioRepository (DBBR) resource. Participants completed an epidemiologic questionnaire and provided a blood sample prior to surgery or other treatment. Clinical and pathologic data were linked to de-identified participant data in the DBBR database. SNPs in BRMS1 (rs11537993, rs3116068, and rs1052566) and SIPA1 (rs75894763, rs746429, rs3741378, and rs2306364) were genotyped by RPCI's Genomics facility using Sequenom® iPLEX Gold and Taqman® real-time PCR assays. Cox proportional hazards regression was used to estimate hazard ratios and 95% confidence intervals.

**Results:** The median follow-up time was 33 months, and 49 deaths and 42 recurrences occurred. Tumors were more likely to be larger, node positive, ER/PR negative, and high grade among patients who experienced a recurrence or death. Recurrence was less likely in older patients and those with higher body mass index, although the latter association was nonsignificant (p=0.06). Patients with at least one variant allele of the BRMS1 rs3116068 genotype experienced shorter overall survival compared to patients with the homozygous common genotype (HR=2.05, 95% CI 1.15-3.63, rs3116068 AG+AA compared to GG). The remaining SNPs were not associated with overall survival, and none of the SNPs were associated with recurrence.

**Conclusions:** In our data, the variant allele of rs3116068 was more common among women whose breast cancer was node negative and HER2-positive, compared to those with the common rs3116068 allele. The rs3116068 variant allele is also associated with poorer survival. While our findings do not support a role for common SNPs in the SIPA1 gene in breast cancer prognosis, BRMS1 rs3116068 may be a useful prognostic biomarker. Future goals are to examine additional SNPs in BRMS1 and other metastasis-related genes in a larger, racially diverse population.
Funding: This research was supported by a gift from the Jayne and Phil Hubbell Family. The DBBR and Genomics Facility are RPCI Cancer Center Support Grant shared resources, supported by P30 CA016056-32. Ms. Roberts is a DOD Predoctoral Award recipient (BC10068) and Dr. Ambrosone is funded by the Breast Cancer Research Foundation.

P1-09-07

Background: The exact contribution of TP53 germline mutations, associated with Li Fraumeni Syndrome - LFS, to the overall burden of cancer is still only partially known. Studies in Southern and Southeastern Brazil have shown that a particular mutant, TP53 p.R337H, has incomplete penetrance and may be present in a significant number of subjects (estimated frequency at the populational level of 1:300 individuals). In an exploratory approach, the aim of this study is to assess the prevalence of the TP53 p.R337H mutation in women with breast cancer diagnosed before 46 and after 55 years of age, unsellected for family history of cancer and resident in Southern and Southeastern Brazil.

Methods: Formalin-fixed paraffin-embedded (FFPE) non-tumoral tissue of 521 women diagnosed with breast cancer between 2000 and 2010 in two pathology laboratories were obtained retrospectively and consecutively, and analyzed after anonymization. Genomic DNA was isolated with the QIAamp DNA Tissue Kit and genotyping performed by allelic discrimination using a TaqMan assay. Confirmation of all mutation-positive and a sample of mutation-negative cases was done by TP53 exon 10 sequencing.

Results: Analysis of the first 299 cases identified the TP53 p.R337H mutation in the germline of 15 (5.0%) cases: 13/142 (9.2%) before 46 years and 2/157 (1.3%) diagnosed after 55 years. The p53 expression pattern assessed by immunohistochemistry in the breast tumors was not different between p.R337H mutation carriers and non-carriers.

Conclusion: Preliminary analysis in a sample of women with breast cancer diagnosed before 46 and after 55 years of age, unsellected for family history of cancer and resident in Southern and Southeastern Brazil indicates that the germline TP53 p.R337H mutation-positive and a sample of mutation-negative cases was done by TP53 exon 10 sequencing.

P1-09-08
Association of Hypoxia-Inducible Factor-1 with Breast Cancer Risk: A Meta-Analysis of Published Studies.
Yin W, Liu G, Lu J, Shen Z, Shao Z. Fudan University Shanghai Cancer, Shanghai, China

Background: Hypoxia-inducible factor-1 (HIF-1) plays an important role in the development and progression of breast cancer. However, conflicting results have been yielded for the association between HIF-1 polymorphisms and breast cancer risk. Therefore, we carried out a meta-analysis to assess the association of HIF-1 1772 C/T and 1790 G/A polymorphisms with breast cancer.

Material and methods: Computerized and manual searches were performed to identify eligible studies comparing allelic and genotypic frequency between cases and controls in breast cancer. Odds ratios (ORs) were used to estimate the association between HIF-1 polymorphisms and breast cancer risk. The fixed-effects or random-effects model was used to combine data. Subgroup analyses by ethnicity were also performed.

Results: This meta-analysis for 1772 C/T polymorphism included 1934 breast cancer cases and 1848 controls, and for 1790 G/A polymorphism included 602 breast cancer cases and 479 controls. We found that 1772C/T polymorphism increased the risk of breast cancer in the recessive model (OR = 2.273, 95% CI: 1.061-4.872, P = 0.035), whereas similar effect failed to be observed in the dominant model (OR = 1.075, 95% CI: 0.717-1.613, P = 0.725). There was a significant increase in breast cancer risk among Asian women (OR = 4.162, 95% CI: 1.508-11.484, P = 0.006) but not Turkish patients in the recessive model. For the 1790G/A polymorphism, we found that it had no exact effect on the decreased risk of breast cancer in both recessive and dominant model.

Discussion: This meta-analysis indicates that the polymorphism of HIF-1 1772C/T rather than 1790G/A polymorphism might be one of the high risk factors for breast cancer. The effect of the 1772C/T polymorphism on breast cancer risk is completely generated by the Asian women.

P1-09-09
Fetal Microchimerism and In Situ Breast Cancer.
Eun JK, Gadi VK. University of Washington, Seattle, WA; Fred Hutchinson Cancer Research Center, Seattle, WA

Background: Haploidentical fetal cells acquired and maintained by a woman in her blood and tissues long after pregnancy completion, also known as fetal microchimerism, is inversely associated with invasive breast cancer. Furthermore, in healthy women, absence of fetal microchimerism serves as a risk factor for development of future breast cancer (J Clin Oncol 29: 2011 suppl; abstr 1574). Here, we test the hypothesis that failure to maintain fetal microchimerism following pregnancy is also associated with in situ breast cancer.

Methods: Buffy coat specimens were obtained from the Roswell Park Cancer Institute Data Bank and BioRepository from parous patients with in situ breast cancer and parous control volunteers with no prior history of cancer. Using quantitative PCR, DNA extracts from peripheral blood buffy coat specimens were tested by a single female operator blinded to case:control status for the presence (and concentrations) of Y chromosome sequence DYS14, a marker of male fetal microchimerism.

Results: In this interim analysis, 83% (34/41) of healthy control women and 55% (29/53) in situ breast cancer patients tested positively for the presence of DYS14. The unadjusted odds ratio was 0.25 (95%-CI of 0.08-0.72; p=0.008). Median concentrations were also
greater in healthy women compared to women with in situ cancer, 0.15 versus 0.02 fetal cell equivalents per 10^5 proband genomes, respectively (p=0.004).

Summary: Preliminary results suggest that the associations of fetal microchimerism and in situ breast cancer are similar in magnitude and direction to that observed for invasive disease. The natural history of in situ breast cancer is for a large portion of patients to develop invasive disease in 8–10 years absent of comprehensive locoregional control; results here point to a failure to maintain or loss of haploidentical fetal cells well before development of invasive disease. Final results from the entire cohort planned (n=200) with adjustment for anthropometric, reproductive, and cancer specific factors will be presented at the meeting.

P1-10-01
Utility of Routine Cardiac Ejection Fraction (CEF) Measurement Prior to Anthracycline-Based Chemotherapy (ABC): A Study of 466 Patients with Early-Stage Her2-Negative Invasive Breast Cancer.

Policepatil SM, Go RS, De Maiffe BM, Gundrum JD, McHugh VL, Gundersen Lutheran Medical Foundation, La Crosse, WI; Gundersen Lutheran Medical Centre, La Crosse, WI; Gundersen Lutheran Medical System, La Crosse, WI

Background: Despite the lack of evidence to support its utility, routine CEF measurement prior to ABC is a common practice in the community, required in most US clinical trials, endorsed by the American Heart Association and American College of Cardiology, and appears on Food Drug Administration-approved labeling guidelines.

Objectives: We determined the frequency of the following events in newly diagnosed invasive breast cancer patients: a) CEF measurement prior to ABC; b) asymptomatic left ventricular dysfunction; c) modification in initial treatment strategy as a result of CEF measurement; d) development of congestive heart failure (CHF) after ABC.

Methods: From our cancer registry, we obtained a list of all female patients with newly diagnosed stage I-III breast cancer who were treated with chemotherapy as part of initial therapy at our institution in 2000-2010 (N=562). We excluded those with prior CHF, ABC, and those who had Her2-positive disease (n=66). CEF <50% was considered low. CHF risk factors including coronary heart disease, cigarette smoking, hypertension, obesity, and diabetes mellitus were collected.

Results: We included 496 patients with the following stage distribution: I (22%), II (54%), and III (24%). The mean age was 53 years (SD±11; range 25-88). In 30 (7%) patients, ABC was considered inappropriate by the physician provider due to poor performance status, co-morbidities, and physician or patient preference. Of the 466 patients considered for ABC, CEF was measured in 241 (52%) patients before chemotherapy. In the latter group, only 1 (0.4%) patient was found to have asymptomatic left ventricular dysfunction with CEF of 48%. Among patients considered for ABC, 10 (2%) did not receive ABC for the following reasons: low or borderline CEF (2), patient preference (3), co-morbidities (2), and randomization to non-ABC in clinical trials (3). After a mean follow up 57 months (SD±34), only 3 of 456 (0.7%) patients who received ABC developed CHF. Two had normal CEF prior to treatment while the other did not have CEF measured. The practice of CEF measurement prior to ABC varied among physician providers, ranging from 23% to 67% (mean/SD 47%/±15%). Those who had CEF measured before chemotherapy were older (55 vs. 50 years; P<0.001) and had more CHF risk factors (1.3 vs. 0.9; P<0.001).

Conclusions: At our institution, routine CEF measurement prior to ABC as initial therapy for early-stage Her2-negative invasive breast cancer patients is a common though not uniform practice. Asymptomatic left ventricular dysfunction is rarely detected and generally mild. Our findings do not support the utility of routine CEF measurement in this population and challenge current practice and guidelines. Potential cost implications to our health care system can be substantial.

P1-10-02

Baffert S, Cottu PH, Kirova Y, Bachelot T, Le Rhun E, Mercier F, Levy C, Gutierrez M, Madrange N, Moldovan C, Guis S, Serin D, Cotte FE, Benjamin L, Simondi C, Maillard C, Laulhere-Vigneau S, Durand-Zaleski I, Institut Curie, Paris, France; Centre Léon Bérard, Lyon, France; Centre Oscar Lambret, Lille, France; Stat Process, Port Mort, France; Centre François Baclesse, Caen, France; Institut Curie, Saint-Cloud, France; Institut Bergonie, Bordeaux, France; Centre Henri Becquerel, Rouen, France; Centre GF Leclerc, Dijon, France; Institut Sainte Catherine, Avignon, France; GlazoSmithKline, Marly Le Roi, France; Ceri Medical, Garches, France; CHU Henri Mondor, Créteil, France

Background
HER2+ status is associated with poor prognosis and a high incidence of brain metastases (BM) in breast cancer (BC). Addition of HER2-targeted therapies to conventional chemotherapy has significantly improved survival in HER2+ patients (pts). Management of BM implies a multidisciplinary therapeutic approach involving medical oncology, radiation oncology and neurosurgery teams. Nevertheless available data evaluating health resources use and associated costs are limited. Our objective was to describe treatment patterns and healthcare costs associated with HER2+ BMBC patients.

Patients and methods
An observational retrospective study was conducted on 207 HER2+ BC pts, newly diagnosed with BM as first site of relapse or as secondary metastases between January 2006 and December 2008. Pts were recruited in 10 hospitals, all funded by a prospective payment system based on Diagnosis Related Groups (DRG). Individual data concerning initial diagnosis, distant and BM relapses, treatments, complications and hospitalization stays were collected during a 2 year - follow-up. DRGs 2007 official tariffs (per-case payment basis) and 2007 expensive innovative drugs tariffs (drugs paid to hospitals by Health Insurance in addition to per-case payments) were used to estimate direct medical costs from the Health Insurance perspective. Survival was estimated using Kaplan Meier method. In the presence of cost-censored data, a partitioned estimator was used to adjust censoring costs (Bang and Tsiatis, Biometrics, 2002).

Results
91.8% (190/207) of BMBC pts received radiation therapy, 84.5% (175/207) received chemotherapy including HER2 targeted treatments and 12.6% (26/207) were treated by neurosurgery. 72.5% (150/207) of pts were hospitalized at least once during the follow-up period. Pts had on average 2.90 hospital stays (range 1-8). The median duration of stay was 9 days (1-221). Complications leading to re-hospitalization were recorded in 45.9% (95/207) of pts. The median overall survival from the diagnosis of BM was 13 m. Hospital healthcare costs were concentrated on the 6 first months following BM diagnosis. Mean cost of BMBC management was 18,480€/patient within the 6 first months and decreased to 16,306€ from 7-12 months, 15,844€ from
13-18 months, and 15,225€ from 19-24 months. The proportion of costs attributed to inpatient hospitalizations (treatments and complications) was similar to the one attributed to drugs whatever the period of follow-up. Pts with BM as first site of relapse consumed more healthcare resources compared to pts with secondary BM (38,813€/pt vs 32,253€/pt after one year of follow-up, respectively).

Conclusions
Healthcare resources spending is mainly concentrated at the beginning of metastatic disease management, especially for patients with BM as first site of relapse. These results illustrate the use of expensive treatments in the first months following BM diagnosis. Individual data derived from this observational study allowed us to gather more specifically treatment patterns for HER2+ BMBC in order to estimate the costs more accurately.

P1-10-03
Colon Stimulating Factor Use with Taxane-Based Therapy for Metastatic Breast Cancer: Claims Analysis of Prophylaxis, Treatment, and Costs.
Force RW, Pugmire BA, Culbertson VL. ImproveRX, LLC, Pocatello, ID: Idaho State University, Pocatello, ID

Background: The taxanes (paclitaxel, docetaxel, and albumin-bound paclitaxel) are used in women with metastatic breast cancer (MBC). Clinical trials indicate that these drugs may differ in their toxicity profiles, including rates of neutropenia and need for colony stimulating factor (CSF) supportive therapy. Utilizing medical claims data, we evaluated prophylactic and treatment-related CSF use among women receive taxane-based chemotherapy regimens.

Objective: To determine if differences exist in rates of CSF use for prophylaxis, treatment and associated costs in women receiving taxane-based chemotherapy for MBC.

Methods: Women with MBC were identified with ICD-9-CM codes and by their prior use of adjuvant chemo regimens. Paid medical claims (source: Ingenix Consulting) from May 1, 2006 to April 30, 2009 were analyzed. Study groups were defined according to the first taxane administered. CSF utilization was classified as prophylaxis (0-5 days post-taxane administration), treatment (6-21 days post-taxane,) or non-taxane associated use (>21 days post-taxane). Comparisons were made between the taxane groups. All CSF costs were captured from date of first taxane to end of taxane therapy +21 days and categorized as above. Patients censored if ≥35 days elapsed with no taxane therapy. Two-stage regression analyses were performed. Control variables included age, Romano comorbidity score, and use of prior and other concurrent chemotherapy.

Results: 4,503 women (mean age: 53 +/- 10 years) with MBC were identified: 2,599 in the docetaxel group; 1,643 received paclitaxel; and 261 received nab-paclitaxel. More patients receiving docetaxel received any CSF (75.6%) than either paclitaxel (49.8%) or albumin-bound paclitaxel (36.8%) P<0.05 for each comparison. For docetaxel 70.5% of women received prophylactic CSF, whereas the rates were 47.0% for paclitaxel and 33.0 for albumin-bound paclitaxel (P<0.05).

The rate of women receiving CSF in the albumin-bound paclitaxel (36.8% P<0.05 for each comparison). For docetaxel 70.5% of women received prophylactic CSF, whereas the rates were 47.0% for paclitaxel and 33.0 for albumin-bound paclitaxel (P<0.05).

Conclusions: Compared with docetaxel and paclitaxel, patients receiving albumin-bound paclitaxel had significantly lower prophylactic CSF use, yet did not experience any difference in treatment-related use. Daily per-patient CSF expenditures for albumin-bound paclitaxel were significantly lower than the other two taxanes.

P1-10-04
Cost-Utility of the 21-Gene Breast Cancer Assay (Oncotype DX®) in the Irish Healthcare Setting
Lacey L, Chien R, Hornberger J. Lacey Solutions Ltd, South Strand, Skerries, County Dublin, Ireland; Cedar Associates LLC, Menlo Park, CA; Columbia University, New York, NY; Stanford University, Stanford, CA

Objective: The Oncotype DX® Breast Cancer Test is a validated 21-gene assay that predicts the likelihood of benefit from adjuvant chemotherapy in early-stage, node-negative and up to 3-node-positive, ER+ breast cancer as well as the likelihood of distant recurrence at 10-years. Study objective was to investigate the cost-utility (incremental cost per QALY gained) of using Oncotype DX® in early stage, node-negative, ER+ breast cancer patients, from the perspective of the Irish Healthcare system.

Methods: A cost-utility analysis was performed over the lifetime of the patient using a state transition model (Markov), which simulated the costs and quality-adjusted survival associated with and without the use of Oncotype DX® to inform adjuvant chemotherapy decisions. The model included 3 health states: no recurrence, recurrence and death. Transition probabilities between health states, utility scores associated with each of the health state, patient cohort characteristics and impact of Oncotype DX® on chemotherapy decisions data were derived from published sources. Direct medical costs associated with chemotherapy were collected from a representative panel of 5 hospitals in Ireland. Costs and outcomes were discounted at 4% per annum and the analysis was conducted over 30 years (lifetime horizon). Probabilistic and one-way sensitivity analyses were conducted.

Results: Costs associated with adjuvant chemotherapy (4 cycles of TC) included the following costs: drug (€1,002); administration and monitoring (€1,646); adverse event prevention (€3,561) and adverse event management (€756). The average total cost of chemotherapy across hospitals therefore summed up to €6,965. The base case incremental cost per QALY gained with ODX testing was estimated to be €9,462. There was a 74% chance for ODX to be cost-effective at a willingness to pay threshold of €20,000.

Conclusions: Using Oncotype DX® as a decision tool to inform adjuvant chemotherapy in node-negative, ER+ breast cancer patients, is likely to be cost-effective in the Irish healthcare setting. This estimate is probably conservative as the cost and disutility associated with long-term impact of chemotherapy related adverse events (i.e. such as cardiotoxicity, secondary leukaemia and potential cognitive impairment) have not been considered.

P1-10-05
Is the 21-Gene Breast Cancer Test (Oncotype DX®) Cost-Effective?
Pronzato P, Plun-Favreau J. Istituto Naz.le Ricerca Cancro, Genova, Italy; Genomic Health International Sàrl, Geneva, Switzerland

Background: The Oncotype DX® Breast Cancer Test is a validated 21-gene assay that predicts 10 year risk of recurrence and the likelihood of benefit from adjuvant chemotherapy in early-stage, node-negative ER+ breast cancer. The cost-effectiveness of using Oncotype DX® has been published in several countries but to date, there hasn’t been any review of these studies.

Materials and methods: The electronic database Pubmed and a selection of congress databases were searched using combinations
of search terms designed to identify publications describing cost-effectiveness analyses of Oncotype DX® in early stage breast cancer patients. Searches were limited to those published in the English language between January 2001 and April 2011. All records were screened for inclusion in the review. The methodological quality of selected publications was assessed using the 35 items methodological checklist from Drummond et al (1996).

Results: Five published health economics analyses and 3 abstracts (two posters and an oral presentation) were identified. The studies were carried out in several countries (US (2), Canada (2), Japan, Israel, Singapore and Hungary and have used a Markov modelling approach based on data from a large multicentre trial (e.g. NSABP B-20) to make estimates of long-term outcomes, and assess the cost-effectiveness of using the Oncotype DX® recurrence score in patients classified as having a high or low risk of distant recurrence using other methods of assessment. All studies were carried out in the perspective of the healthcare payer, and therefore did not consider broader costs to the patients and society. Study comparators, costs, characteristics of the population receiving the test and impact of using the Oncotype DX® results on treatment decisions were adapted to each individual country clinical practice explaining the large range of cost-effectiveness results from these studies. In the US, using Oncotype DX® was shown to be cost-saving when in one of the Canadian studies, it was likely to be cost-effective (incremental cost-effectiveness ratio of $64,063 per QALY gained). Consistently across all five studies, use of Oncotype DX® was projected to improve survival (where reported), quality-adjusted life expectancy and to reduce chemotherapy costs versus comparators. When looking at the methodological quality of studies, they generally scored well with positive responses to 24 or more of the 35 questions on reporting. The exception was the Lyman et al. (US) paper where only 17 positive responses were recorded. The two posters, as expected scored lower than the full scale articles with positive responses of 15 and 18 out of 35 items.

Conclusions: Published literature to date is of good methodological quality and consistently supports the cost-effectiveness of using Oncotype DX® in the various settings. Further analyses should be carried on to assess the budget impact of funding Oncotype DX® and to include a broader perspective of the costs.

P1-10-06
Economic Analysis of Chemotherapy Costs for Adjuvant Therapy in Breast Cancer in France.

Background: Total costs of adjuvant chemotherapy can be estimated using different perspectives. To date, only few studies are available in France and only few of these studies have incorporated all the relevant cost items. Indeed the total cost of adjuvant chemotherapy for breast cancer should include not only the drug costs and their administration but also supportive care, transportation and part of the work absenteeism, because all these costs are borne by the French social security. The study objective was to estimate the total costs of adjuvant chemotherapy in France using two different perspectives: the French social security and society.

Methods: We conducted a retrospective study to calculate the total cost of first line adjuvant chemotherapy for breast cancer in France. We developed an electronic CRF to collect clinical data, chemotherapy drug details, side effects and personal data such as the type of transportation from home to hospital for chemotherapy treatments and duration of work absenteeism. We added the cost of medical consultations, radiology and biology. We also calculated the exact cost of paramedical time and material. All data were collected after patient’s acceptance from clinical records and by phone. Medical resource data were collected from patients’ files for which data were recorded in February 2010 in Tenon hospital (Paris). Unit costs were collected from the French medical insurance database, and other public sources such as national statistics and the technical agency for hospitalization information.

Results: We collected data from 30 patients who had adjuvant chemotherapy for breast cancer. Median age was 57.7 years and 37.9% of patients had a regular work. Using the social security perspective, the mean cost (+/- SD) for pre chemotherapy exams and management (biology, oncologist consultation, implantable port system) was €320 +/-€32. For each chemotherapy cycle, the costs of chemotherapy drugs, preventive medications and chemotherapy administration were €1267 +/-€1424. The cost of chemotherapy adverse events was €405 +/- €829 and €39 +/-€28 for usual monitoring of chemotherapy (biology tests and medical consultations). Transportation costs were estimated at €11 +/-€12 and sick leave payments at €445 +/-€521. The mean total cost per cycle was €1806 +/- €1226 per chemotherapy cycle and €12724 +/- €8426 for the whole adjuvant chemotherapy regimen. Using a broader societal perspective, the total cost of chemotherapy was €14668 +/- €9707 per patient, as it included the full cost of lost productivity due to work absenteeism.

Conclusion: We reported the first cost analysis of adjuvant chemotherapy for breast cancer in France using two different perspectives (the French social security and the society). Using the social security perspective, chemotherapy drugs and their administration accounted for 70% of the total cost of chemotherapy against 60% when using the societal perspective.

Friedman D, Raskind-Hood C, Adams K, Becker E, Habtes I, D’Orsi C, Gundry K, Birdsong G, Gabram-Mendola S. Emory University, Atlanta, GA

Background: Despite advances in diagnosis and treatment of breast cancer in the United States, racial disparities in survival persist. Female breast cancer represented the costliest cancer site in 2010 with further increases projected to 2020. Mammography screening guidelines reflect the inherent difficulty in reconciling mortality reduction with potential harms to patients and cost-effectiveness concerns. Contrary still surrounds the 2009 updated USPSTF recommendations, as critics and advocates alike evaluate lives saved, costs, and how best to compare screening strategies. This study simulates USPSTF and ACS guidelines’ effects on stage, 5-year survival, and cost of treatment vs. usual practice in women treated in an urban public hospital.

Methods: Charts of 84 patients diagnosed with Stage I-III breast cancer in 2008 were reviewed. Published tumor doubling times guided a retrospective model to predict size at diagnosis by simulated ACS or USPSTF guidelines. AJCC-7 stages were then assigned to produce 3 distributions: 1) actual stage; 2) stage under ACS; and 3) stage under USPSTF. Survival estimates by stage and year from diagnosis were drawn from NCDB statistics and applied to each stage distribution, yielding average predicted survival for the actual and hypothetical scenarios. Finally, treatment costs for women continuously enrolled in Medicaid for 18 months were calculated from merged claims and registry data and similarly applied.

Results: Study patients averaged 55 years; 85% were African American. Forty-nine percent were covered by Medicaid and 23%
Racial/Ethnic Differences in Adjuvant Trastuzumab Receipt for Women with Breast Cancer within the National Comprehensive Cancer Network.

Freedman RA, Hughes ME, Ottesen RA, He Y, Weeks JC, Wong V-N, Theriault RL, Keating NL. Dana-Farber Cancer Institute, Boston, MA; City of Hope, Duarte, CA; Harvard Medical School, Boston, MA; Fox Chase Cancer Center, Philadelphia, PA; University of Texas MD Anderson Cancer Center, Houston, TX; Brigham and Women’s Hospital, Boston, MA

Background
Racial/ethnic disparities in breast cancer care are well documented. Although adjuvant trastuzumab has been shown to improve disease outcomes for women with Human Epidermal Growth Factor Receptor 2 (HER2)-positive cancers, the ‘real world’ utilization and toxicity of adjuvant trastuzumab are unknown. Because therapy involves one year of treatment and the costs of treatment are high, a risk for treatment disparity exists. We examined differences in receipt and completion of adjuvant trastuzumab by race/ethnicity, education, employment, and insurance for women diagnosed with HER2-positive breast cancer.

Methods
Using the National Comprehensive Cancer Network (NCCN) Breast Cancer Outcomes Database, we identified 1,146 women with stage I-III HER-2 positive breast cancer who presented to participating NCCN institutions during 2005-2008. In multivariable logistic analyses, we assessed the effect of race/ethnicity on the likelihood of trastuzumab therapy, and among women who initiated trastuzumab, the likelihood of completing ≥ 270 days of therapy, adjusting for center, diagnosis year, age, insurance, comorbidity, education, employment, and tumor characteristics. We also examined reasons for discontinuation of therapy among those who stopped treatment prematurely.

Results
Among patients eligible for this analysis, 75% women were Caucasian, 9% were African-American, and 9% were Hispanic. Most women had managed care insurance (71%) and were employed/student (52%). About one-third (36%) had a college degree and 39% had a high school education or less. Overall, most women (82%) received neo/adjuvant trastuzumab and there were no racial/ethnic
differences in receipt of therapy (adjusted odds ratio [OR] 1.11, 95% confidence interval [CI] 1.72-1.71 for African-American and OR 1.39, 95% CI 1.76-2.54 for Hispanic, versus Caucasian women). Among the 769 women who initiated neo/adjuvant trastuzumab and had ≥365 days of follow-up, 84% completed ≥270 days of trastuzumab. Rates of completion were lower for African-American (72%) and Hispanic (82%) women than Caucasian women (85%). In adjusted analyses, African-American women but not Hispanic women had lower odds of completing therapy compared with Caucasian women (OR 0.45, 95% CI 0.29-0.70, p=0.0003). Indemnity insurance (versus managed care) was associated with lower odds of trastuzumab completion, as was having a high school education or less (versus college education). Among the 123 women who did not complete trastuzumab, 26% stopped early for toxicity, and this occurred more frequently for African-American women than Caucasian women (50% vs. 21%), but small sample precluded a meaningful test for statistical significance.

Conclusion
Compared with Caucasian women, African-American women had similar rates of initiation of adjuvant trastuzumab but much lower rates of completion that were not explained by differences in education, employment, or insurance. Because of the significant benefits conferred by adjuvant trastuzumab therapy for HER2-positive breast cancer, interventions to assure completion of therapy could lead to improved outcomes. Further exploration of racial differences in toxicity and tolerance of therapy are also warranted.

P1-11-03
Wooldridge RD, Borgstrom DC. Bassett Medical Center, Cooperstown, NY

Introduction: For women with early stage breast cancer, it is accepted that BCS followed by radiation therapy yields equivalent results to mastectomy. Over the past 20 years, rates of women choosing BCS have increased. However, the national mastectomy rate remains high. Multiple influential factors have been investigated in efforts to define those that aid in surgical decision making, including age, race, education concerning surgical options, and the influence of their surgeon and discussion regarding surgical options. Our study centered on our rural breast cancer population, anticipating that a woman’s surgical choice might be affected by unique rural factors not present in an urban setting. Methods: Stage 0-II breast cancer patients were identified using the Tumor Registry for 1/2000 through 12/2008. Patients were divided into two groups based on surgical procedure, BCS or mastectomy, and mailed a survey. Questions included basic demographics in addition to concerns of recurrence, driving distance to the nearest radiation center, potential need for another operation, influence by educational materials or family members, discussion of options with their surgeon, as well as if they sought a second opinion. Responses were assigned values using a Likert scale. Univariate analyses were performed to detect relationships between surgery choice and survey variables. Those variables found to be significant at the univariate level were entered into a multivariate logistic regression model predicting the probability of mastectomy versus BCS. Results: An overall response rate of 83.1% was achieved, with a total of 283 completed surveys. The mean age at the time of surgery was 61.1 years (SD 9.3), which was not statistically significant. The univariate analyses detected four statistically significant variables related to surgical choice – the worry about recurrence (91.6% mastectomy patients, 55.4% BCS patients: p-value <0.0001), a faster return to “normal life” (51.7% mastectomy patients, 69.9% of BSC patients: p-value 0.039), avoiding another operation (68.9% mastectomy patients, 45.2% BCS patients: p-value 0.012), and having obtained a second opinion (30.5% of mastectomy patients, 16.7% BCS patients: p-value 0.036). There was no difference in surgical choice when comparing for age, level of education, distance from a radiation center, or concerns about driving in inclement weather. The resulting multivariate logistic regression model showed the strongest independent predictor of surgical choice to be worry about breast cancer recurrence, with a p-value of 0.0005 and an odds ratio of 6.1 (95% CI 2.2-16.7). The desire for a faster return to normal life was also significantly predictive in this model. Regarding the patient’s impression of the discussion with their surgeon about their surgical options, 95.2% of mastectomy patients and 89.2% BCS patients stated that their surgeon discussed both as surgical choices. Conclusions: Anticipated rural-unique factors were not related to surgical decision making in our population of early stage breast cancer patients. Concern about breast cancer recurrence was the most strongly associated factor in the choice of mastectomy over BCS.

P1-11-04
Breast Cancer Treatment Resources and Guideline-Concordant Treatment in Appalachia.
Yao N, Hillemeier MM, Anderson RT, Matthews SA. Penn State, University Park, PA; Penn State, Hershey, PA

Background: Appalachia has poorer cancer outcomes, but little research has been done regarding availability of cancer care resources in this region and how resource availability may relate to cancer outcomes. This study 1) examines associations between radiation therapy resources and receipt of radiotherapy after BCS in counties within Kentucky - a SEER state; and 2) describes spatial patterning of breast cancer treatment resources in all 13 Appalachian states. Methods: For the Kentucky analyses, county-level data from the Area Resource File and SEER registry are analyzed. Bivariate analyses and spatial lag regression using a 6-nearest neighboring counties matrix are conducted. The sample includes stage I or II primary breast cancer patients age 18+ years diagnosed in Kentucky during 2000-2007. The dependent variable is the county-level percentage of patients received BCS without radiation; independent variables include density of radiation therapy providers and facilities and other socioeconomic covariates. For the analyses of entire Appalachian region, descriptive analyses and exploratory spatial data analysis are conducted including 420 Appalachian counties and 644 non-Appalachian counties in 13 states. Results: In Kentucky 16.44% of 17,227 early stage breast cancer patients received BCS without radiation therapy (21.08% in Appalachian versus 14.80% in non-Appalachia, p<0.001). Appalachian Kentucky had significantly fewer radiation oncologists and radiation therapy facilities per capita than non-Appalachian Kentucky. The number of radiation therapy facilities per capita is negatively associated with rates of BCS without radiation when controlling for covariates. Analysis of 13 Appalachian states shows that Appalachian counties, especially in the Central and Southern regions, had significant fewer physicians per capita in Surgery, Anesthesia, Clinical Pathology, and Radiation Oncology. Clustering of scarce breast cancer care resources was observed in Central Appalachia. Conclusions: Appalachian counties, especially in central Appalachia, have fewer breast cancer treatment resources than non-Appalachian counties, and resource availability is associated with cancer health disparities.
P1-11-05

Investigation of Epidemiological Factors as Barriers to Indicated Radiation Therapy in Post-Mastectomy Breast Cancer Patients in South Carolina.

Rhame RM, Wahlquist A, Garrett-Mayer E, Harper J. Medical University of South Carolina, Charleston, SC

Purpose: Post-mastectomy radiation therapy (PMRT) has been shown to provide improved locoregional control and overall survival in intermediate and high-risk breast cancer patients. To investigate the frequency of utilization and potential barriers to receipt of adjuvant PMRT in South Carolina, an analysis of the S.C. Cancer Registry (SCCR) database was undertaken.

Methods: Epidemiological factors such as age, race, and geographic distance from a radiation therapy facility were analyzed as potential predictors of whether patients received the indicated radiotherapy. Post-mastectomy breast cancer patients (n=1080) recorded in the SCCR from 2006-2008 were stratified as low (Tis/T1, N0) (43%), intermediate (T1/T2, N1) (27%), or high (T3/T4, N2/N3) (30%) risk. Logistic regression models were used to predict receipt of adjuvant radiotherapy based on factors such as race, age, and geographical distance from radiation treatment facility.

Results: Adjuvant PMRT was received in 4% (19/469) of low risk patients, 23% (67/288) of intermediate risk patients, and 44% (141/323) of high risk patients. In both intermediate and high risk groups, older patients were less likely to receive PMRT. The odds of receiving PMRT decreased by 3% (OR=1.03; 95% CI: 1.01-1.05; p=0.01) and 2% (OR=1.02; 95% CI: 1.00-1.03; p=0.03) per year in the intermediate and high risk groups, respectively. Race and distance from treatment facility were not predictive of receipt of PMRT in high risk patients.

Conclusion: Utilization of adjuvant PMRT in intermediate and high risk breast cancer patients in South Carolina is low, despite the evidence that it confers a survival benefit in both premenopausal and postmenopausal women. Of the patient-related factors analyzed, only age predicted lower odds of receiving radiotherapy in both the intermediate and high risk group. In high risk patients of advanced age (>70), breast cancer continues to be a major cause of mortality which can be improved by radiotherapy. Future educational efforts should focus on addressing patient and physician bias against radiotherapy based on patient age. Further study is needed to identify socio-economic-, physician- and health system-related factors that may be impacting the underutilization of PMRT in South Carolina.

Barriers to Enrollment in Cancer Therapeutic Clinical Trials: A Comprehensive Cancer Center Experience.

Bourdeanu L, Niland J, Stiller T, Swain-Cabriales S, Somlo G. City of Hope Medical Center, Duarte, CA

PURPOSE: Well-conducted cancer therapeutic clinical trials are essential for improving patient outcomes. Unfortunately, less than 5% of new cancer patients participate in clinical trials on average nationwide. Failure to recruit eligible patients represents a major impediment to the success of clinical trials. Barriers to patient accrual in cancer clinical trials must be identified and overcome to increase patient participation.

MATERIALS AND METHODS: A retrospective analysis of 418 patients with a diagnosis of breast cancer seen at City of Hope Medical Center in 2009 was performed. Along with descriptive analysis of patient demographic data, logistic regression analyses were performed to evaluate predictors of enrollment.

RESULTS: Of the 418 new breast cancer patients in 2009, we determined that 138 (33%) were eligible for available therapeutic clinical trials at City of Hope. At the initial visits, physicians did not consider clinical trials in 32% (44/138) of these patients. Of the 138 eligible patients, 58% (80/138) of patients participated in clinical trials. The remainder (58/138, 42%) either declined trial participation despite meeting eligibility criteria (14/58, 24%), or were not considered for clinical trials by their respective physician (44/58, 76%). By logistic regression analysis, patients with Stages II and III disease were significantly more likely to enroll in clinical trials compared to those with stage 0 or I (OR=2.89, 95% CI, 1.17-7.12, P = .02; OR=9.17, 95% CI, 2.65-31.76, P = .0005; respectively). Age, preferred language, marital status, family history of breast cancer, and race were not found to be significant predictors of enrollment in therapeutic clinical trials.

CONCLUSION: While enrollment of eligible breast cancer patients onto therapeutic clinical trials at City of Hope is high (58%), overall the proportion going onto clinical trials remains low (80/418, 19%), though higher than national averages. We found that the majority of patients did not enroll due to lack of availability of a suitable trial, ineligibility, or lack of offering of trial enrollment by the treating MD. Barriers to cancer clinical trial accrual should be prospectively identified and addressed in future studies, with the hope of leading to more vigorous enrollment.
Impact of Reduction in Cost-Sharing on Screening Mammography Utilization among Rural U.S. Women.

Background: Early detection of breast cancer through mammography screening leads to earlier stage at diagnosis and improved survival. For reasons that are poorly understood, in recent years the rate of screening has demonstrated periods of decline, and screening has proved to be less common in rural compared to urban areas of the U.S. In 2006, the National Rural Electric Cooperative Association (NRECA) which provides health care to over 100,000 electrical workers and their families in primarily rural areas of the U.S. eliminated copayments for screening mammography in an effort to boost screening rates.

We conducted a population based analysis of screening utilization to determine the impact of this policy initiative.

Methods: Using the NRECA insurance database, all women aged 40 to 64 with no prior history of breast cancer or DCIS (based on ICD-9 codes) were identified and we evaluated claims data on annual screening mammography utilization (SMU) between 1999 and 2009 stratified by age group in 5 year intervals. Changes in SMU over time were assessed focusing on the periods before and after the policy change in January 2006. We also evaluated diagnosis of breast cancer and receipt of mastectomy and chemotherapy as a potential proxy for more advanced disease at diagnosis. Descriptive statistics were estimated and the mammography rate was fitted on years using the identity link (proc genmod in SAS). In order to test the impact of the 2006 change in cost-sharing on the trend in mammography rate, we introduced change point terms in slope and intercept to the linear model. Chi-squared test for 2x2 tables was used to compare SMU rates between two consecutive years for each age group. All p-values are two-sided.

Results: During this period, a mean of 20,825 women aged 40 to 64 each year received health insurance through NRECA. SMU increased from 38.1% in 1999 to 49.5% in 2009. Analyzing SMU before and after the change in cost sharing policy demonstrates a significant change in the rate of screening at the 2006 intercept (p = 0.0275) although the slope of year to year change in screening rate did not change. In stratified analysis there was a significant change in SMU between 2005 and 2006 for all age groups. In the 4 years prior to the NRECA change in policy, 554 women were diagnosed with breast cancer and 40 underwent mastectomy and chemotherapy. In comparison, from 2006 to 2009, only 20 women out of 540 with newly diagnosed breast cancer underwent such therapy (7.2% prior to policy change vs. 3.7% following, P = 0.01).

Conclusion: The impact of health plan benefits changes can be evaluated among a primarily rural population of women aged 40 to 64 using the novel NRECA database. Annual SMU remained low, but improved following elimination in copayments suggesting that financial barriers impact screening. Multiple factors may explain changes in SMU and treatment intensity over time. However, cost-sharing for high value health care services may have unintended negative consequences. Further evaluation of this database is planned to evaluate biannual screening rates, correlation with sociodemographic factors, impact of recent controversy over screening guidelines and additional barriers to screening utilization in this rural population.

Breast Cancer Screening Resources and Stage at Diagnosis in Appalachia: A Geospatial Perspective.

Yao N, Hillemeier MM, Anderson RT. Penn State, University Park, PA; Penn State, Hershey, PA

Background: National Cancer Institute has designated Appalachia as a priority area characterized by significant disparities in cancer outcomes. However, little research focuses on the availability of cancer care resources in this region and how resource availability may relate to cancer outcomes. This paper will describe the distribution of breast cancer screening resources in Appalachia and examine the relationship between the screening resources and breast cancer stage at diagnosis at the population level.

Method: Percentages of early stage breast cancer incidence are computed based on the county-level data from the four Appalachian state cancer registry data from 2000 to 2008. Per capita breast cancer screening providers or facilities are computed for these Appalachian states. Descriptive analysis, exploratory spatial data analysis, and spatial regression were conducted.

Results: Appalachian counties had significantly fewer primary physicians, OB/GYN specialists, and diagnostic radiologists per capita than non-Appalachian counties. Spatial analysis demonstrates moderate clustering of scarce breast cancer screening resource and low percentage of early stage breast cancer incidence in West Virginia and Appalachian Kentucky. Those diagnosed at early stages were 67.92% of Appalachian vs. 68.34% of non-Appalachian breast cancer patients. The number of diagnostic radiologists per capita is significantly associated with the percentage of early stage breast cancer incidence when controlling for covariates such as county level poverty rates, uninsurance rate, percentage of adults with college degree, and per capita primary care resources.

Conclusions: Fewer diagnostic radiologists in West Virginia and Appalachia Kentucky are associated with lower percentage of early stage breast cancer incidence in the Central Appalachia region. Public health intervention could include policies and regulations to improve breast cancer screening resources in this region.

Effects of a Multidisciplinary Breast Cancer Clinic in an Appalachian Based Medical Center.

Ingham JA, Creameans DK, Daugherty SL, Myhand RC, Sever WE. Adena Health System, Comprehensive Breast Care Program, Chillicothe, OH

Background: Adena Health System is a not for profit 250 bed institution that provides health care for a 13 county region in southeast, Appalachia Ohio. Access to health care in rural setting is an ongoing challenge. Several barriers to health care access affect this region. Socioeconomic burden and lack of higher education are two of the most dominant barriers. The age-adjusted breast cancer rates are 5.3% higher in the Appalachian region and the stage at presentation is more...
advanced. In December of 2009, we held our first Multidisciplinary Breast Cancer Clinic (MDBCC). The goal of the MDBCC is to facilitate prompt diagnosis and effective treatment. The MDBCC is staffed by a team of physicians consisting of surgeons, medical oncologists, and radiation oncologists. The team meets with the patient in a one on one setting. That same day the patients are discussed by the team with input from pathology and radiology in order to tailor a treatment plan specifically for each patient. After the conference, the recommendations are discussed with the patient before treatment is initiated.

Material and Methods: In a retrospective review, we evaluated the effect of a MDBCC on days to diagnosis, days from diagnosis to treatment, percentage of patients receiving neoadjuvant chemotherapy, and stage at diagnosis. Since December 2009, there have been over 90 breast cancer patients evaluated in the MDBCC. We randomly selected 60 breast cancer patients treated prior to MDBCC between 2008-09 and 66 patients evaluated at the MDBCC between December 2009-2011 from the tumor registry database.

Results: The average number of days to diagnosis pre-MDBCC was 15.5 days as compared to 4 days post-MDBCC. In 2008-09, the average days to treatment (pathology result to a-port placement, surgery or chemotherapy) was 18 days as compared to 12 days post-MDBCC. The percentage of patients receiving neoadjuvant chemotherapy has not changed significantly, however, there is an upward trend approaching statistical significance (10% per-MDBCC vs. 12% post-MDBCC). The stage at presentation has not changed significantly since the start of the MDBCC.

Discussion: The development of the MDBCC has proven to be a successful team oriented approach to breast cancer diagnosis and treatment. Time to diagnosis and initiation of treatment has improved. Providing patients with access to multiple specialists and forming a treatment plan the same day improves quality of care and lessens economic burden. The MDBCC is clearly feasible and particularly suited to the rural hospital setting. System wide, we hope to see a decrease in the stage at presentation and are confident based upon our current data that this is a realistic goal.

P1-11-10
Quality of Breast Cancer Care in a Boston Area Patient Navigator Program.
Raj A, Ko N, Battaglia T, Moy B. Massachusetts General Hospital, Boston, MA; Boston Medical Center, Boston, MA

Background: Elimination of disparities is critically important for lessening the burden of cancer. Patient navigator programs (PNPs) assist with all aspects of care, including access, cancer prevention, screening, post-diagnosis care, and survivorship care. Little is known about the effect of PNPs on patient care and outcomes following the diagnosis of breast cancer (BC). We examined quality measures (QMs) of breast cancer care among women participating in the Massachusetts General Hospital Avon Breast Care Patient Navigator Program (MABCP), which provides patient navigation services to disadvantaged minority communities in the greater Boston area.

Methods: Women diagnosed with BC who participated in the MABCP from 2001 to 2011 were followed to determine the proportion whose care was concordant with American Society of Clinical Oncology/National Comprehensive Cancer Network (ASCO/NCCN) QMs. QMs included 1) hormonal therapy (HT) within 1 year of diagnosis for HR+ tumors > 1 cm; 2) chemotherapy within 120 days of diagnosis of HR- >1cm tumors for women <70 years; and 3) post-lumpectomy radiation therapy (XRT). Descriptive statistics were used to report characteristics of MABCP patients.

Results: Of the 186 MABCP patients diagnosed with BC, some treatment data was available on 158 (85%) and race/stage information was available on 149 (80%) [Table 1]. Among the MABCP patients, concordant care was received by 70/74 (95%) for the HT QM, 15/17 (88%) for the chemotherapy QM, and 65/71 (92%) for the XRT QM. In comparison, available benchmark concordance rates of BC patients treated at 8 NCCN centers from 2003-6 are: 340/382 (89%) for the HT QM, 156/179 (87%) for the chemotherapy QM, and 141/148 (95%) for the XRT QM.

Conclusions: Overall, breast cancer care in the MABCP PNP is concordant with published ASCO/NCCN quality measures. At present, the sample is insufficient to compare concordance rates with NCCN patients but preliminarily, it appears that the quality of care is comparable. Future research should include prospective analyses of quality metrics to assess the process and outcomes of patient navigation in diverse settings, compared with control populations.

P1-11-11
Wait Times for Breast Cancer Care in Manitoba 2009-2010. Time To Face the Challenge.
Carpenter-Kellett T, Nashed M. CancerCare Manitoba, Winnipeg, MB, Canada

Background: Wait times for patients with breast cancer to receive oncological treatment vary significantly. In Manitoba, the radiation treatment wait times improved in the year 2005 compared to 2001. However, other parts of the patient’s journey have lengthened and negated the reduction seen in radiation treatment wait times.

Aims: To examine the overall time from disease suspicion to treatment of breast cancer patients from June 2009 to June 2010 and to compare to the previously published wait times.

Methods: This population-based retrospective study looked at representative samples of women newly diagnosed with breast cancer. Patients were followed from the time of first presentation, either to their family physician or after a suspicious screening mammogram, to the time adjuvant treatment was started. Each patient’s journey was subdivided into different chronological stages. The data was compared to the wait times reported in 2005.

Results: 363 patients’ data was collected and analyzed. The median elapsed time in days for each phase of the journey was calculated. Total wait times from suspicion to diagnosis were also calculated. The wait times of most stages of the patients’ journey have worsened when compared to 2005. However, there was some improvement in the diagnostic part of the journey. Delays to surgery and pathology have contributed to lengthening of the total journey. There was also a systematic and repetitive administration delay at each transition. Screen-detected cases had a shorter journey than those who presented through a family physician.

Conclusions: In spite of improvements achieved in the wait times at some stages of the journey, the total length of the patient journey has not been shortened. This represents not only individual team failures but also a built in complexity in the health system. In order to achieve a meaningful cut in wait times for breast cancer patients, the entire trajectory of care needs to be addressed.
**P1-11-12**

Patterns of Care of Newly Diagnosed Patients with Breast Cancer in Mexico.

Chavarrí-Guerra Y, Liedke PER, Symecko H, Hammond EE, Higgins MJ, Finkelstein D, Goss PE. Massachusetts General Hospital, Boston, MA

Background: Breast cancer is the most common form of cancer and the leading cause of cancer death in women worldwide. More than 55% of breast cancer deaths occur in low and middle income countries. Although incidence rates for breast cancer are lower in developing countries, mortality rates are higher. This phenomenon has been attributed to limited access to care for breast cancer patients, including screening and early diagnosis as well as primary surgical, radiation and systemic therapies. Similar to trends in other poor and middle income countries, breast cancer mortality in Mexico is rising. The goal of this survey of physicians caring for patients with breast cancer in Mexico is to obtain information about current treatment patterns of newly diagnosed patients and to describe their clinical characteristics.

Methods: A web-based closed survey has been sent to 854 physicians providing care to newly diagnosed breast cancer patients across Mexico, including medical oncologists and breast cancer surgeons. The survey instrument contains 35 questions assessing demographic data, access to diagnosis and treatment in a variety of clinical patient scenarios. The responses will be anonymous and entered automatically into a secure database for analysis. Fisher exact test will be used for the frequency analysis. Chi-squared statistics and Kendall correlation will be used for nominal and ordinal variables respectively.

Results: The results will be presented at the 2011 San Antonio Breast Cancer Symposium.

Conclusions: The results of this survey will highlight potential disparities in care received by breast cancer patients across the full geographic and socioeconomic spectrum of Mexico in order to highlight the need for uniform, quality based approaches for the diagnosis and treatment of breast cancer patients in Mexico, and will serve as an example of how one middle income country faces challenges and unmet medical needs regarding access to care of women with breast cancer.

**P1-11-13**

Improvement in the Quality of Care for Patients with Locally Advanced Breast Cancer through Implementation of an Integrated Electronic Care Pathway.

Hogeveen S, Han D, George RL, Sweet-Goldstein M, Dinnwell RE, Muradali D, Brezden CB, Haq R, Simmons CE. St. Michael’s Hospital; Princess Margaret Hospital

Background: Locally advanced breast cancer (LABC) refers to the most advanced stage of non-metastatic tumours with an incidence of approximately 10% in newly diagnosed breast cancers. Currently, for optimal care, patients with LABC require a multidisciplinary approach including coordinated planning with medical, surgical and radiation oncologists. Many barriers may exist in co-ordinating timely management of these patients. Care pathways are important tools to streamline care and data collection and feedback allows for quality improvement in clinical practice. We created an interactive electronic care pathway and self-populating quality assurance database at St. Michael’s Hospital (SMH) to facilitate multidisciplinary teams to track LABC patient histories and patient treatments in order to coordinate therapy effectively and expedite care (LABC E-PATH).

Methods: This is an observational before-and-after cohort study of patients with LABC with a retrospective review pre-implementation and prospective collection of clinical data post-implementation. The completeness of workup and the timeliness of treatment pre- and post-implementation were assessed.

Results: With the implementation of the LABC E-PATH in May 2010, the time between the referral of an LABC patient to a medical oncologist and consultation has decreased from 7 days (range 0 to 493) pre-implementation to 2 days (range 0 to 29) post-implementation. The time between referral to medical oncologist and the start of their chemotherapy treatment decreased significantly from a median of 19 days to 8 days (pre-implementation: range = 0 to 493, post-implementation: range = 0 to 128) (p=0.0028). All pre-treatment staging was completed faster post-implementation of the LABC e-path than pre-implementation, expediting time to initiation of chemotherapy. The number of referrals for LABC to the SMH program increased from < 1 patient per month to 4 patients per month post-implementation.

Conclusions: The LABC E-PATH has achieved its goal of expediting care and overcoming barriers to timely treatment in this patient population. It has also ensured timely and appropriate resource allocation. This unique system may also be applied to other disease sites where coordination of a multi-disciplinary team is critical for appropriate patient management.

**P1-11-14**

Gender and Sexual Orientation of Clients Who Were Linked to Breast Cancer Screening Services through Outreach and Education Supported by the Avon Breast Health Outreach Program.

Background: Lesbian, gay, bisexual, and transgender (LGBT) individuals experience health disparities in breast cancer screening related to multiple socioeconomic factors, including stigma and discrimination. Since 2001, the Avon Breast Health Outreach Program (Avon BHOP) has granted almost $60 million to 240+ organizations to promote breast cancer screening. Avon BHOP beneficiaries collect a standardized set of de-identified, self-reported client level health and demographic data to ensure that programs reach their target population. Prior to 2011, no data on client gender or sexual orientation were collected.

Methods: From 2009-2010, the Avon BHOP conducted a review of the standard confidential client intake form (CIF), last revised in 2006. Based on stakeholder input, including the Avon Foundation for Women and Avon BHOP beneficiaries, the CIF was updated in 2011 to incorporate variables for gender and sexual orientation. Proposed revisions were presented to current beneficiaries in June 2010 for feedback. Although the CIF has historically included many sensitive elements such as race/ethnicity and income, several programs expressed concern that clients or program staff would be uncomfortable addressing questions on gender and sexual orientation in particular. In response, the Avon BHOP Coordinating Center provided standard language that programs could use to help ease the concerns of staff and clients that incorporated three key messages: 1) the same form is used for all clients and programs funded by the Avon BHOP to help ensure funds are reaching clients in need; 2) all responses are kept confidential; and 3) clients may skip any question they are not comfortable answering.

Results: Preliminary CIF data for January-March 2011 were analyzed for 20,672 clients from 109 programs. Overall, 96.6% (n=19,966) indicated female gender; 0.5% (n=101) self-reported gender as
follows: 75 male, 8 transgender, 12 “other”, and 6 “unknown”; and 2.9% (n=605) did not respond to this question. For sexual orientation, 77.7% (n=16,067) of clients selected “heterosexual”. Of the remaining 22.3% (n=4,606), 175 (0.8%) selected “lesbian, gay or bisexual”, 431 (2.1%) selected “other”, 1045 (5.1%) selected “unknown”, and 2,954 (14.3%) did not respond to this question. By program, the non-response rate ranged from 0% to 40.2% for gender, and from 0% to 81.9% for sexual orientation.

Discussion: Avon BHOP programs were able to collect sensitive information on client gender and sexual orientation during the first three months during which this information was requested. Despite concerns expressed among staff, overall response rates were high and rates of “unknown” (which may indicate that a staff person did not ask a client to complete the question) were low. Beneficiaries receive a quarterly summary of their own CIF data, which allows program staff to review client responses and ensure that client needs are met in a culturally sensitive manner. The Avon BHOP is committed to supporting diversity among funded programs; requesting data on client gender and sexual orientation may help improve services for LGBT clients by giving them a voice and reducing stigma.

P1-12-01
Pregnancy during and Following Adjuvant Trastuzumab in Patients with HER2-Positive Breast Cancer: An Analysis from the HERA Trial (BIG 01-01).
Azim, Jr HA, Metzger-Filho O, de Azambuja E, Loibl S, Focant F, Gresko E, Procter M, Piccart-Gebhart M. Institut Jules Bordet, Brussels, Belgium; German Breast Group, Frankfurt, Germany; F. Hoffmann-La Roche, Basel, Switzerland; Frontier Science, Kincraig, United Kingdom

Background: 1-year of adjuvant trastuzumab (T) is the standard of care in managing patients (pts) with early HER2-positive breast cancer (BC). As T is not known to alter fertility, pts with childbearing potential could become pregnant during or following treatment with T. Cases of oligohydramnios, some associated with fatal pulmonary hypoplasia of the fetus have been reported in women receiving T during pregnancy (preg). Here we report the outcome of preg in all pts enrolled in the HERA trial.

Methods: Pregnancies in the HERA trial are reported on a distinct “pregnancy form” for up to 10 years following T completion. The form includes information on approximate date of conception, preg course & outcome, fetal measurements at birth, and congenital anomalies. Any missing data were retrieved from the study site, if available. For this analysis, pts were grouped into 3 groups: 1) preg during and up to 3 months after T, 2) preg > 3 months of last T dose, and 3) preg with no prior exposure to T.

Results: By March 2010, 70 preg were reported in 58 out of 5102 pts randomized. Five, 30 and 7 completed preg were reported in groups 1, 2 & 3 respectively.

* 3 pts got preg on and after T ** 3 twin deliveries

As per protocol, all pts on T were required to use adequate contraceptive measures, yet 16 pts became pregnant during the course of T and up to 3 months thereafter. The percentage of completed preg was lowest in group 1, with 4 spontaneous and 7 induced abortions. In group 2, preg occurred at a mean of 29 months following completion of T, with 6 spontaneous and 4 induced abortions. In group 3, abortion was induced in 3 pts and no spontaneous abortions reported. Across all 3 groups, all but 1 spontaneous abortion occurred during the 1st trimester. Two congenital anomalies were reported; a Down’s syndrome in a 43 year old pt >5 years after completing T for which abortion was induced, and one with partial fusion of the 2nd and 3rd toe born to a pt in group 3.

Conclusions: Unintentional exposure to T during preg may be associated with spontaneous abortion, yet the numbers remain low to draw firm conclusions (spontaneous abortion rate in general population is up to 20%). No oligohydramnios or anomalies were observed in group 1. While an increased risk of oligohydramnios has been reported when T is administered after the 1st trimester, T administered to Cynomolgus monkeys during organogenesis did not cause fetal harm (Pentsuk et al; 2009). Nevertheless, women of childbearing potential should be advised to use effective contraception during and up to 6 months after treatment with T. On the other hand, prior exposure to T did not appear to affect the preg course or outcome. We are planning to collect information from the other T adjuvant trials to confirm our findings.

P1-12-02
Patient-Reported Outcomes (PROs) from a Randomized Phase II Study (TDM4450g/B021976) of Trastuzumab Emtansine (T-DM1) vs Trastuzumab Plus Docetaxel (HT) in Previously Untreated HER2-Positive Metastatic Breast Cancer (MBC).
Bianchi GV, Koecis J, Dirix L, Toriboe Y, Lalla D, Tong YB, Guardino AE, Hurvitz SA. Fondazione IRCCS Istituto Nazionale Tumori, Milan, Italy; Semmelweis University Budapest, Budapest; Sint-Augustinus, Antwerp; Genentech; UCLA/Translational Oncology Research International

Background
T-DM1 is an antibody-drug conjugate in development for HER2-positive cancer. As a single-agent, it has demonstrated promising efficacy and safety when administered after multiple lines of HER2-directed therapy. In the current study, we compared the safety and efficacy of T-DM1 to standard first-line treatment for HER2-positive MBC. This abstract highlights the PRO results in the context of efficacy and safety.

Methods
Patients with HER2-positive MBC and no prior MBC therapy were randomized 1:1 to T-DM1 3.6 mg/kg IV q3w or HT 6 mg/kg IV (8 mg/kg in cycle 1) + T 75 or 100 mg/m2 IV q3w. Primary objectives were investigator-assessed progression free survival (PFS) and safety. Key secondary end points included objective response rate and the FACT-B Trial Outcome Index (TOI). Patients completed the FACT-B on day 1 of each treatment cycle. The FACT-B TOI, the primary PRO end point, comprises a subset of the FACT-B and provides a summary measure of physical and functional well being and breast cancer specific symptoms. Time to FACT-B TOI worsening (ie, ≥5 point decrease in TOI) was assessed with Kaplan-Meier methods and a Cox model. A repeated measures mixed effects (RMME) model was used to evaluate potential treatment effects on TOI across cycles. Preliminary PRO results based on a data cutoff of November 15, 2010, are included here; final data will be presented.

Results
A total of 137 patients were randomized (67 T-DM1, 70 HT). Baseline patient and disease characteristics were similar in each arm. Patients treated with T-DM1 had longer PFS (14.2 vs 9.2 months, HR=0.59, P<0.035) with less toxicity (eg, 46.4% grade 3/4 adverse events
with T-DM1 vs 89.4% with HT) than those treated with HT. ORR was similar in both arms (64.2% T-DM1, 58.0% HT). A total of 132 patients (65 T-DM1, 67 HT) were evaluable for PRO analyses with a high compliance rate. In a preliminary analysis, FACT-B TOI worsening was significantly delayed in the T-DM1 arm compared with the control arm (7.5 vs 3.5 months, HR=0.58, \(P=0.022\)). The RMME model showed a mean difference of 3.65 in FACT-B TOI scores (\(P=0.023\)), mainly driven by physical well being (PWB) scores (mean difference 2.28, \(P=0.002\)), favoring T-DM1. In addition, 5 of 7 PWB items showed significantly better mean scores in the T-DM1 arm: “lack of energy” \((P=0.011)\), “trouble meeting needs of family” \((P=0.025)\), “bothered by side effects” \((P<0.001)\), “feeling ill” \((P=0.016)\) and “forced to spend time in bed” \((P=0.015)\); the 2 remaining items, “nausea” and “pain,” showed numerically better mean scores with T-DM1.

Conclusions

Compared to HT, T-DM1 as first-line treatment of HER2-positive MBC conferred longer PFS and a more favorable toxicity profile. The PRO data suggest that T-DM1 is also associated with meaningfully improved tolerance relative to HT, contributing to an overall clinical benefit and better health-related quality of life. Thus, T-DM1 may improve the standard of care for patients with previously untreated HER2-positive MBC.

P1-12-03

Combined Targeting of the PI3K Pathway and HER2 Overcomes Acquired and De Novo Trastuzumab Resistance.

O’Brien NA, McDonald K, Von Eiw E, Conklin D, Kalous O, Di Tomaso E, Finn RS, Slamon DJ, University of California at Los Angeles, Los Angeles, CA; Novartis-Oncology, Cambridge, MA

Background: Although trastuzumab and lapatinib provide clinical benefit for women with HER2-positive breast cancer, both de novo and acquired resistance to these agents exist. There is increasing evidence to suggest that aberrant activity of the PI3K/akt/mTOR signaling pathway is one of the key mechanisms responsible for resistance. Thus, pharmacologically targeting the PI3K pathway is a rational approach for overcoming resistance to HER2-targeted therapy. However, specifically targeting individual elements of the PI3K pathway may result in feedback activation or in activation of compensatory pathways, whereas targeting the pathway at multiple points may be more effective in permanently shutting down proliferation and inducing cell death.

Materials and Methods: In this study we evaluated the activity of three small molecule tyrosine kinase inhibitors that target specific critical portions of the PI3K pathway; BKM120 (pan-PI3K), RAD001 (mTORC1 specific) and BEZ235 (dual PI3K & mTOR) both individually and in combination with trastuzumab in a panel of HER2-amplified breast cancer cell lines that have previously been characterized for trastuzumab response/resistance.

Results: In the trastuzumab sensitive BT-474 and SKBR3 cell lines, 72 hours of trastuzumab treatment efficiently inhibited cell proliferation and deactivated AKT (S473 & T308), pS6K and ERK signaling. In contrast, the trastuzumab-resistant MDA453 and SUM225 cell lines, as well as the BT-474 cells conditioned to acquire trastuzumab resistance (BT-TR), trastuzumab treatment did not inhibit pAKT, pS6K and pERK levels. RAD001 had significant antiproliferative activity in both trastuzumab sensitive and resistant cell lines and resulted in rapid down regulation of pS6K (mTOR) activity (15 min). However, this deactivation was followed by a reactivation of AKT and ERK signaling (24 to 72 hours). BKM120 also demonstrated anti-proliferative activity independent of trastuzumab sensitivity. Specifically targeting PI3K with BKM120 directly decreased pAKT/pS6K/pERK signaling and feedback activation was less pronounced than that observed with RAD001. Of the three molecules tested, BEZ235 was the most efficacious in the cell line panel (all IC50gs < 20 nM). BEZ235 rapidly (15 min) decreased pAKT/pS6K/pERK signaling in both trastuzumab sensitive and resistant cell lines and this inhibition was maintained at 72 hours. Thus, BEZ235 is effective in shutting down PI3K feedback activation and efficiently shuts down PI3K signaling in trastuzumab resistant HER2-amplified breast cancer cell lines. The combined treatment of trastuzumab and each of the PI3K/mTOR targeting agents resulted in greater inhibition of proliferation and induction of cell death in the HER2-amplified cell lines than each agent used alone. No increase in activity was observed in the HER2-normal control cell lines, MCF-7 and KPL-1.

Discussion: Together, these data indicate that targeting the PI3K/akt/mTOR pathway either alone or in combination with trastuzumab is effective in overcoming trastuzumab resistance. These findings are currently being validated in in vivo models of trastuzumab resistance.
in a dose-dependent manner respective to parental cells. Interestingly, shEBP50 cells demonstrated an enhanced capacity to form mammospheres compared to vector control cells. We demonstrate that EBP50 is able to bind HER2 using immunoprecipitation, suggesting that EBP50 interacts directly with HER2. Confocal microscope analysis demonstrated the colocalization of these two proteins. Inhibitors to c-Src, PI3K, AKT and EGFR were used in combination with Tras; shEBP50 cells were sensitive to both PI3K and AKT inhibitors, and EGFR inhibitors were able to restore Tras sensitivity. 

Discussion: Our data suggest that EBP50 is a novel negative regulator of HER2 signaling, and its loss conferred resistance to both Tam and Tras. EBP50 loss might function to stabilize HER2, and enhance dimerization with EGFR and HER3. We hypothesize that EBP50 levels might be a new predictive biomarker for targeted therapy; patients with low EBP50 levels might best be treated with a combination of therapies including PI3K/AKT inhibitors.

P1-12-05
Complete Pathological Response of Ductal Carcinoma In Situ after Treatment with Neoadjuvant Herceptin.
Chalmers CR, Mallon EA, Tougan N, Horgan KJ, MacPherson I, Doughty JC. The Western Infirmary, Glasgow, Scotland, United Kingdom; Leeds General Infirmary, Leeds, Yorkshire, United Kingdom

Introduction: The introduction of neo-adjuvant herceptin has led to pathological complete response rates of up to 60% in patients with breast cancer. The traditional (NSABP) definition of pathological complete response includes cases demonstrating residual DCIS and little is known about the effects of neo-adjuvant herceptin in this situation. Current evidence suggests that DCIS is chemo-resistant, but it has also been shown that DCIS is more likely to be HER-2 positive than primary cancer.

Results: We describe six patients who received neo-adjuvant chemotherapy and herceptin for biopsy-proven, node-positive, large breast cancers either with an extensive component of concomitant DCIS or a separate DCIS focus. Neo-adjuvant treatment did not result in any changes in the pattern of mammographic calcification seen pre-operatively (Figure 1 a-c), however histopathology of all six specimens showed ductal spaces containing macrophages and calcification but no residual lining epithelium, features consistent with pathological complete response of the DCIS component (Figure 1 d).

Figure 1: Pathologically complete response of DCIS after neo-adjuvant treatment with herceptin. (a) Pre-treatment mammogram (b) Post neo-adjuvant chemotherapy and herceptin mammogram showing resolution of the mass effect of the primary cancer and unchanged residual mammographic calcification associated with the extensive DCIS component (c) Wire-localised specimen demonstrating excision of calcification (d) Histopathology of the same specimen showing calcium-filled ducts and no residual lining epithelium.

Discussion: In conclusion, neo-adjuvant herceptin is associated with complete pathological response of both breast cancer and DCIS. The presence of unchanged persistent mammographic calcification in known regions of DCIS after treatment complicates any role of mammographic surveillance in this group and raises the question of optimal surgical management in the future management of these individuals.

P1-12-06
The Role of MAPK and PI3K/AKT/mTOR Signaling in Innate Lapatinib Resistance.
McDermott M, O’Brien N, McDonald K, Crown J, O’Donovan N, Slamon D. Dublin City University, Glasnevin, Dublin 9, Ireland; University of California Los Angeles, Los Angeles, CA; St. Vincents University Hospital, Elm Park, Dublin 4, Ireland

Background: Lapatinib is a tyrosine kinase inhibitor which blocks downstream MAPK and PI3K/AKT/mTOR proliferation and survival signaling pathways in HER2 positive breast cancer cell lines, tumor xenografts and HER2 positive breast cancer patients. However, pre-clinical and clinical studies have shown that not all HER2 positive patients respond to lapatinib and thus innate resistance to lapatinib exists. The identification of biomarkers of lapatinib response is therefore critical and would enable individual therapeutic decisions to be based on tumor biology rather than basic histopathology data alone.

The aim of this study was to examine the role of MAPK and PI3K/AKT/mTOR signaling in a panel of lapatinib sensitive and resistant HER2-amplified breast cancer cell lines to identify pharmacodynamic markers of response to lapatinib treatment.

Methods: Dose response curves were generated to determine sensitivity to lapatinib in a panel of 17 HER2-amplified breast cancer cell lines. Total and phosphorylated levels of HER2, HER3, EGFR, AKT, ERK, S6K and eEF2 were determined following 24 hours lapatinib treatment in each of the cell lines.

Results: Twelve of the cell lines were sensitive to lapatinib with IC_{50} < 1 μM while 5 of the cell lines were innately resistant to lapatinib with IC_{50} > 1 μM. Levels of pHER2 and pHER3 were decreased in response to lapatinib in all cell lines independent of sensitivity to lapatinib. This suggests that inhibition of HER2/HER3 activation is not indicative of response to lapatinib treatment. There was also no correlation between the levels of HER2, HER3, and EGFR and sensitivity to lapatinib in the cell line panel.

In lapatinib sensitive cell lines, lapatinib decreased PI3K (pAKT), mTOR (pS6K) and MAPK (pERK) signaling and increased pEF2 levels. In contrast the levels of pAKT, pS6K, pEF2 and pERK were maintained following lapatinib treatment in lapatinib resistant cells. The continued activation of these proteins in the presence of lapatinib suggests a possible feedback mechanism that warrants further investigation. These data confirm that maintained signaling through either the PI3K/AKT/mTOR pathway or the MAPK pathways in the presence of lapatinib can be an early pharmacodynamic biomarker of response.

Conclusions: Maintenance of pAKT, pS6K, pEF2 and pERK levels, in response to lapatinib treatment correlates with lapatinib resistance. These data suggest that alterations in the PI3K/AKT/mTOR and MAPK pathways play an important role in innate lapatinib resistance and pharmacologically targeting these pathways is a rational therapeutic approach for overcoming innate lapatinib resistance.
PI-12-07
Pharmacokinetics (PK) of Trastuzumab Emtansine and Paclitaxel or Docetaxel in Patients with HER2-Positive MBC Previously Treated with a Trastuzumab-Containing Regimen.
Lu D, Modi S, Elias AD, Agarwal P, Yi J-H, Guardino AE, Althouse BL, Girish S. Genentech, South San Francisco, CA; Memorial Sloan-Kettering Cancer Center, New York, NY; University of Colorado, Aurora, CO

Background
Trastuzumab emtansine (T-DM1) is an antibody-drug conjugate composed of trastuzumab, DM1 (a potent cytotoxic tubulin polymerization inhibitor), and the stable MCC linker. Based on in vitro and preclinical data suggesting synergy in tumor cell cytotoxicity with T-DM1 + taxanes, these combinations are being tested in phase Ib studies. The assessment of risk for PK-based drug interaction (PK-DI) with these combinations is important. T-DM1 is expected to undergo proteolytic degradation with no significant involvement of cytochrome P450 isoenzymes (CYPs), and DM1 is metabolized mainly by CYP3A4 (and to a lesser extent by CYP2C8). Paclitaxel (P) and docetaxel (D) are metabolized primarily by CYP2C8 and CYP3A4, respectively. None of these drugs inhibits or induces CYPs at clinically relevant concentrations. Since DM1 and D are both metabolized by CYP3A4, PK-DI may occur. This is less likely with DM1 and P since they are primarily metabolized by different CYPs.

Methods
The tolerability, PK, and dose-limiting toxicities of T-DM1 + P or D were investigated in 2 studies (TDM4652g and BP22572) of patients with HER2-positive MBC previously treated with a trastuzumab-containing regimen. For PK-DI analysis, both studies used a staggered dosing design in the first cycle, with same-day dosing in subsequent cycles. Study BP22572 was later amended to give both drugs on the same day in all cycles. Either P (65 mg/m², n=11; 80 mg/m², n=6) or D (60 mg/m², n=12; 75 mg/m², n=6) was combined with T-DM1 at various doses (2 mg/kg or 2.4 mg/kg q3w or 1.2 mg/kg qw for TDM4652g; 2.4 mg/kg or 3.6 mg/kg qw for BP22572). PK of T-DM1, total trastuzumab (conjugated + unconjugated trastuzumab), DM1, P, and D were evaluated and compared with historical single-agent data and across cycles within the study, using population analysis and/or noncompartmental analysis (NCA), as data allowed. Preliminary safety and efficacy data for the historical T-DM1 single-agent studies were reported previously (Krop JCO 2010; Burris JCO 2010; Krop ESMO 2010).

Results
The PK of P and D were similar from cycle 1 to cycle 2 for maximum concentration (Cmax), area under the concentration-time curve, half-life, clearance (CL) and steady-state volume of distribution, and were also similar to historical single-agent data. The Cmax of DM1 was ~8 ng/mL in both studies, and the average Cmax values were similar to historical single-agent data. T-DM1 PK parameters for the combination studies are within the range of historical single-agent data (Table). Data from additional patients and doses in the combination studies will be presented.

Bayesian post hoc PK parameters for T-DM1

Conclusion
The risk of clinically relevant PK-DI between T-DM1 and P or D appears to be low.
P1-12-09
Safety and Efficacy of Neratinib in Combination with Capecitabine in Patients with ErbB2-Positive Breast Cancer.
Saura C, Garcia-Saenz JA, Xu B, Harb W, Moroose R, Phuard T, Kiger C, Germa C, Wang K, Kim S-B. Breast Cancer Unit, Vall d’Hebron University Hospital, Barcelona, Spain; Hospital Clínico San Carlos, Madrid, Spain; Cancer Hospital, Chinese Academy of Medical Sciences, Beijing, China; Horizon Oncology Center, Lafayette, IN; Florida Hospital Cancer Institute, Orlando, FL; Washington University School of Medicine, St. Louis, MO; Pfizer Global Research and Development, Paris, France; Pfizer Inc, Pearl River, NY; Asan Medical Center, Seoul, Korea

Background: Neratinib (HKI-272) is an irreversible pan-ErbB receptor tyrosine kinase inhibitor that has shown antitumor activity in patients with ErbB2+ breast cancer. Capecitabine has demonstrated efficacy and tolerability in combination with lapatinib, a reversible dual ErbB1/ErbB2 kinase inhibitor, in patients with ErbB2+ advanced breast cancer. The current study evaluated the safety and clinical activity of neratinib in combination with capecitabine.

Methods: In part 1 of this open-label, phase 1/2 study, the maximum tolerated dose (MTD) of neratinib in combination with capecitabine was determined in adults with advanced solid tumors. Part 2 of the study further evaluated the safety and clinical activity of neratinib plus capecitabine at the MTD in adults with confirmed ErbB2+ metastatic or locally advanced breast cancer (ECOG Performance Status of 0-2). Eligible patients had received prior taxane treatment and ≥1 prior trastuzumab-containing regimen for ≥6 weeks for metastatic or locally advanced disease. The primary endpoint of part 2 was objective response rate (ORR); tumor responses were assessed by investigators using modified RECIST version 1.0 guidelines every 6 weeks.

Results: In part 1 (n = 33), the MTD was determined to be neratinib 240 mg/day plus capecitabine 750 mg/m² twice daily on Days 1 to 14 of each 21-day cycle. In part 2, as of April 2011, 72 female patients (median age of 52 years [range, 33-79 years]) with ErbB2+ breast cancer were enrolled and treated at the MTD; 7 patients had prior lapatinib exposure and all had prior trastuzumab and taxane exposure. As of the snapshot date, 56% of patients at the MTD were still participating in the study. The most common drug-related adverse events (AEs) in part 2 were diarrhea (89%), palmar-plantar erythrodysesthesia (57%), nausea (33%), vomiting (26%), and decreased appetite (22%). Grade 3/4 drug-related AEs in ≥25% of patients were diarrhea (25%) and palmar-plantar erythrodysesthesia (13%). Eight patients withdrew from part 2 due to AEs, including 4 who withdrew due to diarrhea. Dose interruptions of neratinib and capecitabine, respectively, due to AEs were required by 19 and 22 patients; dose reductions due to AEs were required by 8 and 22 patients. As of June 2010 (interim analysis), 22 patients were evaluable for efficacy in part 2 of the study. Of these 22 patients, 11 achieved a partial response for an ORR of 50%. An additional 2 patients maintained stable disease for ≥24 weeks, resulting in a clinical benefit rate of 59%, and 8 patients had stable disease for <24 weeks. One patient had progressive disease without achieving a response or stable disease. Updated efficacy data will be presented.

Conclusions: The results of this study indicate that neratinib combined with capecitabine is tolerable and has promising antitumor activity in patients with ErbB2+ metastatic or locally advanced breast cancer pretreated with trastuzumab. This study supports further evaluation of this combination in ErbB2+ breast cancer.

P1-12-10
Phase II Study Evaluating Lapatinib (L) in Combination with Albumin Bound Paclitaxel (ab-Pac) in Women Who Have Received 0-1 Chemotherapy Regimen for HER2 Overexpressing (HER2+) Metastatic Breast Cancer (MBC).
Yardley DA, Hart L, Bosserman L, Saleh MN, Waterhouse DM, Richards P, Hagan MK, DeSilvio ML, Mahoney JM, Nagarwala Y. Sarah Cannon Research Institute; Tennessee Oncology, PLLC; Florida Cancer Specialists; Willshire Oncology Medical Group; Georgia Cancer Specialists; Oncology & Hematology Care, Inc.; Virginia Cancer Care; Oncology & Hematology Associates of SW; GlaxoSmithKline, Collegeville, PA

Background: L, a dual kinase inhibitor of epidermal growth factor receptor (EGFR) and the human epidermal growth factor receptor-2 (HER2), approved for the treatment of HER2+ MBC in combination with capecitabine following progression after trastuzumab, anthracycline, and taxane. L in combination with chemotherapy has significantly improved progression free survival in patients (pts) with HER2+ MBC. Ab-Pac is a cremophor free, albumin-bound paclitaxel approved for use in pts with MBC demonstrating superior efficacy and safety when compared to other taxanes.

Methods: Phase II study (LPT111111) evaluated the efficacy and safety of L in combination with ab-Pac in 60 pts with histologically confirmed stage IV HER2+ (IHC 3+/FISH+) invasive MBC. Pts received 0-1 prior chemotherapy regimen in the metastatic setting and no prior treatment with L. Prior taxane therapy permitted provided this was ≥12 months prior to study entry, LVEF>50%, peripheral neuropathy <2, prior CNS mets permitted, and prior endocrine therapy permitted. Pts received ab-Pac (125 mg/m² IV on Days 1, 8, 15, q28 days) plus L (1250 mg daily). Planned safety analysis of the first 5 pts prompted a protocol amendment with a 20% dose reduction for both agents due to Grade (G) 3 neurotoxicity and diarrhea. Subsequent pts received ab-Pac (100 mg/m² IV on Day 1, 8, 15, q28 days) in combination with L (1000 mg daily). Pts with SD or a response continued L alone until progression. Response assessments performed every 2 cycles. The primary endpoint was overall response rate (ORR) and secondary endpoints were progression-free survival (PFS), time to response, duration of response and overall survival (OS).

Results: Here we present the final analysis of all subjects receiving at least 6 months of protocol therapy. Median age is 56 years; 45 pts (75%) received treatment as 1st line therapy and 15 (25%) as 2nd line; 57% hormone receptor positive and 43% negative; 42% received trastuzumab and 40% received a taxane in either (neo) adjuvant or metastatic setting. After a median of 5.6 months, 7% pts had a complete response, 47% a partial response and 17% had stable disease, the ORR was 53% [95% CI: 41% to 66%]. The median time to response = 7.8 wks [95% CI: 7.4 to 8.1] with a median duration of response of 48.7 wks [95% CI: 31.7 to 57.1]. The median PFS was 39.7 wks [95% CI: 34.1 to 63.9]. Duration of exposure to ab-Pac; 48% received less than 6 cycles, 30% received 6 cycles and 22% received greater than 6 cycles. Table 1 shows the most common G ≥2 treatment-related toxicities.

Two fatal adverse events; one pt with a h/o arrhythmia experienced sudden death of presumed cardiac origin and the other subject with h/o COPD, hypertension and uncontrolled diabetes experienced acute renal failure. No G 3/4 elevation in LFTs observed.
Conclusions: L 1000 mg with ab-Pac 100 mg/m² IV on Day 1, 8, 15, q28 day is feasible with manageable and predictable toxicity. The ORR of 53% compares favorably with other HER2 based combinations in this setting and warrants further exploration.

P1-12-11
Neoadjuvant Chemotherapy-Trastuzumab Versus Neoadjuvant Chemotherapy Followed by Post-Operative Trastuzumab: A Multicentre Study.

Palmieri C, Yan K, Oswaldly W, Shah D, Gajis O, North B, Riddle P, Ahmad R, Lewanski C, Coombes RC, Cleator S, Howell S, Beresford M. Imperial College Healthcare NHD Trust, London, United Kingdom; Bristol Haematology and Oncology Centre, Bristol, United Kingdom; Third Faculty of Medicine, Charles University, Prague, Czech Republic; Imperial College London, London, United Kingdom; The Christie NHS Foundation Trust, Manchester, United Kingdom

Background: The addition of neoadjuvant trastuzumab (NAT) to neoadjuvant chemotherapy (NCT) has been shown to increase the rate of breast preservation and pathological complete response (pCR) compared to neoadjuvant chemotherapy alone (NCT). Furthermore, pCR following NCT-NAT is higher and pCR in this setting has been associated with improved disease free survival (DFS) compared to NCT alone group. No study has yet investigated the effect of NCT-NAT versus NCT followed by surgery followed by adjuvant trastuzumab (AT) on disease free survival and overall survival.

Methods: All cases of invasive breast cancer diagnosed at Imperial College Healthcare NHS Trust, Christie Hospital and University Hospitals Bristol NHS Foundation Trust between 2006-2010 were reviewed and all early HER2 positive breast cancers receiving neoadjuvant treatment were identified, and case notes reviewed. Histopathological details, neoadjuvant treatment and where trastuzumab was initiated were recorded. pCR rate was documented and an efficacy analysis performed, disease free survival (DFS) and overall survival (OS) for the whole cohort, and for cases treated with NCT-NAT versus NCT alone followed by surgery and AT.

Results: Between 2006-2010 122 invasive HER2 positive invasive breast cancers were treated in the neoadjuvant setting at the 3 centres. Of these 58% (71) received NAT alone and 42% (51) were treated with NCT-NAT. The median follow up for whole group was 26 months (range 4.9-70.4), 30.5 months (range 10.5-70.4) for NCT group and 20.1 months (range 4.9-59) for NCT-NAT group. 19 (27%) relapse/death events in NCT group compared to 7 (14%) in NCT-NAT group to 7 (14%) in NCT-NAT group. The median follow up for whole group was 26 months.

Conclusion: Neoadjuvant chemotherapy-Trastuzumab is associated with better DFS and OS compared to Neoadjuvant chemotherapy followed by Post-Operative Trastuzumab.
vs trastuzumab + docetaxel was investigated in patients with no prior MBC treatment in the randomized phase II study TDM4450g/BO21976. Here we report the PK of T-DM1 from that study and compare these data with those from studies that enrolled pretreated patients.

Methods

In all 3 studies, PK parameters, including maximum concentration (Cmax), area under the concentration-time curve (AUC), terminal half-life (t1/2), steady-state volume of distribution (Vss), and clearance (CL) were estimated by noncompartmental analysis (NCA) for serum T-DM1, serum total trastuzumab (conjugated and unconjugated), and plasma DM1. The effects of baseline trastuzumab and HER2 extracellular domain (ECD) concentration on T-DM1 exposure were explored and the relationship between T-DM1 exposure and clinical response (objective response rate [ORR] and progression-free survival [PFS]) was modeled.

Results

T-DM1 PK from evaluable patients enrolled in 3 studies are shown in Table 1. No significant correlations were observed between efficacy (as measured by ORR) and T-DM1 exposure (AUC, Cmax) after administration of T-DM1 to pretreated patients; efficacy-exposure analyses (ORR and PFS) for previously untreated patients will be presented. Patients with measurable concentrations of trastuzumab at baseline had a greater AUC during cycle 1; however, this did not impact ORR. Baseline circulating HER2 ECD concentrations also had no effect on ORR for pretreated patients. The impact of baseline trastuzumab and HER2 ECD concentrations on ORR and PFS in previously untreated patients will be presented.

*Median number of non-hormonal therapies for MBC was 5 (range 1–17) in TDM4258g and 7 (range 3–17) in TDM4374g

Conclusions

Single-agent T-DM1 has similar PK in patients who have received prior therapy for MBC and in those who have not. The PK of T-DM1 was not affected by prior trastuzumab treatment or by circulating HER2 ECD, and no significant correlations were observed between efficacy (ORR) and T-DM1 exposure (AUC, Cmax) or HER2 ECD for pretreated patients. The relationships between efficacy and T-DM1 exposure and HER2 ECD concentrations will be presented for patients without prior MBC treatment.

PI-12-14

Genetic Ablation or Pharmacological Inhibition of Autophagy Suppresses Intrinsic Resistance of Breast Cancer to HER2-Targeted Therapies.

Cufi S, Oliveras-Ferraros C, Vazquez-Martin A, Sauri-Nadal T, Del Barco S, Martin-Castillo B, Lopez-Bonet E, Menendez JA. Catalan Institute of Oncology, Girona, Catalonia, Spain; Girona Biomedical Research Institute (IDIBGI), Girona, Catalonia, Spain; University Hospital of Girona Dr. Josep Trueta, Girona, Catalonia, Spain

Autophagy, an evolutionary conserved catabolic process whereby cells generate energy and building blocks by promoting large-scale recycling of cytoplasmic macromolecules and organelles, represents a novel drug-targetable molecular mechanism underlying de novo (primary) refractoriness of HER2 gene-amplified breast cancer (BC) to HER2 inhibition. JIMT-1 cells, which were obtained from a HER2-positive BC patient that rapidly progressed on trastuzumab (Herceptin™) ab initio and that show cross-resistance to multiple HER1/2 inhibiting drugs including lapatinib (Tykerb™), were found to constitutively exhibit an enhanced autophagic vesicle content as assessed by immunoblotting of endogenous ATG8/LC3 lipids and confocal imaging of the recruitment of ATG8/LC3 to autophagic vesicles. A significant decrease in the expression status of the specific autophagy receptor p62/SQSTM1—a protein selectively degraded by autophagy—confirmed further a constitutive activation of the autophagic flux in trastuzumab-refractory JIMT-1 cells. When the Human Autophagy RT Profiler™ PCR Array was employed to profile the expression of 84 genes involved in autophagy, ATG12 was the most differentially up-regulated gene in JIMT-1 cells (>10-fold) as compared with trastuzumab-responsive SKBR3 cells. Upon collection of the transcriptional profile of the ATG12 gene across two sets of >50 widely used BC cell lines, HER2+ BC cells with well-established de novo resistance to trastuzumab were characterized by expressing significantly higher levels of ATG12. When lentiviral-delivered small hairpin RNA was employed to stably & specifically knock-down ATG12 gene, JIMT-1 ATG12-shRNA cells were more significantly growth-inhibited by trastuzumab (up to 5-fold) than parental JIMT-1 cells. Moreover, the half-maximal inhibitory concentration (IC50) values for the small-molecule HER1/2 Tyrosine Kinase Inhibitors gefitinib, erlotinib and lapatinib were drastically reduced by up to 10 times in response to ATG12 gene silencing. Knockdown of autophagy-regulatory genes other than ATG12 (e.g. ATG5, ATG8/ LC3B) similarly suppressed refractoriness to trastuzumab as well as co-existing resistance to other HER1/2-targeted agents. Knockdown of autophagy-specific genes, however, did not alter basal sensitivity of JIMT-1 cells to multiple cytotoxics including doxorubicin, cisplatin, paclitaxel and vinorelbine. When lysosomal degradation was pharmacologically inhibited by using the antimalarial lysosomotropic drug chloroquine we found a massive accumulation of abnormal autophagolysosomes that promoted synergistic re-sensitization of JIMT-1 cells to the growth inhibitory and apoptotic activity of trastuzumab. In summary, autophagy-specific genes appear to play a potent protective role against HER2 inhibiting drugs currently in use. Given that genetic and pharmacological targeting of autophagy was found to be detrimental to intrinsic BC refractoriness to HER2-targeted therapies, our current findings may provide rationale for novel, chloroquine-based therapeutic approaches aimed to circumvent primary-resistance and potentiate the efficacy of both trastuzumab and lapatinib in patients treated for HER2-positive BC disease.

**Adjuvant Trastuzumab Effect on HER2-Positive Breast Cancers According to Hormonal Receptor (HR) Status: Crossover between ER and EGFR/HER2 Pathway May Prevent Trastuzumab from Improving Outcomes in HER2-Positive and HR-Positive Breast Cancers.**

Park YH, Cho EY, Lee JE, Nam SJ, Yang JH, Ahn JS, Im Y-H. Samsung Medical Center

**Background:** Crossover between growth factor receptor, especially the EGFR/HER2 pathway, and ER pathways has been associated with endocrine resistance. Thus, combination therapy targeting both ER and EGFR/HER2 signaling to block the crosstalk between these pathways and eliminate escape routes have been proven effective in both preclinical and clinical models. Anti-HER2 directed therapy has been reported to restore hormone sensitivity in HER2-positive breast cancers. Adding trastuzumab to conventional treatment has been a standard treatment of choice in HER2-positive breast cancer irrespective of hormonal receptor (HR) status. The purpose of the study is to evaluate adding effect of 1 year of trastuzumab to conventional adjuvant treatment in patients with HER2-positive breast cancer who received surgery according to HR status.

**Patients and Methods:** We retrospectively analyzed the clinicopathologic characteristics and outcomes of 618 postoperative HER2-positive breast cancer patients between 2001 and 2008 at the Samsung Medical Center. Most of HER2-positive patients in our institute were treated with 1 year of trastuzumab as a part of adjuvant therapy since 2007 (post-trastuzumab era) compared with 2000-2006 (pre-trastuzumab era). Clinical outcomes including recurrence-free survival (RFS) were analyzed between pre-trastuzumab and post-trastuzumab era according to HR status. We performed Cox regression multivariate analysis for relapse using variables from univariate analysis by log-rank test for relapse. Clinical presentations and clinicopathologic characteristics were evaluated at the time of recurrence between both eras.

**Results:** The median age at diagnosis was 46 years (range, 22-79). During the median 60.0 months of follow-up, the 5-year recurrence rate was 20.2%. The 618 patients were divided into two groups (patients who received (n=175) and did not receive (n=443) adjuvant trastuzumab). Recurrence rate was much lower in post-trastuzumab era than in pre-trastuzumab era (13.6% vs. 32.3%, p<0.0001). Improving outcomes due to adding trastuzumab in patients with HER2+ve/HR-ve patients showed significant benefit from trastuzumab throughout the follow-up period (p=0.004). However, this improving effect appeared not to be consistent with statistical significance in HER2+ve/HR+ve patients (p=0.135). The analyses were performed according to quantitative ER Allred scores in HER2+ve/ER+ve patients, the effect of adding trastuzumab appeared to be mitigated as time over without any statistical significance (p=0.975). Young age (≤35) (hazard ratio (HR) 2.4, p<0.0001), trastuzumab use (HR 0.4, p=0.001), and node positivity (HR 2.8, p=0.002) were identified as independent prognostic factors for recurrence in Cox-regression multivariate analysis. Limiting to HER2+ve/ER+ve patients, the statistical significances of trastuzumab use as independent factors were not maintained in Cox-regression models (p=0.074 for trastuzumab use).

**Conclusion:** Cross-talk between ER and EGFR/HER2 pathways may mitigate trastuzumab effect in HER2+ve/ER+ve breast cancers. Further study is warranted.

**PI-12-16**

**HER-2 Testing and Treatment – Is Age a Factor?**

Singh JK, Ewing K, Howell S, Howe M, Cramer A, Bundled NJ. School of Cancer and Enabling Sciences, University of Manchester; Paterson Institute for Cancer Research, Manchester, United Kingdom; University Hospital of South Manchester, Wythenshawe Hospital, Manchester, United Kingdom; The Christie NHS Foundation Trust, Manchester, United Kingdom

**Aims:** Elderly breast cancer patients have a poorer prognosis due to late diagnosis and sub-optimal treatment. In the UK, HER-2 testing was introduced in 2005 and we sought to determine whether HER-2 testing was performed on patients of all ages and whether HER-2 positive patients of all ages subsequently received Herceptin, from implementation in 2005 until 2008.

**Methods:** Review of all newly diagnosed breast cancers in women over 50 in our Unit between January 2005 and December 2008 was performed. Cases were identified from the hospital pathology electronic database. Patients were considered HER-2 positive if tissue sections scored 3+ on immunohistochemical analysis (intense membranous staining) or if gene amplification was detected using fluorescence in-situ hybridisation (FISH). Patients were eligible for treatment with Herceptin if the tumour exceeded 1cm in size or if they had lymph-node positive disease, per UK guidelines. Herceptin treatment was determined for all patients.

**Results:** In total 703 patients with a median age of 68 years (range 56 to 98) were identified and 628 (89.3%) underwent definitive surgery (mastectomies: 246; wide local excisions: 382) and axillary surgery. In total 371 patients (52.8%) underwent HER-2 testing by immunohistochemistry or FISH. HER-2 tests performed by year: 2005 (51/131; 38.9%); 2006 (59/187; 31.6%); 2007 (71/189; 37.6%) and 2008 (190/196; 96.9%). Fifty six patients (15.1%) were HER-2 positive by immunohistochemistry or FISH. Median age of HER2 positive patients was 66 years (range 57 to 98); median age of HER2 negative patients was 68 years (range 56 to 96). Forty-four HER2 positive patients (78.6%) were eligible for treatment with Herceptin; of these 28 patients (63.6%) were treated with Herceptin. HER2 testing, treatment with Herceptin and overall 5-year mortality rate for patients between 50 to 69 years and patients aged 70 years or older is summarised in Table1.

n: number of patients; p: patients; CI: confidence interval

Twenty percent of patients aged between 50 to 69 years and 71.4% of patients aged 70 years or older eligible for Herceptin were not treated. Reasons for non-treatment included: multiple co-morbidities (4); treatment declined by oncologists (1); no referral to oncologists (1); death prior to treatment (2) and unknown (8). Median follow up time was 43.3 months (range 0.2 to 73.8). All cause mortality was higher in the over 70 year old breast cancer group (Log Rank Test p<0.001) regardless of HER-2 status.

**Conclusions:** National introduction of routine HER-2 testing for all newly diagnosed breast cancers led to a testing rate increase to almost
treatments warrants further investigation.

The predictive impact of the former method on response to anti-HER2 therapy has been assessed. However, the number of gene copies/nucleus appears to represent polysomy of chromosome 17, it can also be a result of gains of 17q with centromere involvement, or amplification of the centromeric region. The classification of HER2-positive tumors according to the HER2/CEP17 ratio may therefore misclassify a fraction of truly amplified cases as polysomic. We prospectively evaluated tumors with chromosome 17 polysomy but no HER2 amplification to assess HER2 status using the above two FISH classifications and immunohistochemistry (IHC).

**Materials and methods:** Tumors were tested for gene amplification by FISH with probes to HER2/neu and CEP17 using the PathVysion HER-2 DNA Probe Kit (Vysis). Classification was based on the HER2/CEP17 ratio (amplified when > 2.2) and average HER2 gene copy number/nucleus (amplified when > 6 copies). Both polysomic and equivocal cases (HER2/CEP17 ratio 1.8 – 2.2) were further studied by IHC using the HercepTest (Dako) with 0-3 scoring system (overexpression when 3+).

**Results:** From March 2010 to May 2011 we evaluated 31 primary breast cancers showing chromosome 17 polysomy. Median HER2/CEP17 ratio was 1.3 (range 0.5–1.9), median HER2 copy number was 5.4 (range 2.6–13.8), and median CEP17 copy number was 4.2 (range 3.2–8.0). Thirteen (42%) had an average HER2 gene copy number > 6/nucleus (median 6.8, range 6.1–13.8) and would therefore be considered as amplified if classified according to the absolute HER2 gene copy number. Nine (75%) of these were 3+ at IHC and the remaining 4 were 2+, whereas among the 18 cases with an average HER2 gene copy number ≤ 6/nucleus, one was 2+, ten were 1+, and 7 scored 0. Twenty-nine cases showed negative HER2/CEP17 ratios (< 1.8) and three cases equivocal HER2/CEP17 ratios (between 1.8 and 2.2). Using HER2/CEP17 ratio as first assessment and IHC only in equivocal cases, only one of the 31 polysomic cases would have been classified as HER2-positive. However, 8 polysomic cases with HER2/CEP17 ratio < 1.8 showed 3+ immunostaining (all with average HER2 gene copy number > 6/nucleus), while other cases had an average HER2 gene copy number > 6/nucleus with 2+ immunostaining.

**Conclusions:** Our results show that both FISH evaluation criteria and IHC can modify the percentage of polysomic tumors classified as HER2-positive. However, the number of gene copies/nucleus appears more frequently associated with 3+ IHC than the HER2/CEP17 ratio. The predictive impact of the former method on response to anti-HER2 treatments warrants further investigation.

**P1-12-18**

**Change in HER2 Status in HER2 Positive Operable Breast Cancer Patients Treated with Neoadjuvant Chemotherapy with or without Anti-HER2 Therapy: Analysis of Two Consecutive Cohorts.**

**Barbieri E, Piacentini F, Dieci MV, Ficarra G, Bettelli S, Conte P, Guarneri V. Modena University Hospital, Modena, Italy**

**Introduction:** Emerging literature data have shown a change of HER2 expression from primary tumors to metastatic deposits. Tumor heterogeneity, genetic drift as well as selective pressure of adjuvant therapy have been suggested to explain this phenomenon. Aim of the present analysis is to evaluate the change in HER2 expression after neoadjuvant chemotherapy with or without anti-HER2 agents.

**Methods:** Two consecutive cohorts of HER2+ breast cancer patients treated with neoadjuvant therapy were identified from a prospectively maintained database including 310 patients. The first cohort (A) includes 38 patients enrolled before 2005, treated with chemotherapy alone. The second cohort (B) includes 48 patients treated with neoadjuvant chemotherapy in combination with antiHER2 agents (trastuzumab or lapatinib).

HER2 expression was evaluated by IHC on pre-treatment core biopsy (tru-cut with 14 gauge needle) and on surgical specimen after neoadjuvant therapy. FISH analysis was performed on IHC 2+ samples.

**Results:** The two cohorts were balanced in respect of tumor stage, patient age, and HR expression. In particular, a co-expression of HER2 and HR was observed in 60% of the patients in cohort A and in 70% of the patients in cohort B (p=0.2). Patients in cohort B have a significantly higher rate of pathologic complete response (pCR) in comparison to cohort A (45% vs 11%, p=0.001). A change in HER2 expression from biopsy to post-therapy samples was observed in 39% of the patients in cohort A vs 12% of the patients in cohort B (p=0.02). No patients with pCR have recurred so far vs 25% of the patients with less than pCR (p=0.005). The rate of recurrence was significantly higher for patients experiencing a change in HER2 expression (50% vs 19%, p=0.018).

**Conclusion:** Contrary to our expectations, patients not receiving anti-HER2 therapy as part of neoadjuvant therapy were more likely to have a change in HER2 status vs patients receiving anti-HER2 neoadjuvant therapy. The change in HER2 status has a negative prognostic impact.

---

**P1-12-19**

**Phase I Study of Single Agent Trastuzumab Emtansine in Japanese Patients with Human Epidermal Growth Factor Receptor2 (HER2)-Positive Metastatic Breast Cancer (JO22591).**

**Aogi K, Ando M, Iwata H, Haru F, Matsubara M, Fujitaya Y. National Hospital Organization Shikoku Cancer Center; Matsuyama, Ehime, Japan; National Cancer Center Central Hospital, Chuo-ku, Tokyo, Japan; Chuo Hospital Aichi Cancer Center, Nagoya, Aichi, Japan; Chugai Pharmaceutical Co. Ltd, Chuo-ku, Tokyo, Japan**

**Background:** Trastuzumab emtansine (T-DM1), first-in-class anti-HER2 antibody–drug conjugate (ADC) is under development for the treatment of HER2-positive recurrent locally advanced or metastatic breast cancer (MBC). T-DM1 is composed of: trastuzumab; DM1, an inhibitor of tubulin polymerization derived from maytansine; and the stable MCC linker that conjugates DM1 and trastuzumab. T-DM1 has been evaluated at multiple dose levels in a phase 1 trial (TDM3569g): every 3 weeks (q3w) (0.3–4.8 mg/kg) and weekly (1.2–2.9 mg/kg), and in two subsequent phase II trials (TDM4258g and TDM4374g).
Methods
This Japanese Phase I study was a single-arm, dose-escalation study in patients with HER2-positive MBC who had received prior therapies that included trastuzumab. The objective of the study was to determine the MTD of T-DM1 during Cycle 1, using the continual reassessment method, among three dose cohorts when administered as a single agent and to investigate safety, tolerability and pharmacokinetics of T-DM1 in patients with HER2-positive MBC. Eligibility criteria were standard for this type of study. T-DM1 was administered every 3 weeks at a dose level of 1.8 mg/kg, 2.4 mg/kg or 3.6 mg/kg. Outcomes were assessed by standard-tumor phase 1 methods. Adverse events were reported using CTCAE version 3.0, and tumor response was assessed according to RECIST version 1.0.

Results
Ten patients were recruited: (1.8 mg/kg [n=1], 2.4 mg/kg [n=4], or 3.6 mg/kg [n=5]). One patient in the 2.4 mg/kg group experienced DLTs (Grade 3 AST increase and ALT increase). No other adverse events corresponding to a DLT were observed in any other patients during the DLT observation period. As a result, the MTD in Japanese MBC patients was determined to be 3.6 mg/kg q3w.

The most frequently reported adverse events, regardless of whether they were related to the study drug, were nausea, fatigue, arthralgia and pyrexia. The main changes in laboratory test values recorded were platelet count decrease, AST increase and ALT increase. Efficacy was preliminarily assessed with tumor responses, a partial response was observed in two patients. Most of the AEs were mild and manageable. There were no marked differences in any pharmacokinetic parameters for T-DM1, DM1 or total trastuzumab following administration of T-DM1 between the JO22591 study and the two Western studies (TDM3569g and TDM4258g), and no data obtained suggested any ethnic differences.

Conclusions
T-DM1 monotherapy (3.6 mg/kg every 3 weeks) was well-tolerated in Japanese patients. PK and safety in Japanese patients were comparable to PK and safety in the Western population. These results support further clinical studies with T-DM1 in Japanese patients.

P1-12-20
The Safety and Tolerability of Vorinostat in Combination with Lapatinib in Advanced Solid Tumors.
Chumsri S, Tait NS, Medeiros MM, Bauer KS, Betts K-MT, Lewis JC, Bao T, Feigenberg SJ, Kesmodel SB, Stearns V, Edelman MJ, Sausville EA, Tkaczuk KHR. University of Maryland Greenebaum Cancer Center, Baltimore, MD; The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD; University of Maryland, Baltimore, MD

Background: Lapatinib has been previously shown to markedly decrease cancer stem cells (CSC) in HER2-positive breast cancer. In preclinical models, we have demonstrated that histone deacetylase inhibitors (HDACi) such as vorinostat can induce differentiation and decrease CSC. The combination of vorinostat and lapatinib is synergistic with a combination index of 0.32 (synergism if CI <1). We therefore undertook a pilot study to evaluate the combination of these two drugs in advanced solid tumors.

Method: Patients were eligible if they were: age ≥ 18 years with incurable solid tumors, ECOG PS 0-2, adequate organ function, and no prior exposure to HDACi. The first 3 patients received lapatinib at the dose of 1,250 mg continuous daily and vorinostat 300 mg 4 days on 3 days off. The second dose level with lapatinib 1,250 mg continuous daily and vorinostat 400 mg 4 days on 3 days off were administered in 6 patients. Cycles were repeated every 21 days until disease progression. Echocardiogram and radiologic evaluation were performed every 12 weeks. During the first cycle, pharmacokinetic (PK) evaluation was performed on days 18 and 21.

Results: Nine consented patients (7 with metastatic breast cancer, 1 with non-small cell lung cancer, and 1 with thyroid cancer) have been enrolled with the median age of 52 (range 25-66). Patients received an average of 6 prior treatments (range 2-10). No dose limiting toxicity or drug related death have been observed. Grade 1-2 toxicities including diarrhea, fatigue, muscle cramps and stomatitis were observed. No grade 3 or 4 hepatic, renal or cardiac toxicity were observed (including no QTc prolongation and no significant reduction in the left ventricular ejection fraction). Patients have received the maximum of 7 cycles (median 3 cycles, range 2-7). Response: as of June 2011, 2 patients are still on treatment. Two patients achieved stable disease (triple negative metastatic breast cancer and HER2-positive breast cancer), 6 patients with progressive disease, and 1 patient is too early to evaluate for response. PK analysis will be presented at the time of the meeting.

Conclusions: The combination of vorinostat and lapatinib is tolerable and has some antitumor activity in heavily pretreated advanced solid tumors. A phase II study in HER2-positive metastatic breast cancer is underway with lapatinib 1,250 mg continuous daily and vorinostat 400 mg 4 days on 3 days off.

P1-12-21
Adjuvant Trastuzumab Treatment without Adjuvant Chemotherapy in Early Breast Cancer.
Dall P, Koch T, Lenzen G, Kahn T, Hielischer C, Reichert D, Maasberg M, Ehscheidt P, Eastermann H, Fischer G. Städt. Klinikum, Lüneburg, Germany; Klinikum Nürnberg-Nord, Nürnberg, Germany; Praxis, Osnabrück, Germany; Brustzentrum, Stuttgart, Germany; Praxis, Sanktmarburg, Germany; Praxis, Westerstedt, Germany; Praxis, Mayen, Germany; Praxis, Neuwied, Germany; WSP, Langenfeld, Germany; Landkreis Mittweida Khs., Mittweida, Germany

Background: Trastuzumab (T) is approved in most Western countries for the treatment of early, HER2+ breast cancer (BC) parallel or sequential to adjuvant chemotherapy (CT). Nevertheless, as in metastatic disease, the antibody seems to be used without chemotherapy in a selected group of HER2+ patients (pt). The purpose of this analysis is to characterize this subgroup as well as describe safety and efficacy outcome parameters in this German prospective observation trial.

Methods: At present, 2870 patients (pts) have been enrolled and documented in this ongoing non-interventional study from 270 German centers. At data base closure for this analysis, sufficient documentation was available from 2422 eligible pts.

Results: The proportion of pts receiving T without preceding or concomitant CT (noCT) was 180/2422 (7.4 %). This subgroup was characterized by higher age (median 58 vs. 56 in the CT group, p=0.0026; ≥70 years: 18%/10%), smaller primaries (pT1 49%/43%, p=0.11), more favorable grading (G3 45%/53%, p=0.045), a higher proportion of positive hormone receptor (67%/61%, p=0.096) and less radiotherapy (64%/79%, p<0.0001). The strong association to radiotherapy is probably due to the fact, that the choice of this additional modality reflects the overall risk assessment of the pt.
In contrast, there was no difference in nodal involvement (pN0: 52%/51%; positive nodes: mean 2.5/2.4). In multivariate analysis (logistic regression model, not incorporating radiotherapy), hormone receptor status is not predictive (p=0.41), while age ≥65 (p=0.0011), grade 1/2 (p=0.046) and pT1 (p=0.089) independently remain at least borderline significant. The mean number of T administrations was 18 and the median duration of T therapy was 12 months in the noCT group as well as the CT group. 57% of the noCT pts received adjuvant endocrine therapy. In the CT group, 81% received anthracyclines and 61% taxanes.

Based on a still low number of only 13 observed events in the noCT group, no differences in relapse-free survival could be detected (p=0.38). Pathological cardiac findings in the pt’s history was not predictive of therapy selection (6%/7%) and were also similarly distributed at the end of T therapy (7%/8%). Cardiac function disorders of CTC grade 3/4 were reported in 1% of both groups, across all grades slightly less frequent in the noCT group (2%/4%).

**Conclusions:** A small, but distinct group of early BC pts without adjuvant chemotherapy receives T treatment for HER2+ disease. These patients are characterized by higher age and favorable primary tumor staging and grading, but not by cardiac comorbidities.

**P1-12-22**

Impact on Survival of the Level of HER2/neu Gene Amplification in Patients with HER2-Positive (HER2+) Advanced Breast Cancer (AdBrCa) Treated with Trastuzumab (H).

Guillo G, Betto D, Zardadelli M, Masci G, Giordano L, Bareggi C, Salvini P, Runza L, Santoro A. St Vincent’ s University Hospital, Dublin, Ireland; Istituto Clinico Humanitas, Rozzano, MI, Italy; Humanitas Cancer Centre, Rozzano, MI, Italy; Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milano, Italy; Cliniche Humanitas Gavazzeni, Bergamo, Italy

**Background** The level of HER2/neu (HER2) amplification, defined as HER2/centromeric region of chromosome 17 (CEP17) ratio at dual-color fluorescent in-situ hybridization (FISH) test presents wide variations in clinical practice but its clinical significance is still undefined. We designed this retrospective study to investigate the correlations between level of HER2 amplification in primary (T) and/or metastases (M) and outcome in a cohort of HER2+ AdvBrCa pts treated with a H-containing therapy. **Methods** Retrospective multicentric study designed according to REporting recommendations for tumor MARKer prognostic studies (REMARK). To be included pts must have all the following: metastatic or locally advanced (not amenable of curative surgery) BrCa, HER2+ tumour defined as score 3+ at immunohistochemistry or FISH positive, treatment with a H-containing regimen (no H in neo- or adjuvant setting was allowed), at least one tumour sample from T and/or M available, measurable or evaluable disease, adequate follow up (FU) information. Outcome parameters included event-free survival (EFS) and overall survival (OS). All FISH tests were prospectively performed in a central laboratory of cytogenetic specifically for this study and in accordance with the international guidelines on FISH testing. **Results** Ninety-one females were identified and 63 included in the final analysis. Forty-seven pts had one specimen available from T or M, 16 pts had two specimens from either T and a corresponding M. All M samples were obtained before treatment with H. Median FU time is 19.2 months (range 1.2-94.6). In 11 out of 16 cases (69%) with two tumour specimens HER2/CEP17 ratio was higher in M than in T with a statistically significant difference in the median HER2/CEP17 ratio between T (8.3; range: 3.1-18.4) and the corresponding M (10.9; range: 4.6-20.8) (p=0.004). The incremental gain in HER2/CEP17 ratio was associated with significantly shorter OS after trastuzumab-based therapy (p=0.023). A trend towards a correlation between increase in level of HER2 amplification assessed in M and shorter EFS and OS was observed. No statistically significant correlation was found between level of HER2 amplification assessed in T and EFS and OS. **Conclusions** Level of HER2 amplification reported as HER2/CEP17 ratio is a dynamic parameter in HER2+ AdvBrCa as it increases from T to the matched M in a significant proportion of pts. The gain in HER2 gene copies may represent a prognostic factor for shorter OS when pts with HER2+ AdvBrCa are treated with a H-based therapy. Further studies on the level of HER2 amplification in BrCa metastases are strongly warranted to better understand the biology of HER2-positive breast cancer and to better identify patients with a poorer prognosis after treatment with H.

HER4 Coexpression Is Associated with Improved Recurrence Free Survival in HER2-Positive, Herceptin Treated Patients.

Brockhoff G, Macbleidt A, Piendl G, Seegers S, Sassen A, Diermeier-Daucher S, Buchholz S, Ortmann O. University Medical Center Regensburg, Regensburg, Bavaria, Germany

**Background** Individual therapy efficiency of HER2-positive metastatic and pre-metastatic breast cancer patients varies significantly and spans from effectual responsiveness over acquired insensitivity to complete resistance from the outset. Thus no predictive information can be deduced from HER2 diagnostics so that molecular biomarkers indicative for sensitivity / resistance to Herceptin are needed to be identified. The HER2 related HER4-receptor has been shown to have ambivalent (pro-apoptotic or pro-proliferative) activity and consequently represents a prime candidate to affect HER2 activity under Herceptin treatment. We retrospectively analyzed potential her4 gene amplification and HER4 protein expression in HER2-positive, Herceptin treated patients. Patient’s overall and recurrence free survival was evaluated as a function of HER2/HER4 expression. **Methods:** Using dual color Fluorescence in-situ Hybridization (FISH) probes, Zytovision, Bremerhaven, Germany) and qPCR (LC480, Roche, Penzberg, Germany) we quantitatively investigated primary breast cancer tissues from nearly 50 (FISH) and 160 (PCR) patients who received Herceptin treatment. We quantified the her4 gene copy numbers and evaluated the protein expression profile of all four known HER4 isotypes (JM-a/CYT1, JM-a/CYT2, JM-b/CYT1, JM-b/CYT2). Results: FISH analysis revealed a positive and independent prognostic marker in Herceptin treated breast cancer patients with respect to overall survival. Moreover by quantitative PCR analysis we found a significant variability of HER4 protein expression (JM-a/CYT1 and JM-a/CYT2; no JM-b isotypes) in HER2 positive breast cancer tissues, whereas HER2/HER4 positive patients show a significant better recurrence free survival compared to HER2 positive but HER4 negative patients (p > 0.003). **Conclusions:** HER4 has been demonstrated to potentially exert tumor suppressing activity and in turn to have a favourable impact on the course of breast cancer disease. We show here that HER4 expression prolongs in particular recurrence free survival of Herceptin treated patients which indicates a functional integration of HER4 into anti-HER2 targeting. Complementing functional studies allowing for isotype specific function of HER4 will elucidate the special role of this receptor tyrosine kinase in the context of Herceptin treatment and might facilitate individualized anti-ErbB-receptor targeting with higher efficiency.
P1-12-24
Adherence and Persistence with Lapatinib in Women with Metastatic Breast Cancer Who Were Previously Treated with Trastuzumab.
Delea TE, Kartashov A, Sharma PP. Policy Analysis Inc. (PAI), Brookline, MA; GlaxoSmithKline, Philadelphia, PA

Background. Lapatinib is an oral small molecule dual tyrosine kinase inhibitor that binds intracellularly to the ATP binding site of the EGFR and HER2 receptors. In a randomized controlled trial (RCT) of women with HER2+ metastatic breast cancer (MBC) previously treated with trastuzumab, an anthracycline, and taxanes, lapatinib plus capecitabine improved time to progression versus capecitabine monotherapy. In an RCT of postmenopausal women with HR+ MBC, 1st-line therapy with lapatinib plus letrozole improved progression-free survival vs. letrozole monotherapy in the primary analysis HER2+ population. Data on adherence and persistence with lapatinib in typical clinical practice are unavailable.

Methods. This was retrospective observational study of adherence and persistence with lapatinib in women with MBC who were previously treated with trastuzumab. Data were from the Thomson MedStat MarketScan® Commercial and Medicare health insurance claims databases spanning 1/2000-3/2010 and representing >90 million covered lives. Subjects included women with ≥1 claims with a diagnosis of breast cancer, ≥1 claims with a diagnosis of distant metastases, ≥1 trastuzumab claim after first distant metastases diagnosis, and ≥1 lapatinib claim after first trastuzumab claim (date of first lapatinib claim = “index date”). Pts with <12 mos. continuous enrollment pre-index or <3 mos. continuous enrollment post-index were excluded. Measures of lapatinib adherence and persistence were calculated from days supplied information on pharmacy claims and included medication possession ratio (MPR), time to discontinuation (end of supply), time to first treatment interruption (gap during treatment of ≥30 days without supply), and duration of continuous therapy (time to gap of ≥30 days without supply or end of supply).

Results. A total of 1299 pts had ≥1 claims with a diagnosis of breast cancer, ≥1 claims with a diagnosis of distant metastases, ≥1 claims for trastuzumab, and ≥1 claims for lapatinib (1106 Commercial, 93 Medicare). Of these, 666 met all inclusion criteria (572 Commercial, 94 Medicare). Mean (SD) age was 52 (8) years in Commercial pts and 52 (8) years in Medicare pts. Among all pts, 73% had claims history of prior taxanes, 27% prior anthracylines, and 24% prior taxanes and prior anthracylines. Mean (SD) initial lapatinib dosage was 1161 (339) mg daily; 84% initiated lapatinib on 1250 mg daily. Sixty-three percent received index lapatinib in combination with capecitabine; 6% in combination with an aromatase inhibitor. Median follow-up was 12 mos. Mean (SD) number of lapatinib claims was 7.1 (4.9). Mean (SD) MPR was 87% (19%); median MPR was 96%. Kaplan-Meier estimated median time to discontinuation of lapatinib was 7.4 months (95%CI 6.7-8.0 mos). Seventy three percent of patients had no treatment interruption during follow-up. Median duration of continuous therapy was 5.2 mos (95%CI 4.8-5.7 mos).

Conclusions. In women with MBC previously-treated with trastuzumab, adherence and persistence with lapatinib in typical clinical practice are relatively high. Further research is needed to identify predictors and consequences of non-adherence so that efforts may be targeted to enhance adherence to effective treatment.

P1-12-25

Background: In patients with HER-2 over-expressing breast cancer, predictors of trastuzumab response and resistance remain unclear and unvalidated. In an exploratory analysis within a phase II trial, we evaluated various biologic markers as predictors of response or resistance to a trastuzumab containing neoadjuvant chemotherapy regimen.

Methods: A tissue microarray (TMA) was constructed from formalin-fixed paraffin-embedded tumor tissue samples obtained prior to neoadjuvant chemotherapy in 21 (from a total of 30) HER-2 positive stage II-III patients. Protocol treatment consisted of 4 cycles of 5-Fluorouracil, Epirubicin and Cyclophosphamide (FEC\textsubscript{50}) followed by 4 cycles of Docetaxel, Carboplatin (AUC 6) and Trastuzumab (TCH). Immunohistochemical (IHC) analyses of estrogen receptor (ER), progesterone receptor (PR), HER-2, Ki67, EGFR and PTEN were performed utilizing previously published protocols and cut-offs. HER-2 equivocal (2+) by IHC cases was confirmed by prior FISH analysis. Fisher’s exact test was used for statistical analysis.

Results: 21 patients had sufficient tumour for analysis. Median age at diagnosis was 49 years old, 67% were pre-menopausal, and biomarker expression was as follows: 43% ER positive, 29% PR positive, and 100% HER-2 positive. 14 patients (67%) had pathologic complete response (pCR) following the completion of neoadjuvant chemotherapy and trastuzumab. In general, tumour samples showed high Ki67 (>14%) staining (62%), low EGFR positivity (14%), and high PTEN expression (71%). Neither high Ki67 expression (p=0.65), any EGFR expression (p=0.26), nor PTEN loss (p=0.60) was associated with higher or lower rates of pCR respectively.

Conclusion: In our small cohort of locally advanced HER-2 over-expressing tumours, baseline expression of Ki67, EGFR and PTEN were not associated with pCR to a neoadjuvant sequential anthracycline and taxane/trastuzumab combination regimen. Additional biomarkers for an activated PI3K pathway and for p95 will be attempted.

P1-12-26
Global Patterns of Care for HER2/Neu Overexpressing Breast Cancer.

Background: Her2/neu overexpression is an independent adverse prognostic factor present in approximately 25% of invasive breast cancers. HER2-overexpressing breast cancer is particularly common in younger patients and therefore poses a significant public health burden. Anti-Her2/neu adjuvant trastuzumab significantly reduces the risk of recurrence as well as improves survival. In view of the serious potential ramifications of not receiving anti-Her2/neu therapy when appropriate, we undertook this international project to determine clinical access to Her2/neu testing and treatment patterns for women with HER2/neu-positive early breast cancer.
Methods: A web-based survey was sent to 386 physicians from 33 countries who participated in the “TEACH” trial, a double blind placebo-controlled phase III study of a novel anti-Her2/neu therapy, lapatinib, in women with primary Her2/neu-positive breast cancer. The survey contained 27 questions addressing physician and patient demographics, access to Her-2/Neu testing in everyday clinical practice, and anti-Her2/neu treatment options in a variety of clinical scenarios.

Results: One hundred and fifty one participants (39%) from 28 countries answered the survey. Ninety eight percent of the participants reported having Her2/neu tumor expression routinely measured for clinical practice in their institutions by immunohistochemistry (83%), FISH (78%) and other methods (17%). Among Asian physicians, 18% did not have routine testing available and sent primary tumors for central testing for TEACH eligibility. Forty eight percent of physicians surveyed reported instances when they had recommended adjuvant Her2-directed therapy to a patient who eventually did not receive it. The proportion of physicians from developing countries that reported patients not receiving therapy was higher than those from developed countries (68% vs. 38%, respectively). The main reason for not receiving trastuzumab was cost in developing countries, while in more developed countries patient refusal and co-morbidities were the main reasons.

Discussion: This survey reflects availability of HER2 breast tumor testing and anti-Her2/neu therapy among physicians from 28 countries worldwide who participated in an anti-Her2/neu therapy clinical trial of a free anti-Her2/neu therapy. These results indicate that a high proportion of women with Her2/neu-overexpressing breast cancer may not receive standard anti-Her2/neu adjuvant therapy especially in developing countries, the barrier to treatment being cost of therapy. We are extending our access to care survey project to a more unslected diverse group of physicians in developing countries.

P1-13-01
An Update of a Phase II Trial of the HER2 Peptide AE37 Vaccine in Breast Cancer Patients To Prevent Recurrence.
Hale DF, Perez S, Sears AK, Clifton GT, Vreeland TJ, Holmes JP, Mittendorf EA, Patil R, Clive KS, Holmes JP, Mittendorf E, Ponniah S, Ponniah S, Papamichail M, Peoples GE, Anderson Cancer Center, Houston, TX; Saint Savas Cancer Hospital, Athens, Greece; Naval Medical Center San Diego, San Diego, CA; Uniformed Services University of the Health Sciences, USMCI, Bethesda, MD; UT M.D. Anderson Cancer Center, Houston, TX

Introduction: AE37 is a tetra-histidine modified Ii-Key hybrid of the HER2-derived peptide AE36 (HER2:776-790). A phase I trial administering AE37 with the immunoadjuvant GM-CSF demonstrated the vaccine to be safe and capable of stimulating CD4+ helper T-cells with HER2-specific anti-tumor activity. Here we present an update of our prospective, randomized, single-blinded, phase II trial of the AE37 vaccine for the prevention of breast cancer recurrence in disease-free, high risk patients.

Methods: After completion of standard therapy, disease-free, node positive or high risk node negative breast cancer patients were randomized to receive either AE37+GM-CSF (vaccine) or GM-CSF alone (control) in six monthly intradermal inoculations. Patients were enrolled with any level of HER2 expression, (IHC 1+ 2+ or 3+). Specific immunologic responses to both AE36 and AE37 were evaluated in all patients at pre-determined intervals: before (RO), mid-series (R3), upon completion (R6), and at six (RC6) and 12 (RC12) months after completion of the vaccine series. In vitro responses were measured using the [3H]-thymidine incorporation assay and in vivo responses using delayed-type hypersensitivity (DTH) reactions. The trial’s primary endpoint is disease recurrence.

Results: To date, 215 patients have enrolled (vaccine=92, control=123). 99% of local and systemic toxicities were ≤ grade 2 or less. There were no grade 4-5 local or systemic toxicities and no difference between toxicity profiles of vaccine and control groups. Vaccine patients exhibited a statistically significant increase from baseline in AE36 and AE37 proliferative responses at each time point, including maintenance of this response up to 12 months post-vaccination (AE36 (cpm): R0=0, R3=1335, R6=1242, RC6=1586, RC12=1360; AE37: R0=0, R3=2859, R6=2300, RC6=3235, RC12=3279, p<0.001) while there have been no proliferative changes for control patients (AE36: R0=91, R3=95, R6=97, RC6=126, RC12=48; AE37: R0=291, R3=399, R6=319, RC6=103, RC12=0). Vaccine patients also had statistically significant increases in DTH reactions to both AE36 and AE37 (AE36 (mm): R0=0, R6=15, RC6=15, RC12=15; AE37: R0=0, R6=24, RC6=17, RC12=20, p<0.001) while controls had no response (AE36: R0, R6, RC6, RC12=0; AE37: R0, R6, RC6, RC12=0). With a median follow up of 17 months, breast cancer recurrences were reduced by 42% in vaccine patients compared to control patients (7.6% vs. 13.2%, p=0.15). In an analysis of patients with low HER2 expression (IHC 1 or 2+), vaccine patients experienced a 49% reduction in recurrence compared to controls (9.5% vs. 18.6%, p=0.16) with no reduction seen in HER2 over-expressing patients (6.0% vs. 7.9%, p=0.49).

Conclusions: The AE37 vaccine is safe and well tolerated with only mild toxicity, which is attributable to the GM-CSF immunoadjuvant. The AE37 vaccine elicits strong peptide specific in-vivo and ex-vivo immune responses, which are maintained for 12 months after completion of the vaccine series. While the number of recurrences are still low, the recurrence rate appears to decrease in vaccinated patients. Administration of the AE37 vaccine may reduce the risk of breast cancer recurrence with the greatest benefit in patients with low levels of HER2 expression.

P1-13-02
Long-Term Clinical Benefit of Adjuvant Breast Cancer Vaccine: 5 Year Efficacy of E75 with Multiple Booster Inoculations.
Vreeland TJ, Clifton GT, Sears AK, Hale DF, Patil R, Clive KS, Holmes JP, Mittendorf EA, Ponniah S, Peoples GE, Brooke Army Medical Center, Ft. Sam Houston, TX; Windber Medical Center, Windber, PA; Naval Medical Center San Diego, San Diego, CA; UT M.D. Anderson Cancer Center, Houston, TX

Background: We are conducting phase I/II clinical trials vaccinating breast cancer patients with E75, an HLA-A2/A3 restricted HER2/neu (HER2) peptide mixed with GM-CSF. The vaccine has been studied in the adjuvant setting to prevent recurrences in clinically disease-free patients after completion of standard therapy. We have previously reported that the vaccine is safe, effectively stimulates HER2-specific immunity, and appears to improve disease-free survival at 24 months. Here, we report long-term data at a median follow-up of 60 months.

Methods: The phase I/II trials were performed as dose escalation/schedule optimization trials enrolling node positive and high-risk, node-negative patients with tumors expressing any level of HER2. Vaccinated patients were given 4-6 monthly inoculations of E75 with GM-CSF immunoadjuvant. Due to waning immunity, a voluntary
booster program was initiated, with inoculations every 6 months after completion of the primary vaccine series (PVS). Patients were monitored for local and systemic toxicities, which were graded by the NCI’s Common Terminology Criteria for Adverse Events. Vaccinated patients and controls were followed for 60 months and recurrences were documented. Demographic differences were compared with the Fisher’s exact test and survival was analyzed by the log-rank test.

### Results
- 187 patients were enrolled; 108 in the vaccine group (VG) and 79 in the unvaccinated control group (CG). The vaccine and control groups were well-matched with the only statistically significant difference being ER-/PR- status (31.1% in VG vs 17.7% in CG, p=0.04). Vaccination was well tolerated with primarily grade 1 and grade 2 toxicity in the PVS (Local Toxicity: 85% Grade 1, 15% Grade 2, 0% Grade 3; systemic toxicity: 71% Grade 1, 14% Grade 2, and 3% Grade 3). Fifty-three of the VG patients received at least one booster, with 34 receiving a second booster, 25 a third, 22 a fourth, 12 a fifth, and 9 receiving at least six boosters. Booster inoculations were well-tolerated with only grade 1 and 2 local and systemic toxicities. There were delayed urticarial reactions in 7/53 (13%) of the boosted patients occurring at a median of 9 days (5-21 days) after inoculation; these were grade 2 reactions and well-tolerated. After a median follow-up of 60 months, there has been a nonsignificant decrease in recurrences observed in the VG compared to the CG (10.6% vs 20.3%, p=0.098). The hazard ratio is 0.52 in the VG. In patients with immunity maintained with voluntary boosters, there have been even fewer (3.8%) recurrences (p=0.03).

### Conclusions
- The E75 breast cancer vaccine is safe and well-tolerated. With long-term follow-up at 60 months, the E75 vaccine continues to show a strong trend toward preventing breast cancer recurrence in vaccinated patients particularly in patients whose immunity is maintained with booster inoculations. To investigate this further, a phase III trial with prospective boosting is being initiated.

### P1-13-03

**Zoledronic Acid Induces an Immune Response in Breast Cancer Patients through Stimulation of Central Memory and Effector Memory gamma/delta T-Cells.**

### Background
- Zoledronic acid (ZA) in combination with endocrine therapy (ET) and ovarian ablation (OA) reported a DFS advantage in premenopausal women with early stage breast cancer (EBC) in ABCSG-12. Emerging evidence from pre-clinical studies suggests that ZA increases gamma/delta T-cells (GDT), an immune cell population with anti-tumor activity. This study examined immune responses to a single dose of ZA in patients with either EBC or metastatic breast cancer (MBC) through sequential measurement of T-cells and immune regulatory cytokines.

### Methods
- Women with EBC/MBC, both pre- and post-menopausal, and no history of immune dysregulation who were scheduled to receive their first-ever dose of ZA were eligible. Blood was collected for serum and blood mononuclear cells at Day 0 (pre-ZA), Day 1 (18-48 hours post-ZA), Day 7 (Day 5-8 post ZA), and Day 28 (Day 25-32 post-ZA). GDT populations and cytokine responses were assayed using flow cytometry and multi-analyte profiling beads (Luminex), respectively. Relative changes from baseline at days 1, 7, and 18 were quantified using log-ratios and analyzed using the Wilcoxon signed-rank test.

### Results
- 24 patients were enrolled from Oct 2009 to Mar 2011. 75% of pts had MBC, and 25% had EBC, while 75% received ET, 17% received chemo (C), and 8% received other. Following ZA administration, a transient decrease in total GDT (CD3+/Vdelta2+) at Day 1 was seen (p<0.003). This was followed by an increase in both effector (CD3+/Vdelta2+/CD45RA+/CD27-) (P=0.005) and central memory GDT (CD3+/Vdelta2+/CD45RA+/CD27+) (P=0.007) and a decrease in naive GDT (CD3+/Vdelta2+/CD45RA+/CD27+) (P=0.006) at day 7; total GDT unchanged. The change in naive GDT and effector GDT appeared to persist at Day 28. IL-1RA (P=0.003), IL-12 (P=0.0005), MIP-16 (P=0.006), IL-10 (P=0.0002) and MIG (P=0.0006), were increased at Day 1 compared to baseline. By day 28, these cytokine levels returned to baseline except IP-10 which appeared to remain elevated. In this limited patient sample, no differences were observed between patients with EBC vs. MBC, ET vs. C, and pre- vs. post-menopausal.

### Conclusion
- ZA appears to induce a highly significant change in immune effector cells in both EBC and MBC patients receiving ET or C. Mobilization of anti-tumor T-cells with a decrease in total (non-specific) GDT followed by a marked increase post-ZA in specific central and effector memory GDT was seen at day 7. Significant increases in cytokine levels, like those seen in this study including those associated with Th1 responses or cell-mediated immunity, as well as IL-12 levels, have been implicated in direct anti-tumor activity. This apparent cytokine and cellular response to ZA could offer an important biologic mechanism for the anti-cancer activity reported in ABCSG-12. Further studies should be performed to determine which subsets of BC patients might achieve these described immune benefits from ZA.

**Phase II Study of Topical Imiquimod and Abraxane for Treatment of Breast Cancer Cutaneous Metastases.**

**Salazar LG, Lu H, Gray H, Higgins D, Childs J, Yushe D, Slota M, Parker S, Disis ML. University of Washington, Seattle, WA**

### Background
- Breast cancer (BC) cutaneous lesions can present as local chest wall recurrence or isolated sites of metastatic disease. Current treatments with full thickness chest wall resection, radiation therapy and chemotherapy are not curative; and have significant morbidity and poor overall response rates. Combining local immunomodulation and systemic chemotherapy may be more effective in treating cutaneous disease. Topical imiquimod (IMQ), a TLR-7 agonist, has shown clinical activity against cutaneous metastasis. Pre-clinical studies have shown IMQ to stimulate Th1 cytokine secretion and up-regulate immune co-stimulatory molecules at the tumor site; resulting in augmented tumor specific T cell immunity and tumor growth inhibition. Use of paclitaxel in BC, has demonstrated immunostimulatory effects of increased serum IFN-γ and enhanced NK/LAK cell activity. Abraxane (albumin-bound paclitaxel) may be used in conjunction with IMQ as steroid pre-treatment is not required. We hypothesize the immune effects of Abraxane may synergize and augment the IMQ anti-tumor effects, resulting in greater clinical response. A phase II single-arm study of chemoimmunotherapy with topical IMQ and Abraxane was initiated to determine its safety and therapeutic efficacy; and examine its effect on augmenting endogenous tumor specific immunity and inducing tumor molecular alterations associated with inhibition of tumor growth and/or common pathways of BC immune escape.

### Materials and Methods
- Up to 15 BC patients with cutaneous lesions no longer amenable to standard therapy are enrolled and receive 3
Results

MBC and no prior chemotherapy for MBC. The primary endpoints and C). Patients were required to have measurable, HER2 negative with bev (15 mg/kg q 3 weeks arm A, 10 mg/kg q 2 weeks arms B and A (8.0 months), overall p=0.065. There were no differences in the median age was 57 (range 29-85), 82% were postmenopausal and 260 mg/m

Background: Nanoparticle albumin-bound paclitaxel (nab-P) is superior to paclitaxel 175 mg/m

Methods: This open-label, phase II study randomized patients (pts) to nab-P at 260 mg/m

Conclusions: Chemoimmunotherapy with topical IMQ and Abraxane is well-tolerated and shows excellent clinical efficacy in treating metastatic cutaneous lesions in heavily pretreated BC patients.

P1-14-01

Randomized Phase II Trial of Weekly vs. q 2-Weekly vs. q 3-Weekly Nanoparticle Albumin-Bound Paclitaxel with Bevacizumab as First-Line Therapy for Metastatic Breast Cancer. Seidman AD, Conlin AK, Bach A, Forero-Torres A, Wright G, Hackney MH, Clawson A, Schofield D, Iglesias J, Hudis CA. Memorial Sloan-Kettering Cancer Center; New York, NY; Providence Cancer Center; Portland, OR; University of Alabama - Birmingham, Birmingham, AL; Florida Cancer Institute, Hudson, FL; Virginia Commonwealth University, Richmond, VA; Celgene Corporation, Summit, NJ

Background: Nanoparticle albumin-bound paclitaxel (nab-P) 260 mg/m² is superior to paclitaxel 175 mg/m² (P) every 3 weeks (Gradishar et al. JCO 2005) in metastatic breast cancer (MBC), and weekly uninterrupted P is more effective than q3wk P in MBC (Seidman et al. JCO 2008). Bevacizumab (bev) nearly doubles response rate and time to progression (TTP) when added to P as 1st line therapy for MBC (Miller et al. NEJM 2007).

Methods: This open-label, phase II study randomized patients (pts) to nab-P at 260 mg/m² q3wk (arm B) vs. 260 mg/m² q 2wk with filgrastim (arm B) vs. 130 mg/m² weekly uninterrupted (arm C), all with bev (15 mg/kg q 3 weeks arm A, 10 mg/kg q 2 weeks arms B and C). Patients were required to have measurable, HER2 negative MBC and no prior chemotherapy for MBC. The primary endpoints were response rate and toxicity.

Results: Of 212 pts randomized, 208 (75 arm A, 54 arm B, 79 arm C) were treated, with balanced demographics and baseline characteristics. The median age was 57 (range 29-85), 82% were postmenopausal and 89% had visceral disease (64% lung, 50% liver). ECOG PS 0-60%, 1-35%, 2-5%. 62% had prior neo-adjuvant or adjuvant chemotherapy for early stage disease: anthracycline: 54%, taxane: 38%. No significant differences in confirmed complete and partial response rates were noted (A: 40%, B: 44%, C: 46%). Median TTP was longer in Arm C (9.0 months) versus both arms B (6.3 months) and A (8.0 months), overall p=0.065. There were no differences in overall survival (Arm A: 21.3 months, Arm B: 19 months, Arm C: 25.3 months). As per protocol-specified stopping rule, arm B was closed early due to an unacceptable safety profile with significantly more grade ≥2 fatigue (B:57%, A: 39%, C:39%, p=0.048) and bone pain (B:19%, A:10%, C:4%, p=0.024). Sensory neuropathy was common; grades 2/3/4: Arm A: 29%/32%/1%, Arm B: 15%/50%/22%, Arm C: 27%/43%/1%. Sensory neuropathy was commonly readily reversible with dose delay and reduction. Febrile neutropenia occurred in <2% of pts in all arms. Arm C patients experienced significantly less arthralgia compared with arms A and B, but dose delays were frequent (86% of pts) on this planned uninterrupted weekly schedule. Bevacizumab-related events were consistent with prior phase III trials of taxane/bev; there were no new safety signals.

Conclusions: Significant and similar antitumor activity was observed in all arms. Weekly nab-P with bev (arm C) resulted in longer TTP. Weekly nab-P with bev (arm C) appears to have the highest therapeutic index, however sensory neuropathy is limiting, suggesting that a 3 week on/1 week off schedule could be preferable and should be studied comparatively.

P1-14-02

Correlation of Circulating Tumor Cells (CTC) and Circulating Endothelial Cells (CEC) with Pathological Complete Response (pCR) during Neoadjuvant Chemotherapy (CT) Combined with Bevacizumab in HER2 Negative Inflammatory Breast Cancer (IBC): Ancillary Study of Phase II Trial BEVERLY I. Pierga J-Y, Bidard F-C, Andre F, Petit T, Dalenc F, Dolozier T, Ronieux G, Bonnettere J, Ferrero J-M, Kerbrat P, Lemonnier J, Viens P, Institut Curie, Paris, France; Institut Gustave Roussy, Villejuif, France; Centre Paul Strauss, Strasbourg, France; Centre Claueldes Regaud, Toulouse, France; Centre Francois Baclesse, Caen, France; Centre Val d’Aurelle, Montpellier, France; Centre Oscar Lambret, Lille, France; Centre Antoine Lacassagne, Nice, France; Centre Eugène Marquis, Rennes, France; Unicancer, Paris, France; Centre Paolo Calmettes, Marseille, France

Background: Prognostic value of CTC detection in blood has been reported in primary breast cancer with a rate around 20% in the neoadjuvant setting. No correlation between CTC and pCR to neoadjuvant CT in operable breast cancer has been reported (Pierga CCR 2008, Riethdorf CCR 2010). Predictive value of CEC for response to anti-angiogenic agents is unclear. Methods: CTC and CEC were detected in 7.5 ml and 4 ml of blood respectively with CellSearch™ System in the neoadjuvant setting of HER2 negative IBC (T4d) patients (pts) enrolled in the phase II multicentre trial BEVERLY I, evaluating bevacizumab (15mg/kg q3w) in combination with sequential neoadjuvant CT of 4 cycles of FEC followed by 4 cycles of Docetaxel. Patients received postoperatively 10 cycles of bevacizumab and hormone therapy if tumor was ER+. Results: From 12/08 to 09/10, 101 pts were included, 96 were evaluable for pCR and 92 for CTC and CEC. Out of 96 pts, 51 (53%) had triple negative breast cancer (TNBC). At baseline, 37 pts out of 92 had ≥1 detectable CTC (40%, 95%CI 30-50%).

At baseline, CTC level was not correlated with CEC level, neither with TNBC nor pCR. A drop in CTC incidence was observed from 12/08 to 09/10, 101 pts were included, 96 were evaluable for pCR and 92 for CTC and CEC. Out of 96 pts, 51 (53%) had triple negative breast cancer (TNBC). At baseline, 37 pts out of 92 had ≥1 detectable CTC (40%, 95%CI 30-50%).
months post surgery) none had pCR (p=0.05 Yates test). There was a significant increase of CEC from baseline to presurgery sample (p <0.001) and a decrease (p=0.04) after tumor removal and end of CT. A higher level of CEC (>20/4ml) before C5 could be associated with a higher probability of pCR (Khi2 test, p=0.003). Conclusions: We observed a high CTC detection rate of 40% in HER2-IBC, including TNBC. CEC levels increased progressively during neoadjuvant treatment and decreased after its interruption. Baseline CTC and CEC levels were not predictive of pCR. Detection of CTC at 8 months of follow-up was associated with the absence of response to neoadjuvant chemotherapy.

PI-14UZ
AVALUZ Study: First Line with Bevacizumab in Combination with Paclitaxel (P) and Gemcitabine (G) in Patients with HER-2 Negative Recurrent or Metastatic BC: PFS Analysis.
Salvador J, Ciruelos E, Codes de Villena M, Jaen A, Gil M, Galan A, Muriás A, Jara C, de la Haba J, Baena JM, Villanueva MJ, Bayo J, Blancas I, Gonzalez E, Perez D, Mel JR, Manso L. Hospital U. de Valme, Sevilla, Spain; Hospital 12 de Octubre, Madrid, Spain; Hospital Virgen Macarena, Sevilla, Spain; Hospital de Jaen, Jaen, Spain; ICO, Bellvitge, Spain; Hospital de Sagunto, Sagunto, Spain; Hospital Insular de Gran Canaria, Gran Canaria, Spain; Fundacion Hospital de Alcorcon, Alcorcon, Spain; Hospital Reina Sofia, Cordoba, Spain; Hospital Puerta del Mar, Cadiz, Spain; Hospital Meixoeiro, Vigo, Spain; Hospital Juan Ramón Jimenez, Huelva, Spain; Hospital San Cecilio, Granada, Spain; Hospital Virgen de las Nieves, Granada, Spain; Hospital Costa del Sol, Marbella, Spain; Hospital Lucas Augusti, Lugo, Spain

Background
The combination of bevacizumab (B) with taxanes, capetcitabine or anthracyclines has shown increased PFS in pts with mBC. The combination with G and P has been evaluated and has demonstrated high response rate and good toxicity profile. The aim of this study is to evaluate the efficacy and toxicity profile of the combination of B with G and P, providing an update of PFS and the toxicity experienced in all patients treated.

Methods
A phase II multicenter, national, open-label study in pts diagnosed of recurrent or metastatic HER-2 negative BC, treated with first line B 10 mg/kg, P 150 mg/m2 and G 2000 mg/m2 day 1 and 15 c/28 d until progression disease, unacceptable toxicity or medical decision. The abstract evaluates efficacy by PFS as primary endpoint and as secondary endpoints: response rate and toxicity profile (NCI CTC v3.0 criteria).

Results
From January 2009 to December 2009, 82 evaluable patients were recruited in 23 sites. The characteristic of the all of patients included (90) are: median age 51.5 (26-81), ER + 68%, PR + 59%, triple negative pts 19%, previous chemotherapy (neoadj or adj) 64.4% (90).

PI-14-04
Prolonged (≥1 Year) Exposure to First-Line Bevacizumab Combined with Paclitaxel in Patients with HER2-Negative Metastatic Breast Cancer Treated in a Routine Oncology Practice Study.
Kuemmel S, Schneegeiss A, Foerster FG, Geberth M, Tesch H, Klare P, Schumacher C, Hollburg W, Soeling U, Schmidt M, Kliniken Essen-Mitte, Essen, Germany; National Center for Tumor Diseases, Heidelberg, Germany; University of Applied Sciences Zwickau, Zwickau, Germany; SPOG-Mannheim, Mannheim, Germany; Oncological Practice Bethanien, Frankfurt, Germany; Oncology Practice Krebsheilkunde für Frauen, Berlin, Germany; St. Elisabeth-Hospital, Köln, Germany; HOPA (Hämatologisch-Onkologische Praxis Altona) im Struenseehaus, Hamburg, Germany; Practice, Kassel, Germany; University Hospital Mainz, Mainz, Germany

Background:
First-line bevacizumab (BEV) combined with weekly paclitaxel (PAC) significantly improves progression-free survival (PFS) and response rate (RR) vs PAC alone in HER2-negative metastatic breast cancer (mBC), as shown in E2100. The benefit of BEV combined with other chemotherapy (CT) agents was demonstrated in AVADO and RIBBON-1. BEV was continued for ≥1 year in 21% of patients in the global ATHENA safety study and in 42% of patients in the JO19901 single-arm Japanese study of BEV–PAC. We analyzed data from the subgroup of patients treated for ≥1 year in a German routine oncology practice study to provide insight into the safety and efficacy of prolonged first-line BEV–PAC.

Methods:
Patients who had received no prior CT for their mBC received BEV–PAC per the European label. Efficacy and safety were documented for up to 1 year (or until progression, death, or BEV discontinuation if earlier) with additional long-term follow-up. Data from patients treated with BEV for ≥1 year were extracted for this analysis.

Results:
By Jan 2011, data were available for 818 patients, of whom 157 (19%) had already received BEV for ≥1 year. Baseline characteristics of this subset relative to the overall population are summarized in the table.

In 79% of those treated for ≥1 year, BEV was continued as a single agent after discontinuation of CT. The overall RR in patients treated for ≥1 year was 81% (complete response in 20%). Median PFS was 1.7 months (events in 44% of patients) vs 9.4 months in the overall population (events in 68%). Overall survival data are immature, as 81% of those treated for ≥1 year are still alive. The most common grade 3/4 adverse events in patients treated with BEV for ≥1 year were hypertension (11% of patients), pain (10%), and leukopenia (7%). There were no cases of gastrointestinal perforation, arterial
In general, the rate of surgical complications was low. A complication was reported in 11% with EC-T compared to 15.3% reported in EC-TB (p=0.80). Any complication was reported in 3.4% with EC-T and 6.3% with ECB-TB (p=0.11). Necrosis was reported in 3.9% with ECB-TB (p=0.39). Delayed wound healing was reported in 6.7% of the patients treated by EC-T and 7.1% with ECB-TB (p=0.88). The rate of pathological complete response was 19.5% with EC-T compared to 23.2% with ECB-TB (p=0.26). The rate of pathological complete response was 46% in the EC-T arm compared to 71.1% in the ECB-TB arm (p=0.54). The rate of pathological complete response was 46% in the EC-T arm compared to 71.1% in the ECB-TB arm (p=0.54). The rate of pathological complete response was 46% in the EC-T arm compared to 71.1% in the ECB-TB arm (p=0.54).

P1-14-05
Surgical Complications from the GeparQuinto Trial of Patients Receiving Preoperative Bevacizumab.
Universitätsklinikum, Kiel; Praxisklinik, Berlin; Luisenko Krankenhaus, Düsseldorf; Onkologische Gemeinschaftspraxis am Bethanien-Krankenhaus, Frankfurt; Städtisches Klinikum, Karlsruhe; Frauenklinik, Rheinfeld; Universityklinikum, Greifswald; Helios Klinikum Berlin Buch, Berlin; Universitätssklinikum, Freiburg; Henriette Stiftung, Hannover; Universityklinikum, Erlangen; Hämatologisch-Onkologische Schwerpunktpraxis, München; Evangelisches Krankenhaus, Gelsenkirchen; St. Barbara-Klinik, Heessen; Universitätsklinikum, Frankfurt; German Breast Group, Neu-Isenburg

Background: Bevacizumab has been reported to increase the risk of surgical complications, especially in its treated with neoadjuvant chemotherapy.

Methods: In January 2010 it was decided to collect surgical complications prospectively on a specifically developed form. All patients received chemotherapy with epirubicin/cyclophosphamide (EC) followed by docetaxel (T) with or w/o bevacizumab. Patients not responding to the first 4 cycles of EC/T-B were enrolled in another setting. All patients receiving bevacizumab were supposed to be operated at 5 weeks after the last infusion of bevacizumab.

Results: Data from 699 patients have been prospectively collected, 329 received EC-T and 370 ECB-TB. Median age was 48 years in both arms. Median tumor size was 30mm in the ET-T arm vs 35mm in the ECB-TB arm (p=0.13). Multifocal or multicentric disease was present in 21% in the EC-T arm vs 22.4% (p=0.74). 36% of the patients received a sentinel node biopsy prior to start of neoadjuvant chemotherapy. All patients receiving bevacizumab were supposed to be operated at 5 weeks after the last infusion of bevacizumab.

Conclusion: In general, the rate of surgical complications was low. Patients treated with bevacizumab had a numerical increase of surgical complications. However, none of the differences were statistically significant. The intervals from last infusion to surgery as defined by the study protocol appear to be safe.

P1-15-01
Oral Fluoropyrimidine (UFT and S-1) May Augment the Efficacy of Aromatase Inhibitor Via the Down-Regulation of Estrogen Receptor in Estrogen-Responsive Breast Cancer Xenografts.
Nakatsuka M, Saito H, Nakagawa F, Abe M, Uchida J, Shibata J, Matsuo K-I, Noguchi S, Kiniva M, Taito Pharmaceutical Co., Ltd., Tokushima-shi, Tokushima, Japan; Taito Pharmaceutical Co., Ltd., Tsukuba-shi, Ibaragi, Japan; Osaka University Medical School, Osaka, Japan

Breast cancer patients have tended to be more personalized by biomarkers, such as estrogen receptor (ER), HER-2 and other risk factors. Adjuvant endocrine therapy is recommended for all ER-positive breast cancer patients, and the addition of adjuvant chemotherapy to endocrine therapy has been shown to further improve the prognosis of ER-positive breast cancer patients. Addition of an oral fluoropyrimidine, UFT was shown to improve the outcome of patients with luminal A cancer. Based on these studies, the present preclinical study was designed to evaluate a new combination therapy comprised of the aromatase inhibitor anastrozole (ANA) and the oral fluoropyrimidines, UFT and S-1 against luminal A breast cancer cell line MCF-7/Arom 14, which was stably transfected with the cDNA of human aromatase. MCF-7/Arom 14 cells showed a high aromatase activity (111.6±69.6 fmole/mg protein/hr) in vivo. Testosterone failed to induce cell growth of parent MCF-7. But, MCF-7/Arom 14 cells were potentiated by both testosterone and E2 in vitro, and ANA and 5-fluorouracil (5-FU) inhibited cell growth at concentrations of 0.005 to 10 and 0.2 to 5 μM, respectively. The combination of 5-FU and ANA added cell growth inhibition. MCF-7/Arom 14 was implantable in vivo, but it failed to grow in the absence of either testosterone or ANA. Testosterone releasing pellet (Tes-P). The growth of MCF-7/Arom 14 was significantly inhibited by ANA and S-1 or UFT alone vs Control (Tes-P alone) in vivo. The combination of ANA with S-1 or UFT administered using a 21-day consecutive, metronomic-like regimen. On day 22, relative tumor volume (RTV) treated by ANA and UFT or ANA and S-1 was significantly lower than either mono-therapy by Welch’s t-test. Based on RTV change the period required for the RTV to reach 3 was estimated, and its differences between control was designated as growth delay period (GDP). GDP of combination-therapy was 2 to 4 times longer than either mono-therapy.

To investigate the mechanisms by which fluoropyrimidines enhance the antitumor activity of ANA, the protein and mRNA expression levels of ER-α in tumor tissue after treatment with S-1, ANA, and the typical chemotherapeutic agents doxorubicin (ADM) or paclitaxel (TXL) were analyzed by immuno-histostain and RT-PCR, respectively. The protein and mRNA expression of ER-α were markedly decreased by S-1 or S-1+ANA, but not for ADM or TXL. The reduced ER-α level might increase antitumor activity of ANA in addition to the decreased estrogen production. As activity of dihydropyrimidine dehydrogenase (DPD) in breast cancer is
higher, UFT or S-1 which is resistant against DPD would be suitable compared other 5-FU derivatives. Therefore, the combination of ANA and S-1 might yield a greater benefit than other chemotherapeutic agents in postmenopausal women with Luminal A breast cancer.

P1-15-02

Nanoparticles Overcome the Decreased Responsiveness of Breast Cancer Cells to a Chemotherapeutic Drug in the Presence of Adipocytes.

DeAngel RE, Sandoval MA, Lansakara-P DSS, Dunlap SM, Hursting SD, Cui Z. The University of Texas at Austin, Austin, TX; UT-MD Anderson Cancer Center, Smithville, TX

Background

Excess adipose tissue plays a role in increasing breast cancer risk and tumor aggressiveness. However, the role of mature adipocytes in tumor progression and response to therapy remains unclear. Despite advances in breast cancer treatment, obese patients still show decreased response to chemotherapy. The incorporation of nanoparticles (NPs) in breast cancer therapeutics represents a novel approach for improving therapy efficacy. NPs increase the drug accumulation in the tumor site resulting in increased drug disposition, decreased cytotoxicity and decreased adverse side effects. However, few studies have evaluated the response to chemotherapy-loaded-NPs in the context of obesity. Gemcitabine is a widely used nucleoside analog that inhibits DNA synthesis. Previously, we prepared a novel gemcitabine formulation by incorporating 4-(N)-stearoyl gemcitabine in solid-lipid NPs (Gem-NPs). We hypothesized that the enhancement of tumor growth and decreased response to therapy in the presence of adipocytes can be offset by treatment with Gem-NPs. To test this we used an in vitro model of adipocyte-conditioned media (CM) and investigated the effects of mature adipocytes on breast cancer cells.

Methods

Murine 3T3-L1 adipocytes were induced to differentiate; adipocyte-CM from these cells was collected, centrifuged and used for most assays. Murine (M-Wnt, E-Wnt) and human (MCF-7) cancer cells were grown in RPMI and DMEM, respectively, supplemented with 10% FBS and 1% penicillin/streptomycin at 37°C with 5% CO2. Once the cells were confluent, cells were split and then cultured with a matrigel invasion assay. CM from undifferentiated 3T3-L1 adipocytes (fibroblasts-CM) were used as a negative control.

Results

After 48 h of culture with CM, all cells (M-Wnt, E-Wnt, and MCF-7) showed increased proliferation (p < 0.05) and the invasiveness capacity was increased in the presence of adipocyte-CM after 20 h in culture. Cells cultured with adipocyte-CM were less responsive to treatment with gemcitabine (p < 0.01) relative to cells cultured with fibroblasts-CM. The apoptotic response to gemcitabine was decreased, and s-phase arrest was not observed in the presence of adipocyte-CM. However, treatment with Gem-NP overcame the decrease in gemcitabine responsiveness caused by adipocyte-CM, restoring apoptotic response and S-phase arrest.

Conclusion

Our results strongly support the role of mature adipocytes in promoting tumor growth and invasiveness while decreasing the response to a standard chemotherapy. Our findings also suggest that incorporating a chemotherapeutic drug into NPs can potentially decrease chemotherapy resistance, particularly in obese patients. Animal studies are underway to evaluate this response in an in vivo mouse model of obesity.

P1-15-03

Multistage Vectored Nanotherapeutics for Breast Cancer Metastasis.

Shen H. The Methodist Hospital Research Institute, Houston, TX

Significant progresses have been made on overall survival rates in breast cancer. The five-year survival rate of women diagnosed with Stage I-III breast cancer has been steadily improving decades over decades. These improvements in survival have primarily been attributed to availability of modern diagnostic tools that allow for early detection, and the increased use of adjuvant systemic therapies. However, the situation with breast cancer metastasis is discouraging, with only marginal improvement in some reports to no improvement at all in other studies in survival of the relapsed metastatic patients. More breast cancer patients are killed by cancer metastasis than by the primary cancer.

Nanotechnology has played an important role in the fight against breast cancer in the last decade. The first nano-liposomal formulation of doxorubicin (Dox), Doxil, was FDA approved in 1994, and is currently used to treat multiple cancer types including recurrent and refractory breast cancers. More nano-formulated drugs have since been approved. These nanotherapeutics work based on the enhanced permeability and retention (EPR) effect, and still cause severe toxicity to the body, however. To overcome these defects of the first generation of nanotherapeutics, we have developed a silicon-based multistage vector (MSV) system with the aim to specifically delivery drugs to cancer tissues with the least toxicity to the normal organs. These are particle-in-particle “Russian Doll” systems with each stage designed to provide transport across a set of sequential biological barriers, and provide associated levels of targeting specificity. We have demonstrated highly reproducible therapeutic efficacy with this system to deliver the conventional chemotherapy drugs and siRNA oligos.

We have generated mouse lung metastasis models with the human breast cancer cell line MDA-MB-231 which was engineered with a luciferase gene, and used multiple doxorubicin formulations to treat the tumor mice. These included free doxorubicin (3 mg/kg weekly), Doxil (6 mg/kg biweekly), a new formulation of doxorubicin in micelles (miDox, 6 mg/kg biweekly), and miDox in MSV (MSV/ Dox, 6 mg/kg biweekly). Tumor growth in the lung was monitored by bioluminescence with a Xenogen IVIS200 optical in vivo imaging system. As expected, treatment with free Dox caused significant weight loss indicating drug toxicity, most likely to the heart. Tumor growth in the free Dox treatment group halted initially, but resumed two weeks later. The tumor cells in these animals might have developed resistance to Dox during the treatment. Doxil treatment also triggered weight loss initially. This correlates with the cardiac side effect of the drug observed in clinic. Neither miDox or MSV/ Dox caused weight loss. Tumor growth was also inhibited in mice treated with both formulations. The result was much more significant with MSV/Dox than with miDox. No tumor cells were observed in the lung after a 6-week treatment with MSV/Dox, while 40% of the miDox-treated mice still had residue, but detectable tumor cells in the lung. These results indicate that we have developed a powerful system for tumor-specific delivery of therapeutic in the treatment of breast cancer metastasis.

Masuda N, Izawa H, Ohno S, Rai Y, Sato Y, Ohsumi S, Hashigaki S, Nishizawa Y, Saeki T, Noguchi S. NHO Osaka National Hospital, Osaka, Japan; Aichi Cancer Center Hospital, Aichi, Japan; Kyushu Cancer Center, Fukuoka, Japan; Sagarara Hospital, Kagoshima, Japan; Nagoya Medical Center, Aichi, Japan; Shikoku Cancer Center, Ehime, Japan; Pfizer Japan Inc., Japan; Saitama Medical University International Medical Center, Saitama, Japan; Osaka University, Osaka, Japan

**Background**  
The steroidal irreversible aromatase inhibitor (AI) exemestane (E), the non-steroidal reversible AI anastrozole (A) and tamoxifen (T) are approved for the first-line treatment of the postmenopausal women with hormone receptor (HR) positive advanced breast cancer (ABC) in Japan. Although there are some studies which compare the efficacy and safety of AIs and T in the first-line disease setting, the number of studies that compare efficacy and safety of AIs is limited. We conducted this multicenter, randomized, double-blinded non-inferiority study, to evaluate the time to progression (TTP) in HR positive ABC randomized to therapy with E or A.

**Methods**  
Patients (pts) who were ≥20 years [yrs], postmenopausal, ECOG PS ≤1 and had HR positive ABC that recurred after the adjuvant therapy or metastatic disease settings were eligible and randomized (1:1) to 25 mg/day of E or to 1 mg/day of A. Data were evaluated for non-inferiority of E compared to A defined as the upper limit of a two-sided 95% confidence interval (CI) of the hazard ratio (HR) of TTP being less than or equal to 1.25. The primary endpoint was TTP assessed by the independent radiological images review committee (RIRC). Secondary endpoints included TTP by investigator, time to treatment failure, overall survival (OS), objective response rate (ORR), clinical benefit rate, and safety.

**Results**  
A total of 298 pts from 58 sites were randomized to E (n=149; mean age: 63.4 yrs) or A (n=149; mean age: 64.0 yrs). The mean BMI for the E and A arms were 23.0 kg/m² and 23.6 kg/m², respectively. Six pts (2 pts in E arm, 4 pts in A arm) were excluded from the full analysis set due to lack of evaluation for anti-tumor response after study medication started. Median TTP (as per RIRC) was 13.8 months (M) vs 11.1 M for E vs. A, respectively (HR 1.007; 95% CI: 0.771–1.317). Median TTP (Investigator) was 13.8 M vs. 13.7 M for E vs. A, respectively (HR 1.059; 95% CI: 0.816–1.374). The median OS for A treated pts was 60.1 M, OS for E was not reached (as of data cut-off: December 8, 2010). ORR for E was 43.9% (95% CI: 35.3–52.8) and 39.1% (95% CI: 30.6–48.1) for A. Other analyses, including sub-population analyses are ongoing.

The incidence of treatment related adverse events (AEs) in E arm was 71.1% (n=106) and in A arm 59.7% (n=89); the AEs were mostly grade 1 and 2 in 61.7% (n=92) and 53.7% (n=80) of pts respectively. They were expected and manageable. Treatment related SAEs were similar in both groups: 6 (4.0%) in E arm and 5 (3.4%) in A arm. The most common AEs for E were hot flushes (22.1%), arthralgias (16.8%), musculoskeletal stiffness (11.4%) and γ-GTP increased (10.1%); in A arm, hot flushes (14.8%) and arthralgia (16.8%) were observed in >10% pts.

**Conclusions**  
Although median TTP (RIRC) of E is slightly improved compared with that of A, the result of TTP did not meet the non-inferiority criteria. There were no significant differences found between E and A in ORR. Although AEs in E were numerically higher, the observed AE profiles were similar to those previously reported for E and A. This study shows that E is comparable to A in efficacy and safety.

**Background**  
Figitumumab (CP-751,871) is a fully human IgG2 monoclonal antibody that inhibits IGF-1R. Exemestane profoundly reduces estrogen production and has activity as first-line treatment in postmenopausal metastatic hormone receptor-positive (HR+) breast cancer (BC). Preclinical studies suggest cross-talk between the IGF-1R and estrogen receptor pathways. Combining agents that inhibit these pathways could benefit women with advanced BC.

**Methods**  
This was an open-label, multicenter, randomized, phase II trial of first-line figitumumab + exemestane (Arm A) vs. exemestane alone (Arm B) in HR+ postmenopausal advanced BC. Eligibility included: age >18 yrs with Stage IIB or IV disease; baseline ECOG PS ≤2. A high rate of grade [G] 3 and 4 hyperglycemia after figitumumab treatment prompted a protocol amendment in February 2010 requiring patients (pts) to have a baseline HbA1c <5.7%. Patients received exemestane 25 mg po daily ± intravenous figitumab 20 mg/kg every 21 days. The primary endpoint was progression-free survival (PFS) in pts with baseline HbA1c <5.7%. Secondary endpoints included clinical benefit rate (CBR) and safety.

**Results**  
Between 2007 and February 2011, 103 pts were randomized to Arm A and 102 to Arm B. Of these, 37 pts in Arm A and 40 pts in Arm B had baseline HbA1c <5.7%. These data are from an unplanned interim analysis which preceded premature study termination by the Sponsor for clinical development reasons and to expedite availability of data collected to date. Baseline demographics were balanced between arms. PFS, CBR and safety are summarized in Table 1.

**Conclusions:**

The addition of figitumumab to exemestane was tolerable but overall did not improve PFS compared with exemestane alone in pts eligible for this trial. However, a trend toward benefit with figitumumab combined with exemestane in pts without evidence of baseline metabolic syndrome (HbaA1c <5.7%) was observed together with improved tolerability; further study with this combination may be warranted.

**P1-17-02**

A Phase 1/2 Study of SAR245408 (S08) in Combination with Trastuzumab (T) or Paclitaxel (P) and T in Patients with HER2+ Metastatic Breast Cancer (MBC) Who Progressed on a Previous T-Targeted Regimen.

**Methods:**

We are conducting a phase I study to determine the maximum tolerated dose (MTD), pharmacokinetic (PK) and pharmacodynamic profiles (PD), and preliminary anti-tumor activity of veliparib in combination with CP and V in patients (pts) with pretreated metastatic breast cancer.

**DISCUSSION:**

S08 can be combined with either T or with T+P. Additional safety, PK and efficacy data will be presented from phase 1.

Phase 1 Study of PARP Inhibitor ABT-888 (Veliparib) in Combination with Cisplatin and Vinorelbine for Patients with Advanced Triple Negative Breast Cancer and/or BRCA4-Mutation Associated Breast Cancer.

Rodler ET, Specht JM, Gadi VK, Kurland BF, Griffin MJ, Hammond JJ, Gralow JR, University of Washington/Seattle Cancer Care Alliance, Seattle, WA; Fred Hutchinson Cancer Research Center, Seattle, WA

**Background:**

Inhibitors of poly(ADP-ribose) polymerase (PARP) have shown preclinical and clinical activity in targeting tumors with pre-existing DNA repair defects, in particular BRCA1 and BRCA2 deficient tumors. Cisplatin (CP) has demonstrated synergy with ABT-888 (veliparib) in breast cancer xenograft models and has anti-tumor activity in triple negative (TN) and BRCA4-1 deficient breast cancer. Vinorelbine (V) combined with CP has shown safety and efficacy in patients with pretreated metastatic breast cancer. Methods: We are conducting a phase I study to determine the maximum tolerated dose (MTD), pharmacokinetic (PK) and pharmacodynamic profiles (PD), and preliminary anti-tumor activity of veliparib in combination with CP and V in patients (pts) with metastatic breast cancer who are either TN or who have BRCA1 or BRCA2 mutation associated breast cancer. Cohorts receive escalating doses of ABT-888 orally BID days 1-14, CP 75 mg/m2 intravenously (IV) day 1 and V 25 mg/m2 IV days 1,8 every 21 days, in a 3+3 design. Results: As
of 6/14/11, 18 eligible female pts have been enrolled. The median age at registration was 50 years (range 34-78 years). Sixteen pts received at least one prior metastatic regimen (range 0-8). Three pts had previously treated brain metastases. **BRCA** mutation status was as follows: **BRCA1**+ (3 pts); **BRCA2**+ (2 pts); confirmed mutation negative (8 pts); unknown (5 pts). Four pts received the 20 mg BID veliparib dose (one patient in the cohort died of progressive disease early in cycle 1 and was replaced), 3 received 30 mg BID, 6 received 40 mg BID, and 5 have been enrolled at dose level 4 (60 mg BID). Dose limiting toxicities occurred in one patient at the 40 mg BID dose (grade 4 thrombocytopenia), and one patient at the 60 mg BID dose (grade 3 neutropenic fever). Adverse events are typical for a platinum-based chemotherapy regimen and include nausea, fatigue, thrombocytopenia, and neutropenia. MTD has not been reached. Of 11 pts evaluable for radiographic response to date, 6 (55%) had a PR (3 of whom have a **BRCA** mutation) and 5 (45%) had stable disease. Correlative studies will use immunohistochemistry and gene expression array to evaluate the profile of TN breast cancer and predictors of response to treatment. **Conclusion:** Veliparib in combination with CP and V has been generally well tolerated to date. Objective anti-tumor activity was seen in **BRCA** mutation carriers and in pts with sporadic TN breast cancer. PK, PD, and biomarker analysis is underway. Enrollment continues in the dose escalation cohorts.

**Preliminary Results of a Randomized Phase 2 Study of PD 0332991, a Cyclin-Dependent Kinase (CDK) 4/6 Inhibitor, in Combination with Letrozole for First-Line Treatment of Patients (pts) with Post-Menopausal, ER+, HER2-Negative (HER2–) Advanced Breast Cancer.**

Finn RS, Crown JP, Boer K, Lang I, Parikh RJ, Patel R, Schmidt M, Hagenstad C, Lim H, Pinter T, Amadori D, Chan D, Dicelmman RA, Walshe J, Brezuzna A, Kim ST, Randolph S, Slamon DJ. University of California at Los Angeles, Los Angeles, CA; Irish Cooperative Oncology Research Group, Dublin, Ireland; Szent Margit Koriha, Budapest, Hungary; National Institute of Oncology, Budapest, Hungary; Comprehensive Cancer Centers of Nebraska, Henderson, NV; Comprehensive Blood and Cancer Center, Bakersfield, CA; University Hospital Mainz, Mainz, Germany; Suburban Hematology-Oncology Associates, Lawrenceville, GA; British Columbia Cancer Agency, Vancouver, BC, Canada; Peto Aladar Megyei Okato Korhau, Gyor, Hungary; Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori, Meldola, Italy; Cancer Care Associates Medical Group, Redondo Beach, CA; Central Coast Medical Oncology Corporation, Santa Maria, CA; Pfizer Oncology, La Jolla, CA; Pfizer Oncology, New York, NY

**Background:** PD 0332991 is an orally bioavailable selective inhibitor of CDK 4/6 and prevents cellular DNA synthesis by inhibiting progression of the cell cycle from G1 into the S phase. Preclinical evaluations suggest that reduction in **CDK2A** (p16) expression and cyclin D1 (CCND1) overexpression confer susceptibility to PD 0332991 (Finn 2009). In addition, PD 0332991 was synergistic in combination with tamoxifen in vitro in ER+ human breast cancer cell lines. Based on these observations, a phase 1/2 study in combination with letrozole as first-line therapy for advanced ER+ post-menopausal breast cancer was initiated. The phase 1 part of the study (completed) determined the recommended phase 2 dose to be PD 0332991 125 mg QD on Schedule 3/1 (3 weeks on treatment followed by 1-week off treatment) in combination with letrozole 2.5 mg QD. The combination was generally well tolerated and encouraging antitumor activity was observed. We present preliminary data from the randomized Phase 2 portion comparing letrozole alone to letrozole plus PD 0332991.

**Methods:** The Phase 2 portion of the study is designed as a two-part study; we present data from Part 1. In both parts, eligible patients are randomized 1:1 to letrozole 2.5 mg QD alone (control) or PD 0332991 125 mg QD on schedule 3/1 and letrozole 2.5 mg QD (treatment, tx). Part 1 enrolled post-menopausal women with ER+, HER2– cancer using only ER+, HER2– as a selection criteria. Part 2 is now enrolling post-menopausal women with ER+, HER2– breast cancer with CCND1 amplification and/or loss of p16 by FISH (target N=150). The primary endpoint is progression-free survival (PFS); secondary endpoints include overall survival, response rate, safety, and correlative studies. Pts are stratified for disease site and length from prior adjuvant therapy. Pts continue assigned study treatment until disease progression, unacceptable toxicity, or consent withdrawal and are followed every 2 months to assess disease status. Tumor tissue was required for participation. **Results:** 66 patients have been randomized in Part 1. At the time of data cut-off (April 2011) median duration of treatment is 20 (range 4–64) wks for control and 27 (2-59) wks for tx. Dose reductions occurred in 9 pts on the tx arm and none on the control arm. There are no complete responses. The number of partial responses for pts with measurable disease are similar between arms (4/22 control vs 5/24 in tx). The number of pts with stable disease≥ 24 weeks was higher in the tx arm (5 vs 8). The number of pts with best response of progressive disease is lower in the treatment arm (2 vs 6). PFS data are immature. Twelve pts remain on control vs. 21 on tx. As in the Phase I portion of the study, the most common treatment-related AEs were neutropenia and leukopenia without febrile neutropenia. Biomarker studies for CCND1 amplification, p16 loss, RB status, and Ki67 are ongoing. **Conclusion:** The combination of PD 0332991 and letrozole is well tolerated as first-line treatment of ER+, HER2– post-menopausal breast cancer. Updated efficacy data and biomarker data will be presented.

**P1-17-06**

**A Phase II Trial of the CDK 4/6 Inhibitor PD0332991 in Women with Advanced Breast Cancer.**

**Background:** Dysregulation of the G1/S checkpoint of the cell cycle is a feature of many breast cancers. PD0332991, a potent oral inhibitor of cyclin-dependent kinases (CDKs) 4 and 6 is well-tolerated and has demonstrated activity in a phase I trial in a variety of solid tumors. The combination therapy (tamoxifen plus PD0332991) was generally well tolerated with a manageable safety profile. In the phase II dose of 125 mg daily on a 3-week on/1-week off schedule. Preclinical data suggest that this agent is most active in ER+ (luminal) breast cancers. We are performing a phase II study of PD0332991 in women with advanced breast cancer, one of several parallel disease cohorts under study.

**Methods:** Patients with histologically-confirmed stage IV breast cancer were eligible if they had primary or metastatic tissue from prior adjuvant therapy. Pts are stratified for disease site and length from prior adjuvant therapy. Pts continue assigned study treatment until disease progression, unacceptable toxicity, or consent withdrawal and are followed every 2 months to assess disease status. Tumor tissue was required for participation. **Results:** 66 patients have been randomized in Part 1. At the time of data cut-off (April 2011) median duration of treatment is 20 (range 4–64) wks for control and 27 (2-59) wks for tx. Dose reductions occurred in 9 pts on the tx arm and none on the control arm. There are no complete responses. The number of partial responses for pts with measurable disease are similar between arms (4/22 control vs 5/24 in tx). The number of pts with stable disease≥ 24 weeks was higher in the tx arm (5 vs 8). The number of pts with best response of progressive disease is lower in the treatment arm (2 vs 6). PFS data are immature. Twelve pts remain on control vs. 21 on tx. As in the Phase I portion of the study, the most common treatment-related AEs were neutropenia and leukopenia without febrile neutropenia. Biomarker studies for CCND1 amplification, p16 loss, RB status, and Ki67 are ongoing. **Conclusion:** The combination of PD 0332991 and letrozole is well tolerated as first-line treatment of ER+, HER2– breast cancer. Updated efficacy data and biomarker data will be presented.

**241s** Cancer Res; 71(24 Suppl.) December 15, 2011
Results: 36 patients were screened, 32 (89%) stained positive for Rb, and 14 have enrolled on study. The only reported toxicities are neutropenia (7 patients, 4 grade 3/4), thrombocytopenia (1 patient, grade 1) and fatigue (1 patient, grade 2). 3 patients (23%) have had dose interruptions and 5 (38%) have had dose-reduction for neutropenia, though no episodes of febrile neutropenia have occurred. Among 11 patients assessable for response to date, there is 1 (7%) partial response (PR), 6 (43%) with stable disease (SD) and 4 (29%) with progressive disease (PD). 3 of 6 patients with stable disease have received greater than 6 months of therapy, and these sustained responses have occurred with dosing as low as 50 mg/day. All PR/SD have occurred in patients with ER+ tumors; all PD have been in patients with triple negative (ER-/PR-/Her2-) disease. The cyclin D1 status of all patients are being assessed. Of the 10 ER+ patients, 3 are cyclin D1 amplified, 5 are non-amplified and 2 are pending assessment. 2 in 4 cyclin D1 non-amplified patients had SD, while 2 of 2 evaluable patients with amplification had PD. PK and PD analyses are in progress.

Conclusions: PD 0332991 is an extremely well-tolerated, oral CDK 4/6 inhibitor that demonstrates prolonged single-agent activity in ER+ breast cancer patients who have progressed on hormonal therapy. These data have prompted expansion of this breast cancer cohort to further delineate activity and translational studies examining predictors of response are underway.

P1-17-07
Phase II Trial of RAD001 Plus Carboplatin in Patients with Triple-Negative Metastatic Breast Cancer.

Background: RAD001 is an oral mTOR inhibitor that has exhibited activity in breast cancer. Triple negative breast cancer patients are unable to repair double stranded DNA breaks and hence have sensitivity to platinum agents that cause interstrand cross-links. Rapamycin acts synergistically with platinum agents to induce apoptosis and to repair double stranded DNA breaks and hence have sensitivity to platinum agents that cause interstrand cross-links. Consequently, we are investigating a phase II trial of RAD001 plus carboplatin in patients with triple negative metastatic breast cancer.

Methods: This study is a phase II trial that will enroll 25 women with hormone-refractory, HER2-negative breast cancer which has progressed to first or second line therapy. Eligibility criteria include hormone receptor positive, triple-negative breast cancer with measurable disease, age 18-70, Karnofsky performance status of 70-100%, adequate marrow, prior trastuzumab is not allowed. Patients will be treated with 10mg of RAD001 orally daily for 21 days, followed by 1 week of rest. Carboplatin AUC=6 will be administered intravenously every 3 weeks.

Results: Fourteen patients of a planned 25 have been recruited thus far. Median age is 58.5. Median number of prior regimens is 2 (0-3). Of the 7 patients assessable for response at this time, there have been 2 PR’s and 5 patients with SD. One SD was achieved in a patient progressing on single agent carboplatin at study entry. Median duration of SD + PR is 28.5 weeks (5 patients have ongoing response ranging from 8-46.5 weeks). Five of 8 patients assessable for toxicity had grade 3 or 4 thrombocytopenia and 2 patients had grade 3 neutropenia. No cases of febrile neutropenia were observed. Four patients have required blood transfusion and one patient has required platelet transfusion. All patients have had treatment held and/or dose reductions secondary to hematological toxicity, however, since amended carboplatin dose the regimen has been very well tolerated with only one out of six patients) with grade 3 neutropenia and grade 3 thrombocytopenia. There have been no non-hematological grade 3 or 4 toxicities. Conclusions: Clinical benefit was observed in all 7 assessable patients. Dose limiting thrombocytopenia was an unexpected side effect requiring protocol amendment. We continue to accrue study subjects at the amended dosing.
3 AEs were limited to 2 pts: 1 with an asymptomatic and reversible elevation in serum amylase, and the other with abdominal pain and diarrhea requiring a dose reduction to 175 mg/m². Of the 10 pts evaluable for efficacy, there is 1 confirmed partial response (PR), 1 minor response (MR) and 2 pts with stable disease (14%). The pt with MR had TNBC and was taken off-study due to a complicated pneumonia requiring hospitalization (unrelated). The remaining 3 pts had HER2+/BC; 2 of these 3 (1 PR, 1 SD) are continuing on study and have completed 4 cycles thus far. Updated toxicity and efficacy data will be presented.

Conclusions: These data show activity for single agent ganetespib in different subtypes of breast cancer. Ganetespib was well tolerated, with expected gastrointestinal toxicity that was mild in nature and manageable in all patients. Accrual continues and we will present updated data at the meeting.

P1-17-09
A Phase 1/2 Dose-Escalation Study of SAR245408 (S08) or SAR245409 (S09) in Combination with Letrozole (L) in Subjects with Hormone Receptor-Positive and HER2-Negative (HR+/HER2-) Breast Cancer (BC) Refractory to a Nonsteroidal Aromatase Inhibitor (AI).

Baselga J, Tolaney S, Hart L, Gomez P, Gartner E, DeCillis A, Ruiz-Soto R, Lager J, Burris H. Massachusetts General Hospital, Boston, MA; Dana Farber Cancer Institute, Boston, MA; Florida Cancer Specialists Drug Development Unit, Ft Myers, FL; HU Vall d’Hebron Oncology Service, Barcelona, Spain; Wayne State University/Karmanos Cancer Institute Hematology/Oncology, Detroit, MI; Exelixis, San Francisco, CA; Sanofi, Cambridge, MA; Sarah Cannon Research Center, Nashville, TN

Background: Upregulation of PI3K activity is a common molecular mechanism involved in resistance to AIs. S08 is a potent, orally bioavailable, pan-PI3K inhibitor. S09 is a potent, orally bioavailable inhibitor of PI3K which also possesses mTOR inhibitory activity. Both compounds exhibit robust PI3K and ERK pathway inhibition in paired human tumor biopsy samples from phase 1 studies (Edelman G, et al. ASCO 2010; Brana I, et al. ASCO 2010).

Methods: This ongoing, open-label, multicenter, phase 1/2 study (NCT01082068) was designed to evaluate the safety and tolerability of L in combination with either S08 (Arm 1) or S09 (Arm 2). Eligible female patients (pts) were ≥18 yrs, ECOG PS 0-1, with advanced or metastatic BC refractory to an AI. Up to 4 prior treatment regimens (hormonal excluded) for MBC were allowed. Tumor response was assessed every 6 wks per mRECIST 1.0. Treatment beyond wk 12 was based on response: pts with partial response (PR) continued with open-label cabozantinib, those with stable disease (SD) were randomized to cabozantinib or placebo, and those with progressive disease were discontinued. The primary endpoint was objective response rate (ORR) in the lead-in period, and progression-free survival in the randomized period. Post-hoc evaluations of bone scans were conducted.

Results: 20 MBC pts were enrolled with a median age of 55 years (range: 31-71). 19 pts had invasive ductal carcinoma (1 pt with inflammatory MBC), and 1 pt had invasive lobular carcinoma. 75% of pts were ER/PR [+]; 15% were HER2/neu [+]. 85% of pts had visceral disease including 65% with liver metastases; 70% had bone disease. The median number of prior regimens was 3; 45% received prior anti-VEGF therapy. Most common related adverse events ≥ Grade 3 were fatigue/asthenia, 20%; and hand-foot syndrome, 20%. Dose reductions and permanent discontinuations for AEs occurred in 35% and 15% of pts, respectively. Soft tissue effects: At wk 12, ORR
per RECIST was 10% and overall disease control rate (PR+SD) was 45%. Notably, tumor shrinkage was observed in 15/16 pts (94%) with ≥1 post-baseline tumor assessment. Bone effects: 2/3 pts evaluable by bone scan at baseline had partial resolution of lesions and one pt had SD on follow-up bone scans as early as Wk 6. Out of 7 pts receiving narcotics for bone pain, 3 pts reported improved pain and 2 pts had decreased narcotic use, per investigator. The majority of pts analyzed had declines in plasma CTx, an osteoclast marker. Additional enrollment and further bone marker analyses are ongoing.

Conclusions: Cabozantinib exhibits clinical activity in pts with MBC regardless of receptor and prior treatment status as reflected by high rate of tumor regression and effects on bone metastases. Cabozantinib is generally well tolerated and the safety profile is comparable to that seen with other tyrosine kinase inhibitors.

P1-18-01
Z-ACT1: Zometa Combined with Standard Therapy in Patients with Metastatic Breast Cancer Further Decreases the Proportion of Patients with CTC Counts of 5 or above.
Bruzicky A, Beck J, Dakhil S, Hallmeyer S, Tezcan H, Yardley D, Tran D, Warsi G, Culver K. McGee Women’s Hospital of University of Pittsburgh Medical Center, Pittsburgh, PA; Highlands Oncology Group, Fayetteville, AR; Cancer Center of Kansas, Wichita, KS; Oncology Specialist, SC; Park Ridge, IL; Kootenai Cancer Center, Post Falls, ID; Sarah Cannon Research Institute, Nashville, TN; Tennessee Oncology, PLLC, Nashville, TN; Novartis Pharmaceuticals Corporation, East Hanover, NJ

Introduction: Zoledronic acid (ZOL) has been shown to reduce the risk of recurrence and residual tumor size in the adjuvant/neoadjuvant setting in patients with early/intermediate-stage breast cancer (BC). In addition, ZOL combined with neoadjuvant chemotherapy reduced numbers of disseminated-tumor cells in the bone marrow compared with chemotherapy alone. However, the activity of ZOL on disseminated- or circulating-tumor cells (CTCs) in patients with metastatic breast cancer (MBC) is not well defined. Cristofanilli M, et al (J Clin Oncol. 2005; 23: 1420-30) reported that CTCs in MBC are an independent predictor of overall survival (OS) and progression-free survival (PFS). Accordingly, this study is evaluating the potential anticaner benefit of adding ZOL to standard therapy in patients with newly diagnosed MBC as assessed by the change in CTC count from baseline to 3-5 weeks.

Methods: Eligible patients had HER2-negative MBC, newly diagnosed or at first relapse after adjuvant therapy with or without bone metastases. In this open-label 3-arm study, patients without bone metastases were randomized to standard therapy + ZOL every 3-4 weeks for the first 6 months (Arm A) or standard therapy + ZOL during month 6-12 after standard therapy initiation (Arm B). All patients with bone metastases received ZOL every 3-4 weeks (Arm C). The primary endpoint is PFS. Secondary endpoints include the proportion of patients with CTCs ≥5 or <5 per 7.5 mL of peripheral blood 3-5 weeks after standard therapy initiation. Data were compared with historical controls (patients with MBC receiving first-line standard treatment alone; Cristofanilli M, et al. 2005). CTCs were quantified using CellSearch™.

Results: In Z-ACT1, 29 previously untreated MBC patients with bone metastases were enrolled in Arm C, all of whom had ≥1 CTC at study entry (range, 1-117). 53% received hormonal therapy alone, 42% chemotherapy alone, and 5% received various combinations. In patients receiving standard therapy + ZOL, the percentage of patients with CTC ≥5 decreased from 55% to 25% at 3-5 weeks. At baseline, the median uNTX level was 46.5 (n = 10) in patients with < 5 CTCs and 57 in patients with ≥5 CTC (n = 13). At 3-5 weeks, the median decrease from baseline in uNTX was 74% (n = 10) in the < 5 CTC group and 25% (n = 5) in the ≥5 CTC group. At 3-5 weeks, the median uNTX levels in the <5 and ≥5 CTC groups were 12 and 22 nmol bce/mmol, respectively. This study has now been modified to a 2-arm study (standard therapy +/- ZOL) in MBC patients with no bone metastases. CTC, uNTX, and PFS data will be presented from this new head-to-head analysis. Changes in CTCs out to 6 months and correlation with uNTX and PFS in this original bone metastasis cohort will also be presented.

Conclusions: This preliminary analysis suggests that the addition of ZOL to standard therapy in women with bone metastases from MBC results in a further decrease in CTC numbers at 3-5 weeks after initiation of therapy.

P1-18-02
Descriptive Analysis of the Management of Breast Cancer Patients with a Solitary Lesion Diagnosed with 18-Fluorodeoxyglucose Positron Emission Tomography/Computed Tomography Scan.
Redmana S, De Carolis V, Racca M, Zago G, Varetto T, Montemurro F, Aglietta M, Evangelista L. Fondazione Piemontese per l’Oncologia - IRCC, Candiaio, TO, Italy; Istituto Oncologico Veneto - IOV, Padova, PD, Italy

Background: A small percentage of breast cancer (BC) patients (pts) will develop oligo-metastatic disease (OMD), often with a solitary lesion (SL). Growing evidences suggest a survival benefit for pts who undergo local treatment for SL. However, 18-fluorodeoxyglucose (FDG) positron emission tomography/computed tomography (PET/CT) scan might improve the detection of truly SL, an important prerequisite for local treatments. We describe pattern of presentation and management of pts with SL diagnosed by FDG-PET/CT.

Methods and Patients: From a bi-institutional database we retrospectively identified 137 pts who underwent a PET/CT because of rising tumor markers (95, 69%) or clinical/radiological suspect of disease recurrence (42, 31%). Median time from surgery of primary tumor to metastatic progression was 48 months (range 6-216 months). Comparisons of categorical and continuous variables were analyzed by the Chi-Square test and Mann-Whitney U test. Significance was set at p<0.05.

Results: PET/CT was positive in 78/137 pts. In 35 pts (26%) abnormal PET/CT findings consisted of a single area of increased metabolic activity, whereas in the other 43 (31%) multiple hyper-metabolic lesions were found. Twenty/thirty-five pts with single hyper-metabolic spots had confirmed malignant SL: 17 (49%) were BC recurrences and 3 (9%) were new primary tumors other than BC. In the remaining 15 pts, hyper-metabolic SL were consistent with areas of inflammation, past trauma, thyroid struma and physiological ovarian functioning. Eight pts with SL (2: liver, 3: bone, 2: soft tissues, 1: lung) underwent local therapy, which consisted of surgical excision + radiation therapy (4 pts), percutaneous cementoplasty and radiation therapy (2 pts), radiation therapy alone (1 pts) and percutaneous radiofrequency ablation (1 pts). After local treatment 7 pts also received systemic therapy: chemotherapy for 3 and endocrine therapy for 4 pts. Pts with solitary bone lesion also received zoledronic acid. Nine pts received only systemic therapy (4: soft tissues, 2: bone, 2: liver, 1: lung). Median age at the time of diagnosis of SL, histology of primary tumor, hormone receptor status, HER2 status, site of SL and prior exposure to adjuvant chemotherapy did not differ between pts treated with local or systemic therapy. At the time of this analysis,
11/17 pts with confirmed SL had progressed (5 had been treated with local and systemic therapy and 6 with systemic therapy alone), and all the pts were alive.

Discussion: Our retrospective analysis suggests that FDG-PET/CT is a useful tool to identify BC pts with OMD susceptible of local and aggressive treatment, despite the impressive number of solitary non-neoplastic lesions. Our numbers are too small to point out any benefit from the addition of local over systemic treatment, and survival analyses were not significant. Nevertheless, due to growing evidences of a benefit of aggressive treatments for SL, treatment options for pts with OMD cannot leave aside local treatments. However, with the limitation due to small numbers and retrospective design, our data are hypothesis generating, and should be interpreted with caution.

Pharmacological Inhibition of RANKL Attenuates Mammary Tumor Development and Lung Metastases in the MMTV-neu Transgenic Spontaneous Tumor Model.

Background: RANK and its ligand (RANKL), key factors for bone remodeling and metastasis, are crucial for the development of mouse mammary glands during pregnancy. In a mouse model of mammary carcinogenesis induced by the hormone medroxyprogesterone (MPA) and a carcinogen (DMBA), treatment with a RANKL inhibitor RANK-Fc reduces hormone-induced mammary epithelial proliferation, incidence of preneoplasias, and mammary adenocarcinomas. This study assessed the expression of mouse RANK and RANKL in FVB wild-type (WT) and MMTV-neu mice and whether RANKL inhibition could inhibit mammary tumor formation and lung metastases in this model.

Materials and Methods: MMTV-neu mice were treated with the RANKL inhibitor RANK-Fc (10 mg/kg, 3x/week) or vehicle (muFc) beginning at 20 weeks. Mammary tumor formation was determined by palpation and confirmed by histologic examination. The presence of preneoplastic lesions and histotype of tumors was determined on H&E-stained tissues. Entire lungs from tumor-bearing MMTV-neu mice were step-sectioned at 75 μm and assessed histologically for the presence of metastases. Epithelial proliferation was measured by BrdU labeling of the mammary epithelium. The expression of RANK, RANKL, cyclin D1, progesterone receptor (PR), F4/80, FOXP3, and CD3 was determined by immunohistochemistry (IHC).

Results: RANK-Fc treatment of MMTV-neu mice resulted in a significant reduction in total number of mammary tumors and lung metastases quantified at necropsy but did not impact median survival.

Discussion: RANKL is expressed in normal mammary epithelia of MMTV-neu mice but is not detected in any stage of atypia, including MIN, mammary adenocarcinoma, or lung metastases. Selective pharmacological inhibition of RANKL by RANK-Fc treatment attenuated mammary tumor development and lung metastases in the MMTV-neu transgenic spontaneous tumor model.

P2-01-03
Insulin-Like Growth Factor I (IGF) Induced Metastasis Signature Correlates with Poor Prognosis and Decreased Distant Metastasis-Free Survival in Human Breast Cancer.
Sachdev D, Sarver AL. University of Minnesota, Minneapolis, MN

The insulin-like growth factors (IGFs) acting via the type I insulin-like growth factor receptor (IGF-1R) regulate tumor growth, survival and metastasis of multiple types of cancers. Agents targeting IGF-1R are currently being tested in phase II/III clinical trials in human cancers. We have previously reported that IGF1R can regulate metastasis independently of primary tumor growth in a model of high risk metastatic breast cancer using the triple negative MDA435/LCC6 metastatic cancer cells, which form spontaneous lung metastases when injected into the mammary fat pad of mice. We have shown that disruption of IGF signaling either with an antibody against IGF1R, AVE1642, or a dominant negative IGF-1R construct, does not affect growth in the mammary fat pad but inhibits pulmonary metastases and colonization of the lungs. Regulation of such a phenotype will not be measured in clinical trials and these findings imply that clinical trials of this therapeutic strategy may need to adjust their endpoints for assessing benefit by taking into account that inhibition of IGF1R signaling may inhibit metastasis but not primary tumor growth.

Here, we sought to develop an IGF induced metastasis signature that may be useful in selecting patients that could benefit from IGF1R targeted therapy and determine if changes in expression of the genes in the signature can be useful in monitoring response. Serumstarved LCC6-WT cells (with wild-type functional IGF1R) and LCC6-DN (cells with dominant negative IGF1R) were treated with IGF-I, AVE1642 (fully human antibody against IGF1R that inhibits metastasis but not tumor growth in the mammary fat pad), or AVE1642+ IGF-I for 4 and 24 hours and microarray analysis was performed using the U133 Plus 2.0 human arrays with 47,000 transcripts. IGF-I regulated over 100 transcripts in LCC6-WT cells compared to IGF-I in LCC6-DN cells. Over 400 transcripts were basally differentially expressed in LCC6-WT cells compared to LCC6-DN cells. Array data were also analyzed to determine genes regulated by IGF-I signaling in LCC6-WT cells compared to untreated LCC6-WT cells and if disruption of signaling with AVE1642 affected genes whose expression was regulated by IGF-I signaling. A total of 263 transcripts were regulated by IGF signaling in LCC6-WT cells compared to untreated cells and AVE1642 treatment reversed the regulation of all transcripts induced by IGF-I in LCC6-WT cells.

53 of the most significantly regulated genes were used to query two different human breast tumor datasets to determine if genes in IGF signaling induced metastasis signature are associated with lymph node metastasis and poor prognosis in human tumors. IGF regulated metastasis signature genes were expressed in human tumors in the van’t Veer and Wang datasets. Further, IGF activated metastasis.
signature was correlated to decreased survival and decreased distant metastasis-free survival in breast cancer patients. Our results suggest that presence of IGF-induced metastasis signature in patients confers prognostic value and identifying IGF-driven metastasis signatures may be useful to identify and monitor patients who could benefit from IGFR1 targeted therapy for inhibition of metastatic disease.

P2-01-04
The Post-Partum Diagnosis of Pregnancy Associated Breast Cancer Confers an Increased Risk for Metastasis without Increased Incidence of Poorer Prognosis Biologic Subtype.
Borges VF, Callihan ES, Jindal S, Lyons T, Manthey E, Gao D, Schedin PJ. University of Colorado Anschutz Medical Campus, Aurora, CO; Colorado School of Public Health, Aurora, CO; University of Colorado School of Medicine, Aurora, CO

**Background:** All women who complete a childbirth have an increased risk for the subsequent breast cancer regardless of age at their first birth. In younger women, this period truncates 10 years later and pregnancy then becomes protective, whereas in older mothers the risk persists. Moreover, breast cancers diagnosed subsequent to a recent childbirth have an increased risk for metastasis and death. However much of the existing data is confounded by inclusion of cases diagnosed during pregnancy. **Hypothesis:** Our preclinical models of pregnancy associated breast cancer (PABC) has identified the “involution hypothesis”, where the normal physiologic post-partum breast involution is the pregnancy-related event promotional of breast cancer growth, invasion and metastasis. We have performed a retrospective cohort study, restricted to postpartum PABC and controls, to fully characterize post-partum PABC by biologic subtype and known predictors for metastasis. Also we identify if the specific period of post-partum PABC has a higher risk for metastasis then non-PABC, as predicted by our animal model studies. **Methods:** We performed a retrospective cohort of 527 cases of breast cancer diagnosed at age 45 or younger from 1981-2011. Pregnancy status was identified from medical records and defined as nulliparous (n=107), PABC (up to 5 years post-partum of last childbirth, n=114), and Later Parous (>10 years post-partum, n=239). Clinicopathological characteristics were obtained from pathology records. Outcomes data obtained through the University of Colorado Tumor Registrar. Hazard ratios of risk of metastatic recurrence of nulliparous and PABC groups were analyzed using a Cox Proportional Hazards Model and time to metastatic recurrence was analyzed using standard Kaplan Meier curves. **Results:** Compared to nulliparous cases, PABC cases were more frequently diagnosed at Stage IV (11.4% vs. 4.9%), T3 tumor size (17.3% vs. 13.1%), poorly differentiated (36.6% vs. 49.0%), lobular histology (4.5% v. 1.0%), with lymphovascular invasion (30.4% vs. 24.5%) and with involved lymphnodes (57.6% v. 48.6%). No differences were seen between Luminal A, Luminal B, Her 2 and Triple Negative subtypes. Average follow-up was 3.4 years for nulliparous, 3.5 for PABC and 4.6 for Later Parous. Survival analysis revealed a cumulative 5-year metastatic recurrence free probability of 80.6% for nulliparous, 68.5% for PABC and 80.5% for Later Parous. Compared to nulliparous, PABC had greater than a three times higher risk for subsequent metastatic recurrence (HR 3.29, 95% CI: 1.25-8.63). No significant difference in the risk of metastatic recurrence for Later Parous compared to nulliparous was observed (HR: 1.079, 95% CI: 0.46-2.55). **Conclusion:** Post-partum PABC is characterized by higher stage at diagnosis but without enrichment for poorer prognosis biologic subtypes. Post-Partum PABC has an increased risk for metastasis within five years of diagnosis, with an overall 3.29 times higher risk of a metastatic recurrence. These data support our hypothesis that the post-partum window, and the associated role of naturally occurring involution, may be promotional of tumor growth, invasion and metastasis as previously identified in our animal models.

P2-01-05
Integrin αvβ6 Mediates HER2-Driven Invasion in Breast Cancer.
Moore KM, Hart IR, Jones LJ, Marshall JF. Barts Cancer Institute - a CR-UK Centre of Excellence, Queen Mary University of London, London, Greater London, United Kingdom

We have shown strong expression of integrin αvβ6 reduces the 5 year survival of HER2-positive breast cancers from 66% (HR 1.84) for moderate/low αvβ6 expressing to 54% (HR 2.18) in cases with strong expression (2063 cases, unpublished). This is in direct comparison to HER2/αvβ6-double negative cases, where strong αvβ6 expression reduces survival from 86% (HR 1.00) to 77% (HR 1.20). The biological mechanism underlying these observations was investigated in two isogenic breast cancer models: MCF-7-neo-1 and MCF-7/HER2-18 (a gift from Prof. M-C. Hung, USA) and MCF10A and MCF10A.CA1a.

Flow cytometry showed MCF-7/HER2-18 expressed high levels of both HER2 and αvβ6 whereas MCF-7-neo-1 expressed low levels of both receptors. MCF10A and MCF10A.CA1a both expressed high levels of αvβ6 whereas only MCF10A.CA1a expressed elevated levels of HER2. In charcoal-stripped (cs)-serum, comparing MCF-7/neo-1 and MCF-7/HER2-18, HRGβ1 (1µM), which stimulates HER2/HER3 heterodimers, increased proliferation by 50.2%±9% (P=0.048) and 66.2%±5.5% (P=0.003), in MCF-7-neo-1 and MCF-7/HER2-18 cells respectively. In contrast, Herceptin reduced proliferation by 32.3%±13.4% (P=0.003) and 15.2%±3.4% (P=0.028), respectively. MCF10A and MCF10A.CA1a proliferation remained unchanged with HRGβ1 treatment and antibody-blockade of αvβ6 did not affect proliferation of any cell line. (NB, in complete serum there was no effect on proliferation of any of the above treatments). Invasion through Matrigel of MCF-7/HER2-18 was inhibited by antibody blockade (10µg/ml) of αvβ6 (mAb 10D5; 38.6%±20.8%, P=0.005) or HER2 (Herceptin, 10µg/ml; 40.1%±28.6%, P=0.01). The same trend was observed in MCF10A.CA1a invasion (83%±30.2% (P=0.025) with 10D5 and 80.4%±8.7% (P=0.022) with Herceptin). Combination of both antibodies had no additional effect.

siRNA knockdown of αvβ6 or HER2 in MCF-7/HER2-18 and MCF10A.CA1a cells also reduced invasion to a similar extent as the blocking antibodies. This suggests that HER2 driven breast carcinoma invasion is mediated by αvβ6. To investigate this further HER2/3 was stimulated with HRGβ1, which consistently increased invasion by 111.5%±35.4% (P=0.011) in MCF-7/HER2-18 cells and by 57%±34% (P=0.042) in MCF10A.CA1a cells; an increase that was abrogated by co-treatment with 10D5 or Herceptin.

To determine the mechanism through which HER2 and αvβ6 cooperate we examined several signalling pathways. Analysis of total or activated Akt, ERK1/2, e-Jun or Src in the MCF-7 model showed no changes. However, elevated total and phospho-Stat3 in MCF-7/HER2-18 were observed and siRNA knockdown, or small-molecule inhibition, of Stat3 suppressed invasion of MCF-7/HER2-18 cells (54.5%±27.3% (P=0.008) and 55.3%±33.3% (P=0.01) respectively), possibly suggesting that activation of Stat3 may link αvβ6 and HER2 co-operative signalling in this model. Interestingly, Akt was constitutively phosphorylated in MCF10A.CA1a cells and, moreover, 10D5 reduced these levels suggesting αvβ6 may influence HER2 signalling via Akt in these cells.

These data confirm HER2-driven invasion is αvβ6-mediated and
provide a mechanistic explanation for our clinical observations. We suggest HER2 and avp6 should be considered as dual targets for future therapy of some breast cancers.

P2-01-06
NSAID Analgesic Ketorolac Used Perioperatively May Suppress Early Breast Cancer Relapse: Something for Nothing in Breast Cancer

Retsky MW, Rogers RA, Demichelis R, Hrushesky WJM, Gukas ID, Vaidya JS, Baun M, Forget P, De Kock M. Harvard School of Public Health, Boston, MA; Istituto Nazionale Tumori, Milano, Italy; University of South Carolina, Columbia, SC; James Paget University Hospital, Great Yarmouth, United Kingdom; Royal Free and UCL Medical School, London, United Kingdom; Cliniques Universitaires Saint-Luc, Universite Catholique de Louvain, Brussels, Belgium

Background: Over a decade ago, we were confronted with data that showed an unexpected bimodal pattern of hazard of relapse among early stage breast cancer patients treated by mastectomy without any adjuvant systemic treatment. This pattern has now been identified in 20 independent databases from US, Europe and Asia. There is an early peak of relapses at 18 months, a nadir at 50 months and a broad second peak extending from 60 months to over 15 years. Fifty to eighty percent of relapses, the proportion increasing with primary tumor size, reside within the first peak. This pattern was not explainable by accepted theories. We proposed based on computer simulations that the broad second peak relapses result from steady stochastic progressions from single dormant malignant cells to avascular micrometastases and then on to growing deposits. To explain the first peak, we had to postulate that something happened at about the time of surgery to provoke sudden exits from dormant phases to active growth and then to detection. There was a particularly sharp early relapse mode within 10 months for premenopausal patients with positive nodes that appeared to be surgery-induced angiogenesis of dormant avascular micrometastases. We have been able to explain a wide variety of breast cancer observations with this hypothesis. These include high effectiveness of adjuvant chemotherapy only for premenopausal node positive women and why early detection works better for women age 50-59 than for women age 40-49.

Methods and Materials: Forget et al reported data from a retrospective study of 327 consecutive patients comparing various perioperative analgesics and anesthetics in one Belgian hospital and one surgeon. Patients were treated with mastectomy and conventional adjuvant therapy. Follow-up is average 27.3 months with range 13-44 months.

Results: NSAID ketorolac, a common analgesic used in surgery, produced far superior disease-free survival in the first 5 years after surgery. The expected prominent early relapse peak is all but absent. These results are superior to any adjuvant therapy we have examined. Discussion: If this observation holds up to further scrutiny, it could mean that the simple use of this safe and effective anti-inflammatory agent at surgery might eliminate early relapses. Concerning a possible mechanism, since ketorolac is the only anti-inflammatory agent among the analgesics studied, our attention is drawn to inflammation. Might this imply that transient systemic inflammation accompanying surgery is part of the metastatic tumor seeding process? Inflammation can be a very rapidly occurring effect since bump and redness following a mosquito bite occur within seconds. It is well established that many cancer patients have circulating cancer cells. Data show a surge in circulating epidermal cells after primary breast cancer surgery but that intriguingly occurs days later. Blood speed in capillaries is 0.03cm/sec which would make leaky capillary venules a very efficient way for circulating cancer cells to enter tissue. From our simulations the few relapses in the ketorolac data look like the leading edge of the late broad peak - viewable for the first time.

P2-01-07
Proto-Oncogene PELP1 Promotes Metastasis through miR-200 Dependent Pathway.

Background: Endocrine therapy is the most important component of adjuvant therapy for patients with early stage estrogen receptor (ER)-positive breast cancer. Despite positive effects of hormonal therapy, initial or acquired resistance to endocrine therapies frequently occurs and tumor recurs as advanced metastatic disease. Accumulating evidence suggests that ER-coregulators play an essential role in cancer progression and that metastatic tumors have increased expression of coregulators. Proline glutamic acid rich protein (PELP1) is an ER coregulator, its expression is upregulated during breast cancer progression to metastasis. PELP1 is an independent prognostic predictor of shorter breast cancer specific survival and its elevated expression positively associates with markers of poor outcome. The objective of this study is to examine the mechanism and significance of PELP1 mediated signaling in breast cancer metastasis.

Methods: To examine the significance of PELP1 in metastasis, we have used two ER+Ve (ZR75, MCF7) and one ER-ve MDA-MB 231 model cell that either stably express PELP1 or PELP1 shRNA. MCF7 and ZR75 cells were used as controls. Role of PELP1 on metastasis was studied using Boyden chamber, wound healing, invasion, MMP and reporter gene assays. Epithelial to Mesenchymal Transition (EMT) real time qPCR Array (Super array) was used to identify PELP1 target genes. Whole genome based microarray analysis was performed to identify PELP1 regulated microRNAs. miRNA mimetics and antamiRs were used to establish the mechanism. Nude mice based assays were performed to study the role of PELP1 on in vivo metastasis.

Results: Boyden chamber and wound healing assays showed PELP1 down regulation substantially affect migration of both ER+ve and ER-ve cells and showed alterations in the expression of the EMT markers. Focused microarray studies identified PELP1 modulate expression of eight genes involved in the EMT (including Snail, Twist, ZEB1 and MMPs). In xenograft assays, overexpression of PELP1 in non-metastatic cells increases their propensity for metastasis in vivo, while PELP1 knockdown in metastatic model cells decreased in vivo metastatic potential. Whole genome microRNA array analysis revealed that miR 200a and miR141 were upregulated in cells expressing PELP1-shRNA compared to control shRNA expressing cells. Accordingly, over expression of PELP1 in low metastatic model cells decreased expression of miR200a and miR141. Mechanistic studies showed PELP1 down regulate expression of metastasis suppressive microRNAs (miR200a and miR141) by promoting chromatin modifications. Ectopic expression of miR200a and miR141 mimetic decreased PELP1 mediated metastatic functions.

Conclusions: These results suggest that PELP1 play a role in breast cancer metastasis by promoting cell motility/EMT by modulating microRNA expression and blockage of PELP1 axis has potential to reduce metastasis potential of breast cancer cells. Understanding how NR coregulator PELP1 plays a role in metastasis will be useful in maximizing treatment opportunities for metastatic breast cancer. This study is funded by DOD grant.

Gene Expression Alterations in the Lymph Node Microenvironment in Response to Successful Metastatic Colonization.
Ellsworth RE, Valente AL, Kane JL, Ellsworth DL, Shriver CD, Henry M. Jackson Foundation, Windber, PA; Windber Research Institute, Windber, PA; Walter Reed Army Medical Center, Washington, DC

Background: Breast stroma is known to play an active role in tumorigenesis, undergoing both phenotypic and molecular changes to facilitate and promote tumor development and growth. The metastatic microenvironment also plays a role in successful colonization; however, the genetic changes in these secondary microenvironments associated with metastasis are not well described.

Methods: Women with invasive breast cancer with at least one lymph node with macrometastases and one lymph node with no detectable metastases were identified from the Clinical Breast Care Project. Lymph node tissue was microdissected from both the metastatic lymph node microenvironment and negative nodes and hybridized to U133A 2.0 gene expression arrays. Differential expression was detected using Partek® Genomics Suite™6.5 using a cutoff of P<0.001, >2-fold change.

Results: Nineteen genes were differentially expressed between negative lymph nodes and lymph node tissue microdissected from lymph nodes with metastatic tumors. Eleven genes, including EPCAM, KRT19 and MUC1 were expressed at significantly higher levels in lymph node tissue from metastatic lymph nodes while eight genes, such as CXCL2 and CXCL5, were expressed at significantly higher levels in negative lymph nodes. Results have been validated in external sample sets for AZGP1, CLEC4M, CXCL2, EPCAM, MUC1, PIP and TFPI.

Conclusions: Lymph node tissue differs in gene expression between those harboring metastatic tumors and those without metastasis. Genes expressed at higher levels in lymph nodes with macrometastases are involved in tumorigenesis, suggesting that like the breast stromal microenvironment, the metastatic microenvironment undergoes cross-talk with the tumor cells. In addition, a cluster of genes involved in immune function are expressed at lower levels in metastatic lymph nodes, suggesting that suppression of proper immune response may be required for successful metastatic colonization.

P2-01-10
Blockage of Autocrine TGF-b Signaling Reduces Tumorigenicity and Lung Metastasis in a Murine Breast Cancer Cell Line, NMuMG-ST.
Liu Z, Robert NW, Wang L, Bandyopadhyay A, Sun L-Z. University of Texas Health Science Center at San Antonio, San Antonio, TX; Baylor College of Medicine, Houston, TX

Transforming growth factor beta (TGF-b) is known to have a dualistic role in breast cancer cells, acting as a tumor suppressor or a tumor promoter. This dualistic property varies in different cells and at different progression stages. Studies show that autocrine TGF-b is necessary for the growth and survival of MDA-MB-231 cells, and was also known to enhance the survival of MCF-7 cells. However, the role of autocrine TGF-b in spontaneously transformed cells is still less understood. We have retrovirally transduced a dominant negative TGF-b Type II receptor (DN RII) into a spontaneously transformed murine mammary gland epithelial cell line NMuMG-ST (DN RII cells). The expression of DN RII reduces TGF-b sensitivity of NMuMG-ST cells in a gene transcription assay and a growth inhibition assay. Interestingly, the autocrine TGF-b supports the survival of NMuMG-ST cells, although the exogenous TGF-b inhibits the growth of NMuMG-ST cells. Moreover, more apoptosis were observed in the DN RII cells compared to the control cells in both in vivo and in vitro experiment. We found that AKT and ERK pathway mediates autocrine TGF-b’s survival signal. Results of western immunoblot for several stem cell markers and mammosphere formation assay suggest that autocrine TGF-b signaling is essential for the maintenance of stem like cell subpopulation in NMuMG-ST cells. By using immunocytostaining, we found that the DN RII cells expressed more E-cadherin and less Vimentin when compared to the control NMuMG-ST cells, which indicate that blocking autocrine TGF-b signaling pathway could inhibit the process of EMT in NMuMG-ST cells. Notably, when the cells were inoculated orthotopically in nude mouse mammary glands, tumors formed by DN RII cells grew at a similar rate as those formed by control cells, but caused fewer lung metastases. Our finding identified that the autocrine TGF-b signaling is important for the survival and metastatic ability of NMuMG-ST, which could provide an important foundation for further investigation on the role of autocrine TGF-b signaling in breast cancer.

P2-01-11
Fish Oil Targets miR-21 To Increase PTEN Expression for Inhibition of Bone Metastatic CSF-1 in Breast Cancer Cells.
Mandal CC, Ghosh-Choudhury T, Ghosh Choudhury G, Ghosh-Choudhury N. University of Texas Health Science Center at San Antonio, San Antonio, TX; Baylor College of Medicine, Houston, TX

Current therapy for the breast cancer patients is aimed at treating the cancer mainly at the primary site with limited ability to block metastasis. We have recently shown that fish oil (FO) diet significantly prevents MDA MB-231 breast cancer cell (MDA) metastasis to bone in a mouse model. Colony stimulating factor-1 (CSF-1) is one of major osteoclastogenic cytokines responsible for osteolytic metastasis of breast cancer. Quantitative RT-PCR (qRT-PCR) analysis showed significant inhibition of CSF-1 mRNA expression in fish oil fed mice xenograft tumor samples and docosahexaenoic acid (DHA) and eicosapentaenoic acid (EPA), two ω-3 fatty acids in fish oil, inhibited CSF-1 mRNA and protein expression in MDA cells. A positive correlation was observed between expression of CSF-1 and the bone metastatic potential of different breast cancer cells. We have demonstrated recently upregulation in PTEN expression by FO diet as a mechanism of breast tumor growth arrest in mice. Over expression of PTEN inhibited migration of MDA cells. PTEN is a negative regulator of PI3 kinase/Akt signaling. We investigated the mechanism of CSF-1 expression by breast cancer cells. Cotransfection of the CSF-1 promoter-driven luciferase plasmid (CSF-1-Luc) in MDA with PTEN or dominant negative (DN) PI3 kinase or DN Akt, inhibited the transcription of CSF-1, indicating requirement of PI3 kinase/Akt signaling. Several oncogenic microRNAs including miR-21 have been shown to induce metastasis of cancer cells. Fish oil fed mice tumors and DHA- and EPA-treated MDA cells significantly blocked miR-21 expression in MDA. PTEN mRNA 3'UTR contains miR-21 recognition element. Over expression of miR-21 inhibited PTEN 3’UTR-Luc reporter activity but it was increased by downregulation of miR-21, indicating functional targeting of PTEN mRNA by miR-21 in MDA. Similarly, expression of either miR-21 or miR-21 Sponge (plasmid-coded anti-miR-21 sequences) in MDA significantly suppressed or increased PTEN protein, respectively. Moreover, DHA-increased PTEN expression is reversed by over expression of miR-21 indicating a critical regulation of PTEN by miR-21. miR-21 over expression increased migration of MDA cells and partially reversed DHA- or EPA-mediated inhibition of migration. Since PTEN
regulates expression of CSF-1, we examined the involvement of miR-21. Expression of miR-21 enhanced while miR-21 Sponge reduced expression of CSF-1 mRNA and its transcription. Furthermore, DHA-inhibited CSF-1 mRNA expression is reversed by over expression of miR-21. Together these results uncover a novel function of fish oil, which beheads miR-21 signaling to dampen expression of CSF-1 thus preventing osteoclastogenesis and osteolytic lesions in breast cancer.

P2-01-12
Determining the Molecular Signature That Drives Breast Cancer-Induced Brain Metastasis in a Mouse Xenograft Model.

Mukhopadhyay KD, Elkahloun AG, Yoon K, Cornell JE, Yu L, Liu Z, Sun L-Z. UT Health Science Center, San Antonio, TX; National Human Genome Research Institute- NIH, Bethesda, MD

Breast cancer (BCa) is the most common malignant disease in women in U.S. and the mortality in BCa patients is due to the metastasis of the disease from primary site. Brain metastasis accounts for nearly 20% of all metastases in BCa. It is the most feared complication of BCa because of very few effective treatment regimens available, leading to lower survival rate in patients. The exact molecular mechanism for metastases of BCa into brain is unknown. Rodent model systems have been reported for brain metastasis in BCa but the current models for brain metastasis have limitations. Therefore, there is a need of efficient model system that can significantly contribute towards our understanding of different factors from both host and tumor leading to brain metastasis.

Previously we reported isolation and characterization of estrogen independent B6TC cells that are derived from the stable spontaneous fusion of MDA-MB-231/GFP/Neo and ZR-75-1/GFP/puro in mouse bone marrow microenvironment. This chimeric B6TC has propensity to metastasize to brain when inoculated through intracardiac (I.C.) route, and express stem cell-like features. In the present study using B6TC, we have developed an efficient and novel mouse model for studying BCa-induced brain metastasis. We have generated three cell lines from B6TC through three successive rounds of inoculation in mouse and subsequent isolation of brain metastatic cells. Each round of selection enhanced the brain metastatic propensity. An initial microarray analysis identified genes like MMP1, HB-EGF, ST3GAL1, PTGS2, ITGA3, and CXCR4, which showed significant up-regulation in B6TC compared to its parental metastatic MDA-MB-231 or non-aggressive ZR-75-1 cells. These genes are implicated in metastasis regulation. A second round of RNA microarray was performed with three sublines of B6TC with successively enhanced brain metastatic propensity to identify unique potential brain metastatic genes showing gradual up or down-regulation over generations. From analysis of the gene expression profiles, apart from potent brain metastatic genes detected earlier, we also identified some molecular pathways, including TGF beta signaling pathway that are associated with enhanced brain metastasis. The B6TC model is novel for studying the molecular mechanism of brain metastasis, as in this model, apart from experimental metastasis in brain through I.C. route, cells show spontaneous metastases to the brain from the primary tumor and this unique feature will enable us to study the mechanisms of the early steps of brain metastasis progression. Further analyses to find out common miRNAs that are over or under-expressed in the sublines over successive generations and determination of gene targets of miRNA are underway. This study will not only provide valuable insight into molecular mechanism of BCa-induced brain metastasis but also lay the foundation to identify novel prognostic and therapeutic markers of brain metastases, leading ultimately to the discovery of novel molecularly targeted drugs to prevent and eradicate BCa metastasis initiation, progression and recurrence.

P2-01-13
Impact of Erlotinib on MSC-Mediated TIC Expansion and EMT.

Lacerda L, Solley T, Deheb B, Xu W, Krishnamurthy S, Ueno N, Reuben J, Klopp A, Woodward W. UT MD Anderson Cancer Center, Houston, TX

Background: Recently, we have demonstrated that mesenchymal stem cells (MSC) and MSC secreted factors (MSC-CM) have a profound effect on tumor initiating cells (TIC) enriched mammosphere formation and latency of tumor xenografts formation from breast cancer cell lines. Furthermore these interactions increased the expression of epithelial mesenchymal transition (EMT)-associated proteins which are associated with tumor cell invasion and metastasis as well as the TIC phenotype. (Klopp, A. H. et al., 2010, PLoS One. 5, e12180). Our data suggest that the presence of MSC in the tumor microenvironment may increase metastases by conferring stem progenitor cell biology on more differentiated non-metastatic cells. In addition, preliminary data suggested MSC-CM upregulated EGFR signaling in breast cancer cells. Therefore, we hypothesized that inhibiting EGFR signaling with erlotinib (tyrosin kinase inhibitor) can suppress MSC-mediated TIC expansion and EMT.

Methods & Results: In order to demonstrate that erlotinib inhibits MSC-CM promoted expansion of TIC, we cultured breast cancer cells lines (SUM149, SUM159, SUM190, MDA-IBC3 and MCF-7) in anchorage independent conditions with MSC-CM and treated them with increasing concentrations of erlotinib. The efficiency of mammosphere formation was examined after 5 days. We found that erlotinib inhibited MSC mediated increase in mammosphere formation in triple negative cell lines SUM149 and SUM159, and HER2-positive cell lines SUM190 and MDA-IBC3, but not in ER-positive, erlotinib resistant MCF-7 cells. Furthermore, we evaluated the impact of erlotinib on cell cultures grown with breast cancer patient-derived fluids, such as seroma and malignant pleural effusions. We observed that the effect of erlotinib on mammospheres formation was attenuated by both types of patient fluids.

Discussion: Patients with triple negative breast cancer have the highest rates of metastases and no available targeted therapies for treatment. EGFR is expressed in a significant proportion of triple negative breast cancers, and recent clinical and preclinical studies suggest that EGFR may contribute to the metastasis or aggressiveness of triple negative breast cancer. Here we demonstrate that host and environmentally-derived factors are critical for determining resistance to erlotinib. In vivo studies regarding the ability of erlotinib to prevent MSC-enhanced TIC survival and metastases are underway.

P2-01-14
High Level of CD44 Expression and Soluble CD44 Secretion Mediate Trastuzumab Resistance in HER2 Positive Breast Cancer.

Jin Q, Baek JM, Boulbes DR, Esteva FJ. MD Anderson Cancer Center, Houston, TX

Background: Overexpression of HER2 occurs in 15–25% of invasive breast cancer. Trastuzumab, a humanized monoclonal antibody targeting the extracellular domain of HER2, markedly improves disease-free and overall survival in patients with HER2-positive breast cancer. However, resistance to trastuzumab develops in most patients with HER2-overexpressing metastatic breast cancer. Breast cancer stem cells have been shown to express HER2, although its role in the
development or maintenance of stem cells is not well characterized. CD44 is one of the proposed markers for breast cancer stem cells. We investigated the role of CD44 in acquired trastuzumab resistance in HER2 positive breast cancer.

Methods: CD44 mRNA expression was measured by quantitative real-time PCR. The proportion of CD44 positive cells was measured by fluorescence-activated cell sorting (FACS). Soluble CD44 level was detected by enzyme-linked immunosorbent assay (ELISA). In vitro tumorigenicity was evaluated by soft agar colony formation assay. Cell invasion was tested by using a matrigel invasion assay. In vivo tumor growth was evaluated using a mammary fat pad xenograft mouse model.

Results: CD44 mRNA expression, CD44 positive cell population by FACS, and CD44 secretion were significantly increased in both SKBR3 derived trastuzumab resistant SKBR3 clone 3 and BT474 derived trastuzumab resistant HR20 cells compared to parental, trastuzumab sensitive cells. Consistent with the increase in CD44, trastuzumab resistant cells showed an increase in soft agar colony formation and cell invasion, which were blocked by siRNA-induced downregulation of CD44 expression. Tumor growth and incidence were enhanced in mice injected with trastuzumab resistant HR20 cells compared to the mice injected with trastuzumab sensitive parental BT474 cells. Knock-down of CD44 expression by the transfection with CD44-specific siRNA suppressed in vivo tumor growth in the mice injected with trastuzumab resistant HR20 cells. Finally, we found high serum CD44 levels correlated with advanced tumor progression in HER2 positive breast cancer.

Conclusion: Our findings indicate that high levels of CD44 mediate trastuzumab resistance in HER2 positive breast cancer cells as well as tumor progression in mice. Circulating CD44 is prognostic in patients with HER2 positive breast cancer. CD44 may be a therapeutic target for HER2 positive breast cancer.

P2-01-15
RT-PCR Gene Profiling for the Prediction of Bone Metastases in Primary Breast Cancer:
Ibrahim T, Mercatali L, Ricci R, Scarpi E, Liverani C, Serra L, Guerra D, Casasco A, Amadori D. Istituto Scientifico Romagnolo per lo Studio e la Curia dei Tumori (I.R.S.T.), Meldola, (FC), Italy; I.R.S.T., Meldola, (FC), Italy; Maggionni-Pierantoni Hospital, Forlì, (FC), Italy

Background: Patients with breast cancer frequently develop bone metastases, which are responsible for high morbidity and mortality. It is known that numerous molecules are involved in the bone metastasization process and that only cancer cells with a specific molecular profile are capable of reaching and colonizing bone tissue. The early detection of patients with a high probability of relapsing to bone could be used to select candidates for tailored therapy with bone-specific drugs such as bisphosphonates or RANK-L inhibitors. The aim of the present study was to identify a pattern of tissue markers from primary breast cancer capable of predicting bone metastatization.

Material and methods: The expression of different markers was retrospectively analyzed in frozen breast cancer tissue samples from 40 patients comprising 15 cases with no evidence of disease (NEDP), 15 with bone metastases (BMP), and 10 with visceral metastases (VMP). Twelve transcripts were analyzed by Quantitative Real time PCR: trefoil factor 1 (TFI), DKK1, bone sialoprotein (IBSP), heparanase (HPSE), osteopontin (SPP1), Agr2, SPARC, CTGF, COMP, follistatin (FST), osteoprotegerin and RANK. The predictive accuracy of each marker was calculated using receiver operating characteristic (ROC) curves.

Results: Analysis of marker expression in the 3 different subgroups showed twofold higher median values of COMP and HPSE in BMP with respect to either NEDP or VMP (no significant difference). Furthermore, TFF1 median value was about sevenfold higher in BMP than in the other 2 subgroups (p=0.05). The area under the curve (AUC) was 0.73 for TFF1 and 0.62 for COMP and HPSE. Considering markers as dichotomous variables, TFF1 expression in BMP reached 67% compared to 21% and 20% in NEDP and VMP, respectively. In dichotomous variable analysis, the most important result was observed for TFF1; in particular, TFF1 positivity was observed in 67% of cases in the BMP subgroup compared to only 21% and 20% in NEDP and VMP, respectively. The combination analysis of TFF1 and other markers showed that positivity to at least one of the three markers, TFF1, DKK1, or IBSP, was observed in 80% of cases for the BMP group, and in only in 21% and 20% of cases in NEDP and VMP subgroups (p=0.041). Another interesting marker was RANK, although sensitivity was fairly low (12%), specificity reached 100% in both control groups.

Conclusions: Our preliminary study identified a RT-PCR gene expression pattern in primary breast cancer that could predict patients destined to bone relapse. Such patients could consequently benefit from adjuvant treatment with bone-targeted therapy.

P2-01-16
Dissecting the Cellular Mechanism of Induction and Sustenance of Dormancy by Rho GTPases in Breast Cancer.
Chatterjee M, van Golen KL. University of Delaware, Newark, DE

Tumor dormancy has been a very real problem in breast cancer survivors where recurrences are common and usually fatal. Molecular mechanisms involved in this process are often poorly understood and are a hot spot in breast cancer research today. We have found that RhoGTPases, specifically RhoC, is hyperactivated in low metastatic dormant breast tumor cells while RhoA is downregulated. We also found RhoC causes phosphorylation of c-jun NH2 terminal kinase (JNK) in these cells which in turn activates the process of autophagy, a possible mode of cell survival in dormant tumor cells. Modulating RhoC affected phosphorylation of JNK. Also, abrogating JNK by a pharmacological inhibitor SP600125 inhibited expression of the autophagy marker LC3B-II. Autophagy genes like Atg 5 and Atg12 were expressed along with the autophagy marker LC3B-II. On inhibiting autophagy by a specific inhibitor 3-Methyladenine (3-MA), cells did not readily undergo apoptosis but on stressing them doubly with LY294002, an inhibitor of Class I PI3K, although sensitivity was fairly low (12%), specificity reached 100% in both control groups.

Conclusions: Our preliminary study identified a RT-PCR gene expression pattern in primary breast cancer that could predict patients destined to bone relapse. Such patients could consequently benefit from adjuvant treatment with bone-targeted therapy.
P2-01-17
L1-CAM Promotes Adhesion of Breast Cancer Cells to the Endothelium.
Milde-Langs cock K, Dippel V, Schröder C, Wicklein D, Hein S, Jänicke F, Müller V, Schumacher U. University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background: Overexpression of the adhesion molecule L1-CAM (L1) in breast cancer is correlated with nodal involvement, high grading, and a shorter recurrence-free and overall survival, but the mechanism leading to this effect is poorly understood. L1 is also expressed in endothelial cells promoting the interaction between lymphatic cells and endothelia via homophilic L1-L1 interaction. This mechanism might also mediate adhesion of breast cancer cells to endothelia and thus promote metastasis. To examine this likely role of L1, the impact of L1 expression in breast cancer cells on their adherence to human pulmonary microvascular endothelial cells (HPM EC) was investigated and potential L1 ligands on these cells were identified.

Methods: MDA-MB231-Fra2 breast cancer cells expressing high levels of L1 were stably transfected with shRNA vectors to generate two clones with strong L1 downregulation (L1 low clones). Adherence of these clones to endothelial cells was studied in dynamic cell-flow adhesion assays in channels seeded with HPM EC simulating in vivo-conditions. Rolling or adherent cells per minute were counted using CapImage software. For the cell-flow assay HPM EC were activated with TNFa. In order to identify the L1 ligand, endothelial cells were partly pre-incubated with blocking antibodies directed to the potential binding partners L1, ALCAM, ICAM-1 and E-selectin before interaction with tumor cells. In additional experiments, flow chambers were coated with recombinant L1-CAM, ICAM1, ALCAM or E-selectin, and the adherence of MDA-MB231 cells with high or low L1 expression to these proteins was investigated.

Results: Adhesion of MDA-MB231 cells to activated HPM EC was significantly higher in L1 high cells compared to L1 low clones, where the number of adherent cells was only 40-50% of the L1 high control (p=0.025; p=0.035). Blocking experiments showed that the adherence of L1 high cells could be reduced by antibodies directed to ALCAM (p=0.0007), but not to ICAM1. Anti-L1 antibodies had a significant effect only in passages of endothelial cells which showed L1 expression, whereas E-selectin blocking strongly diminished adherence of breast cancer cells irrespective of their L1 expression. In addition, L1 low clones showed significantly lower adhesion to recombinant L1, ALCAM and E-selectin proteins compared to the parental cells.

Conclusion: Our experiments indicate that L1 expression in breast cancer cells leads to an increased adherence to activated endothelial cells via homophilic (L1-L1) or heterophilic (L1-ALCAM) interactions. This mechanism is a possible explanation for the increased metastatic potential and poor prognosis in L1-positive carcinomas observed in vivo. Our results suggest that this adhesion molecule might be a suitable target for therapeutic interventions.

P2-01-18
Cancer Stem-Like Cells in Breast Cancer Progression.
Valeio FAM, Andrade JM, Sicchieri RD, Antonio HMR, Marana HRC, Mouro LR, Oliveira TMG, Benevides L, Silva JS, Muggia VF, Tuzzii DG. Faculdade de Medicina de Ribeirão Preto - University of São Paulo, Ribeirão preto, SP, Brazil; Faculdade de Medicina de Ribeirão Preto - University of São Paulo, Ribeirão Preto, SP, Brazil

Background: increasing evidences support the presence of cancer stem-like cells (CSCs) within breast carcinomas. A subset of cells enriched for CSCs within the tumor can be identified by flow cytometry. It has been supposed that CSCs component is responsible for tumor resistance and metastasis. However, the analysis of such population has never been evaluated during breast cancer progression.

Patients and Methods: We prospectively included 98 women with histologically proven breast carcinomas to assess the presence of CSCs within the primary tumor. According to clinical stage (CS), five patients were CS 0 (palpable DCIS), 16 CS 1, 20 CS II and negative lymph nodes (IIA-), 20 CS II and positive lymph nodes (IIA+), 6 IIIa, 17 IIb, IIIc and 2 CS IV. Additionally, ten lymph node metastases from IIA- patients were analyzed. Invasive ductal carcinoma (IDC) was observed in 79 patients. We excluded from the analysis patients with non ductal histology (n=11). The percentage of CD44+/CD24- (n= 79), ALDH1+ (ALDEFLUOR®) (n= 29), ABCG2+ (n= 44 ) and CXCR4+ (n= 46 ) cells within ESA+ cells was determined by flow cytometry in fresh sampled tumors. The mammosphere assay was studied in 14 samples. The relationship between cytometry analyses and clinical and pathological features was analyzed.

Results: The median prevalence of CD44+/CD24- cells within ESA+ population was 1.63% in stage 0, 2.39% in stage 1, 0.42% in stage II, 8.15% in stage IIA+ and 0.52% in stage III (p=0.005). The CD44+/CD24- cell population was analyzed in 10 lymph node metastasis and, the median prevalence of this population within ESA+ cells was 4.7%. There was no variation of median prevalence of ALDH1+, CXCR4+, ABCG2+ and the median number of spheres among clinical stages (p=0.1, p=0.8, p=0.8, respectively). We didn't observe any association among the expression of, ABCG2+, CXCR4+ with histological grade and the expression of ER and PgR. The median percentage of CD44+/CD24- cells was higher (2.39% vs 0.41%) in ER positive tumors (p=0.003). The median percentage of ESA+ CXCR4+ cells was higher (42.5% vs 9.7%) in HER2- tumors. There was no correlation between the studied markers and the patients' age and clinical tumor diameter. The results are summarized in Table 1.

Discussion: We found a significant variation in CSCs population during breast cancer progression. Our data show a gradual increase in CD44+/CD24- cells within ESA+ population from stage 0 to stage IIA+ and a significant decrease in stage III tumors. This observation supports the hypothesis that a population of CSCs could be associated with breast cancer progression.

Expression of Receptor Like Protein Tyrosine Phosphatases mu (PTPRM) in Breast Cancer and the Biological Effects of PTPRM on Breast Cancer Cells.

Sun P-H, Ye L, Mansel RE, Jiang WG. Cardiff University School of Medicine, Cardiff, Wales, United Kingdom

Introduction:
Protein tyrosine phosphatases (PTPs) play a major role in many cellular functions including cell survival, proliferation, differentiation and motility. The receptor-like protein tyrosine phosphatase mu (PTPRM) has a similar structure to cell-cell adhesion molecules and has been shown to exhibit homophilic binding and confer cell-cell adhesion in cells including epithelial and cancer cells. However, the role played by PTPRM in breast cancer remains unclear. The present study investigated the expression of PTPRM in breast cancer and the biological impact of PTPRM on breast cancer cells.

Methods:
Expression of PTPRM protein and gene transcript was examined in a cohort of primary breast cancer tumours. The association of PTPRM transcripts level and pathological and clinical aspects was then analysed. Expression of PTPRM transcript in breast cancer cells were knocked down using a specific anti-PTPRM transgene. The impact of PTPRM knockdown on breast cancer was evaluated using a series of in vitro cell models and in vivo tumour model.

Result:
PTPRM protein was seen generally distributed in the breast tissues, including tumours and normal background tissues. A stronger staining was revealed in cytoplasm of both mammary epithelia and cancer cells in comparison with the surrounding stromal cells. A significantly decrease was seen in poorly differentiated tumours (92.5±279), and moderately differentiated tumours (288±110), compared with that of well differentiated (472±114), p=0.011 and p=0.031 respectively. PTPRM transcript levels were decreased in patients died from breast cancer. The expression of PTPRM transcripts was significantly associated with disease free survival. Patients with lower expression of PTPRM had shorter survival compared with those with high level of PTPRM expression (p=0.029). Knocking down PTPRM from breast cancer cells significantly increased cell adhesion compared with control cells (p=0.001). Likewise, the knockdown also marked increase the rate of cell migration (102.9±11.3µm for control vs 115.3±10.5µm for PTPRM knockdown, p=0.05).

Conclusion: The expression of PTPRM transcripts is decreased in poorly differentiated breast tumours and is correlated with poorer long term survival. This is likely to be contributed to by the biological impact of PTPRM on the aggressiveness of breast cancer cells.

**P2-01-20**

Reduced Plakoglobin Expression Increases the Metastatic Potential of Breast Cancer Cells.

Otewell PD, Whitworth J, Cross SS, Nutter FH, Holen I. University of Sheffield, Sheffield, Yorkshire, United Kingdom

The majority of deaths from breast cancer are a result of metastases, however, little is understood about the genetic alterations underlying their onset. A recent study of human breast cancer biopsies showed alterations of expression of 9 genes in primary tumours that had metastasized compared to benign tumours. Of these, plakoglobin was the most altered, with metastatic tumours showing a 3x decrease in expression compared to benign. Furthermore, expression of plakoglobin is reduced upon autocrine production of human growth hormone, which is associated with increased breast tumour cell invasion in vivo. Plakoglobin codes for the adhesion protein gamma-catenin, an integral part of the cadherin-catenin complex involved in cell-to-cell adhesion. The aim of the current study is to investigate the effects of plakoglobin knockdown on cell proliferation, migration, adhesion and invasion in vitro and in vivo.

The non-metastatic human breast cancer cell lines MCF7 and T47D that express high levels of plakoglobin and gamma-catenin were stably transfected with miRNA to two different regions of the plakoglobin gene, or scramble vector, to produce plakoglobin knockdown and controls for each cell line. Plakoglobin gene expression was monitored by qPCR and gamma-catenin expression by Western blot. Cell proliferation was assessed 24, 48, 72 and 96 hours post seeding; cell migration and invasion were measured over 24 and 48 hours using scratch and modified Boyden Chamber assays. Cell-cell adhesion was assessed by spheroid formation in agar matrix. For in vivo experiments, MCF7 plakoglobin knockdown and control cells were inoculated into the 5th and 10th mammary fat pads of 12-week old female balb/c mice (n=10 per group). Tumour growth was monitored by caliper measurements and local invasion was investigated 6 weeks after tumour inoculation on histological sections. Shedding of tumour cells into the blood stream and evidence of metastatic bone lesions was monitored by flow cytometry and μCT, respectively. Plakoglobin and gamma catenin expression were reduced by more than 80% in all knockdown cell lines used but were unaltered following transfection with the scrambled vector. Furthermore, knockdown of plakoglobin did not effect expression of its binding partner, e-cadherin. Reduced expression of plakoglobin resulted in a more than 3-fold increase in MCF7 and T47D cell proliferation in vitro (p<0.005) and a 2-fold increase in MCF-7 proliferation in vivo (p<0.005), compared with control. In addition plakoglobin knockdown cells showed a 6 – 15 fold increase in invasion through basement membrane (p<0.005), a 2-fold increase in migration (p<0.005) and exhibited reduced cell-to-cell adhesion compared with control cells. Data show that decreased expression of plakoglobin increases the early pro-metastatic behaviour of cells including increased cell proliferation, migration and invasion.

**P2-01-21**

The Biological Influence of Brain Derived Neurotrophic Factor (BDNF) on the Aggressiveness of Human Breast Cancer Cells.

Yang MX, Martin TA, Jiang WG. Capital Medical University, Beijing, China; Cardiff University School of Medicine, Cardiff, United Kingdom

Introduction: Brain derived neurotrophic factor (BDNF) is a member of the neurotrophin superfamily and has been indicated in the pathophysiology of the nervous system and is important in a number of neurological and psychological conditions. Recently, BDNF has also been shown to play a role in the development and progression of solid tumours myeloma, lung cancer and prostate cancer. It has been recently reported that BDNF is also aberrantly expressed in human breast cancer and that a raised level of BDNF is associated with poor clinical outcome and reduced survival. The present study aimed to investigate the biological role of BDNF in human breast cancer.

Materials and methods: A panel of human breast cancer cells were used in the present study. The expression profile of BDNF was evaluated using RT-PCR. We constructed a set of anti-BDNF transgenes which were used to transfect breast cancer cells in order to generate BDNF knockdown cells (MCF<sub>10AT500</sub>). The impact of BDNF knockdown on growth and cellular migration were evaluated using standard growth assays and ECIS (electronic cell impedance sensing) technology.

Results: BDNF gene transcripts were successfully detected in the
breast cancer cell lines, MCF-7, MDA-MB-231 and ZR 75-1. MCF-7 wild type cells were subject to transfection of anti-BDNF transgenes, followed by the establishment of BDNF knockdown sub-lines and empty vector control cells (MCF-BDNF). Loss of BDNF in breast cancer cells resulted in reduction of cell growth rate (growth rate in MCF-BDNF by day 3 1.60+/-.01, compared with 2.06+/-.04 in MCF-wt, p=0.006). Using electronic cell-cell substrate impedance sensing, it was found that loss of BDNF in breast cancer cells resulted in a significant increase in the rate of cellular attachment and migration (migration rate over 14 h in ohms: MCF-BDNF 6310.125+/-.595.183 compared with MCF-wt 5115.5 +/-422.394, p=0.0003).

Conclusion: When BDNF was stably knocked down in MCF-7 cell lines, the growth and proliferation were decreased. The ECIS results also showed that cell migration was decreased in MCF-7 cells stably transfected with ribozymes for BDNF compared with the vector control. It is concluded that BDNF, a neurotrophic growth factor aberrantly expressed in cancers such as breast cancer, has a profound impact on the cellular behaviour of breast cancer cells and that loss of BDNF is associated with a reduction of the aggressiveness of breast cancer. BDNF is therefore a potential therapeutic target in breast cancer and its effect in human breast cancer requires further investigation.

P2-01-22
Characterization of Four ER-Negative Breast Primary Tumor Dissociated Cultures as a Model for the In Vitro and In Vivo Study of Tumorigenesis, Metastasis and Angiogenesis.
Drews-Elger K, Brinkman JA, Dean SJ, El-Ashry D. University of Miami, Miller School of Medicine, Miami, FL

ER negative breast carcinomas comprise a subtype of tumors for which there are few therapies with successful response. Currently, the use of established cell lines has allowed detailed molecular and cellular studies on cancer mechanisms ranging form stem cells to proliferation, from tumorigenesis to invasion and metastases, and from tumor suppressors to oncogenes. But while cell lines provide a source of homogeneous, propagatable material, a drawback of this model is that most breast cancer cell lines are derived from metastatic lesions that may harbor additional mutations and have little resemblance with the primary tumor of origin. Additionally, the continuous passage of these cells over the last 20-plus years has given rise to well-established differences in growth rate, hormone receptor status, karyotype and clonogenicity. Our purpose here was to characterize four primary dissociated tumor (DT) cell cultures from ER-negative breast tumors, the establishment of which we had previously described, to determine if they could provide more accurate models for both in vitro and in vivo studies. These four DT cultures (DT16, DT22, DT25 and DT28) display a triple negative phenotype and were characterized by their genomic profile by the PAM50 predictor analysis as belonging to the basal (DT22, DT25 and DT28) and luminal B (DT16) subtypes. Of those cultures for which primary tumor sample was available, microarray gene expression profiling and cell line clustering analysis show the primary tumor and dissociated culture cluster together and to similar breast tumors. Interestingly, of the three basal DT cultures, DT22 clusters with Claudin-low tumors and cell lines. We have established that each of these 4 DTs are tumorigenic in the NOD/SCID mouse model, and are now assessing their metastatic potential. DT16 generated metastases in 25% of the mice (6 out of 24; two in liver, four in lymph node). DT22 generated highly vascularized tumors, which may provide a relevant model for study of the in vivo vascular recruitment process. In addition, we have analyzed and characterized the role of pivotal signaling pathways often deregulated in breast cancer such as EGFR, P-MAPK, PI3k/mTOR, p53, TGFβ, Hedgehog, Notch, and Wnt in both the 2D culture as well as in sections of xenograft samples. Given that the scope of primary tumor heterogeneity and consequently the early stages of breast tumorigenesis are under-represented by current in vitro models in breast cancer research, the use of these DT cell cultures could more accurately recapitulate the disease in both the in vitro and in vivo settings.

P2-01-23
Seprase Promotes the Growth and Impairs the Migratory Ability of Breast Cancer Cells.
Jia J, Martin TA, Jiang WG. Peking University, Beijing, China; Cardiff University School of Medicine, Cardiff, United Kingdom

Background: Seprase or Fibroblast Activation Protein alpha (FAP-a) is an integral membrane serine peptidase. It has been shown that it plays an important role in tumour proliferation, migration, invasion and angiogenesis. However, previous work has not satisfactorily explained both the suppression and promotion effects that have been observed. Furthermore, the interaction of Seprase with other membrane molecules or pathway had not been well investigated. This study aimed to investigate the role of Seprase in human breast cancer.

Methods: The full length of Seprase cDNA was isolated from normal human prostate tissue using RT-PCR and then cloned into an expression vector (pEF6-V5 His, TOPO). Following confirmation of successful cloning, the plasmid was transfected into the two human breast cancer cell lines, MCF-7 and MDA-MB-231. The function of Seprase in these two cell lines was then analysed using cell function assays and ECIS, and the potential interaction with other signalling pathways explored.

Results: Compared with the MCF-7 wild type cells (MCF-7 wt) and the MCF-7 cells transfected with pEF6/V5 empty vector (MCF-7 exp), the MCF7 cells transfected with Seprase (MCF-7 sef) had increased growth ability and impaired migratory ability. The growth rate of MCF-7 wt cells was 1132.72% on day 5 while those of MCF-7 exp and MCF-7 sef control cells were 897.24% and 990.99% respectively (p=0.011 and 0.032). The resistance increase of MCF-7 wt cells at 2 hours after wounding in ECIS assays was 478.22ohms compare with 1063.75 ohms and 1563.09 ohms in MCF-7 exp and MCF-7 exp cell lines (p<0.05). In MDA-MB-231 cells, over-expression of Seprase resulted in impaired motility. The resistance increase of the MDA-MB-231 wild type cells (MDA-MB-231 wt) and the MDA-MB-231 cells transfected with pEF6/V5 vector (MDA-MB-231 exp), and the MDA-MB-231 cells transfected with Seprase (MDA-MB-231 sef) at 3 hours after wounding in ECIS assay were 216.75ohms, 216.00ohms and 120.16ohms respectively. The growth of MDA-MB-231 cells and the adhesion and invasion ability of both MCF-7 cells and MDA-MB-231 cells were not dramatically influenced with Seprase expression. An inhibitor to focal adhesion kinase (FAK) restored the reduced motility ability of both MCF-7exp cells and MDA-MB-231exp cells. However, inhibitors to PI3K, ERK and ROCK had no influence on it.

Conclusion: These results suggest that Seprase promotes proliferation but inhibits the migration of breast cancer cells by potentially regulating the FAK pathway.
P2-01-24
Triple-Negative Breast Cancer Emerges from the Luminal Progenitor Compartement.

Nogi H, Kamio M, Kato K, Kawaase K, Toriumi Y, Takeyama H, Uchida K. The Jikei University School of Medicine, Tokyo, Japan

Background: Triple-negative breast cancers (TNBC) are defined as tumors that lack expression of estrogen receptor (ER), progesterone receptor (PgR), and human epidermal growth factor receptor type 2 (HER2). Majority of TNBC (approximately 80%) are basal-like breast cancers. The question of whether there is a specific, identifiable cell in the normal breast form which basal-like breast cancers arise is controversial. We evaluated the frequency and receptor status of ductal carcinoma in situ (DCIS) and ductal components associated with T1 invasive ductal carcinoma (IDC) to clarify the developmental pathway of TNBC.

Methods: From our institutional archives between April 2000 and April 2011, we reviewed 758 cases of DCIS and T1 invasive ductal carcinoma without prior operative treatment. Immunohistochemistry for ER, PgR and HER2 was performed on ductal components and invasive components. Statistical analysis was performed using Fisher Extract Test.

Results: The frequencies of triple-negative (TN) subtype at each size were not seen significant differences. Ductal components were seen in 51 (84%) TN-IDC cases. Within 51 cases, the ductal components were TN in 49 cases. The remaining 3 cases were positive for ER and PgR, but negative HER2.

Frequencies of each subtype: TN-HR+HER2-: no expression of ER and/or PgR, but positive HER2; TN-HR+HER2+: positive ER and/or PgR, and positive HER2; TN-HR-HER2+: negative ER and/or PgR, and negative HER2. HR: hormone receptor

Conclusion: The resemblance between ductal components and invasive components and the coincident frequency of TNBC at each size sustain the hypothesis that TNBC arise from the luminal progenitor compartment.

P2-01-25
Truncated p110 ERBB2 (CTF611) Increases Migration and Invasion of Breast Epithelial Cells by Inhibiting STAT5b Activation.

Ward TM, Iorns E, Hoe N, Kim P, Singh S, Ernani V, Liu X, Jegg A-M, Gallas M, Lippman ME, Pergam MD. University of Miami Miller School of Medicine, Miami, FL; Prometheus Laboratories, San Diego, CA

Background: Truncated ERBB2 receptors are present in a subset of human ERBB2+ amplified/overexpressing breast tumors, and are associated with trastuzumab resistance, metastasis, and poor clinical prognosis. However, whether truncated ERBB2 receptors are drivers of metastasis has not been well defined. In this study, we examined effects of full-length (p185) and truncated (p110) ERBB2 on the migration and invasion of human mammary epithelial cells, including HMLE and MCF10A cells.

Material and Methods: Recombinant p185 and p110 ERBB2 were stably expressed in human mammary epithelial cells (HMLE) and MCF10A cells via retrovirial vector. Expression of comparable levels of p185 and p110 in cells was confirmed by western blot. The phosphorylation states of downstream signaling proteins including STAT5 were assayed via phosphoimmunoblotting and Collaborative Enzyme Enhanced Reactive (CEER™) immunoassay. The effects of the p110 constructs on cell migration and invasion were investigated by transwell assays. shRNA-encoding lentivirus was used for specific silencing of STAT5b in HMLE cells, and STAT5b silencing was confirmed at the protein level using western blot.

Results and Discussion: Expression of p110 ERBB2 increased cell migration (HMLE, p = 0.04; MCF10A, p< 0.01) and invasion (HMLE, p= 0.03) when compared to expression of p185. Furthermore, expression of p110 in HMLE cells was associated with reduced phosphorylation of STAT5b. shRNA mediated silencing of STAT5b was sufficient to increase the migration (p < 0.01) and invasion of HMLE cells, phenocopying the p110 driven effects on HMLE cells. In clinical studies, loss of activated STAT5 protein correlates with breast cancer progression and is a negative predictor of survival. By analyzing publicly available gene expression datasets, we found that STAT5b mRNA expression is also significantly decreased in breast cancer compared to normal breast tissues in several studies, as well as in ERBB2 amplified vs. nonamplified samples. To our knowledge, this is the first reported perturbation of STAT signaling by truncated ERBB2 receptor, and suggests a mechanism by which truncated p110 ERBB2 (CTF611) increases migration and invasion of breast epithelial cells. This study extends the available data regarding STAT5 loss in breast cancer progression.

P2-01-26
TIMPv: a novel downstream transcriptional target gene that underpins CD146-suppressed breast tumor invasion.

Ouhtit A, Abdelmageed Z, Fernando A, Gaur RL, Raj MHG. College of Medicine & Health Sciences, Sultan Qaboos University, Muscat, Oman; Louisiana State University Health Sciences Center; Stanley S Scott Cancer Center, New Orleans, LA, United States

Background: CD146, a marker of endothelial cells, promotes tumor progression of many cancers including melanoma and prostate. Strikingly, several lines of evidence suggest that it is a suppressor of breast cancer (BC) progression. Not only the ligand(s) has not been identified, but CD146-downstream signaling mechanisms remain unknown.

Material and Methods: Here, we report the functional importance of CD146 and that of a novel transcriptional target of CD146-signaling, variant of tissue inhibitor of metalloproteinases (TIMPv) identified by microarray analysis, in underpinning the suppression of BC invasion, using novel validated Enhanced Green Fluorescent Protein (EGFP)-inducible systems of CD146 expression both in vitro and in vivo. Results: In functional experiments, induction of CD146 inhibited BC cell migration and invasion. TIMPv was identified by expression profiling as a novel transcriptional target of CD146-signaling, an association validated by quantitative PCR and immunoblotting experiments in a range of breast and melanoma cancer cells. However, siRNA inhibition of CD146 in the SKMel-28 melanoma cell line increased TIMPv expression, suggesting that while TIMPv is a positive transcriptional target of CD146 in BC cells, it is negatively regulated in melanoma cells. Furthermore, the functional relevance of TIMPv to CD146-suppressed metastasis was demonstrated by selective suppression of TIMPv in CD146-expressing BC inducible cells using RNAi. More interestingly, induction of CD146 expression in vivo using mouse EGFP-inducible system of CD146 expression resulted in suppression of breast tumor growth.

Discussion: Our study is the first report to provide a functional molecular link of TIMPv to cancer via unique axis that underpin TIMPv: a novel downstream transcriptional target gene that underpins CD146-suppressed breast tumor invasion.
P2-02-01  A Novel Inflammatory Breast Cancer-Specific Oncogene, Tazarotene-Induced Gene 1, Promotes Tumorigenicity and Invasiveness through the Receptor Tyrosine Kinase Axl.

Wang X, Sas0 H, Iwamoto T, Pusztai L, Gong Y, Woodward WA, Reuben JM, Hortobagyi GN, Ueno NT. Morgan Welch Inflammatory Breast Cancer Clinic; The University of Texas MD Anderson Cancer Center, Houston, TX; University of Texas MD Anderson Cancer Center, Houston, TX

Background: Inflammatory breast cancer (IBC) is the most lethal and aggressive form of breast cancer and is highly metastatic. The prognosis of patients with IBC is poor, and effective standard therapies for IBC are limited because the molecular mechanisms underlying the pathogenesis of IBC remain unknown. We recently found that tazarotene-induced gene 1 (TIG1) expression is significantly higher in IBC cell lines than in non-IBC cell lines. In both IBC and non-IBC data sets, estrogen receptor-negative/HER2-negative samples had significantly higher expression of TIG1 than did other clinical subtypes (estrogen receptor-positive/HER2-negative and HER2-positive). Therefore, we hypothesized that TIG1 plays an important role in the malignant process of IBC. In these studies, we determined the biological function of TIG1 in IBC cells and elucidated the molecular mechanism by which TIG1 regulates the invasiveness of IBC cells.

Methods: TIG1 expression in SUM149 and KPL-4 IBC cells was stably knocked down, and the effects of this knockdown on in vitro cell proliferation, migration, and invasion were analyzed. The effects of restoring TIG1 expression on TIG1-silencing IBC cells were also examined. To determine the tumorigenic activity of TIG1 in vivo, TIG1 stable-knockdown SUM149 cells and control shRNA-transfected cells were implanted into the mammary fat pads of athymic nude mice, and tumor growth was monitored. The receptor tyrosine kinase Axl, a potential functional partner of TIG1, was identified using DNA microarray analysis. The interaction between TIG1 and Axl in IBC cells was examined using immunoprecipitation and confocal microscopy assays. The signaling pathway in IBC cells in which TIG1 participates was also investigated.

Results: Knockdown of TIG1 expression in IBC cells reduced their proliferation, migration, and invasion in vitro. Also, silencing of TIG1 dramatically inhibited IBC tumor growth in a xenograft model. Moreover, restoring TIG1 expression rescued the proliferation, motility, and invasiveness of TIG1-silenced IBC cells. Most importantly, we identified Axl as a functional partner of TIG1 by showing that TIG1 interacted with and stabilized Axl in IBC cells. TIG1 regulated the invasiveness of IBC cells through mediation of the Axl signaling pathway. In SUM149 cells, TIG1 depletion decreased Axl expression, which led to downregulation of expression of matrix metalloproteinase-9, a molecule required for Axl-mediated invasion, and inactivation of nuclear factor-kB, ultimately leading to decreased invasiveness of IBC cells.

Conclusion: Our results identified TIG1 as an oncogenic gene that contributes to the tumorigenic and metastatic properties of IBC. Our data also linked TIG1 with the key tumorigenic gene Axl in IBC cells. Further studies designed to establish TIG1 as a therapeutic target in the treatment of patients with IBC are under way.

P2-02-02  Mutation of the APC Tumor Suppressor Stimulates Breast Cancer Cell Proliferation through Hyperactivation of FAK/Src/JNK Signaling.

Prosperi JR, Yang FF, Goss KH. University of Chicago, Chicago, IL

Background: The Adenomatous Polyposis Coli (APC) tumor suppressor gene is silenced by hypermethylation or mutated in as many as 70% of human sporadic breast cancers. In mouse models, germline mutation of APC disrupts normal mammary development and predisposes to mammary tumor formation. In an effort to more accurately model human breast cancer and determine the role for APC inactivation in the context of other oncogenic events, our laboratory has recently demonstrated that APC loss promotes mammary tumor development in the presence of the Polyoma virus middle T antigen (PyMT) oncogene, and results in a tumor phenotype resembling human metaplastic breast cancer. In this model, ApC mutation significantly enhances tumor cell proliferation but does not impact Wnt/β-catenin signaling. Because APC loss also induces mammary tumor cell spreading and morphological changes, we hypothesized that APC may regulate proliferation via signaling by the focal adhesion kinase (FAK) and Src (kinases) downstream of altered cell-matrix interactions.

Materials and Methods: Cell lines were established from primary cultures of experimental (MMTV-PyMT;ApCMin+/+) and control (MMTV-PyMT;ApCMin/-) mammary tumors and maintained in RPMI 1640 supplemented with 10% FBS and antibiotics at 37°C with 5% CO2. Cell proliferation was measured by incorporation of 5-bromo-2-deoxyuridine (BrdU), and subsequent immunofluorescence (IF) with an anti-BrdU antibody. Western blot analysis and IF were utilized to quantify the expression of functional signaling molecules and determine their localization, respectively. To investigate Wnt/β-catenin pathway activation, dual-luciferase reporter assays were performed using cells transfected with either Top-Flash or Fop-Flash reporter constructs.

Results: Cell lines isolated from mammary tumors from MMTV-PyMT;ApCMin/+ mice had altered morphology and increased rates of proliferation, both of which are consistent with our previous in vivo findings using this mouse model. In vitro, ApC mutation was associated with increased phosphorylation of FAK, Src and Jun kinase (JNK). Activation of both Src and JNK were required for the enhanced proliferation in the MMTV-PyMT;ApCMin/+ cell lines. In contrast, we did not observe any change in the expression of Wnt/β-catenin target genes, β-catenin subcellular localization, or β-catenin/TCF-mediated transcriptional activity. Combined, these data suggest that the proliferative and morphological changes mediated by APC loss in the PyMT breast cancer model are dependent on enhanced signaling downstream of cell-matrix interactions but do not involve the Wnt/β-catenin pathway.

Discussion: These data indicate that APC status is an important determinant of breast cancer cell behavior and specifically suggest that integrin-mediated signaling networks, including FAK, Src and JNK, are hyperactivated by APC loss to promote tumor cell proliferation. Moreover, these preclinical model systems offer a platform for further dissecting the molecular mechanisms by which APC contributes to breast carcinogenesis as well as identifying therapeutic strategies that may be effective in APC-deficient breast cancers.
P2-02-03
**MAP3K3, Amplified in Human Breast Cancer, Promotes Breast Tumor Progression and Defines Poor Prognosis.**

Dong J. Baylor College of Medicine, Houston, TX

Gene amplification in the 17q chromosomal region is observed frequently in breast cancers. An integrative bioinformatics analysis nominated MAP3K3 gene, located in 17q23, as a potential therapeutic target in breast cancer. This gene encodes the mitogen-activated protein kinase kinase kinase 3 (MEKK3), but has not yet been associated with cancer-causal genetic aberrations. We found that MAP3K3 was amplified in approximately 8-20% of breast carcinomas, and that its over-expression was an independent prognostic marker for poor outcome with respect to relapse-free and overall survival, especially among the estrogen receptor-positive breast cancer patients.

shRNA-mediated knockdown of MAP3K3 expression significantly inhibited cell proliferation and colony formation of MAP3K3-amplified breast cancer cell lines MCF7 and MDA-MB361, and promoted breast cancer cell apoptosis induced by TNFa, TRAIL, or a doxorubicin. In addition, ectopic expression of MAP3K3, in collaboration with Ras, induced colony formation in both primary mouse embryonic fibroblasts and immortalized mammary epithelial cells (MCF-10A). Together, these results suggest that MAP3K3 is a potential biomarker indicating poor prognosis, contributes to resistance to therapy, and is an oncogene in breast carcinogenesis. Therefore, therapeutic targeting of MAP3K3 may be attractive in breast cancer patients with MAP3K3-amplified breast cancer.

P2-02-04
**Novel Functions of vps34 in Non-Transformed Epithelial Cells: Regulation of Cell Proliferation and Tumorigenesis.**

Su H, Xu T, Ganapathy S, Yuan Z-M. UTHSCSA, San Antonio, TX

Autophagic and endocytic pathways are tightly regulated membrane rearrangement processes that are crucial for homeostasis, development and disease. A list of proteins regulating these cellular processes show altered expression in cancers, suggesting derailed autophagy or endocytosis as an emerging feature of cancer. Class III phosphatidylinositol 3-kinase (PI3kinase) Vps34 regulates both autophagic and endocytic systems by recruiting proteins containing PtdIns3P binding domains. Recently, many new insights into the biology of class III PI3Kinase have been reported. Most of these studies, however, used mainly transformed cells. It is unclear whether class III PI3Kinase works similarly in non-transformed cells. In the recent study, we explored this by depleting both transformed and non-transformed mammary epithelial cell lines of Vps34 using shRNA. In consistent with previous finding, vps34-depleted cells are defect in formation of FYVE-GFP puncta, and showed altered early and recycling endosome dynamics. In a shark contrast to transformed cells where knockdown of Vps34 was associated with decreased growth, Vps34 deficiency in non-transformed cells resulted in a marked increase in cell proliferation. The deregulated autophagy function found in Vps34-depleted cells appeared to be not involved in cell growth regulation as silence of either Atg7 or Beclin1 expression did not affect the growth rate. On the other hand, reporter luciferase-based ten-pathway screens suggested an altered activity of the MAPK pathway. Indeed, biochemical analysis indicated a sustained ERK activation resulting from the impediment of endosome-mediated EGFR turnover in Vps34 deficient cells. A contribution of the endosomal pathway to Vps34-mediated regulation of cell proliferation was further confirmed by using Rab5 and Rab11 mutants that deregulated early and recycling endosome, respectively. Importantly, inactivation of Vps34 compromized the cellular barrier against oncogene-mediated transformation, as demonstrated by the increased susceptibility of Vps34-depleted cells to Ras-induced colony formation in vitro and tumor development in mice. All together, our data uncover a novel role for the class III PI3Kinase-endosomal pathway in regulation of cell proliferation.

P2-02-05
**Molecular Mechanism for Src Homology Phosphotyrosyl Phosphatase 2 Regulation of Cell Motility and Migration.**

Hartman ZR, Agazie YM. West Virginia University School of Medicine, Morgantown, WV

Background: The Src homology phosphotyrosyl phosphatase 2 (SHP2) acts as a transducer of mitogenic and cell survival signaling downstream of receptor tyrosine kinases, cytokine receptors and integrins. As such, SHP2 promotes cell growth, transformation, survival, and motility, among other processes. Recent studies suggest that SHP2 is overexpressed in breast cancer and is essential for the maintenance of the transformed phenotype both in the HER2-positive and the basal-type/triple-negative breast cancer (BTBC) cells.

Materials and Methods: The expression of SHP2 in BTBC cells was suppressed constitutively by lentivirus-mediated transduction of specific shRNA. Impact of SHP2 inhibition on cell migration was determined by the monolayer wound healing assay. The SHP2 substrate-trapping mutant was used to identify FAK as an SHP2 substrate. Site-directed mutagenesis, binding studies and phosphatase assays were employed to further characterize FAK as a bona fide SHP2 substrate. Immunofluorescence microscopy was conducted to visualize the amounts of phosphorylated FAK and its location in the cell after adhesion.

Results: We demonstrate that SHP2 is essential for the migration of BTBC cells as evidenced by loss of the enhanced migratory behavior upon its inhibition. Using the SHP2 substrate-trapping mutant, FAK was identified as a biological substrate of SHP2. Site-directed mutagenesis, binding studies and phosphatase assays confirmed that SHP2 indeed associates with and dephosphorylates FAK at the pY397 site, a site known to promote the focal adhesion activity of FAK. Immunofluorescence of breast cancer cells with SHP2 inhibition were found to have higher levels of FAK pY397 further confirming that FAK is an SHP2 substrate. The increase in pY397 level correlated with loss of cell polarity, enhanced focal adhesion formation, and acquisition of non-transformed morphology.

Discussion: These results suggest that dephosphorylation of pY397 of FAK by SHP2 is the major mechanism by which it is able to modulate cancer cell migration. Together with previous findings, the current studies show that SHP2 is a suitable target for therapeutic intervention to combat breast cancer metastasis.

P2-02-06
**Inhibition of CDK4 Phosphorylation of Smad3 Decreases Cyclin D Overexpressing Breast Cancer Cell Proliferation and Migration.**

Tarasewicz E, Hardy A, Straehla J, Foucar C, Zelivianski S, Jeruss J. Northwestern University Feinberg School of Medicine, Chicago, IL

Introduction: Several aspects of breast cancer onset and disease progression have been linked to members of the TGFβ superfamily and their associated downstream signaling components, the Smads. Alterations in Smad signaling have been directly implicated in the dichotomous role of TGFβ in malignancy, enacting both tumor suppressant and tumor promoting behaviors in breast carcinogenesis. Our previous work characterized Smad3 as a tumor suppressor and found that Smad3 action is inhibited upon phosphorylation
by cyclin D/CDK4 in breast cancer cells. Others have shown that CDK phosphorylation of Smad3 can affect cell motility. Based on these findings, we hypothesized that activation of CDK4 leads to phosphorylation and inhibition of Smad3, thus releasing cell cycle arrest and promoting cell proliferation and metastasis.

Methods: MCF7 parental and cyclin D overexpressing cells (MCF7 CD1) were treated with a CDK4 inhibitor alone or in combination with doxorubicin or paclitaxel and cell proliferation was determined using the MTS assay. MCF7 study cells were also transduced with lentiviral empty vector, wild-type (WT) Smad3, or Smad3 containing mutant CDK sites (T179V and 5M) resistant to inhibitory cyclin D/CDK phosphorylation. Stably transduced cells were plated in Matrigel 3-dimensional (3D) culture and treated with CDK4 inhibitor alone or with doxorubicin over a 12 day time course. Colony area was measured using MetaMorph software. Transwell migration and Matrigel invasion assays were used to determine the effect that transfection with Smad3 CDK phosphorylation site mutants or treatment with a CDK4 inhibitor had on highly metastatic cyclin D expressing MDA-MB-231 cells. Study wells were fixed/stained and the number of migrated or invaded cells was counted.

Results: Treatment with the CDK4 inhibitor alone resulted in a growth inhibitory effect on proliferation of MCF7 parental and CD1 cells. Treatment with the CDK4 inhibitor in combination with chemotherapy resulted in the greatest inhibition of cell proliferation. In 3D culture, colonies formed by MCF7 study cells transduced with T179V or 5M Smad3 mutant constructs had smaller acinar size when compared with vector-transduced control cells. When compared to untreated cells, the MCF7 CD1 cells treated with CDK4 inhibitor or chemotherapy alone had smaller acinar size, with greatest decrease in size observed when the treatments were combined. Lastly, MDA-MB-231 cells transfected with the 5M Smad3 mutant construct, containing mutations in all 5 CDK phosphorylation sites, resulted in the greatest decrease in cell migration and invasion, when compared with cells transfected with both vector control or WT Smad3. Treatment of the MDA-MB-231 cells with the CDK4 inhibitor also resulted in a significant decrease in cell migration and invasion.

Conclusions: Mutation of CDK phosphorylation sites in the Smad3 construct or direct inhibition of CDK4 resulted in a decrease in breast cancer cell proliferation, 3D colony formation and cell migration and invasion. Treatment with the CDK4 inhibitor in combination with chemotherapy further augmented these results. Inhibition of CDK4 and restoration of Smad3 activity may have a role in the treatment of breast cancers overexpressing cyclin D.

P2-02-07
Regulation of mTOR Signaling by Proto-Oncogene PELP1.
Gonugunta VK, Cortez V, Rethman C, Nair BC, Sareddy GR, Vadlamudi RK. UTHSCSA, San Antonio, TX

BACKGROUND: Despite positive effects of hormonal therapy, initial or acquired resistance to endocrine therapies frequently occurs. Emerging evidence suggests that ER activity is complex and requires functional interactions with coregulators. In addition, ER also participates in extra-nuclear signaling events in the cytoplasm and growth factor cross talk with ER is implicated in the development of therapy resistance. The mammalian target of rapamycin (mTOR) is a serine/threonine kinase that plays an important role on cell growth and proliferation. Proline, Glutamic-acid and Leucine-rich Protein 1 (PELP1) is an ER coregulator that functions in nuclear as well as extra-nuclear actions. PELP1 functions as a proto-oncogene and is a prognostic indicator of shorter breast cancer specific survival. The objective if this study is to examine whether PELP1 participates in ER-growth factor signaling cross talk via mTOR pathway.

METHODS: To test this hypothesis, we have used ER-positive model cells (MCF7, ZR75) along with PELP1 over expressing (MCF7-PELP1, ZR75-PELP1) and PELP1 knock down cells (MCF7-PELP1 shRNA, ZR-75-PELP1 shRNA). Estrogen and Heregulin were used as signal inducers. Rapamycin that inhibit mTORC1 and AZD8055, an inhibitor of both mTORC1 and mTORC2 activities were used as pharmacological inhibitors to block mTOR pathway. The affect of blocking mTOR axis on PELP1 mediated oncogenic functions was determined using ERE and E2F reporter gene assays, cell proliferation (MTT) and anchorage independent assays. Cell cycle progression was monitored by flow cytometry. PELP1 modulation of mTOR signaling was validated using siRNA approach in MCF7, ZR75 cells and/or by PELP1 overexpression in PELP1-shRNA clones and evaluated the role of identified components for changes in the mTOR signaling using Western analysis. IHC analysis of mTOR signaling components was performed using tissues collected from PELP1 overexpressing and PELP1 siRNA lenti homoe treated tumors.

RESULTS: Over expression of PELP1 enhanced the estrogen and heregulin mediated cell proliferation in breast cancer cells. Knock down of PELP1 with siRNA significantly reduced the activation of mTOR signaling components (p70S6K and 4E-BP1). Accordingly, over expression of PELP1 in the breast cancer cells correlated with increased mTOR signaling. Pharmacological inhibition of mTOR substantially reduced PELP1 mediated ER coactivation functions in ERE reporter gene assays. Rapamycin (10^-5M) or AZD8055 (10^-M) abolished PELP1 mediated growth advantage in estrogen and heregulin stimulated breast cancer cells. Further, combinatorial treatment of mTOR inhibitors sensitized PELP1 overexpressing cells to tamoxifen therapy. IHC studies using xenograft tissues with PELP1 overexpression or down regulation, showed correlation of PELP1 expression with the activation of mTOR signaling components.

CONCLUSIONS: Our results suggest that PELP1 driven oncogenic functions involve PELP1 modulation of mTOR signaling and blockage of mTOR signaling render PELP1 driven tumors highly sensitive to therapeutic inhibition.

P2-02-08
Int6 Regulates Both Protesomal Degradation and Translation Initiation and Is Critical for Proper Formation of Acini by Human Mammary Epithelium.
Seo J, Snider SJ, Lloyd RE, Chang EC. BCM

The mammalian INT6/EIF3E gene has been implicated in breast tumor formation, but its functional activities remain poorly defined. Consistent with the fact that Int6 is frequently down-regulated in human breast tumors, we found that repressing INT6 expression induced transformed properties in normal human mammary epithelial cells (MCF10A) in both 2D and 3D cultures. Int6 contains a PCI domain, found in several components of both the proteasome and the translation initiation factor eIF3, suggesting that it can functionally interact with both. Indeed, our data show that Int6 associates with proteasomes in human cells, and that INT6 knockdown prevents proper assembly of active proteasomes. In addition, we show that down-regulation of INT6 reduces translation initiation (both polysome formation and global protein synthesis). However, Int6 regulates translation selectively, reducing translation from cap-dependent and Becl-2- IRES reporters, but stimulating translation from the CVB3 IRES. These data collectively suggest that Int6 controls both protein synthesis and protein degradation, and is thus capable of fine-tuning
protein levels. Abnormal levels of regulatory proteins caused by Int6 abnormalities may thus be responsible for disrupting normal morphogenesis of mammary epithelial cells and causing transformed phenotypes.

P2-02-09
TP53 Mutation Patterns in Breast Cancer Subgroups.

Tumor protein 53 (TP53) is the most commonly altered gene in human cancers. In breast cancers, TP53 is mutated in approximately 30% of all cases, but this frequency fluctuates widely within the different molecular subclades. Different types of mutations may be observed, such as substitutions (replacement of a nucleotide pair by another one), or complex mutations (deletions or insertions of one or more nucleotides). Mutation types may reflect mechanism of DNA lesion or DNA repair deficiencies. Furthermore, mutations can give rise to different effects such as truncating mutations leading to loss of function, or missense mutations often leading to dominant negative activity. Those mutation effects can be advantageous in tumorigenesis and thus can be subject to selective pressure.

Here we classified 572 breast tumors in three groups, according to microarray data: luminal, basal and molecular apocrine. TP53 status was assessed by a yeast-based functional assay (FASAY) and cDNA sequencing. We then assessed whether any feature of TP53 mutations would be preferentially associated to a specific subtype of breast cancer.

- In term of TP53 mutation frequencies, as expected, lowest frequency was observed in luminal subgroup (26%) and highest in basal (90%) and molecular apocrine (70%). Notably, much higher rate of TP53 mutations occurred in luminal B subgroup (41%) than in luminal A one (17%), suggesting that TP53 may be an important feature in progression from luminal A to B.

- In term of mutations types, luminal tumors showed high frequency of substitutions, while molecular apocrine and basal presented increased rate of deletions and insertions, reflecting probably increased rate of DNA breaks. This suggests that same mutational events may occur in basal and molecular apocrine tumors.

- In term of mutation effects, we found high frequency of missense mutations in luminal tumors (notably AT to GC) and much higher rate of truncating mutations in basal tumors. These observations point to an existence of different selection pressure in each of them, such as a strong pressure for P53 mutations with potential dominant negative inhibition of P73/P63 (recently shown to favor invasion), in luminal tumors. Collectively, these results point not only to different mechanisms of P53 gene inactivation, but also different functional consequences among the different breast cancer subclades.

P2-03-01
Genetic Reduction of Circulating Insulin-Like Growth Factor (IGF)-1 Differentially Impacts the Effects of Diet-Induced Obesity and Calorie Restriction on Mammary Tumor Progression.
Ford NA, Nunez NP, Perkins SN, Hursting SD. University of Texas at Austin, Austin, TX; National Cancer Institution, Rockville, MD

Background: Epidemiological evidence suggests that obesity worsens breast cancer prognosis in pre- and postmenopausal women. Previously we demonstrated that diet-induced obese (DIO) mice and rats have higher circulating levels of IGF-1 and enhanced mammary tumor burden compared to normoweight controls. In contrast, we have found in several mouse models that a 30% calorie restricted (CR) diet regimen reduced serum IGF-1 levels and decreased mammary tumor growth. The present study investigated the effects of CR and DIO on mammary tumor growth in mice with normal serum levels of IGF-1 (wild-type) or mice with reduced circulating levels of IGF-1 (LID).

Our goal was to identify new targets and strategies (with a focus on the IGF-1 pathway) for breaking the obesity-breast cancer link, which is important given the high prevalence of obesity in the U.S., and the strong association between obesity and breast cancer.

Materials and Methods: Virgin female liver-specific IGF-1-deficient (LID) and wild-type (FVB/Ncr) mice (10-12 weeks of age) were randomized (n=10-14 per group) to receive: control diet (modified AIN-76A), a 30% CR regimen, or a DIO regimen (60 kcal% fat diet). Mice consumed the experimental diets for 11 to 15 weeks prior to orthotopic injection (4th mammary fat pad) of Met-1 tumor cells derived from a polyoma middle-T antigen transgenic mouse mammary tumor. Transplanted tumors were allowed to grow for 4 weeks and tumor volume was measured by electronic calipers biweekly. Mice were then killed, serum was collected and
stored at -80°C, and tumors were excised, weighed and either formalin-fixed, paraffin-embedded or flash-frozen.

Results: Using the LID mouse model of IGF-1 deficiency, this study established that decreased circulating IGF-1 (relative to wild-type mice) dramatically reduces Met-1\(^{fvb2}\) mammary tumor growth regardless of diet treatment (P=0.034). We also showed in LID mice that CR (44 +/- 15.6 mm\(^3\)), relative to control diet (89 +/- 33 mm\(^3\)) has no significant effect on Met-1\(^{fvb2}\) tumor growth, suggesting nearly all of the suppressive effects of CR on tumor growth (at least in the Met-1\(^{fvb2}\) model), can be explained by reduced systemic IGF-1. In contrast, while most of the DIO effect on tumor growth was ablated in the LID mice (332 +/- 104 mm\(^3\)) vs. wild-type mice (3130 +/- 421 mm\(^3\)), tumor growth in LID/DIO mice was significantly higher than LID/control mice (89 +/- 33, P=0.006) despite no change in IGF-1 levels, suggesting that a mechanism independent of IGF-1 contributes to some of the effects of DIO on Met-1\(^{fvb2}\) mammary tumor growth. Within LID mice, serum insulin, resistin and adiponectin were not modified by the CR or DIO diet.

Discussion: We conclude that components of the IGF-1 pathway represent promising mechanistic targets for mimicking the anti-cancer effects of CR and breaking the obesity-breast cancer link. However, there are likely other mechanisms independent of IGF-1 that contribute to the breast tumor enhancing effects of DIO and that need to be defined.

P2-03-02
An IGF1R Antibody Does Not Inhibit Growth of Tamoxifen Resistant MCF-7 Cells.
Fagan DH, Yee D. University of Minnesota, Minneapolis, MN

The role of the insulin-like growth factor (IGF) system in breast cancer has been well defined, and inhibitors of this pathway are currently in clinical trials. The majority of anti-IGF1R clinical trials are in estrogen receptor-positive patients who have progressed on prior endocrine therapy with some early reports showing no benefit for addition of IGF1R inhibitors to endocrine therapy. The effect in endocrine-resistant models, mimicking the clinical trial scenario, has not been adequately investigated. To examine the effectiveness of IGF1R inhibitors in vitro, tamoxifen-resistant (TamR) cells were generated by culturing MCF-7L cells in the presence of 4-hydroxy-tamoxifen for more than 1 year. TamR cells had diminished levels of IGF1R with unchanged levels of insulin receptor (IR), and enhanced phosphorylation of Akt. Further, TamR cells failed to further respond to IGF-1-induced Akt activation while retaining responsiveness to both insulin and IGF-II. Additionally, IGF-1 failed to enhance the proliferation and anchorage-independent growth of TamR cells; however, both insulin and IGF-II stimulated proliferation and anchorage-independent growth. An IGF1R antibody (dalotuzumab) was able to inhibit IGF-I-mediated Akt phosphorylation, proliferation, and anchorage-independent growth in parental MCF-7L cells and had minimal effect on insulin and IGF-II stimulation. In TamR cells, dalotuzumab failed to inhibit proliferation or anchorage-independent growth in response to either insulin or IGF-II. An IGF1R tyrosine kinase inhibitor, (AEW 541) with equal potency for the IGF1R and IR, inhibited IGF-I, IGF-II, and insulin-stimulated Akt phosphorylation, proliferation, and anchorage-independent growth in parental MCF-7L cells. Interestingly, AEW 541 also inhibited insulin- and IGF-II-stimulated Akt phosphorylation, proliferation, and anchorage-independent growth in MCF-7L TamR cells. We conclude that cells selected for tamoxifen resistance in vitro have downregulated IGF1R making antibodies directed against this receptor ineffective. Preliminary studies in vivo, suggest that initial co-treatment with tamoxifen plus dalotuzumab was more effective than either drug alone. In contrast, acquired tamoxifen resistance might require dual inhibition of IGF1R and PI3K targets to completely suppress IGF system signaling as currently under study in the clinic. Alternatively, IGF1R tyrosine kinase inhibitors may be effective by inhibiting both IGF1R and IR signaling in cells selected for tamoxifen resistance.

P2-03-03
An Insulin-Like Growth Factor I (IGF-I)-Induced Gene, Solute Carrier Family 7 Member 11 (SLC7A11)/xCT, Mediates IGF-I-Induced Biological Behaviors in Breast Cancer Cells.
Yang Y, Becker MA, Yee D. University of Minnesota, Minneapolis, MN

Our laboratory studied the gene expression profiles of a series of T47D variant cell lines with differential insulin receptor subtype (IRS) adaptor protein expression to develop predictive IGF-I pathway biomarkers. We identified an IGF-I-induced gene, SLC7A11 (or xCT), which is specifically regulated through IRS-1. xCT encodes the cystine/glutamate transporter subunit of the heterodimeric amino acid transport system xc- which is a major plasma membrane transporter for the cellular uptake of cystine in exchange for intracellular glutamate. xCT is involved in the regulations of proliferation, metastasis, and drug resistance in various cancers. However, to date, the linkage between xCT and the IGF-I signaling pathway has not been described. To study the role for xCT in mediating IGF-I-induced biology in breast cancer cell lines, we examined xCT mRNA expression upon IGF-I stimulation in two breast cancer cell lines; the MCF-7 (IRS-1 activated) and MDA-MB-231 (IRS-2 activated) cells. Significant increased xCT expression was observed only in MCF-7 cells after IGF-I treatment. Immunoblots showed that xCT protein expression was elevated after IGF-I treatment and induced glutamate/cystine exchange in MCF-7 cells. shRNA was used to downregulate xCT in MCF-7 and MDA-MB-231 cells. In MCF-7, IGF-I-stimulated cell monolayer growth was suppressed by xCT shRNA or by the xCT inhibitor sulfasalazine (SASP). In MDA-MB-231 cells, xCT downregulation did not affect IGF-mediated Boyden chamber migration. Thus, IGF-I induction of cellular xCT levels is associated with cell growth in the IRS-1 activated MCF-7 cells, while MDA-MB-231 cells were not affected by downregulation of this gene. Therefore, our data imply that xCT may mediate IGF-I induced biological functions in breast cancer cell lines through an IRS-1 dependent pathway.

Novel Pathways Underlying the Initiation and Transition of DCIS to IDC of HER2-Overexpressing Breast Cancer Model.
Pradeep CR, Koestler W, Lauriola M, Nair H, Rao R, Mills GB, Yarden Y. MD Anderson Cancer Centre, Houston, TX; Weizmann Institute of Science, Rehovot, Israel; Southwest National Primate Research Center, San Antonio, TX; University of Texas Health Science Center San Antonio, San Antonio, TX

Background: The HER2/Neu -oncogene is amplified in 20-25% of human primary breast cancers and this alteration is associated with disease behaviour. The HER2/neu oncogene encodes a receptor-like tyrosine kinase, whose overexpression in breast cancer predicts poor prognosis and resistance to conventional therapies. Whereas signalling pathways emanating from HER2 have been characterized, much less is known about the transcriptionally regulated genes controlled by HER2 that contribute to the initiation of Ductal Carcinoma Insitu (DCIS) and their transition to an invasive ductal carcinoma (IDC).
Materials and Methods: Normal and HER2 overexpressing mammary epithelial cells (MCF10A) were grown in extracellular matrix to form 3D structures. When grown in extracellular matrix as 3-dimensional spheroids, control cells developed a hollow lumen, but HER2-overexpressing cells populated the lumen by evading apoptosis. On the next step, upon the growth factor stimulation HER2-overexpressing cells grown in extracellular matrix, which protruded invasive outgrowths. Highly variable genes were selected from the described phenotypes using RNA isolated from the 3D structures and hybridized to an Affymetrix HuGene 1.0 ST oligonucleotide array.

Results: Using microarrays we analysed transcriptional events responsible for the morphological changes and found several novel sets of genes such as integral proteins, transcription factors, matrix proteases, Notch genes and chemokines were highly altered in the HER2 overexpressing group which were not appreciated before. Using gene annotation we defined molecular-pathways responsible for the phenotypical changes. More specifically, our study proposes a two hit model describes the pathways involved in the initiation of the Ductal Carcinoma In situ and their transition to Invasive Cancer underlying the HER2 transcriptional network.

Discussion: According to the proposed model, expansion of ductal hyperplasia is limited by intraluminal apoptosis, unless they overexpress HER2, which drives proliferation and forms DCIS due to HER2 induced Notch pathways genes. Secondly, results obtained with the 3D system and their reflection in clinical outcome, we propose that neither HER2 amplification nor the presence of GFs, is sufficient for development of IDC, but their co-occurrence can instigate metastasis by the activation of genes of integrin-adhesion signaling. The more virulent scenario combines HER2 amplification with GFs, thereby switching a robust, auto-stimulatory program.

Lin S, Yang J, Ellekholou AG, Bandyopadhyay A, Wang L, Cornell JE, Yeh F-T, Aygijn JK, Sun L-Z. University of Texas Health Science Center; San Antonio, TX; NIHGRF-NIH, Bethesda, MD

Triple negative, basal-like breast cancer is highly aggressive and has a poor prognosis. The molecular mechanisms that drive its progression are elusive and no molecular target has been identified for its prevention or treatment. Here, we demonstrate that triple negative human breast cancer cells and clinical samples show an attenuated transforming growth factor-beta (TGF-β) signaling. Therefore, we developed a series of isogenic basal-like human mammary epithelial cells (HMECs) with altered TGF-β sensitivity and different malignancy, resembling a full spectrum of basal-like breast carcinogenesis, and determined the molecular mechanisms that contribute to oncogene-induced transformation of basal-like HMECs when TGF-β signaling is attenuated. We found that expression of a dominant-negative RI1 (DNRII) receptor of TGF-β1 abrogated autocrine TGF-β1 signaling in telomerase-immortalized HMECs and suppressed H-ras-V12-induced senescence-like growth arrest (SLGA). Furthermore, co-expression of DNRII and H-ras-V12 rendered HMECs to become highly tumorigenic and metastatic in vivo in comparison with H-ras-V12-transformed HMECs that spontaneously escaped H-ras-V12-induced SLGA. By using microarray analysis, we found that p21 is the major player mediating Ras-induced SLGA and attenuated or loss of p21 expression contributed to the escape from SLGA when autocrine TGF-β signaling is blocked in HMECs. Furthermore, knockdown of p21 also suppressed H-ras-V12-induced SLGA. Our results identifies that autocrine TGF-β1 signaling is an integral part of cellular anti-transformation network by suppressing the expression of a host of genes including p21-regulated genes that mediate oncogene-induced transformation in basal-like breast cancer.

Endothelin-1/Endothelin A Receptor Signalling in Breast Cancer.
Tamkus D, Leece C, Gallo K, Madhukar BV, Dimitrov N. Michigan State University (MSU)

Background: Endothelin-1 (ET-1) and endothelin A receptor (ETAR) are implicated in breast cancer growth and progression. ET-1 is secreted by both tumor cells and stroma (macrophages, endothelial cells). The purpose of this study is to evaluate ET-1/ETAR role on cell proliferation and its effects on EGFR signaling pathway.

Materials and Methods: Two breast cancer cell lines: MCF-7 and MDA-MB-231 were stimulated with ET-1. Proliferation of breast cancer cells was analyzed using MTT assay. Protein expression (EGFR, pEGFR, AKT, pAKT, ERK, pERK ) was evaluated by Western blot. siRNA knockdown of endothelin A receptor (ETAR) was performed in MCF-7 and MDA-MB-231.

Results: ET-1 stimulated proliferation in both cell lines. Interestingly, at higher ET-1 concentrations cell proliferation was more pronounced in MCF-7 when compared with MDA-MB-231. Stimulation with ET-1 activated EGFR and downstream signaling proteins (pAKT and pERK) in both cell lines. Incubation of breast cancer cells with ET-1 for 48 hours had different effect on total EGFR level: 3 fold increase of total EGFR was seen in MCF-7, while no change was detected in MDA-MB-231. siRNA against ETAR decreased ET-1 induced cell proliferation and reduced total EGFR level in MCF-7.

Conclusions: These observations suggest that ET-1/ETAR plays an important role in survival and proliferation of breast cancer cells. However, those effects are diverse in different subtypes of breast cancer. Our results may represent an improved selective targeted treatment strategy, especially for estrogen receptor positive breast cancer.

P2-04-01
Extracellular PAI-1 – t-PA – IGFBP3 Cascade Mediates Chemotherapy-Induced Senescence of Breast Cancer Cells.
Shioji Y, Etzi DJ, Song M, Hakala K, Weintraub ST. The University of Texas Health Science Center; San Antonio, TX

Upon successful chemotherapy, cancer cells undergo either apoptosis or senescence. Whereas the mechanism of cancer cell apoptosis is relatively well understood, there is only scant knowledge on how chemotherapy-induced cancer senescence occurs. Here we report that a cascade of secreted proteins, plasminogen activator inhibitor 1 (PAI-1) - tissue-type plasminogen activator inhibitor (t-PA) – insulin-like growth factor-binding protein 3 (IGFBP3), mediates chemotherapy-induced senescence of breast cancer cells.

MCF-7 breast cancer cells display robust senescence induction upon doxorubicin treatment and we found that the conditioned medium from senescent MCF-7 cells can induce senescence in non-senescent MCF-7 cells, which suggested the presence of secreted mediator(s) of senescence. To identify such mediator(s), we undertook a quantitative proteomic analysis of the protein secretion from senescent MCF-7 cells and observed significantly increased levels of secreted IGFBP3. Increased extracellular IGFBP3 levels were also observed upon doxorubicin-induced senescence of ZR75-1 breast cancer cells and primary mammary epithelial cells. We demonstrated that IGFBP3 induces senescence in breast cancer cells, which requires the Rb and
p53 pathways. Conversely, shRNA-mediated knock-down of IGFBP3 alleviated doxorubicin-induced senescence of breast cancer cells. These results suggest that IGFBP3 functions as a secreted mediator of chemotherapy-induced breast cancer senescence.

To gain insight into the regulation of IGFBP3-induced senescence, we undertook a proteomic screening for IGFBP3 interactors in the secretome and identified t-PA as candidate interactor. t-PA is a secreted protease that is known to cleave and activate plasminogen. We found that t-PA cleaves IGFBP3 and abolishes IGFBP3-induced or doxorubicin-induced senescence of breast cancer cells. The protease activity of t-PA toward plasminogen is inhibited by PAI-1 and we demonstrated that PAI-1 also protects IGFBP3 from cleavage by t-PA. Interestingly, PAI-1 was previously identified as an inducer of senescence that acts downstream of p53 (Nature Cell Biology 8:877-84, 2006). We showed that IGFBP3 knock-down by shRNAs abolishes senescence induction by PAI-1, suggesting that IGFBP3 is a critical downstream mediator of PAI-1-induced senescence. We also observed dramatically increased extracellular PAI-1 levels upon doxorubicin-induced senescence of breast cancer cells. Importantly, RNAi suppression of PAI-1 in breast cancer cells resulted in concomitant suppression of extracellular IGFBP3 levels upon doxorubicin treatment and abrogation of senescence induction. Taken together, these results suggest a role for extracellular PAI-1 – t-PA – IGFBP3 cascade in mediating chemotherapy-induced senescence of breast cancer cells.

This study uncovered the extracellular components of senescence signaling for chemotherapy-treated breast cancer cells. Senescence mediators secreted from chemotherapy-treated breast cancer cells may amplify the senescence response and provide a non-cell autonomous tumor suppression mechanism. These extracellular senescence mediators could be exploited to increase the efficacy of breast cancer chemotherapy.

Identification of a Novel Glycosyltransferase-Like Gene as an Autophagic Inducer in Human Mammary Carcinoma Cells Via Down Regulation of BCL-2.

Shastri BG, Jung Y, Steiner M, Perry JK, Lobie PE, Liu D-X. Liggins Institute, Auckland, New Zealand; Cancer Science Institute of Singapore, Singapore, Singapore

Here we report the identification of a previously undescribed glycosyltransferase-like gene, GLTx, and its cellular effect on mammary carcinoma cells. GLTx codes for a novel human protein which is highly conserved in primates. Data obtained from the mRNA expression database Oncomine, demonstrate that GLTx is differentially expressed in a variety of cancers including breast cancer. Western blot analysis of a multiple human tissue blot using a rabbit polyclonal antibody against GLTx demonstrated that GLTx was highly expressed in liver, moderately in kidney, intestine and stomach and undetectable in any other tissues. To functionally characterize GLTx, we attempted to establish stable cell lines with forced expression. However, forced expression of GLTx was completely lethal and resulted in severe cell death in the mammary carcinoma cell lines, MCF-7 and BT549, as well as in any other cell lines tested. Staining of MCF-7 cells transiently transfected with a GLTx expression plasmid by either Hoechst 33258 or fluorescein isothiocyanate-conjugated annexin V and propidium iodide confirmed that the observed cell death was not caused by apoptosis. Further investigation confirmed that GLTx expressing cells exhibited cytolytic accumulation of autophagosomes, consistent with the induction of autophagy, as measured by the fluorescently labelled autophagosome marker LC3. In addition we have shown that GLTx downregulated BCL-2, an inhibitor of autophagy, as measured by BCL-2 gene promoter luciferase activity assay and western blot assay following transient transfection of a GLTx expressing plasmid. Thus, we have demonstrated that GLTx is a novel autophagic inducer that causes cell death by down regulating BCL-2.

Acquired Tamoxifen Resistance Promotes Angiogenic Responses in ER+ Breast Cancer Cells.

Hayes E, Smith C, Nicholson RI, Gee J, Hiscox S. Cardiff University, Wales, United Kingdom

Background: In the treatment of pre-menopausal women with oestrogen positive (ER+) breast cancer, tamoxifen represents a first line of adjuvant treatment with demonstrable benefits. Despite this, resistance is frequently acquired to tamoxifen with an associated poor prognosis. Breast cancer cell models have revealed the importance of growth factor signalling networks in sustaining growth of endocrine-resistant cancers and, more recently, their ability to promote a highly migratory and invasive phenotype, together with the expression of genes with pro-angiogenic ontology. The potential of endocrine resistant cells to elicit angiogenic responses, however, remains unknown.

Materials and Methods: Real-time PCR was used to validate results from preliminary Affymetrix-based gene profiling of pro-angiogenic gene expression in endocrine-sensitive MCF7 cells and their tamoxifen-resistant (TamR) counterparts. The expression of pro-angiogenic factors in conditioned media (CM) from these cells was assessed by ELISA. The proliferative and migratory effects of MCF7 and TamR CM on vascular endothelial cells (HUVEC and HECV cells), was determined by MTS cell proliferation assay, wound closure assays and Matrigel tube formation assays. Changes in endothelial cell migration following co-culture with endocrine-resistant cells were examined using Boyden-chamber chemotaxis assays. Growth factor signalling and migration pathway activation in endothelial cells in response to CM was determined by Western blotting.

Results: TamR cells were found to express high levels of HIF-1α, IL-8 and VEGF-A at an mRNA level compared with expression in MCF7 cells. High levels of VEGF-A protein were also confirmed in the conditioned media from TamR cells versus their endocrine-sensitive counterparts. TamR conditioned media promoted endothelial cell proliferation, migration and the formation of tubules to a greater extent than that seen in MCF7 CM treated cells. TamR conditioned media was found to stimulate VEGFR2 phosphorylation and downstream activation of MAPK in endothelial cells compared to MCF7 CM. Pharmacological inhibition of VEGFR2 activity in endothelial cells suppressed TamR-induced endothelial cell proliferation and VEGFR phosphorylation. Further pharmacological manipulation of erbB receptors and intracellular kinases in TamR cells revealed an ERGF/Her2-Src kinase dependent mechanism of VEGF-A production in these cells.

Discussion: These data suggest acquired tamoxifen resistance is accompanied by development of an erbB receptor/Src kinase-dependant pro-angiogenic phenotype which, if recapitulated in vivo, may promote tumour progression. Therapeutic targeting of erbB/Src axis may prove beneficial in such cases.

PGC1, Peroxisome Proliferator Activated Receptor-gamma (PPAR-gamma) Coactivator-1, Is Necessary in PPAR-gamma Modulated Angiogenesis.
Jiang WG, Li X, Mansel RE. Cardiff University School of Medicine, Cardiff, Wales, United Kingdom

Background. Peroxisome proliferator activated receptor-gamma (PPAR-gamma), a nuclear hormone receptor, has been shown to be an important regulator of gene expression. PPAR-gamma agonists have been shown to have anti-cancer properties by ways of inducing expression of tumour suppressor genes. It has been indicated that this action of PPAR-gamma is manifested by forming a complex with the PPAR-gamma coactivators (PGC1 & 2) and in association with other transcription factors such as SRC-1 and CREB binding proteins. Both PPAR-gamma and PGC-1 have been shown to be aberrantly expressed in human cancer including human breast cancer (1). PPAR-gamma also plays a role in regulating angiogenesis and that PPAR-gamma agonists have been shown to have anti-angiogenic functions. In the present study, we investigated the role of PGC-1 in PPAR-gamma mediated actions on vascular endothelial cells.

Materials and methods. Mammalian expression systems for human full length PGC-1 were constructed again using human mammalian expression vector in pCDNA3.1. Anti-PGC-1 transgenes were constructed again using human mammalian expression vector in order to knock down PGC-1 transcript from the cells. Human vascular endothelial cell, HECV, was used in the study. Cell functions linked to angiogenesis including cell adhesion and cellular migration was evaluated using the electric cell impedance sensing method. PPAR-gamma agonists and antagonists were used in the cell models during the analyses.

Results. HECV cells weakly expressed PGC-1 and PPAR-gamma. Using the transgenes created, sublines over-expressing PGC1 (HECVPGC1exp) or with PGC-1 expression knockdown (HECVPGC1KD) were established. Loss of PGC1 showed marked increase in both adhesion and cellular migration, opposite was true for HECVPGC1exp cells. PPAR-gamma agonist, pioglitazone and ciglitizone, reduced the adhesion of control cells. In contrast, PPAR-gamma antagonist SR202 exhibited a concentration dependent stimulation of both adhesion and migration of the control cells. Knocking down PGC1 in endothelial cells rendered cells lost response to SR202.

Conclusions. PGC-1 is essential in the modulation of endothelial cells by PPAR-gamma. Together with the aberrant expression of both PPAR-gamma and PGC-1 in breast cancer, it is concluded that PGC-1 is a central player in PPAR-gamma mediated action in both cancer cells and angiogenesis.

P2-05-03

Is Breast Cancer Tryptase a Novel Anti-Angiogenic Molecular Target?

Tryptase, a serine protease stored and released from mast cells granules has been identified as a new non-classical angiogenic factor. Tryptase is an agonist of proteinase-activated receptor-2 a G protein involved in cellular proliferation and angiogenesis. On the other hand mast cells can release tryptase following c-Kit receptor activation. We have evaluated the correlations among the number of MCs positive to tryptase (MCDPT), the number of c-Kit receptor expressing cells (C-KREC) and microvascular density (MVD) in a series of 91 primary T1-3, N0-2 M0 female breast cancer by means of immunohistochemistry and image analysis methods. Six-micrometers thick serial sections of formalin-fixed and paraffin-embedded biotpic tumor samples were microwaved at 500 W for 10 min. and treated with a 3% hydrogen peroxide solution. Sections were incubated with primary antibodies: anti-trypotase (AA1; Dako, Glostrup, Denmark), anti-c-Kit receptor (A4502; Dako, Glostrup, Denmark) and anti-CD34 (QB-END 10; Bio-Optica Milan, Italy). In serial sections MVD, MCDPT and C-KREC were counted by means of image analysis (Quantimet 500 Leica) at x400 microscopic fields. Data demonstrated a significantly (r= ranging from 0.72 to 0.91; p: ranging from 0.001 to 0.003 by Pearson’s analysis respectively) correlation between MVD, MCDPT and C-KREC to each other. Published in vitro data suggest that tryptase induce angiogenesis in vascular endothelial cells and breast cancer cells lines. According to these data we shown that MVD, MCDPT and C-KREC paralleled to each other suggesting a role in vivo breast cancer angiogenesis. In this context the inhibition of c-Kit mast cells tryptase degradation by several tyrosin kinase inhibitors might be evaluated in clinical trials. Finally available tryptase inhibitors such as gabexate mesilate or nafamost mesilate might be evaluated in clinical trials as a new antiangiogenic approach.

P2-05-04

Mapping the Specific Gene Families Activated in the Lymphangiogenesis and Vasculogenic Mimicry Exhibited by Inflammatory Breast Cancer.
Liu H, Luo AZ, Ma Z, Chu K, Ye Z, Alpaugh RK, Fernandez S, Boley KM, Jin J, Wright MC, Cristofanilli M, Robertson FM. The University of Texas, MD Anderson Cancer Center, Houston, TX; Fox Chase Cancer Center, Philadelphia, PA

Background: Inflammatory breast cancer (IBC) is the most metastatic variant of locally advanced breast cancer. Although IBC is diagnosed less commonly than other types of breast cancer, it is extremely aggressive, and accounts for a disproportionate number of breast cancer related deaths annually. IBC exhibits very specific patterns of lymphangiogenesis and vasculogenic mimicry, however detailed studies of the genes and proteins involved in these angiogenic processes are lacking. This study performed whole unbiased gene transcription studies with validation by protein arrays using all available pre-clinical cell lines and in vivo xenograft models of IBC; including a new model of IBC, FC-IBC01, which exhibits lymphovascular invasion, to identify the specific pathways involved in the distinctive angiogenesis observed in IBC.

Materials and Methods: Real-time quantitative RT-PCR, cDNA microarray gene profiling, immunofluorescence with confocal imaging and protein arrays were used to examine differential expression of specific angiogenic gene families including VEGF,A,B,C,D, VEGF Receptor genes, and ANG/TIE genes linked to angiogenesis and lymphangiogenesis.

Results: Activity of the matrix metalloproteinase, MMP-2, is required for IBC tumor cells to undergo vasculogenic mimicry (VM), which is associated with a loss of TIMP-2, a well known inhibitor of angiogenesis. Therapeutics that target MMP activity can successfully inhibit this VM. Furthermore, pre-clinical models of IBC that form IBC tumor emboli exhibit lymphovascular invasion that is associated
with distinct patterns of expression of genes that encode for distinct receptor tyrosine kinases that may represent important therapeutic targets for IBC.

Discussion: Identification of the distinct angiogenic pathways that are activated in IBC provides insight into the therapeutic targets that may abrogate the distinct lymphovascular invasion and vasculogenic mimicry that are linked to the aggressive metastasis of IBC.

**P2-05-05**
**Receptor-Like Protein Tyrosine Phosphatase Kappa (PTPRK) and Its Biological Role in Angiogenesis.**
Sun P-H, Ye L, Mason MD, Jiang WG. Cardiff University School of Medicine, Cardiff, United Kingdom

Introduction: Protein Tyrosine Phosphatases (PTPs) are known as signalling molecules which affect cell growth, differentiation and oncogenic transformation. PTPs have been indicated in tumourigenesis and progression of various solid tumours. PTPRK, receptor-type protein tyrosine phosphatase kappa, has been shown to down-regulate transcriptional activity of beta-catenin and impact distribution of beta-catenin/E-cadherin complexes on cancer cell membrane. However, the role played by PTPRK in angiogenesis remains unknown. In present study, the effect of PTPRK knock-down on functions and tubule formation ability of HECV cells was investigated. (Or in the present study, the effect of PTPRK on angiogenesis process was investigated.)

Methods: anti-PTPRK ribozyme transgenes were constructed to knock-down PTPRK expression in vascular endothelial cells, HECV cells. The subsequent effect upon in vitro cell growth, adhesion, migration and microvascular tubule formation was examined using a variety of functional assays.

Result: Knock-down PTPRK in HECV cells (HECVPTPRK) resulted in a decrease of cell growth in vitro. The growth rate of HECVPTPRK was 276.3±16.4, p=0.01 compared with HECVPTPRK (314.8±21.9) controls. However, knock-down of PTPRK in HECV cells increased cell motility. The cell migration distance of HECVPTPRK was 83.8±19.8µm, p=0.008 compared with HECVPTPRK (61.8±11.8µm) controls. No effect on cell adhesion by PTPRK knockdown was seen in HECVPTPRK (81.2±6.6), compared with HECVPTPRK control (78.8±15.6). Furthermore, knock-down of PTPRK suppressed tubule formation in HECV cells, the length of total tubules (µm) in HECVPTPRK was 2167.4±943.2, p=0.05 compared with HECVPTPRK (3130.6±386.9) control.

Conclusion: Knock-down of PTPRK reduced the growth and tubule formation abilities of vascular endothelial cells. It suggests that PTPRK is pivotal regulator for angiogenic process. Further investigations are required to identify the downstream pathways involved in these impacts.

**P2-05-06**
**Role of Repulsive Guidance Molecule b (RGMb) in HGF Mediated Angiogenesis.**
Sanders AJ, Ye L, Mason MD, Jiang WG. Cardiff University School of Medicine, Cardiff, United Kingdom

Introduction: Hepatocyte Growth Factor (HGF) has been widely documented as playing a key role in enhancing the aggressive nature of cancer through its ability to promote cellular processes such as migration, invasion and angiogenesis. Development of a blood supply is vital to advanced tumour growth and increased metastatic potential. In the current study we identified RGMb (DRAGON), a member of the Repulsive Guidance Molecule family, as being upregulated by HGF and assessed its potential to contribute to HGF mediated pro-angiogenic traits.

Methods: Expression of RGMb was identified as being upregulated in human endothelial HECV cells following 4 hour treatment with HGF (40ng/ml) using micro array analysis and Q-PCR. Subsequently, the expression of RGMb was targeted through the transfection of HECV cells with a plasmid containing a ribozyme transgene specifically targeted to RGMb. The role of RGMb in HGF mediated cellular migration and tubule formation in vitro was examined.

Results: Significant increases in RGMb expression in HECV cells were observed on the micro-array following 4 hour treatment with HGF (P = 0.004) and this trend was also identified using Q-PCR. Transfection with the ribozyme transgene brought about substantial reductions in RGMb expression at both transcript and protein levels as assessed using RT-PCR, QPCR and Western blot analysis. Knockout of RGMb brought about a significant increase in migration rates, compared to HECV cells transfected with a closed pEF6 plasmid only (HECVpEF6), following a 90minute period (p = 0.034 at 90 minute time point vs pEF6 control). Treatment of HGF enhanced migration rates of HECV control cells with significant differences between untreated and HGF treated pEF6 cells obvious following 60 minutes (p < 0.05 at 60 and 75 minutes, p = 0.002 at 90 minutes). In contrast to this, HECV cells transfected with the RGMb ribozyme transgene (HECVRGMbKO) were unaffected by HGF treatment, with no significant differences observed between treated or untreated HECVRGMbKO cells at any time points. A similar trend was observed in the angiogenic tubule formation assay, where treatment of HECVRGMbKO cells with HGF could significantly enhance the levels of tubules formed (mean tubule perimeter, untreated 8087+/− 632 vs HGF treated 13131+/− 988, p = 0.001). Treatment of HECVRGMbKO cells with HGF did not significantly enhance levels of tubule formation (mean tubule perimeter, untreated 7523+/−2458 vs HGF treated 11050+/−1512, p = 0.21).

Conclusions: Targeting of RGMb in endothelial cells appears to reduce their sensitivity to the promotional effect of HGF on cell migration and tubule formation, important traits in the angiogenic cascade. Our data suggests that RGMb may be one molecule involved in the process through which HGF enhances angiogenic potential and targeting this molecule may be a useful strategy in a number of cancer types to interfere with HGF promoted angiogenesis.

**P2-05-07**
**Combined Antiangiogenic and Anti-Estrogen Therapy in Breast Cancer. Molecular Mechanisms Involved.**
de la Haba J, Berciano M, Cañabate M, Porras I, Valverde A, Cañas A, Rodríguez A, Aranda E. Hospital Universitario Reina Sofia, Instituto for Biomedical Research Maimonides IMIBIC, Cordoba, CO, Spain; Hospital General Universitario, Ciudad Real, CR, Spain

Background: Much is known about the mechanisms involved in the response to anti-hormonal treatment or those involved in the response to antiangiogenic therapy. It is also known the association between angiogenesis and hormonal status, both in physiological and pathological settings. However, the molecular and cellular mechanisms contributing to the efficacy of combined antiangiogenic-antihormonal therapy in breast cancer are still unknown. This
Combination is currently in clinical trials, but unfortunately there are scarce preclinical studies contributing to the rationale of combining antiangiogenic and antihormonal therapies.

**Aims:** To define the mechanisms involved in the response to combined antiangiogenic-antihormonal treatments in breast cancer cells.

**Methods:** Breast cancer cell lines with different estrogen dependence (MCF-7, BT-474, MDA-MB-231) were subjected to an estrogen gradient (estradiol), and treated with fulvestrant (antiestrogen), plus bevacizumab (anti-angiogenic). Cellular proliferation and apoptosis were determined using the corresponding kits. Proliferation and survival intracellular signaling pathways, estrogen alpha and VEGF receptors activation and COX-2 expression were analysed by western-blots using specific antibodies.

**Results:** In estrogen-dependent breast cancer cells (MCF-7 and BT-474) the pro-proliferative effect of estradiol decreased after bevacizumab treatment.

**Table 1. Proliferation 48 hours (%) ± SD**

Furthermore, the combination of the antiangiogenic with an antiestrogen enhanced this antiproliferative effect, that was also related to the reduction in the levels of VEGF-A in the culture medium and to diminished ER alpha phosphorylation. The combined treatment also altered the phosphorylation of Akt and Erk1/2 signaling kinases. Interestingly, bevacizumab treatment augmented COX-2 activity in MCF-7.

**Conclusions:** Our results suggest that in estrogen dependent breast cancer cells the anti-proliferative effect of bevacizumab depends on estradiol concentration, that in turn affects VEGF production levels, using a different mechanism to apoptosis. The combination of bevacizumab with antioestrogens enhances this antimutator effect, altering intracellular signaling pathways of proliferation and survival.

**P2-05-08**

**Expression of VE-Statin/egfl7 in Breast Cancer.**

Lauriand-Philippin G, Baranzelli M-C, Fournier C, Samson C, Soncin F, Bonnetierre J. Centre Oscar Lambret, Lille, France; Institut de Biologie de Lille - CNRS UMR 8161, Lille, France; Université Lille Nord de France, Lille, France

**Patients and methods:** Specimens of breast cancer (174 invasive and 37 in situ) were obtained from 205 patients (pts) treated in our institution in 2005. Their median age was 57 years (39-92). VE-statin expression was studied by immunohistochemistry (IHC) using anti-hVE-statin/egfl7 (AF3638, R&D) and by RT-qPCR on formalin-fixed paraffin sections. 174 invasive carcinomas (141 ductular and 30 lobular) and 37 DCIS were studied. Determination was done twice by two different observers. Statistics used Chi2 and Fisher’s exact tests for categorical data and Kruskall-Wallis test for continuous variables.

**Results:** Pathological characteristics of the patients with invasive tumors were as follows: 81% ductular, 17% lobular; median tumor size 18 mm (2-100); SBR grade 1 in 27%, 2 in 58% and 3 in 15% of the tumors; estradiol receptor (ER+) in 90%, progesterone receptor (PR) + in 66%, 6.5% HER2 positive. In 105 cases there was DCIS together with invasive tumors. For invasive tumors and DCIS, progression-free survival (PFS) at 5 years were 83% and 100% and overall survival (OS) 96% and 95%, respectively. Characteristics of the DCIS were median tumor size 18 mm (2-60), ER+ in 88%, PR+ in 62%. IHC results were obtained in 159 invasive carcinoma and 34 DCIS, RT-qPCR results in 96 samples. In the group of invasive tumors, a cytoplasmic VE-statin/egfl7 signal was obtained in 80% of invasive cells, more frequently than in normal glandular cells (71% vs 41%, p=0.003) but significantly less than in peritumoral DCIS (71% vs 89%, p=0.001). The signal was higher in ductular than in lobular carcinoma (85% vs 54%, p=0.003). In RT-qPCR analyses, RNA levels were higher in SBR1 grade tumors (p=0.008), in ER+ invasive tumors (p=0.02) and in pN- tumors (p=0.003). In the group of DCIS, a cytoplasmic signal was obtained in 82% of the cells. It was more frequently observed in tumor than in normal glandular cells (82% vs 52%, p=0.02). A+ cytoplasmic signal was more frequent in DCIS alone than in DCIS associated with invasive carcinoma (23% vs 6%, p=0.02). No prognostic significance differences were observed on PFS or on OS.

**Discussion:** This work is the first expression study of VE-statin/egfl7 in breast cancer. The results were reproduced by two different observers. IHC signal was cytoplasmic and higher in DCIS than in invasive carcinomas. Furthermore the signal was even higher when there was only DCIS than when it was associated with invasive lesion. The signal was higher in ductular than lobular carcinoma, consistent with previous publications on other angiogenesis mediators. Similarly, the signal was higher in low SBR grade, as well in ER positive tumors. Phase 1 studies are ongoing in order to evaluate the effects of inhibition of VE-statin/egfl7.

**Secondary Inflammatory Breast Cancer: A Possible Model for Post-Surgical Dissemination of Cancer.**

Hashmi S, Zolfaghari L, Levine PH. George Washington University, Washington, DC

**Background:** The phenomenon of accelerated tumor growth following surgery has been observed repeatedly and merits further study. Inflammatory breast carcinoma (IBC) is widely recognized as an extremely aggressive malignancy characterized by micrometastasis at the time of diagnosis. It is fast growing, highly angiogenic and angiogenic, features that are present from its inception. The idea of a dormant cancer cell and awakening of metastatic disease following a surgical/traumatic event may well be exemplified by secondary IBC, a term used to describe the IBC appearing following surgery for a non-inflammatory primary breast carcinoma. One possible mechanism can be related to the stimulation of dormant micrometastasis through local angiogenesis occurring as part of postsurgical healing. It is therefore possible that secondary IBC can be used as a model to support local angiogenesis as an important contributor to the development of an aggressive cancer.

**Materials and Methods:** Cases of secondary IBC were identified in a review of patients referred to the IBC Registry (IBCR). In this report we document the histories of three patients with secondary IBC as well as two additional patients whose disease presentation also supports the possible occurrence of IBC secondary to breast trauma. Secondary IBC cases were defined as women who had surgery for non-inflammatory breast cancer with recurrence at the previous mastectomy site manifest as skin erythema shown to be associated with angiogenesis occurring as part of posttraumatic healing. It is therefore possible that secondary IBC can be used as a model to support local angiogenesis as an important contributor to the development of an aggressive cancer.

**Results:** Two of the patients with secondary IBC developed pathologically confirmed dermal lymphatic invasion two and 42 months after partial mastectomy for non-inflammatory breast cancer. The third had been apparently free of recurrence for seven years when she had reconstructive surgery, which was followed by IBC seven months later. Two additional cases are presented, one in which IBC manifested one month following ductogram procedure and had a...
contralateral breast IBC recurrence 2 years later. The other patient was diagnosed with IBC one year following nipple piercing and ring removal.

Discussion: Recent publications have focused on the role of surgery in the subsequent development of metastatic breast cancer, many of them focusing on a hormonal mechanism triggered by removal of the primary tumor. We propose local angiogenesis as another possible mechanism for post-surgical dissemination of cancer. In view of the hypothesis that trauma can stimulate angiogenesis which can accelerate tumor growth, the documentation of IBC appearing at the site of a traumatic event merits consideration. Our experience with IBC, noted in the case reports above suggest that local trauma probably mediated in large part by angiogenesis can be an important trigger of IBC. We would therefore suggest that secondary IBC be considered for investigation of one possible mechanism for post-surgical tumor dissemination.

Brain-Derived Neurotrophic Factor, BDNF, and Its Biological Impact on Vascular Endothelial Cells.
Jiang WG, Ye L, Yang X, Mansel RE. Cardiff University School of Medicine, Cardiff, Wales, United Kingdom; Capital Medical University, Beijing, China

Background: BDNF, Brain-derived neurotrophic factor is a member of the neurotrophin superfamily and is known a growth factor for both central and peripheral nervous systems. While BDNF has been shown to play a role in the development of a number of clinical conditions including epilepsy, Alzheimer’s and Parkinson’s disease, it has recently been implicated in human cancers, primarily in neurological related malignancies, as well as ovarian cancer, lung cancer and skin malignancies. We have recently reported a pivotal relationship between BDNF and disease progression and clinical outcome in human breast cancer. Certain members of the neurotrophin family have also been shown to play a role in the regulation of angiogenesis. In the present study, we examined the impact of BDNF on the biological behaviour of vascular endothelia cells.

Materials and methods. Human vascular endothelial cells were used in the present study. A human BDNF expression plasmid was constructed from a cDNA library of normal tissues. Anti-BDNF transgenes were constructed based on the secondary structure of human BDNF and used to knockdown the expression of BDNF from the cells. Vascular endothelial cells with differential expression of BDNF were generated using the expression construct. Cell-matrix adhesion, cell migration and growth were determined.

Results. Human vascular endothelial cells (HECV) expressed very low levels of BDNF, traceable by PCR method. The cells were transfected with BDNF expression plasmid, which allowed establishment of BDNF over-expressing sublines, HECVBDNFexp. Expression of BDNF had a marked influence on matrix adhesion of the endothelial cells (adhesion indices for control and HECVBDNFexp cells being 3.3± 0.83 and 2.18± 0.94, respectively; p=0.01). It is interesting to note that the change of adhesion was likely to involve the focal adhesion (FAK) pathway as a FAK inhibitor, PF573228, had a profound impact on the adhesion of both control and HECVBDNFexp cells. Manipulation of BDNF in endothelial cells had a similar effect on the cellular migration, although to a lesser degree. Conclusions. Brain-derived neurotrophic factor, BDNF, has a profound impact on the biological functions of vascular endothelial cells. This may have implications in the angiogenic process seen in solid tumours.

Oikawa M, Yoshiura K-I, Kondo H, Miura S, Kurashige T, Nagayasu T, Yano H, Nakashima M. Atomic Bomb Disease Institute, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan; Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan

Background: Sixty-six years after two atomic bombs (A-bombs) explosion on Hiroshima and Nagasaki, the incidence of breast cancer in A-bomb survivors still higher than that in controlled populations. We have reported a higher incidence of HER2 and C-MYC oncogene amplification in breast cancers from A-bomb survivors, which suggested genomic instability (GIN) induced by A-bomb radiation exposure might promote breast carcinogenesis in A-bomb survivors. The purpose of this study was to clarify the effect of A-bomb radiation exposure on GIN in breast cancer using microarray-comparative genomic hybridization (aCGH). Materials and Methods: DNA was extracted from the paraffin-embedded tissues of invasive ductal cancers from 11 survivors exposed at 1.5km from the hypocenter and 9 calendar year-matched non-exposed patients followed by aCGH analysis using a high-density oligonucleotide microarray (Agilent® SurePrint G3 8x60k microarray). The total length of chromosomal aberrant region was used as an indicator of GIN, and correlation with clinicopathological factors were statistically tested. Results: The mean of the derivative log ratio spread (DLRSpread), which estimates the log ratio noise by calculating the spread of log ratio differences between consecutive probes along all chromosomes, was 0.60 (range, 0.30 to 1.05). The concordance of aCGH results with FISH results for HER2 gene amplification was 90%. Samples from A-bomb survivors had significantly more copy number aberrations (CNA) than samples from control patients (P= 0.040). Samples with C-MYC gene amplification determined by aCGH analysis tended to harbor more CNA (P= 0.20), and age at the time of diagnosis tended to be inversely associated with the total length of chromosomal aberrant regions (P= 0.13). The multivariate analysis with covariance revealed that the status of A-bomb exposure was the only independent factor which was significantly associated the total length of chromosomal aberrant regions (P= 0.0324). Conclusions: This study suggested that A-bomb radiation may affect the development of chromosomal aberrant regions including oncogene amplification by inducing GIN and may be associated with a higher histological grade in breast cancer found in A-bomb survivors.

P2-06-02
FOXO3a Genotype Predicts Age of Breast Cancer Onset and Correlates with Lymph Node Involvement.

Background: Ageing mechanisms and genetic traits underlying the aging process are intimately linked with mechanisms that protect against cancer. FOXO3a genotype might be an important clue in this regard, as single nucleotide polymorphisms in this gene have been related to longevity, but also to differences in cancer susceptibility. FOXO3a is thought to work as a cellular ‘switch’, by either promoting apoptosis or halting proliferation and protecting from oxidative stress.

Survivors: An Analysis of Microarray-Comparative Genomic Hybridization with Old Archival Tissues.
We have assessed FOXO3a genotype in a cohort of breast cancer patients to investigate possible associations with patient and/or breast tumor characteristics. 

**Patients and methods:** Eligible subjects were all early breast cancer patients with upfront surgery, diagnosed at our center between 2000 till 2010, from which germline DNA (peripheral blood) was available. 2 SNP's in the FOXO3a gene, known to correlate with ageing or age associated diseases were assessed by Sequenom (rs 9400239 and rs 6911407).

**Results:** 2047 patients were included in the study. Age at diagnosis was found to be lower for patients homozygous for the minor allele at position rs6911407 (genotype A/A) (median age at diagnosis 52 years; P=0.001; 95% C.I. 50.7–53.3). Patients homozygous for the wild type allele (genotype C/C) at this position had a higher median age at diagnosis 55.0 years; 95% CI. 54.0–56.0. After correction for possible confounding variables BMI at diagnosis and parity, the association between age at diagnosis still remained significant (P=0.025, N=1348). We also assessed the relationship of the specific genotypes with tumor characteristics. We found that rs6911407 is positively correlated with lymph node status. This finding remains significant after correction for possible confounding variables ER, PR, Her-2, tumor size and tumor grade (OR=1.224 for homozygous mutants versus wild type; P=0.014; 95% C.I. 1.042–1.437).

**Conclusion:** In our cohort of primary breast cancers, we found that patients homozygous for the minor allele at position rs6911407 in the FOXO3a gene, develop breast cancer at younger age, and have more lymph node involvement compared to patients homozygous for the wild type allele. SNP's in nearly complete linkage disequilibrium with rs6911407 have previously been correlated with healthy longevity. At first sight, this seems contradictory with our current findings. However, our results are in accordance with the trade-off that has been described to exist between longevity and risk of cancer. It is generally assumed that FOXO3a and p53 function are oppositely controlled by common regulation systems, such that changes in FOXO activation would always be counterbalanced by an inverse change in p53 activation. If FOXO3a is strongly activated in order to protect against DNA damage (i.e. longevity function), p53-mediated cancer protection will concomitantly be diminished. This mechanism reconciles the apparent paradox between the longevity phenotype that has previously been linked with rs 6911407 on the one hand, and, on the other hand, our current findings of earlier breast cancer onset and increased lymph node metastasis. Further research on the function of FOXO3a in both aging and cancer is required to shed more light on the molecular mechanisms underlying these observations.

Phosphatidylinositol-3-Kinase Pathway Mutations Are Common in Breast Columnar Cell Lesions.

Troxell ML, Brunner AL, Montgomery K, Zha SX, Neff T, Warrick A, Beadling C, Corless CL, West RB. Oregon Health & Science University, Portland, OR; Stanford University, Stanford, CA

The phosphatidylinositol-3-kinase pathway is one of the most commonly mutated in invasive breast carcinoma, with PIK3CA mutations present in ~25% of invasive carcinomas, and AKT1 mutations identified in up to 5%. Several studies have demonstrated the same complement of mutations in ductal carcinoma in-situ (DCIS), as well as benign papillomas. We sought to investigate whether PIK3CA mutations occur in breast columnar cell lesions (CCL). Twenty-five breast resection specimens containing CCL (including columnar cell change, columnar cell hyperplasia, and flat epithelial atypia) were identified from the files of Stanford University Pathology; 15 of these had associated invasive carcinoma (IDC) or carcinoma in situ. DNA was prepared from punchs of formalin-fixed paraffin-embedded tissue blocks using standard methods. DNA extracts were screened for a panel of point mutations using a multiplex PCR panel with a mass-spectroscopy readout (Sequenom MassARRAY). The panel covers 321 mutations in 30 genes, including ABL, AKT1/2/3, BRAF, CDK4, CTNNB1, EGFR1, ERBB2, FBX4, FBXW7, FGFR1/2/3, FLT3, GNAQ, HRAS, JAK2, KIT, KRAS, MAP2K1/2, MET, NRAS, PDGFR, PIK3CA, PTPN11, RET, SOS1, and TP53.

The majority of mutations were confirmed by Sanger sequencing. PIK3CA mutations were identified in 12/25 CCL (48%); paired normal breast tissue was tested in 21 cases and was negative for mutations in all but one case. In associated DCIS, 4/8 (50%) harbored PIK3CA mutations, while 3/9 IDC had mutations (33%; 2 PIK3CA, 1 AKT1). The mutation status of CCL and carcinomas was frequently discordant. Of 15 cases, only 6 demonstrated the same genotype in matched samples of CCL and carcinoma (5 wildtype, 1 PIK3CA H1047R). Interestingly, 5 patients had mutations in CCL with wildtype DCIS or IDC; 2 patients had different point mutations in CCL and carcinoma, including one patient with discordant mutant DCIS and wildtype IDC. Only 3 cases had wildtype CCL and mutated carcinoma.

Grizzle WE, Steg AD, He Q, Stecuk MR, Byan-Parker S, Johnson MR, Grunda JM. University of Alabama at Birmingham, Birmingham, AL; Tuskegee University, Tuskegee, AL

Background: Recent studies suggest that the poorer outcome of breast cancer patients observed in African-American women (AAW) may, in part, result from underlying genetic factors. The purpose of this study was to investigate gene expression differences between Caucasian-American women (CAW) and AAW that may contribute to this poorer prognosis.

Methods: The expression of genes involved in breast carcinoma prognosis, response to therapy, estrogen signaling, and tumor aggressiveness was assessed in age- and stage-matched CAW and AAW paraffin-embedded breast cancer specimens. The Wilcoxon-Mann-Whitney Test was used to identify genes with a significant difference in expression between CAW and AAW. To determine if the differentially expressed genes could segregate between the CAW and AAW, we performed semi-supervised principle component analysis (SSPCA).

Results: Twenty genes were differentially expressed between AAW and CAW. SSPCA incorporating these 20 genes separated AAW and CAW into two distinct groups. AAW were significantly (p < 0.05) more likely to display aberrations in G1/S cell-cycle regulatory genes, decreased expression of cell-adhesion genes, and low to no expression of ESR1, PGR, ERBB2 and estrogen pathway targets.

Conclusions: The gene expression differences identified between AAW and CAW may contribute to more aggressive disease, resistance to therapy, enhanced metastatic potential and poor clinical outcome. Impact: These findings support the hypothesis that breast cancer specimens collected from AAW display distinct genetic differences compared to similar tissues obtained from CAW. Additional population-based studies are necessary to determine if these genetic variations contribute to the highly aggressive and treatment-resistant breast cancer phenotype frequently observed in AAW.
The nearly 50% PIK3CA mutation prevalence in CCL is greater than reported in most studies of invasive breast cancer. Further, CCL and carcinoma were frequently discordant for PIK3CA/PTEN mutation status; most commonly the CCL harbored a PIK3CA mutation, while the associated carcinoma was wildtype. Although these findings need validation in a larger study, they raise interesting questions as to the role of PIK3CA/PTEN pathway in breast carcinogenesis, and as to the biologic/precursor potential of CCL.

P2-07-01
Copy Number Variants in Early-Onset-Breast Cancer.
Ludwig S, Ivanovich J, Graubert TA, Goodfellow PJ. Washington University in St.Louis, SOM, St. Louis, MO

Background: Copy number variants (CNVs) are known to contribute to the risk for development of immune diseases, neurological disorders and to a lesser extent cancer. Many CNVs do not directly involve gene sequences. CHL1, a cell adhesion molecule with homology to L1CAM, is down-regulated in a large proportion of breast cancer. A deletion CNV immediately 5' of the CHL1 transcriptional start site has been described. The CHL1 CNV's role in breast cancer risk has not previously been explored.

Material and Methods: 50 research subjects recruited to the Washington University/Siteman Cancer Center Young Women's Breast Cancer Program (YWBCP) were selected for a CNV discovery study. These women were diagnosed breast cancer < age 40, tested negative for BRCA1/2 mutations and have a negative family history for breast cancer. The selection criteria enriched for de novo mutations. Comparative genomic hybridization (CGH) analyses were undertaken using the NimbleGen 2.1 million oligonucleotide array. DNA copy number was compared between proband and each of her parents to identify potential deletions or amplifications in the daughter relative to both parents (de novo changes). PCR was used to confirm a subset of the CGH-predicted differences in copy number. Chi-square test was used to determine statistical significances of CNV occurrences near the CHL1 gene between women with breast cancer and control cases.

Results: aCGH data analysis has been completed for 25 YWBC trios (patients and parents). 247 differences in copy number in the breast cancer cases relative to their parents were identified (1-18 putative de novo CNVs per case). 91% of the observed changes were deletions and 9% were amplifications. One proband showed an 11,560 bp deletion 5' of the CHL1 gene that was not seen in her parents. Conventional PCR confirmed a homozygous deletion of a ~3 kb region in the patient, in the region of a known CNV with a reported frequency of ~3%. Testing an additional 368 early-onset breast cancer cases for the CHL1 deletion revealed 25 additional homozygous deletions (6.8%). The deletion was present in 9 of 197 controls (4.5%). qPCR studies revealed the parents of the patient with the CHL1 deletion each carried a single copy of the CNV, making de novo copy number change in the proband very unlikely. Deletion specific assays for the CHL1 CNV are being used to test CNV genotypes in an extended case-control study.

Discussion: CHL1 expression has previously been shown to be down-regulated in primary breast tumors. Our preliminary analysis of YWBC cases and controls indicates the CHL1 regulatory region CNV is unlikely to be associated with risk for early-onset breast cancer. Additional candidate de novo copy number changes seen in the genomes of patients with early-onset breast cancer are being evaluated to determine their roles as genetic risk factors.

P2-07-02
Germline Genetic Variants Disturbing the Let-7/LIN28 Double-Negative Feedback Loop Alter Breast Cancer Susceptibility.
Yu K-D, Shao Z-M, Chen A-X. Fudan University Shanghai Cancer Center, Shanghai, China

Previous studies have shown that let-7 can repress the post-transcriptional translation of LIN28, and LIN28, in turn, could block the maturation of let-7, forming a double-negative feedback loop. In this study, we investigated the effect of germline genetic variants on regulation of the homeostasis of the let-7/LIN28 loop and breast cancer risk. We initially demonstrated that the T/C variants of rs3811463, a single nucleotide polymorphism (SNP) located near the let-7 binding site in LIN28, could lead to differential regulation of LIN28 by let-7. Specifically, the C allele of rs3811463 weakened let-7-induced repression of LIN28 mRNA, resulting in increased production of LIN28 protein, which could in turn downregulate the level of mature let-7. This effect was then validated at the tissue level in that the normal breast tissue of individuals with the rs3811463-TC genotype expressed significantly lower levels of let-7 and higher levels of LIN28 protein than those individuals with the rs3811463-TT genotype. Because previous in vitro and ex vivo experiments have consistently suggested that LIN28 could promote cellular transformation, we then systematically evaluated the relationship between rs3811463 as well as other common LIN28 SNPs and the risk of breast cancer in a stepwise manner. The first hospital-based association study (n = 2,300) demonstrated that two SNPs were significantly associated with breast cancer risk, one of which was rs3811463, while the other was rs6697410. The C allele of the rs3811463 SNP corresponded to an increased risk of breast cancer with an odds ratio (OR) of 1.25 (P = 0.0091), which was successfully replicated in a second independent study (n = 1,156) with community-based controls. The combined P-value of the two studies was 8.0 × 10-5. Taken together, our study demonstrates that host genetic variants could disturb the regulation of the let-7/LIN28 double-negative feedback loop and alter breast cancer risk.

P2-07-03
Collective Evidence Suggests Neutrality for BRCA1 V1687I, a Novel Sequence Variant in the Conserved THV Motif of the First BRCT Repeat.
Cortesi L, De Nicoló A, Medici V, Marino M, Turchetti D, Pradella LM, Rossi G, Parisini E, Federico M. University of Modena and Reggio Emilia, Modena, Italy; Dana-Farber Cancer Institute, Boston, MA; Harvard Medical School, Boston, MA; University of Bologna, Bologna, Italy; Italian Institute of Technology, Milan, Italy; These Authors Contributed Equally to This Work

Background: Unequivocal classification of BRCA1 and BRCA2 variants of uncertain significance (VUS) with respect to their effect on protein function is a challenge with consequent implications for clinical decision-making. Currently, integration of different types of evidence derived from independent sources appears to be the most reliable approach to help define disease relevance for each single VUS. During a routine screening for BRCA1 and BRCA2 mutations carried out by the Modena study group for familial breast and ovarian cancer we identified a novel BRCA1 sequence change (c.5178G>A) that causes a valine to isoleucine (V to I) substitution at position 1687. The sequence alteration was found in a patient diagnosed with early onset breast cancer and it was present neither in other breast/ovarian cancer families screened nor in unaffected control individuals. No co-occurrence of the variant with any known clinically relevant BRCA1 mutations was observed.
The C-terminally located BRCA1 V1687I lies in the conserved THV motif of the first BRCT repeat. Disease-causality has previously been suggested for two neighbouring sequence alterations, BRCA1 V1688del, whose repercussions on protein stability and function were also reported (De Nicolo et al., 2009), and BRCA1 H1686Q (Giannini et al., 2008). We aimed at garnering evidence that, together with family and genetic data, could help assess the clinical significance of the V1687I variant.

Methods: We employed a multimodal approach that included immunohistochemistry on tumor sections, in silico analyses, comparative structural modeling, and ascertainment of BRCT-mediated functional associations.

Results: Whereas tumor histology, receptor and HER2/neu status were compatible with a BRCA1-deficient phenotype, most algorithms we used to assess sequence and structure variation based on evolutionary conservation predicted the BRCA1 V1687I variant to be benign. In line with this prediction, analysis of the modeled BRCA1 V1687I BRCT domain did not reveal any major structural changes relative to the wild type counterpart and suggested that BRCA1 V1687I leaves the local architecture and overall stability of the protein largely unaltered. Consistently, the BRCA1 V1687I protein was properly expressed and localized to the nucleus, and it was still capable of binding BRIP1/FANCJ, ChiP and Abraxas, three BRCT-interacting, DNA damage response and repair partner proteins.

Conclusions: Based on our collected evidence, the BRCA1 V1687I amino acid change, although occurring in an evolutionary conserved region, does not seem to affect the function of the correspondingly encoded protein, and hence it is a likely benign sequence alteration.

Impact of Aromatase Inhibitors on Background Parenchymal Enhancement and Amount of Fibroglandular Tissue on Breast MRI.

Goldfarb SB, King V, Sung J, Pike M, Nulsen B, Jozefara J, Hudis C, Morris E, Dickler M. Memorial Sloan-Kettering Cancer Center, New York, NY

Background: On breast MRI, background parenchymal enhancement (BPE) and volume of fibroglandular tissue (FGT) have been shown to reflect a patient's hormonal status. Tamoxifen has been shown to reduce mammographic breast density and may serve as an early predictor of response in the prevention setting (Cuzick, JNCI 2011). We have shown that adjuvant tamoxifen can reduce BPE in the unaffected breast with breast cancer. We hypothesize that aromatase inhibitor (AI) induced endocrine changes in breast tissue should also be evident and therefore we performed a study to evaluate whether adjuvant AI therapy influences BPE or amount of FGT in the contralateral breast.

Methods: An electronic medical record review identified 856 postmenopausal women with stage I-III breast cancer who had at least two breast MRIs and took adjuvant AI treatment. A retrospective chart review was conducted to select those patients without a history of prior tamoxifen or raloxifene treatment who had a MRI of the contralateral breast both before and during 6 to 12 months of AI treatment. After exclusion of all irradiated breasts, 168 women were eligible. MRIs were performed between August 1999 and June 2010. Two radiologists who were blind to AI treatment status, independently rated level of BPE and amount of FGT using categorical scales: BPE – Minimal, Mild, Moderate, Marked; FGT – Fatty, Scattered, Heterogeneously Dense, Dense (based on proposed BI-RADS criteria for BPE and on ACR criteria for FGT). Blinded side-by-side direct comparison evaluated whether there was a category change between the two MRIs. A consensus was reached in cases of disagreement. The Wilcoxon signed-rank test was used to assess changes in rating categories for BPE and FGT between before and during AI breast MRIs. A waiver of authorization was granted by the institutional review board for this study.

Results: In this study 127/168 (76%) women were treated with anastrozole, 33/168 (20%) with letrozole and 8/168 (5%) with exemestane. Based on the blinded side-by-side comparison, a category (or more) decrease in BPE occurred during treatment with AIs (p=0.0001). There was an overall shift from higher to lower degree of BPE in 35% (45/127) of the women taking anastrozole while a category increase occurred in only one woman (1%; p <0.0001). A similar result was seen in the women taking letrozole [45% (15/33) had a decrease versus 3% (1/33) an increase; p=0.0003] and exemestane [25% (2/8) had a decrease versus 12.5% (1/8) an increase; p=0.50]. For FGT a category decrease occurred in 5% (6/127) of anastrozole users while no increase occurred [0% (0/127); p=0.016]. The respective numbers for letrozole were 3% (1/33) and 0% (0/33), and nobody on exemestane had a change in FGT.

Conclusions: After 6 to 12 months of treatment with adjuvant AIs, there was a statistically significant category (or more) decrease in BPE. BPE is more sensitive than FGT to changes in normal breast stroma that occur during adjuvant treatment with AIs and BPE may be a marker of anti-hormonal activity in the breasts.

Impact of Aromatase Inhibitors on Background Parenchymal Enhancement and Amount of Fibroglandular Tissue on Breast MRI.

Goldfarb SB, King V, Sung J, Pike M, Nulsen B, Jozefara J, Hudis C, Morris E, Dickler M. Memorial Sloan-Kettering Cancer Center, New York, NY

Background: On breast MRI, background parenchymal enhancement (BPE) and volume of fibroglandular tissue (FGT) have been shown to reflect a patient’s hormonal status. Tamoxifen has been shown to reduce mammographic breast density and may serve as an early predictor of response in the prevention setting (Cuzick, JNCI 2011). We have shown that adjuvant tamoxifen can reduce BPE in the unaffected breast with breast cancer. We hypothesize that aromatase inhibitor (AI) induced endocrine changes in breast tissue should also be evident and therefore we performed a study to evaluate whether adjuvant AI therapy influences BPE or amount of FGT in the contralateral breast.

Methods: An electronic medical record review identified 856 postmenopausal women with stage I-III breast cancer who had at least two breast MRIs and took adjuvant AI treatment. A similar result was seen in the women taking letrozole [45% (15/33) had a decrease versus 3% (1/33) an increase; p=0.0003] and exemestane [25% (2/8) had a decrease versus 12.5% (1/8) an increase; p=0.50]. For FGT a category decrease occurred in 5% (6/127) of anastrozole users while no increase occurred [0% (0/127); p=0.016]. The respective numbers for letrozole were 3% (1/33) and 0% (0/33), and nobody on exemestane had a change in FGT.

Conclusions: After 6 to 12 months of treatment with adjuvant AIs, there was a statistically significant category (or more) decrease in BPE. BPE is more sensitive than FGT to changes in normal breast stroma that occur during adjuvant treatment with AIs and BPE may be a marker of anti-hormonal activity in the breasts.

Magnetic Resonance Imaging as a Predictor of Pathologic Response in Patients Treated with Neoadjuvant Systemic Treatment for Operable Breast Cancer (TBCRC 017).

De Los Santos J, Cantor A, Mcguire K, Golshan M, Meric-Bernstam F, Horton J, Nanda R, Amos K, Forero A, Hudis C, Meszoely I, Hwang S. University of Alabama at Birmingham, Birmingham, AL; University of North Carolina Chapel Hill, Chapel Hill, NC; Dana-Farber Cancer Institute, Boston, MA; Duke University Medical Center, Durham, NC; Memorial Sloan Kettering Cancer Center, New York, NY; University of Pittsburgh Medical Center, Pittsburgh, PA; MD Anderson Cancer Center Houston, TX; Vanderbilt University, Nashville, TN; University of Chicago, Chicago, IL; University of California at San Francisco, San Francisco, CA

Background: Increased pathologic complete response (pCR) rates observed with neoadjuvant chemotherapy for invasive breast cancer has prompted interest in whether patients with pCR can be identified preoperatively and potentially spared the morbidity of surgery. This multicenter retrospective study was performed to determine the accuracy of preoperative MRI in predicting pCR in the breast and whether MRI performance differs by molecular subtype, histology, and treatment regimen.

Methods: 770 women from 8 institutions were retrospectively identified as having received neoadjuvant systemic therapy with MRI obtained at baseline and after completion of systemic treatment. Tumor phenotypes were defined on the basis of estrogen and progesterone receptor (ER/PR or HR) and HER2 receptor status. Univariate and multivariate analyses of factors influencing radiographic complete response (rCR) and pCR were recorded, with rCR defined as resolution of any abnormal enhancement, mass, or distortion on MRI, and pCR defined as resolution of both invasive disease and DCIS.
Results: rCR and pCR for the total group were 182/746 (24%) and 179/746 (24%), respectively, with the highest rate of pCR seen among the triple-negative (TN; 57/155; 37%) and HR-/HER2+ (38/101; 38%) subtypes. Covariates significantly associated with rCR included T stage (p = 0.0002), tumor grade (p = 0.005), IHC phenotype (p = 0.005), and chemotherapy regimen (p = 0.0001). On multivariate analysis, only tumor phenotype was independently associated with likelihood of rCR, with both TN (OR = 2.00, 95% CI 1.20–3.33) and HR-/HER2+ (OR = 2.30, 95% CI 1.09–4.83) more likely to achieve rCR than HR+HER- (reference group). Overall accuracy of MRI for prediction of pCR was 74%. Sensitivity, NPV, PPV, and accuracy differed significantly among tumor subtypes, with the greatest NPV in the HR-/HER2+ and TN subtypes (Table 1). Among patients with rCR, ER-, status (OR = 6.4, 95% CI 1.1 to 35.6), PR-status (OR = 3.8, 95% CI 1.2 to 11.4), and tumor grade of 3 vs 1 or 2 (OR = 2.49, 95% CI 1.22–5.07) were independently associated with likelihood of rCR.

Discussion: MRI performance for predicting pCR in patients with invasive breast cancer receiving neoadjuvant systemic therapy differed significantly among breast cancer subtypes; however, this difference is likely due to subtype differences in frequency of pCR and not to intrinsically better or worse MRI detection. The relatively low NPV of MRI following neoadjuvant systemic therapy does not support using MRI rCR alone to accurately identify those patients that can safely avoid surgery.

Performance of Post-treatment MRI in the Breast

Computer-Derived Breast MRI Features Have Complementary Value for Preoperative Selection of Systemic Drug Therapy in Node-Negative Stage-I/II Breast Cancer Patients.

Ghilujs KGA, Pengel KE, Dmitriev I, Paape A, Rutgers EJTH, Wesseling J, Loo CE. The University Medical Center Utrecht, Utrecht, Netherlands; The Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands.

Background: Typical guidelines for adjuvant systemic drug therapy require assessment of lymph node status, tumor extent and grade. Increasing interest exists, however, for preoperative therapy (neoadjuvant drug therapy and preoperative partial breast irradiation).

Here, representative excision specimens are not available to assess eligibility for systemic therapy. Moreover, tumor grade may be difficult to assess in core biopsies resulting in underestimation rates up to 40%. Contrast-enhanced MRI has been shown to correlate with underlying tumor biology, but it is unknown whether it can complement eligibility criteria for systemic drug therapy.

Purpose: To assess the complementary value of MRI to determine eligibility for systemic drug therapy prior to breast-conserving surgery in node-negative stage-I/II breast cancer patients.

Materials and methods: Patients with preoperative node-negative invasive breast cancer ≥1.0 cm and eligible for breast-conserving therapy after conventional breast imaging and MRI were consecutively included between February 2000 and March 2007. Informed consent was obtained from all patients. Eligibility to systemic therapy was determined on the basis of national guidelines using age, size, tumor grade, as well as axillary lymph node status at final pathology. Twenty temporal and morphological features of contrast uptake at MRI were automatically analyzed by a previously build CAD workstation.

Preoperative lymph node status was derived from ultrasound-guided fine-needle aspiration. Multivariate logistic regression and receiver-operating characteristics (ROC) analysis was used to assess associations between preoperative features (age, ER status, computer-
Purpose: To investigate the effect of bevacizumab infusion on vascular parameters available through dynamic contrast-enhanced magnetic resonance (DCE-MR) imaging and to test their association with pathological response in primary breast cancer.

Materials and Methods: 73 patients (median age, 47 yrs; age range, 29-70 yrs) with biopsy-proven, previously untreated, primary breast cancer were recruited from October 2009 to November 2010 in this phase II, multicenter and non-randomized clinical trial. Patients (pts) received single infusion of bevacizumab (15 mg/kg) (C1) 3 weeks prior to the beginning of neoadjuvant chemotherapy consisting of 4 cycles of docetaxel (60 mg/m²), doxorubicin (50 mg/m²) and bevacizumab (15 mg/kg) every 21 days (C2-C5) following by 4 cycles of docetaxel (60 mg/m²), doxorubicin (50 mg/m²) and paclitaxel (200 mg/m²). DCE-MR imaging was performed before (n=72) and after (n=71) C1. K(trans), K(ep), V(e) and IAUGC(60) values were significantly different at the baseline and after C1 (p<0.01). Median changes were, respectively, -51, -101, -52.5 and -4.8. Fifty-two (74%) pts achieved response (G3-G4-G5) after C5 whether 18 (24%) were considered as no responder (G1-G2); for 3 (4%) patients Miller/Payne tumor evaluation was not available. At univariate analysis, negative estrogen receptor (ER) status and higher post-C1 K(ep) (p=0.057) showed a trend toward an association with response. At multivariate analysis, only ER status remains a significant predictor of response (p=0.04).

Conclusion: Computer-analysis of contrast-enhanced MR images has potential to complement preoperative selection of stage I/II node-negative breast-cancer patients for systemic drug therapy.

P2-08-05 Use of Dynamic Contrast-Enhanced MR Imaging To Predict Pathological Response in Primary Breast Cancer.

Boni V, Pina LJ, Hernandez B, Lopez-Vega JM, Calvo EG, Plaizuela A, Morales S, Anton A, Sanchez-Gomez RM, Alvarez I, Ilarramendi JJ, De Juan A, Martinez P, Llongart A, La Huerta A, Dominguez I, Garcia-Vellioso MJ, Garcia-Gonzalez M, Lao Romera J, Puertolas T, Scherer S, Sabarz L, Garcia-Foncillas J, Clinic University of Navarra, Pamplona, Navarra, Spain; Hospital Marques de Valdecilla; Hospital Civil de Basauri; Onkologoia; Hospital General Yagues de Burgos; Hospital Arnau de Vilanova de Lleida; Hospital Miguel Servet; Hospital de San Millan, Logroño; Hospital Donostia; Hospital de Navarra; Roche Basel; Roche Madrid

Purpose: To investigate the effect of bevacizumab infusion on vascular parameters assessed by dynamic contrast-enhanced magnetic resonance (DCE-MR) imaging and to test their association with pathological response in primary breast cancer.

Materials and Methods: 73 patients (median age, 47 yrs; age range, 29-70 yrs) with biopsy-proven, previously untreated, primary breast cancer were recruited from October 2009 to November 2010 in this phase II, multicenter and non-randomized clinical trial. Patients (pts) received single infusion of bevacizumab (15 mg/kg) (C1) 3 weeks prior to the beginning of neoadjuvant chemotherapy consisting of 4 cycles of docetaxel (60 mg/m²), doxorubicin (50 mg/m²) and bevacizumab (15 mg/kg) every 21 days (C2-C5) following by surgery. All pts underwent DCE-MR imaging before and 14-21 days after C1. Quantitative and semiquantitative kinetic parameters were calculated at baseline and after C1, including the volume transfer constant (K(trans)), which primarily reflects the wash-in of the contrast agent, the bloodflow rate constant (K(ep)), extracellular volume fraction (V(e)) and the initial area under the gadolinium concentration-time curve over 60 seconds (IAUGC(60)). Changes in the DCE-MRI kinetic parameters K(trans), K(ep), V(e) and IAUGC(60) were calculated and Wilcoxon test was used to assess significant effects induced by bevacizumab on kinetic parameters.

Pathological response on surgical specimens after C5 was assessed according to Miller and Payne classification. Pts with tumor reduction >30% were considered as responders (G3-G4-G5) whether tumor reduction <30% were considered as no responders (G1-G2). DCE-MR imaging parameters and clinical-pathological characteristics were correlated with pathological response using Mann-Whitney test in univariate and logistic regression in multivariate analyses. Receiver operating curves (ROC) was used to define the best cut-off of the parameter found associated with pathological response.

Results: DCE-MRI was performed before (n=72) and after (n=71) C1. K(trans), K(ep), V(e) and IAUGC(60) values were significantly different at the baseline and after C1 (p<0.01). Median changes were, respectively, -51, -101, -52.5 and -4.8. Fifty-two (74%) pts achieved response (G3-G4-G5) after C5 whether 18 (24%) were considered as no responder (G1-G2); for 3 (4%) patients Miller/Payne tumor evaluation was not available. At univariate analysis, negative estrogen receptor (ER) status and higher post-C1 K(ep) (p=0.057) showed a trend toward an association with response. At multivariate analysis, only ER status remains a significant predictor of response (p=0.04).

Conclusion: Bevacizumab affects tumor vasculature, perfusion and permeability as shown by the significantly reduction in all kinetic vasculature parameters obtained in DCE-MR imaging after C1. However, in our population these changes were not associated with pathological response. On the other hand, backflow rate constant, K(ep), a perfusion-related parameter derived from DCE-MRI yielded after C1 major than 80, may be associated with higher pathological response with a specificity of 88% and sensitivity of 90%. Future studies are warranted to confirm these findings.

P2-08-06 Improved Spatial Resolution Diffusion-Weighted Imaging for Characterizing Tumors and Treatment Response in Patients with Invasive Breast Cancer.

Background: Diffusion weighted magnetic resonance imaging (DWI) is a non-invasive technique that is sensitive to tissue microstructure. Previous studies have shown that DWI adds positive predictive value in diagnostic studies of breast cancer and it has been shown to predict tumor response to neoadjuvant chemotherapy. While DWI shows promise for evaluating breast cancer, the technique suffers from limitations. Specifically, image distortion is common with the echo planar sequence available for DWI on clinical scanners, and spatial resolution is lower than that of other MRI sequences. The group has optimized a high-resolution reduced field-of-view DWI acquisition, originally developed for the spine by Saritas et al., for breast imaging. The goal of this work was to compare high resolution (hr)-DWI to standard resolution (std)-DWI for characterizing breast tumors.

Methods: Patients undergoing neoadjuvant chemotherapy were scanned with MRI before and after one cycle of chemotherapy. Apparent diffusion coefficient (ADC) maps were calculated from hr-DWI and std-DWI data using previously described methods. One tumor region of interest (ROI) was defined on the hr-DWI slice estimated to contain the largest tumor area. This tumor area ROI was then applied to the corresponding slice and location on the std-DWI and hr-DWI ADC maps. Mean tumor ADC as well as 15th,
25th, 50th, 75th, and 90th percentile ADCs were calculated for both DWI acquisitions for all subjects.

Results: The mean tumor ADC values measured prior to treatment were similar for the hr-DWI and std-DWI acquisitions, however there was a significant difference between hr- and std-DWI 15th and 25th percentile ADC values ($p=0.0495$, $p=0.0717$) For the early treatment time point, significant differences between the two DWI acquisitions were found: mean tumor ADC, 15th, 25th, and 50th percentiles ($p=0.0302$, 0.0075, 0.0212, and 0.0488, respectively), with the most significant difference found for the lowest (15th) percentile measured. Tumor hr-DWI ADCs were consistently lower than std-DWI ADCs.

Discussion: These data show that although the mean ADC values calculated from the pre-treatment hr-DWI and std-DWI are similar, the lower percentile (15th, and 25th) ADC values are significantly lower for the hr-DWI acquisition. Our results also showed larger difference in lower percentile ADC values after the two sequences after one cycle of chemotheraphy. The differences in the lower percentile ADC values calculated from the hr-DWI are consistent with reduced partial voluming between viable tumor tissue, which is characterized by high ADC values, and normal fibroglanular tissue. This may be particularly important for post-treatment ADC measurements where tumor size may decrease, potentially making partial volume effects more pronounced. Continuing studies are evaluating the relationship between low percentile ADC values from hr-DWI and tumor stage and response to treatment.

Ex-Vivo High Resolution MRI of Sentinel Lymph Nodes Following Subcutaneous Injection of Superparamagnetic Iron Oxide Nanoparticles.

Doeuk M, ter Beek O, Johnson L, Pankhurst Q, Parikh J, Schaeffer T, Purushotham A, Charles-Eduards G. King’s College London, London, United Kingdom; The Royal Institution of Great Britain, London, United Kingdom; Guy’s & St Thomas’ Hospitals, London, United Kingdom

Background: Superparamagnetic iron oxide (SPIO) enhanced axillary MRI is a promising novel imaging modality that could be used to characterize sentinel nodes non-invasively. In order to better characterize lymph nodes and evaluate their morphological features, we imaged nodes ex-vivo using high resolution MRI, following a pre-operative subcutaneous injection of SPIO.

Material and methods: Prior to surgery patients received a circumareolar injection of SPIO (Endorem, Guerbet, Paris) into the upper outer quadrant of the affected breast. Sentinel lymph nodes excised during surgery were transported to the imaging department fresh. Nodes were placed in glass tubes and scanned using a Bruker 9.4T MRI system (T2 mapping: turbo spin echo, 16 equi-spaced TEs from 7.1 to 113.6 ms, TR = 1616 ms. T2* mapping: gradient echo, 6 equi-spaced TEs from 3.5 to 21 ms, TR = 1000 ms, flip angle = 30 degrees. Diffusion-weighted: spin echo, b-values 0 and 1000 s/mm2, TE = 18 ms, TR = 6500 ms.). Slice thickness was 1 mm with an in plane spatial resolution of 100μm. Image analysis was undertaken using OsiriX (v3.8, 64-bit).

Results: A total of 40 nodes were successfully imaged, excised from 14 patients. The internal architecture of nodes was clearly seen and in the 3 involved nodes, a macrometastasis was identified. Three patients received a 4ml injection of SPIO and 11 patients, a 2ml injection. More SPIO deposition was seen within nodal sinuses following 4ml of SPIO, but there was no significant decrease in mean T2 value. Four nodes were re-imaged following formalin fixation and nodal architecture was unchanged with a trend towards an increase in mean T2 values within nodes. SPIO was identified in all sentinel nodes.

Discussion: Ex-vivo MRI with subcutaneous SPIO contrast, is a useful method for imaging and characterization of sentinel nodes. A better understanding of ex-vivo features is a useful aide to understanding the morphological features seen following in-vivo SPIO enhanced axillary MRI.

**P2-08-08**
Benefit of Preoperative Breast MRI in Patients with Newly Diagnosed Breast Cancer.

Miesbauer M, Sheu H, Schiesser E, Kirchwegger B, Waldenberger P. St. Vincent Hospital, Linz, Austria

Objective: The aim of our study was to evaluate the effect of routinely performed preoperative Breast MRI (pMRI) on the planned therapeutic management of all patients with newly diagnosed Breast cancer.

Subjects and Methods: 180 patients with newly diagnosed Breast cancer between 9/2009 – 12/2010 were enrolled in this retrospective study performed in a certified European Breast Cancer Unit; mean age 60,6 years; 1,5 T MRI (TIM-Symphony, Siemens Germany). Results: In 53/180 (29,4%) cases the preoperative MRI changed the planned therapeutic management concerning surgical and chemotherapeutical options. In 42/180 (23,3%) patients additional lesions were identified only by pMRI, 33/42 (78,6%) have been malignant and 8/42 (19%) were benign. The real extent of the tumor was detected in 43/53 (81%) cases – group A; a bilateral carcinoma was detected in 4/53 (7,5%) cases – group B; in 6/53 (11,5%) cases the malignant lesion could only be detected with preoperative MRI - group C; for group A the pMRI led to wider excisions with 15 segmental - or quadrant resections and 28 mastectomies; for group B the pMRI resulted in 4 additional lumentectomies; for group C the pMRI caused 4 lumentectomies, 1 segmental resection and 2 mastectomies. 5 of 6 patients got neoadjuvant chemotherapy only due to results of pMRI; in 3 of these 5 patients breast conserving surgery was possible. Histology: DCIS 23/53 (43,4%), invasive cancer 23/53 (43,4%), multicentric/multifocal malignant lesions 7/53 (13,2%). The sensitivity of the pMRI was not influenced by the histology of the lesion, the age of the patient or menopausal status. The maximum periode between initial presentation of the patient and breast surgery was 21 days.

Conclusion: In 29,4% of our patients the pMRI resulted in a significant change of the planned therapeutic regime. Histology of the lesion, patients age or menopausal status did not influence the sensitivity of pMRI. There was no relevant delay in the initiation of treatment. Therefore we recommend performing pMRI in breast cancer staging routinely.

**P2-08-09**
The Impact of Preoperative Breast MRI in Newly Diagnosed Breast Cancer. A Prospective Study of Treatment Outcome in Patients Selected for Breast-Conserving Surgery in a Norwegian Multidisciplinary Breast Cancer Clinic.

Raben T, Rodegerdts E, Bachmann H, Funder V. Department of Surgery, Nordland Hospital, Bodø, Norway; Department of Radiology, Nordland Hospital, Bodø, Norway; Faculty of Health Sciences, University of Tromsø, Tromsø, Norway

Background: The aim of the study was to evaluate the impact of preoperative breast MRI on primary surgical treatment in a specialized multidisciplinary breast cancer clinic. The diagnostic tools routinely used are conventional mammography, ultrasound with core needle biopsy, and clinical examination including palpation of breast and...
axillary nodes. If indicated, the examination includes ultrasound examination and fine needle biopsy of axillary glands. We offer all patients selected for breast-conserving surgery preoperative breast MRI.

Material and methods: We included consecutively 145 breast cancer lesions in 143 women (two had bilateral cancer) aged 35-75 in a prospective study, collecting data from January 2009 to December 2010. The patients were all selected for breast-conserving surgery based on the criteria recommended by the Norwegian Breast Cancer Group. That is, tumor ≤ 4 cm, or acceptable tumor:breast ratio, and age > 35. Multifocal lesions, defined as more than one tumor > 1 cm apart, size of tumor > 4 cm, or a large tumor:breast ratio, extensive ductal carcinoma in situ (DCIS), or known genetic disposition for breast cancer, indicates mastectomy according to these criterias. In addition, when postoperative radiation therapy is contraindicated, mastectomy is indicated. If the patients filled the criteria for breast-conserving surgery, they were offered preoperative breast MRI and included in the study. Patients who either choose mastectomy, or did not get a breast MRI for technical reasons, were excluded from the study. Two experienced breast radiologists evaluated the breast MRIs, and three experienced breast radiologists studied the mammographies and did the ultrasound examinations and biopsies. All additional MRI findings were examined by ultrasound-guided biopsy and given a histological diagnose before it influenced the surgical method.

Results: We excluded 28 patients from the study; 10 patients choose mastectomy, 13 patients were excluded due to problems with the MRI technology, and 5 patients were excluded for other reasons. Among the remaining 117 patients, 96 were treated by breast-conserving surgery, and 21 by mastectomy. The change of operative method was induced by the preoperative breast MRI in 16 patients, because of multifocality in 11 patients, and because of a more extensive tumor than discovered by conventional diagnostic tools, in 5 patients. Five patients had a secondary mastectomy, due to histopathological findings in the lump. In one patient preoperative MRI revealed cancer in the contralateral breast, and in one patient the additional findings on MRI resulted in preoperative systemic chemotherapy. The multifocality diagnosed on the preoperative MRI was confirmed on histopathological examination of the breast in 10/11 patients. In one patient who received preoperative systemic chemotherapy, the removed breast was without sign of malignant cells on microscopic examination.

Discussion: In this prospective study preoperative breast MRI give additional information that have impact on the primary surgical treatment in 16/117 or 13.7% of the patients selected for breast-conserving surgery.

Correlation of Mammography, Ultrasound and MRI in Patients with Nipple Discharge.

Deshmankar VH, Mulani S, Lodh N, Pungavkar S, Bhaduri A, Deshpande R, Madhavale C. P.D. Hinduja National Hospital, Mumbai, Maharashtra, India; Nanavati Hospital, Mumbai, Maharashtra, India

BACKGROUND: Breast cancer mainly originates in the epithelial lining of milk ducts or lobules. Once early pre-malignant or malignant changes occur in the ductal lining there is a long latent period before they manifest symptoms or are detected on imaging. Symptomatic nipple discharge (SND) is a common symptom noted in approximately 5% of patients. Although, usually benign it may be the earliest sign of cancer. The current standard evaluation of patients with nipple discharge includes clinical examination (CE), mammography (MMG) and ultrasound (US). Contrast enhanced MRI is considered the most sensitive imaging modality for the breast and reports suggest it may be of benefit in the evaluation of nipple discharge. We have combined MRI with standard evaluation in an ongoing prospective study to determine its utility in patients with SND.

PATIENTS AND METHODS: Between July 2004 and 31st May 2011, 75 women underwent surgery for SND. All were initially evaluated by CE, MMG and US following which a contrast enhanced breast MRI was requested. MRI was performed on a 1.5T MR unit using a dedicated breast coil. A STIR sequence in the coronal and sagittal planes along with an unenhanced fat-suppressed T1 W sequence was used to evaluate the ducts. The imaging findings were used to direct surgical excision. All specimens were oriented and evaluated by the pathologist by sectioning at 1 cm interval, from the ductal end to the periphery. The results of preoperative MMG, US and MRI findings were compared with pathology.

RESULTS: The incidence of cancer in this series was 29% and high risk lesions were noted in 43%. MMG and US were performed in 75 patients. MRI was requested in all 75 patients but could be performed in 64. MRI proved to be the most sensitive technique for detection of an abnormality in the breast (92%) compared to MMG 25%, and US 63%. MMG, US and MRI were suggestive of benign change in 64 (85%), 65 (87%) and 43 (67%) patients respectively, of which 14 (22%), 15 (23%) and 7 (16%) were malignant on pathology. MMG, US and MRI reported suspicious change in 11(15%), 10 (13%) and 21(33%) patients respectively of which 8 (73%), 7 (70%) and 9 (43%) patients had cancer on pathology. MRI had the highest sensitivity for malignancy (54%) compared to MMG (36%) and US (32%) but MRI had a low specificity (74%) (MMG 94%; US 94%). However, MRI had a high negative predictive value (86%) (MMG 78%; US 73%). Of the 22 patients with cancers, 12 were deemed to be normal on CE, MMG and US examination. Thus standard evaluation would have missed 54% of the cancers detected in this series.

CONCLUSIONS: Nipple discharge is associated with significant incidence of cancer and high risk changes. The majority of these are missed on standard evaluation (CE, MMG, US). MRI is the most sensitive method for the detection of an abnormality in these patients. It defines the location and extent of the abnormality and can guide surgical excision. However, MRI is unable to accurately differentiate malignant from benign lesions. Hence, excision of an identified abnormality and pathological evaluation remains essential.

P2-08-12
Additional Lesion Found in Preoperative Breast MRI: Is Routine Use Justified?

Kim J, You J, Shin H, Ahn S, Moon H-G, Cho N, Moon W-K, Han W, Noh D. Seoul National University Hospital, Seoul, Korea

Preoperative breast MRI has been increasingly performed in patients with newly diagnosed breast cancer due to its high sensitivity in assessing the extent and additional malignant foci. But due to it’s low specificity, role of routine preoperative breast MRI has become an issue. In this study we aught to analyze the characteristics of the additional lesion found in preoperative breast MRI and to evaluate the clinicopathological factors in association with likelihood of having additional malignancy. We retrospectively reviewed 2491 patients who undergone surgery due to breast cancer in Seoul National University Hospital(SNUH) between Jan 2006 and Dec 2010. Neoadjuvant chemotherapy cases, patients undergone initial sonography in other center or ones with...
prior excision were excluded and total 1068 patients were analyzed. The additional lesion was defined as the lesion not found in initial sonography and detected in preoperative breast MRI. The pathology of the additional lesion was reviewed and the association between the clinicopathologic factors and additional malignancy were evaluated. Accuracy of breast MRI was estimated regarding cancer yield, positive predictive value (PPV).

Mean age at diagnosis was 50.9 years (21 to 85 years). Overall detection rate of additional lesion was 26.2% (280 out of 1068). Mean size of the additional lesion was 9.8 mm (3-21). Additional lesions consist of 99 (35.4% of 280) C4 or higher, 174 (62.1% of 280) below C4, 7 (2.5% of 280) C0 lesions. Among them 100 patients undergone onsite surgery. 55% (55 of 100) lesions were in ipsilateral breast and 45% (45 of 100) in contralateral breast. Breast conserving surgery and mastectomy rate of the 100 onsite-operation group was 36% versus 64% and 64.6% versus 35.4% in total 1068 patients, showing no significant change of operation method of the primary cancer owing to additional lesion.

Among the 100 patients, 54 (19.3% of 280) were benign, 3 (1.1% of 280) were atypical ductal hyperplasia, 13 (4.6% of 280) were in situ carcinoma, 19 (6.8% of 280) were invasive carcinoma and 1 (3.9% of 280) were unknown. Cancer yield was 2.99% (32 out of 1068) and PPV of preoperative breast MRI was 39.0% (31 out of 82).

In univariate analysis, young age and premenopausal patients showed to have higher rate of additional cancer found in MRI (p=0.022, p=0.036). Breast density, size and LN status of the primary cancer didn’t show significance and neither the hormone receptor status with each p value 0.705, 0.381, 0.973, 0.375 respectively. Lobular carcinoma (ILC) or mixed IDC with ILC and low grade carcinoma showed significance of having additional malignancy (p=0.019, 0.022). In multivariate analysis, age, low grade carcinoma and lobular carcinoma showed independent association with p value 0.014, 0.039, 0.035 respectively (HR 0.95, 95%CI:0.94 o 0.99), (HR 0.39, 95%CI:0.16 to 0.96), (HR 5.66, 95%CI:1.13 to 28.39).

Routine preoperative breast MRI use can result in overtreatment also with delay in surgical management. In our data, younger age, low grade carcinoma, lobular carcinoma showed independent association having additional malignant foci in breast MRI. With the basis of mammography and sonography, preoperative breast MRI should only be done when additional gain is considered to overcome the flaws.

P2-08-13 Does Routine Use of Preoperative Magnetic Resonance Imaging (MRI) in Breast Cancer Influence the Outcome?
Grofe R, Kantelhardt EJ, Steer S, Spinda AK, Vetter M, Ruschke K, Thomssson C. Martin-Luther-University Halle-Wittenberg, Halle (Saale), Germany

Introduction: The role of routine preoperative breast MRI in patients diagnosed with breast cancer is still under discussion. In a milestone review, Houssami et al. (CA Cancer J Clin 2009;59:290) did not demonstrate an advantage with regard to DFS or OS. We reviewed our case series (n=793) in order to add evidence to the current discussion of whether or not preoperative MRI would influence the outcome.

Material and Methods: In our database we identified four years of diagnosis (2004-07) in which a high percentage (72%) of patients (349 of 483) with histologically confirmed invasive breast cancer received preoperative MRI. In the following years (2008/09), MRI was still done in 31% of the cases (97 of 309). All pts were treated according to national guidelines; however, patients with additional lesions in MRI were subjected to an additional MRI-guided needle biopsy or additional wire-guided excision. The median follow-up time was 31.5 months (0-81). The patients were followed clinically. In most cases local surveillance was done by mammography.

Results: In the total cohort, 20% of the patients had additional needle biopsies and/or wire-localisation due to MRI-findings. By MRI, lesions that subsequently led to an additional preoperative needle biopsy were found in 82 pts. Interestingly, only ten contralateral second cancers were found. In 357 pts, MRI was used as guidance during the operation with (n=118) or without MRI-supported wire localization (n=238). The percentage of additional MRI-needle biopsy or MRI-supported localization did not differ between invasive ductal (n=655) and lobular cancer (n=91): 10% versus 13% needle biopsies and 15% versus 20% wire localisations. The number of surgical procedures to achieve tumor-free margins did not differ between patients with or without preoperative MRI. In this series, 69 of 100 patients who received neoadjuvant chemotherapy, also had MRI-imaging. Considering the patient cohort with follow-up available (n=737), no significant difference of DFS probability was observed between pts with and without preoperative MRI.

Discussion: This retrospective analysis did not demonstrate any advantage for routine preoperative MRI with regard to local treatment and DFS probability. The observed rate of 20% additional operative procedures corresponds to similar published data (16% additional multicentric or multifocal lesions found by MRI, Solin, Breast. 2010;19:7).
HER2 expression. All other biopsies confirmed that the metastases were still positive or negative in line with the subject’s primary lesions. None of the subjects had any adverse reactions due to the investigations.

Conclusion: ABY-025 can be used safely in humans with similar excellent whole body HER2-receptor molecular imaging capabilities as have already been observed in animal models. Promising indications of in vivo HER2-receptor status discriminatory capabilities were observed.

**P2-09-02**

Predicting Response to Bevacizumab in Primary Breast Cancer Using 18F-Fluorothymidina (FLT) and 18F-Misonidazol (MISO) Positron Emission/Computed Tomography (PET/CT) as Imaging Biomarkers.

**Dominguez I, Boni V, Garcia-Vellosi MI, Lopez-Vega JM, Martinez P, Plazaola A, Llombart A, Anton A, Galve E, Alvarez IM, Hernando B, Sanchez-Gomez R, Illarramendi JJ, Morales S, De Juan A, Richter JA, Lahuerta A, Garcia-Gonzalez M, Lao Romera J, Puertolas T, Scherer S, Sabariz Luis, Garcia-Foncillas J. Clinic University of Navarra; Hospital Marques de Valdecilla; Hospital de Basurto; Oncologikoa; Hospital Arnau de Villanova de Lleida; Hospital Miguel Server; Hospital Civil de Basurto; Hospital Donostia; Hospital General Yagues de Burgos; Hospital de San Millan; Hospital de Navarra; Roche Basel; Roche Madrid**

**Background:** To investigate the hypothesis that early changes in tumor proliferation and hypoxic status induced by bevacizumab and assessed by imaging biomarkers might predict response to bevacizumab therapy.

**Methods:** 73 chemotherapy naïve, stage II-III breast cancer (BC) patients (pts) were enrolled in the training set of this phase II, single-arm, multicentric and prospective clinical trial from October 2009 until November 2010. Pts received single infusion of bevacizumab (15 mg/ kg) (C1) 3 weeks prior to the beginning of neoadjuvant chemotherapy (NAC) consisting in 4 cycles of docetaxel (60 mg/mq), doxorubicin (50 mg/mq) and bevacizumab (15 mg/ kg) every 21 days (C2-C5) following by surgery. Tumor proliferation and hypoxic status were evaluated using FLT and MISO PET/CT at baseline and 14-21 days after bevacizumab (C1). Standardized uptake values (SUV) for FLT and MISO and ratios to reference tissues, mediastinum (T/Me) or muscle (T/Mu), for MISO were calculated. Pathological response on surgical specimens was assessed according to Miller/Payne grading system. Pts with reduction in tumor cells >30% (G3-G4-G5) or <30% (G1-G2) were respectively classified as responders and non-responders. Association between pathological response, baseline and changes induced by bevacizumab (C1) in imaging biomarkers was analyzed using Mann-Whitney test. Receiver operating characteristic (ROC) curve was performed to test sensitivity and specificity of the biomarker found associated to response. Its value as independent predictor was tested in multivariate analysis using logistic regression.

**Results:** Median baseline MISO and FLT SUV values in tumors were 1.2 (range 0.69-2.39) and 2.89 (range 0.97-7.18). Significant change after C1 was observed in FLT (2.7 vs 1.8, p<0.001) but no in MISO uptake. Fifty-two (74%) pts achieved response (G3-G4-G5) whether 18 (24%) were considered as no responder (G1-G2); for FLT SUV baseline and changes after C1 in MISO SUV, T/Mu and T/Mc were all significantly associated with pathological response (p=0.057, 0.03, 0.016, 0.010). ER expression and T/Mu change remained significantly associated with response in multivariate analysis (OR=24.8, IC95% 1.8-334, p=0.01 and OR=0.95, IC 95% 0.92-0.99, p value=0.02). Decrease in MISO T/Mu uptake >20% yielded a ROC curve area of 0.7 (95% CI: 0.56 - 0.85) with 94% sensitivity and 87% specificity. Conclusion: Bevacizumab determined a marked decrease in tumor proliferation. Interestingly, a decrease greater than 20% in tumor hypoxic status after C1 and assessed by MISO was found significantly associated with pathological response suggesting a potential value of early decrease in hypoxic tumor status as predictive biomarker of response. Bevacizumab, causing normalization of the tumor microvasculature, seems to potentiate the effect of cytotoxic agents on primary BC. A validation set is warranted to confirm these findings.

**P2-09-03**

**Sella T, Sklar-Levy M, Maya C, Rozin M, Tanir A, Maira S, Libson E, Ezkay D, Hadassah Hebrew University Medical Center, Jerusalem, Israel; Chaim Sheba Medical Center; Tel Hashomer, Israel; Rabin Medical Center; Petach Tikva, Israel; Assuta Medical Center; Tel-Aviv, Israel; Kaplan Medical Center, Rehovot, Israel; Meir Medical Center, Kfar Sava, Israel; Real Imaging Ltd., Airport City, Israel**

**Introduction:** A novel prototype system performing functional three-dimensional (3D) infrared imaging (RUTH), coupled with multi-parametric computer analysis (MIRA), was evaluated for non-invasive breast cancer detection. The technique utilizes non-ionizing radiation and automatically provides risk assessment based on parameters derived from a clinically known training set.

**Materials and methods:** Following IRB approval, prospective multicenter, two-armed blinded evaluation, was performed on 102 women, which included 43 patients with biopsy proven breast cancer and 59 women with a normal (BI-RADS 1) mammogram. RUTH imaging (Real Imaging Ltd, Israel) was acquired on a continuous temporal timeline for 5 minutes during which a cold-stress test was applied for one minute. Acquired data were analyzed using multiple computed algorithms (MIRA) which were combined to develop a master algorithm for risk assessment of breast cancer. Analysis was blinded to the clinical status. Results were displayed as risk assessment scale with 100 being suspicious for breast cancer and -100 inferring normal healthy breasts.

**Results** Thirty-nine of 43 cancers (91.7%) were identified using this novel technology. The sensitivity and specificity of RUTH coupled with MIRA for detecting breast cancer were 90.7% and 67.8% respectively. The AUC defined by the ROC curve was 0.832. Twenty-seven of the 39 (70%) detected cancers were smaller than 20mm in size.

**Conclusions:** This preliminary study shows adequate performance of the novel technology examined for detecting breast cancer. Performance is comparable to the reported performance of new adjunctive breast imaging technologies such as tomosynthesis and contrast-enhanced mammography, and superior to the published sensitivity of mammography. Our results warrant further evaluation of the RUTH and MIRA technologies in detecting and characterizing breast cancer.
P2-09-04
Near Infra Red Quantum Dots as Novel Probes for Sentinel Lymph Node Biopsy.
Rizvi SB, Yang SY, Bala R, Shirin G, Seifalian AM, Keshtgar M. University College London, London, Hampstead, United Kingdom

Background
Sentinel Lymph Node Biopsy (SLNB) is a standard procedure in breast cancer surgery. The current tracers for SLNB including the blue dye and radiocolloids have various limitations like anaphylactic reaction to the dye and exposure of radioactivity to both patients and staff. Quantum dots (QDs) are fluorescent nanoparticles (2-10nm in diameter), with unique photophysical properties like enhanced photostability and size tunable emission wavelengths, that can potentially replace the current tracers for SLNB. QDs emitting in the Near Infra Red (NIR) range of the electromagnetic spectrum can be tracked in deep tissues as biological tissues are transparent to NIR wavelengths (700-2000nm). We have developed Near Infra Red emitting Quantum Dots (NIR QDs) as alternative probes for SLNB and set up a live NIR imaging system to track them in deep tissues.

Materials and Methods
NIR emitting QDs based on CdTe:Hg were synthesized by a one pot aqueous method and characterized using Transmission Electron Microscopy (TEM), UV-Vis spectrometry and photoluminescence studies. 100µl of QDs (1mg/ml) were co-injected intradermally with blue dye into the hind legs of rat models (n=4) and compared to controls (n=4) which were injected with blue dye only. The procedure was conducted under inhalational anaesthesia using isoflurane and rats were monitored for hemodynamic instability for a period of 2hrs after injection. QDs were tracked using a live NIR imaging system including an excitation light of 630nm, emission filter of 850nm and a Hamamatsu Orca 2 UV-Vis-NIR thermoelectrically cooled CCD camera.

Results
NIR QDs had a core diameter of 7nm on TEM and emitted at 860nm upon excitation with a 630nm light source. Within 3 minutes of an intradermal injection QDs entered the lymphatic tracts. The lymphatics converged to the groin and a small surgical incision at this site revealed the underlying sentinel lymph node with minimal dissection. The rats remained hemodynamically stable throughout the duration of the procedure with no significant difference in comparison with the controls.

Conclusion
NIR emitting QDs can be used for accurate localisation of the SLN prior to surgical incision, making this an even more minimally invasive procedure and possibly an office based procedure in the future. The nanosize, surface chemistry and deep tissue visibility of these novel nanoprobes allow relentless possibilities for in vitro and in vivo molecular and cellular imaging. NIR QDs can be conjugated to biomolecules for cancer localisation, detection of micrometastasis and image guided targeted drug delivery of chemotherapeutic agents.

Further studies to investigate their in vivo biodistribution are in progress to take this technology one step closer to clinical application.

P2-09-05
Molecular Imaging of Hedgehog Induced Epithelial-Stromal Interactions.
Sims-Mourtada J, Yang DJ, Tworowska I, Larson R, Smith D, Mourtada F, Woodward W. RadioMedix, Inc, Houston, TX; The University of Texas M.D. Anderson Cancer Center, Houston, TX

Introduction: Epithelial-stromal Hedgehog (HH) pathway signaling, originating from Sonic Hedgehog (SHH) ligand secreted by tumor cells, promotes breast cancer growth and metastasis. Furthermore, high tumor SHH expression is associated with poor prognosis in invasive ductal carcinoma. Studies have also shown high expression of Patched (PTCH) mRNA in SHH expressing tumors as well as cancer stem-like cells. This is in part due to a feedback loop that results in increased PTCH gene expression upon HH signaling. We sought to exploit this feedback loop by using radiolabeled derivative of SHH to identify tumors that have a high level of hedgehog signaling. These agents can potentially be used for molecular imaging of HH induced changes in PTCH expression originating from tumor expressed SHH.

Methods: Recombinant N-terminal SHH derivatives were radioiodinated with iodine-131 using the idogen method. Iodinated proteins were obtained with radiolabeling yields of 50-60 % and specific activity of 9.3E10Ci/mol. Receptor binding studies were performed on breast cancer cell lines with varying SHH expression. Studies were also conducted on cells cultured in stem cell promoting conditions (mammospheres), after exposure to ionizing radiation or treatment with the hedgehog inhibitor cyclopamine. Scatchard plots were generated using Graph pad software. Pilot studies were conducted with 110I-SHH to test the potential of imaging PTCH receptor expression in a rat model of breast cancer. Fisher rats bearing breast cancer xenografts were injected with approximately 250 microCi of 110I-SHH. Planar scintigraphy was conducted at 2, 4 and 24 hours. Studies were performed with iodinated BSA as a control for extracellular perfusion and retention. Tissue biodistribution studies were also performed using this model.

Results: Receptor binding of 110I-SHH was significantly increased in cell lines with high endogenous HH pathway activation. Receptor binding was also increased after exposure to ionizing radiation and significantly decreased following treatment with hedgehog inhibitors. Scatchard analysis revealed up to a 14 fold increase in PTCH receptor sites in mammospheres compared to the entire breast cancer population. A 10-fold increase in PTCH receptor binding sites was also observed in cells after exposure to ionizing radiation. In vivo imaging and biodistribution studies revealed significant accumulation of 110I-SHH within tumor tissue as compared to normal organs. Tumor: muscle ratios were approximately 8:1 at 4 hours, while tumor to blood and tumor to bone were 2:1 and 5:1 respectively. Significant uptake was also observed in liver tissue, as a result of protein degradation and excretion and endogenous PTCH expression.

Conclusions: These studies show that expression of the PTCH receptor is increased in cells with active HH signaling and in breast cancer mammospheres. Our findings also show that PTCH receptor expression is decreased upon treatment with HH signaling inhibitors. Preliminary imaging studies show that 110I-SHH is capable of in vivo detection of breast tumors with high hedgehog signaling. Our data suggests that radiolabeled SHH derivatives may provide a method to follow epithelial-stromal HH interactions and determine response to SHH targeted therapies.

**Relevance of Breast Cancer Subtypes in Response Monitoring with 18F-FDG PET/CT during Neoadjuvant Chemotherapy.**

Koolen BB, Pengel KE, Wesseling J, Vogel WV, Vrancken Peeters MJ, Gilhuijs KG, Rutgers EJ, Valdés Olmos RA. Netherlands Cancer Institute - Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands

Background – Neoadjuvant chemotherapy (NAC) is increasingly applied in stage II and III breast cancer. Response monitoring with magnetic resonance imaging (MRI) has been shown valuable, but knowledge of the breast cancer subtype is essential for correct interpretation of response assessment. (Loo et al, J Clin Oncol 29:660-6, 2011)

The aim of the present study was to evaluate the relevance of breast cancer subtype for 18F-fluorodeoxyglucose (FDG) positron emission tomography with computed tomography (PET/CT) markers for monitoring of therapy response during NAC.

Methods – Evaluation included 94 women with primary stage II or III breast cancer and measurable (quantifiable) FDG tumor uptake. FDG PET/CT scans were performed before and after six weeks of NAC using similar prone patient positioning. FDG uptake of the primary tumor was quantified using maximum standardized uptake values (SUVmax). Tumors were divided into three subtypes using immunohistochemistry: human epidermal growth factor receptor 2 (HER2) positive, estrogen receptor (ER) positive/HER2 negative and triple negative. Tumor response was assessed as presence of residual tumor in the surgery specimen (no response or partial response) or absence thereof (near complete or complete response). Multivariate regression analysis and receiver operating characteristic (ROC) analyses were employed to determine significant associations.

Results – A (near) complete response at pathology was observed in 16 (73%) of 22 HER2 positive tumors, 5 (12%) of 43 ER positive/HER2 negative tumors and 20 (69%) of 29 triple negative tumors. In the multivariate regression analysis for the whole group, (near) complete response in the surgery specimen was significantly associated with relative reduction of SUVmax of the tumor between both scans and breast cancer subtype (area under the curve of the ROC curve 0.88 [95% confidence interval 0.81-0.95], p<0.001); no significant associations were found for FDG uptake at baseline and age. In a subgroup analysis of breast cancer subtype, a significant association was found between pathologic response and relative reduction of SUVmax for ER positive/HER2 negative and triple negative tumors (p=0.012 and p<0.001, respectively), but not for HER2 positive tumors (p=0.151).

Conclusion – Knowledge of the breast cancer subtype appears relevant for the assessment of response to NAC with FDG PET/CT. Response monitoring with FDG PET/CT may predict a pathological response adequately in ER positive/HER2 negative and triple negative tumors, but seems less accurate in HER2 positive tumors. The reasons for these differences need to be elucidated in further investigations.

Disclosure – This study was performed within the framework of CTMM, the Center for Translational Molecular Medicine (www.ctmm.nl), project Breast CARE (grant 030-104).

---

**P2-09-07**

**Metabolic Response by FDG-PET in Patients (pts) Receiving Trastuzumab (T) and Lapatinib (L) for HER2+ Metastatic Breast Cancer (MBC): Correlative Analysis of TBCRC 003.**

Yap JT, Locascio T, Najita JS, Mayer IA, Hobday TJ, Falkson CI, Dees EC, Gelman RS, Rimawi MF, Nanda R, Berkovic J, Franchetti Y, Wolf AC, Winer EP, Lin NU, Van den Abbeele AD. Dana-Farber Cancer Institute, Boston, MA; Vanderbilt-Ingram Cancer Center, Nashville, TN; Mayo Clinic, Rochester, MN; University of Alabama, Birmingham, AL; University of North Carolina at Chapel Hill, Chapel Hill, NC; Baylor College of Medicine, Houston, TX; University of Chicago, Chicago, IL; Johns Hopkins Kimmel Cancer Center, Baltimore, MD

Background: We evaluated the safety and efficacy of L+T in pts with 0-2 prior lines of chemotherapy (CT) for HER2+ MBC. In the context of this phase II trial, we evaluated metabolic response by FDG-PET and explored the relationship between metabolic response and clinical outcomes.

Methods: Pts with measurable, HER2+ MBC were eligible. Cohort 1: No prior T, L, or CT + T for MBC, and ≥1 yr from adjuvant T, if received. Cohort 2: 1-2 prior lines of CT for MBC, including T, or relapse within 1 yr of adjuvant T. Pts received L 1,000 mg QD + T (2 mg/kg weekly or 6 mg/kg Q3W). Staging studies were done with CT or MRI at baseline (BL) and every 2 cycles (1 cycle=4 weeks [wks]). Objective response was assessed by local investigator according to RECIST 1.0. FDG-PET/CT was performed at BL, Wk 1, and Wk 8 per NCI guidelines. Central quality assurance, review, and analysis were performed on FDG-PET studies. Up to 5 target lesions were identified on BL FDG-PET images based on hypermetabolic uptake. Percent change in the summed maximum standardized uptake value (SUVmax) was calculated at Wk 1 or Wk 8, compared to BL. Metabolic response was assessed according to EORTC criteria for % change in SUVmax (progressive disease [PD]: ≥25% increase; partial response [PR]: ≥25% decrease; stable disease [SD]: <25% change). Metabolic response at Wk 1 was compared to Wk 8 as well as to clinical outcome, including objective response, clinical benefit, and progression-free survival (PFS).

Results: 87 pts were registered to the study. Of these, one pt did not begin protocol therapy and one pt did not have MBC on further testing, and are not included. 81/85 pts had FDG-PET data at Wk 1; 75/85 had data at Wk 8. Metabolic PR at Wk 1 was observed in 28/39 (72%) pts in Cohort 1 and 20/42 (48%) pts in Cohort 2. Metabolic PR at Wk 8 was observed in 27/34 (79%) pts in Cohort 1 and 18/41 (44%) pts in Cohort 2. Wk 1 and Wk 8 metabolic responses were similar. In cohort 1, 18/28 (64%) pts who achieved Wk 1 metabolic PR had clinical benefit; 5/22 (23%) who achieved Wk 1 metabolic SD had clinical benefit. In cohort 2, 9/20 (45%) pts who achieved Wk 1 metabolic PR had clinical benefit; 5/22 (23%) who achieved Wk 1 metabolic SD had clinical benefit. In cohort 2, 9/20 (45%) pts who achieved Wk 1 metabolic PR had clinical benefit; 5/22 (23%) who achieved Wk 1 metabolic SD had clinical benefit. In exploratory analysis of progression-free survival (PFS) showed that pts in Cohort 1 who achieved Wk 1 metabolic PR experienced a median PFS of 9.1 months (95% CI 7.1-11.0); for pts with metabolic SD, median PFS was 1.6 mos (95% CI 0.8-5.5). For pts in Cohort 2, Wk 1 metabolic PR was associated with median PFS of 6.5 mos (95% CI 3.3-7.8), whereas for pts with metabolic SD, median PFS was 3.7 mos (95% CI 1.8-5.5).

Conclusions: L+T is associated with a high rate of early and sustained metabolic response by FDG-PET. Exploratory analyses suggest that metabolic PR may be associated with clinical benefit and longer PFS.
P2-09-08
FDG-PET in the Staging of the Axilla in Women with Breast Cancer Treated with Primary Chemotherapy.

Lao Romera J, Puértolas Hernandez T, Alvarez Alejandro M, Godoy Molias A, Hernandez Garcia A, Millastre Bocos E, Garcia Mur C, Ubieto Laguarda MA, Artal Cortes A, Anton Torres A. Hospital Universitario Miguel Servet, Zaragoza, Spain; Clinica Quirón, Zaragoza, Spain

Background: FDG-PET has proven to be useful during the initial staging of several tumor types. The aim of the present study was to assess the accuracy of this test in the assessment of initial axillary status in patients referred to treatment with induction chemotherapy.

Material and Methods: Women with stage II-IIIA (tumors measuring ≥3cm or positive-staged axillary involvement) to be treated with neoadjuvant Docetaxel-Doxorubicin-Cyclophosphamide (TAC) scheme were included. In every patient a physical exam, MRI, ultrasound-guided FNAB and FDG-PET were performed prior starting chemotherapy. The criteria to consider the axilla to be initially positive were positive surgical staging or type-D pathological response (Miller-Payne) in the axilla. The ability of FDG-PET to predict pathological response in patients with breast cancer was assessed and compared with other routine procedures.

Results: 42 patients (p) were included. Median age was 45 years (30-66). 11p (26.2%) were triple-negative. 2p (4.8%) were Her-2 +. By clinical stage, 13p (30.9%) were IIA, 17p (40.4%) IIB and 12p (28.2%) IIIA. 41p (97.6%) underwent surgery after induction chemotherapy. According to surgical staging 31p (75.6%) were deemed to be N+ from the diagnosis (19p with pathologic N1-3a and 12p with type-D nodal response). PET scan positively detected deposits in the axilla in 26p (63.9%) of those patients compared to 22p (70.9%) with ultrasound-FNAB, 19p (61.3%) physical exam and 14p (45.2%) MRI.

Conclusions: In this study FDG-PET could predict axillary involvement more precisely than other routine staging procedures in these patients submitted to be treated with induction chemotherapy.

P2-09-09
Dynamic FDG PET and DCE-MRI To Assess Tumor Metabolism and Blood Flow in Response to Neoadjuvant Sunitinib and Paclitaxel Followed by AC + G-CSF in Patients with Locally-Advanced (LABC) and/or Inflammatory Breast Cancer (IBC).

Specht JM, Kurland BF, Dunnwald LK, Doot RK, Eun JK, Schubert EK, Partridge SC, Ellis GK, Gadi VK, Gralow JR, Linden HM, Rodler ET, Mankoff DA. University of Washington, Seattle, WA; Fred Hutchinson Cancer Research Center, Seattle, WA; Seattle Cancer Care Alliance, Seattle, WA

Background: Kinetic analysis of FDG PET and DCE-MRI can identify patterns of breast tumor metabolism and perfusion that predict pathologic response, relapse, and survival in patients (pts) receiving neoadjuvant chemotherapy (NC). We are enrolling pts with LABC or IBC on a phase II trial of neoadjuvant sunitinib and metronomic chemotherapy. The addition of sunitinib, a tyrosine kinase inhibitor of VEGFR1-3, PDGFR, c-KIT, to NC is hypothesized to increase rate of pathologic complete response (pCR). Assessment of FDG PET measures of glucose metabolism (Ki), glucose delivery (Kg), and MRI measures of blood flow and vascularity (peak enhancement (PE), signal enhancement ratio (SER), and volume) during NC offers the opportunity to evaluate the in vivo pharmacodynamics of sunitinib.

Methods: Pts with HER2-negative LABC or IBC participated in a companion imaging trial with [18F]-FDG PET and DCE-MRI before NC (T0), after a 1 wk run-in of sunitinib 25 mg po daily (T1), after 12 wks of paclitaxel 80 mg/m2 IV Qwk and sunitinib 25 mg po daily (T2), and prior to breast surgery (T3) after 15 wks of doxorubicin 24 mg/m2 IV Qwk, cyclophosphamide 60 mg/m2 po daily with G-CSF 5 mcg/kg SC days 2-6 each wk. FDG metabolic rate (Ki), glucose delivery (Kg), and MR indices (PE, SER, volume) were assessed. Imaging parameters were compared for groups defined by NC pathologic complete response (pCR) vs. non-pCR using a two-sample t-test.

Results: The imaging trial included 14 pts. Median age was 50 years (43-79). All had HER2-negative LABC (n=13, 93%) or IBC (n=1, 7%). Most tumors were ductal (n=12, 86%) and high grade (n=9, 64%). Seven (50%) tumors were ER negative. pCR was observed in 4/14 (29%) pts in this cohort. Changes in Ki, Kg, and MRI volume were observed between baseline (T0) and the sunitinib run-in (T1). For example, 8/14 (57%) had a decrease in Kg of ≥20%, and 3 (21%) had an increase of ≥20%. These 1 week changes did not predict subsequent response to NC. However, declines in Ki and Kg between baseline (T0) and following sunitinib and paclitaxel (T2) did predict pCR. The average change in glucose metabolism (Ki) was a 95% decline with pCR and a 68% decline otherwise (p=0.007). The average T0-T2 Kg change was 83% decline for pts with pCR and 47% decline otherwise (p=0.029). In contrast to our previous studies in LABC pts treated with NC where decline in Ki was predictive of response, decline in Ki appears to be the more robust predictor of response in this cohort. Of 11 pts with PET scans at T2 and T3, 5 showed marked increase (>20%) in Ki and 6 showed marked increase in Kg after withdrawal of sunitinib.

Conclusion: Changes in breast tumor glucose metabolism (Ki), glucose delivery (Kg), and blood flow (MR PE, SER, volume) can be detected after 1 wk of sunitinib, but are not predictive of response to NC. In the setting of anti-vascular therapy, measures of tumor metabolism (Ki) are predictive and, perhaps, more predictive of outcome than measures of glucose delivery (Kg) which may be altered by sunitinib.

Giant or Windmill? 18F-FDG-PET/CT Semi-Quantitative Parameters and Biological Prognostic Parameters in Women with Breast Cancer Treated with Neoadjuvant Chemotherapy: A Multicentric Study in La Mancha.

del Mar Muñoz-Sánchez M, García-Vicente A, Ortega-Ruipérez C, Palomar-Muñoz A, Molina-Garrido MJ, Olaverri-Hernández A, Santiago-Crespo JA, Martín-Ordoñez F, Val-Pérez E, Cordero-Garcia JM, Chacón JJ, Fernández-Aramburu A, Espinosa J, Viana A, Sorianó-Castrejón A. Hospital General Virgen de la Luz, Cuenca, Spain; Hospital General Universitario de Ciudad Real, Ciudad Real, Spain; Complejo Hospitalario de Toledo, Toledo, Spain; Complejo Hospitalario Universitario de Albacete, Albacete, Spain; Hospital General Ntra Sª del Prado, Talavera, Toledo, Spain

Background: To analyze the possible predictive- prognostic value of 18F-FDG-PET/CT to evaluate response to primary preoperative neoadjuvant (NA) chemotherapy (CT) in women with breast cancer (BC) a multicenter study is being conducted in most Hospitals in Castilla – La Mancha (central Spain). As per protocol a PET/CT study has to be conducted prior to 1st cycle, after 2nd cycle and at the end of induction CT. We report here the initial results with the correlation between the PET/CT results and pathological-radiological-clinical findings prior to NA CT.

Aim: To analyze the correlation between 18F-FDG uptake assessed by PET/CT and histopathological and immunohistochemical prognostic factors in BC prior to NA CT.

Material and methods: 68 women diagnosed of BC (36 with locally advanced BC) were prospectively evaluated. PET/CT was requested in the initial staging previous to NA CT. Clinical and metabolic stages were assessed according to TNM classification. All biological prognostic parameters, such as ER, PR, p53 and c-erbB-2 expression, proliferation rate (Ki-67), and grading (SBR) were determined from tissue of the primary tumour prior to NA CT. All patients underwent an 18F-FDG PET/CT with a dual-time-point acquisition performed in the early phase 1 h after FDG administration (PET-1) and in the delayed phase 3 h after FDG administration (PET-2). Both examinations were evaluated qualitatively and semiquantitatively with calculation of SUVmax values in PET-1 (SUV-1) and in PET-2 (SUV-2) and the percentage variation of the standard uptake values (retention index) between PET-1 and PET-2. Metabolic, clinical and biological parameters were correlated. Student, ANOVA and Bonferroni tests were used to compare the means, chi-score to compare proportions and Pearson correlation to compare two quantitative variables.

Results: A positive relationship was found between the SUVmax, tumour size, clinical and metabolic stages. SUV-1 and SUV-2 values showed significant statistical correlation (p<0.05) with PET stage and tumour size assessed by PET. On the contrary, the retention index showed relation with clinical stage (p<0.05). About the biological parameters, retention index showed the best results with positive and significant relation (p<0.05) with histological grade, ER status, Ki-67 and c-erbB-2 expression. Isolated SUV values only showed significant relation to Ki-67 expression.

Conclusion: The retention index showed the best correlation with biological and clinical parameters compared to isolated SUVmax values. It may be useful as a predictive marker of tumor biological behavior. Nevertheless these are only the results of PET/CT prior to NA CT, with longer follow up we hopefully will be able to look at the correlation between PET/CT and radiological, clinical and pathological response after NA CT.

P2-09-11

Role of 18FDG-PET/CT in the Staging of Large Primary Operable Breast Cancer.

Background: Prospective evaluation of the role of 18FDG-PET/CT in patients with large primary operable breast cancer.

Material and Methods: During 56 months, consecutive patients with large (>2cm) breast cancer and clinical stage IIA/IIB/IIIA (based on clinical examination, mammography, breast MRI and ultrasonography) underwent 18FDG-PET/CT. The nuclear physician was blind to the results of any other procedure (bone scan, chest X-ray, liver ultrasound, or thoraco-abdominal CT scan).

Results: Out of the 131 examined patients, 36 had clinical stage IIA (34 T2 N0, 2 T1 N1), 48 stage IIB (20 T3 N0, 28 T2 N1), and 47 stage IIIA (29 T3 N1, 9 T2 N2, 9 T3 N2). 18FDG-PET/CT modified staging for 5.6% of stage IIA patients, for 14.6% of stage IIB patients, and for 27.6% of stage IIIA patients. However, within stage IIIA, the yield was specifically high among the 18 patients with N2 disease (56% stage modification). When considering stage IIB and primary operable IIIA (T3 N1) together, the yield of 18FDG-PET/CT was 13% (10/77); extra-axillary regional lymph nodes were detected in 5 and distant metastases in 7 patients. In this series, 18FDG-PET/CT outperformed bone scan with only 1 misclassification versus 8 for bone scan (p=0.036).

Discussion: 18FDG-PET/CT provided useful information in 13% of patients with T3 N0 / T2 N1 / T3 N1 disease. The yield was more modest in patients with T2 N0 disease. The very high yield in the case of lymph nodes classified N2 demonstrates that stage IIIA comprises two quite distinct groups of patients.

P2-09-12

High Resolution Diffusion MRI Characterizes Tumor Stromal Boundaries.

McLaughlin RL, Nevitt DC, Wilmes LJ, Sinha S, Wisner DJ, Hylton NM, UC Berkeley and UCSF, Berkeley and San Francisco, CA; UCSF, San Francisco, CA

Background: Studies of 3D cell cultures have shown that mammary epithelial cell growth and morphogenesis is regulated by extracellular matrix (ECM) stiffness, linking ECM stiffening to malignant transformation. Tumors are consistently stiffer than normal adjacent tissue, and matrix stiffening is caused by ECM cross-linking and increased deposition of collagen. Some evidence suggests that collagen orientation at tumor boundaries can promote tumor metastasis. Measuring the stiffness of the tumor boundaries and adjacent stromal tissue may give additional information 1) about tumor microenvironment and 2) to guide treatment. Diffusion-weighted imaging (DWI) MRI measures the mobility of water in tissue and may be sensitive to this phenomenon.

Material and Methods: MRI data was collected on patients with locally advance breast cancer enrolled in an IRB-approved study at UCSF and signed informed consent. In addition to a standard dynamic contrast enhanced (DCE) MRI, a high-resolution diffusion-weighted image (HR DWI) was acquired with an echo planar imaging sequence and the following parameters: TR/TE=4000/64.8 ms, b=0,600, FOV=70x140mm, matrix=28x64, and voxel size=0.55x0.55x0.4mm. Apparent diffusion coefficient (ADC) maps were created. HR DWI images were segmented into tumor and non-enhancing, surrounding stromal tissue. A proximity mapping method was used to measure ADC values at the inner edge of tumor and at increasing distances.
from the tumor boundary on HR DWI. The mean was calculated for the voxels in 1 mm increments, starting at 5 mm into the tumor (-5 mm) and ending at 2.5 cm away from the tumor (25 mm).

Results: The average of the changes per 1 mm shell was largest for the transition of the tumor boundary (Table 1). In Table 1, the -5 to 0 mm, 0 to 5 mm, and 5 to 25 mm columns represent inside the tumor, tumor boundary, and outside the tumor, respectively. In general, ADC values were consistently lower inside the tumor than outside. The greatest changes per 1 mm shell was seen in the transition from inside to outside tumor, although the values varied among tumor types. Each of the three cases analyzed had different patterns of ADC values.

Discussion: These preliminary studies show that water mobility measurements change at the tumor boundary, with different patterns observed among individual patients. We are further investigating the influence of density and tumor margin morphology on these ADC measurements.

### P2-09-13
**The Value of FDG PET/CT in Screening Detected Breast Cancer Patients.**

Koo HR, Moon WK, Cho N, Chang JM, Kang KW, Yi A. Seoul National University Hospital, Seoul, Korea

Background: To evaluate the diagnostic value of FDG PET/CT for initial staging of screening detected breast cancer.

Methods: Between January 2008 and June 2010, a total of 77 women (mean age 54 years, range 31-77 years) with screening detected primary breast cancer (mean invasive tumor size 1.65cm, range 1-70mm) underwent whole body fluorine-18 fluorodeoxyglucose (FDG) PET/CT for initial staging and were included in this retrospective study. Two patients had bilateral breast cancer. The sensitivity of FDG PET/CT for the detection of primary tumor and the sensitivity, specificity, PPV and NPV for the detection of axillary lymph node metastases were determined. Systemic staging with whole body FDG PET/CT was also performed. For analysis of diagnostic performance of FDG PET/CT, quantitative measurement of the maximum standardized uptake value (SUVMmax) criteria 1.0 was used. The final histopathology following surgery served as the gold standard.

Results: The primary tumor was FDG PET/CT positive in 65 of 79 lesions (82%). Depending on the tumor size, there was a variation in diagnostic sensitivity (63% in ≤1cm tumor, n=19 vs. 88% in >1cm tumor, n=60) and the uptake of FDG was significantly higher in >1cm tumor than in ≤1 cm tumor (mean SUVMmax 2.85 vs. 1.11, p<0.05). The uptake of FDG was significantly higher in ductal carcinomas compared to lobular carcinomas (median SUVMmax 2.0, n=72 vs. 1.3, n=7, p<0.05). Of the 77 patients included in this study, 16 patients were found to have axillary node metastasis. The sensitivity, specificity, PPV and NPV of FDG PET/CT for detection of LN metastasis were 63% (10/16), 89% (54/61), 59% (10/17) and 90% (54/60), respectively. FDG PET/CT showed distant uptake in 9 patients and 8 of 9 were false positive results. 4 lesions were confirmed histopathologically as benign and 4 lesions were evaluated with radiologic methods. One of nine was true positive result. Distant involvement was skeletal and visible on the conventional bone scintigraphy. The patient staged as cT1N3M1.

Conclusion. FDG PET/CT has limited value for the initial staging of screening detected breast cancer patients. Considering high costs, radiation exposure and false positivity, FDG PET-CT is not recommended for the preoperative evaluation of screening detected breast cancer patients.

### P2-09-14
**Evaluation of Angiogenesis Using Synchrotron Radiation in Xenograft Mouse Models of Breast Cancer.**

Gu S-M, Zhang X, Li R-M, Jin W, Shen Z-Z, Shao Z-M, Xu X-M, Wu J. Cancer Hospital/Institute, Fudan University, Shanghai, China; Shanghai Jiao Tong University, Shanghai, China

Visualization of microvasculatures is an important step in understanding the mechanism of early vessel disorders in breast cancer and developing effective therapeutic strategies. However, quantitative evaluation of breast cancer angiogenesis using immunohistochemistry has been limited in generating detailed and reproducible data. To analyze the diversification of angiogenesis in the development of tumor growth and evaluate anti-vascular effects of Avastin, a new method of microvascular imaging was introduced in this paper. We used New X-ray microangiography and third-generation synchrotron radiation-based micro-computed tomography (SR micro-CT) to investigate the structures and density of microvessels at each stage of xenograft mouse models that were created by inoculation with MDA-MB-231HM cells (one breast cancer cell line with high metastasis potential). Barium Sulfate Nanoparticles, was used as a blood vessels contrast agent through left cardiac ventricle. Three dimensional structures of microvessels were displayed with a high spatial image resolution at around 20-30 μm. The density of microvessels was significantly reduced from the third week in mouse xenograft models. This observation with SR micro-CT was consistent with the results analyzed by immunohistochemical techniques. In addition, human breast cancer–bearing mice were treated site-specifically with humanized monoclonal antibody (Avastin) that targets all isoforms of VEGF-A. Tumor volume and the density of angiogenesis were significantly reduced in xenograft mouse models of breast cancer treated with avastin compared with untreated mice as assessed by SR micro-CT. Specifically, the density of smaller vessels (di<50μm) was decreased significantly while the density of larger vessels was little changed in the Avastin-treated mice. Therefore, synchrotron radiation technique is a novel method for investigating breast cancer angiogenesis, and this might be considered as an additional complementary tool for more precise quantification of angiogenesis.

### P2-09-15
**Functional Measurements of Tumor Response during Neoadjuvant Chemotherapy Infusion and Early during Treatment Using Diffuse Optical Spectroscopic Imaging.**

Background: Non-invasive markers of neoadjuvant chemotherapy response early during treatment would provide physicians a valuable tool to make evidence-based changes to treatment strategies. In a retrospective study of 23 patients presented at SABCS 2011 we demonstrated that Diffuse Optical Spectroscopic Imaging (DOSI) can discriminate non-responding from responding subjects on the first day after the start therapy based on the presence or absence of an oxyhemoglobin flare. Here we present results of an ongoing prospective study designed to confirm the predictive nature and
biological origins of oxyhemoglobin flare and to determine if similar functional changes occur at even earlier timepoints such as during infusion.

Methods: DOSI was used to measure hemodynamic and metabolic information from tumors and surrounding normal tissue in patients prior to neoadjuvant chemotherapy, during chemotherapy infusion, and daily for the first week of treatment. DOSI uses temporally modulated near-infrared light to determine absolute tissue concentrations of oxyhemoglobin, deoxyhemoglobin, water and lipid content and requires no exogenous contrast agent. Measurements are made using a simple handheld probe placed on the skin. Blood samples were also collected at baseline and daily for seven days after the first infusion and tested for a panel inflammatory cytokines. Patients received paclitaxel + carboplatin + bevacizumab. Overall response to therapy was determined by the decrease in anatomic tumor size.

Results: To date three subjects have been measured, two of which have completed neoadjuvant chemotherapy and undergone surgery. One subject was a pathologic complete responder (pCR) and the other a non-responder (NR). In both the pCR subject and the subject still undergoing therapy there were significant functional changes measured in the tumor during infusion. A decrease in oxyhemoglobin and oxygen saturation occurred after paclitaxel infusion (saturation changes: -4.8% and -9.7% for each subject respectively), followed by an increase in these quantities after carboplatin infusion (saturation: 3.8% and 5.9% respectively). In the NR subject both oxyhemoglobin and oxygen saturation had only small fluctuations during infusion (saturation: 1.1%). Oxyhemoglobin flare was also observed 24 hours after infusion for each of the patients. Plasma levels of several inflammatory cytokines including G-CSF, MIP-1α, and C-reactive protein increased 24 hours after infusion for the first two subjects and subsequently decreased at 48 hours.

Discussion: We have confirmed the presence of oxyhemoglobin flare on day one after infusion in this small prospective patient cohort. Increased plasma levels of inflammatory cytokines were correlated in time with the presence of oxyhemoglobin flare suggesting a possible link between optical measurements and inflammatory processes induced by chemotherapy. Additionally, we report for the first time significant changes in tumoral oxyhemoglobin and oxygen saturation during chemotherapy infusion. These changes may be of prognostic significance. DOSI allows functional measurements of tumor response at timepoints unachievable with current functional medical imaging modalities.

P2-10-01
Extracellular Matrix Stiffness and Mammographic Density in the Human Breast.
Acerbi I, Au A, Chen Y-Y, Hwang S, Weaver V. Center for Bioengineering and Tissue Regeneration, University of California San Francisco, San Francisco, CA; University of California San Francisco, San Francisco, CA; Eli and Edythe Broad Center of Regeneration Medicine and Stem Cell Research and Helen Diller Family Comprehensive Cancer Center, UCSF, San Francisco, CA

Introduction: Mammographic density (MD) is associated with greater risk to malignancy. MD is also correlated to high collagen content in the extra cellular matrix (ECM). Data from our group and others have highlighted the importance of mechanical cues from the ECM in breast tissue homeostasis and tumor progression to invasion [1; 2; reviewed in 3]. Whether the stiffness of the ECM could also initiate breast cancer and if so how remains unknown. Because elevated collagen levels increases ECM stiffness, we hypothesize that MD increases breast cancer risk because the ECM is stiffer.

Materials and Methods: We studied breast tissues obtained through prophylactic mastectomy from women with low (BIURADS 1) versus high MD (BIURADS 4). From each surgically excised breast, samples of 0.5cm x 0.5cm x 1cm dimension were removed from the retroareolar region and from 4 peripheral quadrants. Sample sections were subjected to biophysical, morphological and biochemical analysis. Biophysical analysis included the application of Atomic Force Microscopy to obtain an extensive force map of distinct anatomical regions of the ECM associated with the intra-lobular and inter-lobular ECM. Topological analysis of ECM architecture was performed using two photons and SIM-POL imaging coupled with picrosirius staining, polarized light imaging and image quantification. Biochemical and morphological analysis consisted of immunohistochemistry for markers that detect mechano-signaling in the epithelium and stromal fibroblasts, and H&E to visualize cellular and ECM organization.

Results and Discussion: We found that the intra-lobular ECM associated with the terminal end-buds in the breast contained anisotropic relaxed collagen fibrils and was very compliant. By contrast, the inter-lobular ECM of the breast contained oriented collagen fibrils and was relatively stiffer. Notably, the ECM associated with the retroareolar region, which is typically detected as very dense using mammographic imaging, contained oriented collagen fibrils, and was significantly stiffer than the ECM associated with the peripheral quadrants. Intriguingly, preliminary data suggested that the ECM associated with the terminal end-buds in the upper outer quadrant showed a trend towards greater stiffness in women with high MD (BIURADS 4) than low MD (BIURADS 1). Although, it is tempting to speculate that ECM stiffness could enhance risk to malignancy, further sample analysis is now necessary.

Conclusions:
· In the human breast there is anatomical heterogeneity with respect to ECM organization and mechanical properties.
· High MD appears to reflect elevated ECM stiffness.
· The intra-lobular ECM is considerably stiffer in the upper outer quadrant than in the other peripheral regions of the breast.
· Atomic Force Microscopy is a tractable method to monitor ECM stiffness and mechanical heterogeneity in the human breast.

Assessment of Tumor Response to Neoadjuvant Chemotherapy Using Ultrasound-Guided Near Infrared Light.
Zhu Q, DeFusco P, Tannenbaum S, Ricci A, Cronin E, Hegde P, Kane M, Tavakoli B, Xu Y. University of Connecticut, Storrs, CT; Hartford Hospital, Hartford, CT; University of Connecticut Health Center, Farmington, CT

Background: Neoadjuvant chemotherapy has been increasingly used in treating breast cancers. Because breast cancer is a heterogeneous disease, it is important to effectively monitor the tumor response to assist in tailoring treatments to response. In our early study, we have
introduced a novel ultrasound (US)-guided diffused light imaging in the near infrared (NIR) spectrum to monitor tumor vascular changes which correlated to tumor response. The objectives of this study are: (a) to validate the initial findings with a larger patient pool, and (b) to assess vascular changes at every treatment cycle and to correlate early vascular changes with the tumor pathological response.

**Methods:** 33 patients who underwent neoadjuvant treatment were recruited from Dec. 2007 to May 2011 and their tumor vascular content was assessed with a combined imager consisting of a commercial US system coupled to a NIR imager. Patients were imaged before their treatment, at the end of each treatment cycle and before their surgery. The co-registered US was used to localize the tumor and the NIR imager was used to map the tumor vascular distribution which was assessed based on a percentage total hemoglobin (%Hb) concentration normalized to the pre-treatment level. 18 patients were treated with AC followed by Taxol. This group of patients was monitored every two weeks at the end of each treatment. The remaining patients were on 3-week cycles of chemotherapy and monitored every 3 weeks. 6 patients were treated with TC without Adriamycin (TC), or with Adriamycin (TAC). 2 HER2 positive patients were treated with TC and Herceptin (TCH); and 3 patients were treated with AC/Bevacizumab. Pathologic response was graded based on Miller and Payne system as grade 1: non-responders (A); grades 2 and 3: partial responders (B); 4: near-complete and 5: complete responders (C).

**Results:** In the AC/Taxol group (n=18), there were 5 responders (C), 9 partial (B) and 4 non-responders (A). The statistical significance based on %Hb between groups A and C was achieved at the end of cycle 5 and the rest of the treatment cycles (p<0.05), however, the statistical significance between A and B was only obtained at end of cycle 5 (p<0.05) and not maintained for cycles 6-8. The statistical significance between B and C was only achieved at the end the treatment (p<0.05). For the TC, TAC and TCH group (n=12), there were 6 responders(C) and 6 partial responders (B). The statistical significance between these two groups was achieved at the end of cycle 3 and the rest of the treatment cycles (p<0.05). For the 3 patients who were treated with AC/Bevacizumab, 2 patients achieved complete response and one partial with grade 2. The complete responders had more than 50% reduction in %Hb at the end of cycles 3-4; while the partial one showed only 10-15% reduction during the entire treatment course.

**Discussion:** Our findings indicate that tumor vascular changes assessed by %Hb can be used to predict the tumor pathological response. This is a powerful tool to help predict responsiveness to therapy. Interestingly, dramatic and early responses were noted in the patients who received the biologic agents (bevacizumab and herceptin) and this may be very valuable in following responses using these agents.

**P2-10-04**

**3D Mapping of Total Choline in Human Breast Cancer Using High-Speed MR Spectroscopic Imaging at 3T: A Feasibility Study.**

Posse S, Royce M, Dayao ZR, Zhang T, Zhao C, Sillerud L, Lopez S, Casey L, Eherhardt SC, Lomo I, Lee S-J, Rosenberg R, Rajput A, Bolan P. University of New Mexico School of Medicine, Albuquerque, NM; University of New Mexico Cancer Center, Albuquerque, NM; New Mexico Cancer Center, Albuquerque, NM; University of Minnesota, Minneapolis, MN

**Purpose:** To assess the feasibility of quantitative high-speed MR spectroscopic imaging (MRSI) of total Choline (tCho) as an adjunct to dynamic-contrast enhanced (DCE) MRI to improve lesion characterization and monitor treatment response in patients undergoing neoadjuvant chemotherapy.

**Method and Materials:** Seven patients with biopsy-confirmed, infiltrating ductal carcinoma were studied using a clinical
3T MR scanner (Siemens Medical Solutions, Erlangen, Germany) equipped with 8- and 16-channel breast array (Hologic Inc., Bedford, MA). Measurements were performed using PRESS prelocalized 3D Proton-Echo-Planar-Spectroscopic-Imaging (PEPSI) using TR/TE=2000ms/135ms, matrix size up to 32×128, voxel size=1,cc, and total acquisition time of 10 minutes (including water reference scan). Additional data were collected at TE 60 ms to enhance sensitivity for detecting tCho and J-coupled resonances. TE-averaging (8 steps, ATE: 2.5 ms) was employed to minimize gradient sideband artifacts. Quantification of tCho in reference to tissue water was performed using spectral fitting and relaxation correction.

RESULTS: Strongly elevated tCho with maximum concentration ranging from 0.3 to 4.1 mmol/kg was measured in five patients with single and multi-centric enhancing lesions larger than 2 cm volume (Table 1). The measured tCho concentration in Grade 3 tumors was higher than in lower grade untreated and treated tumors. Strong decreases in tCho concentration were measured in 2 patients undergoing neoadjuvant therapy in a follow-up scan. At short TE an additional resonance was detected that was elevated in enhancing lesions and tentatively assigned to Taurine. Two patients had lesions smaller than 2 cm with surgical clips in which tCho was not detectable due to line broadening. MRSI data sets were preferentially collected before contrast injection, since it increased spectral line width by up to 50%.

CONCLUSION: This study demonstrates feasibility of quantitatively mapping tCho in invasive breast carcinoma using high-speed MRSI. The long-term goals are to utilize high-speed MRSI as an early predictor of treatment failure in women undergoing neoadjuvant therapy (i.e. chemotherapy, endocrine therapy or biologic therapy) for breast cancer and to develop an improved screening protocol for high-risk patients.

Cryo-Microcomputed Tomography (CT) with Synchrotron Radiation: Visualization of Human Breast Cancer Tissue and Comparison with Their Histopathologic Findings.

Jeong YJ, Jeong HY, Bong JG, Park SH, Kim HT, Kim JK, Huang JY. Daegu Catholic University Medical Center, Daegu, Republic of Korea; Pohang University of Science and Technology, Pohang, Republic of Korea

Background: A synchrotron radiation (SR)-based X-ray source offers a powerful tool for diagnosis of breast disease due to the energy spectrum properties and the peculiar laminar beam geometry. The aims of this study were to estimate the visualization of the human breast cancer tissue with SR cryo-micro CT and to compare the results with histopathological examinations.

Material and Methods: The cancerous breast tissue samples were routinely fixed in 10% neutral buffered formalin, and each specimen was cut down to a cylindrical sample with 2 mm diameter and 10 mm height. Each breast cancer sample was rapidly frozen with dry ice, mounted on a computer-controlled precision stage and maintained at cryogenic temperature throughout data collection. Experiments were performed at the bending magnet beamline 7B2 of Pohang Light Source (PLS) in Accelerator Laboratory (PAL) which is a third-generation SR facility with 2.5 GeV operating energy. The white beam imaging system developed for synchrotron tomography consists of a 1 mm Si attenuator, 100 μm-thick CdWO4 scintillator and a full-frame charge-coupled device camera. The detector is placed 10 mm downstream from the sample on an optical table which can be rotated in the fan beam about a vertical axis for tomography. For tomography, images were collected at 0.18° increments through 180°.

The visual image was magnified using a 20x microscope objective and captured using a digital CCD camera. The spatial resolution determined by standard sample was about 1.5 μm. Three-dimensional volume images of the specimen were obtained by applying a filtered back-projection algorithm to the projection images using a software package OCTOPUS. Surface reconstruction and volume segmentation and rendering were performed using Amira software. After imaging the samples were split into several sections, processed and embedded in paraffin. Obtained tomography images were compared with corresponding histopathological findings in optical microscopy.

Results: A total of 1000 synchrotron tomography images were acquired from the samples and only a small number of different typical cases were selected for a detailed analysis. The correspondence between tomography images and histopathological findings were determined. Synchrotron tomography images yield high contrast from smoothly varying internal structures corresponding to information on actual structures seen at histopathological analysis.

Discussion: Since the projection of 3D anatomic information onto 2D image will complicate subtle difference in X-ray transmission and objects at different depths will be superimposed on each other, the subtle difference in subject attenuation, diffraction and contrast may not be clearly visible or completely lost. Tomography with SR has superior visualization of subject contrast, together with depth localization, so it is useful for visualizing anatomical structures in the sample. In this study, the obtained SR cryo-micro CT images of human breast cancer tissue were comparable with standard histopathologic findings. The results suggest that tomography with SR has a great potential as a diagnostic tool and also its clinical application is feasible, especially in breast imaging.

P2-10-06

Yamamoto S, Maeda N, Yoshimura K, Oka M, Yamaguchi University Graduate School of Medicine, Ube, Yamaguchi, Japan

Background: Real-time virtual sonography (RVS) systems display virtual multiplanar reconstruction (MPR) images obtained from three-dimensional (3D) computed tomography (CT)–lymphography (LG), significantly improving preoperative detection of sentinel lymph nodes (SLNs). The purpose of this study was to prospectively evaluate SLN metastasis using an RVS system.

Methods: We identified SLNs in 73 clinically node-negative breast
cancer patients using an RVS system to display in real time a virtual MPR obtained from CT volume data corresponding to the same cross-sectional image from ultrasonography (US). CT volume data were obtained using our original 3DCT-LG, which accurately detects SLNs in breast cancer. We then prospectively attempted to predict metastasis to SLNs. SLN metastases were assessed by measuring the cortex thickness in the presence of a visible hilum. We defined suspected SLN metastases as SLNs with a cortex thickness of at least 2.5 mm on the basis of our preliminary data. All patients underwent SLN biopsy and SLN metastases were examined pathologically with serial 2.0-mm-thick multiple slices.

Results: Suspected SLN metastases were identified in 24 of 73 patients, and 13 of these 24 patients were pathologically positive. The remaining 49 patients displayed no suspected SLNs, and 46 of these 49 were pathologically negative. Sensitivity, specificity, positive predictive value, negative predictive value, and overall accuracy of measuring cortical thickness for predicting metastatic involvement of SLNs were 81, 81, 54, 94, and 81%, respectively.

Conclusion: If cortical thickness of the SLN is less than 2.5 mm, SLN metastasis is unlikely to be present. If cortical thickness of the SLN is at least 2.5 mm, preoperative fine-needle aspiration cytology may be recommended to verify the possibility of SLN metastasis.

Discussion:
TNBC and non-TNBC seem to have different ultrasonographic features. This can be explained by the unique pathologic profile of this breast cancer subtype. As some of the distinct ultrasound criteria of TNBC are associated with benign masses, TNBC may mimic nonmalignant lesions. Being familiar with these features can avoid false-negative classification of TNBC.

P2-10-08
Electrical Impedance Imaging Characteristics of Nodular and Edematous-Infiltrative Forms of Breast Cancer.
Korotkova M, Karpov A, Bulatov A, Frizyuk A. Clinical Hospital 9, Yaroslavl, Russian Federation

Introduction:
The purpose of this research is to establish diagnostic criteria of electrical impedance mammography, which are typical for nodular and diffuse forms of breast cancer.

Materials and Methods:
From 2008 to 2011, we examined 558 patients, 34 of whom had various forms of breast cancer (BC). All the patients were examined with electrical impedance potential mammography utilizing the electrical impedance computer mammograph MEIK, which enables to acquire images of 3-D conductivity distribution layers within mamma’s tissues up to 5 cm depth.

Group I comprised 27 women suffering from nodular forms of BC. Among them 9 women without clinical signs of the disease were put into subgroup Ia.

19 patients having significant clinical signs, such as edema, inflammation and infiltration, were put into subgroup Ib.

Group II included 6 patients with diffuse BC.

102 patients without any mammary gland disease were put into the control group.

Both visual and quantitative assessment of electrical impedance mammograms (EIM) was conducted.

Result:
Distinctions of kind were revealed between EIMs of the abovementioned patient groups.

In case of nodular BC both general and local changes were observed in EIMs.

General changes include deformation of mamma’s contour, hyperimpedance contour and displacement of inner structures.

Local changes comprise focal changes of electrical conductivity in form of an- or isoimpedance areas and hyperimpedance contour on the border of the tumor and surrounding tissue.

In EIM mammograms of 100% patients belonging to subgroup Ia only local changes of electrical conductivity were detected in a form of animpedance area presented on several scan planes in the location corresponding to the tumor (electrical conductivity index >0.95), while there were no general changes in the image. The size of lesions detected in this group was less than 1 cm.

Clinical signs of the decease were always present in group Ib patients. EIMs of these patients revealed both general and various local changes.

Visual estimation of images revealed deformation of the mammary gland contour in 50% of the cases, subcutaneous fat infiltration - in 61%, anatomic changes with displacement of internal structures in 78%, perifocal infiltration in 94%. The quantitative analysis established the following: mean electrical conductivity index of a healthy mammary gland, as a rule, exceeded the index of mean electrical conductivity of the affected one; and the index of the
mean electrical conductivity of a tumor exceeded the index of mean electrical conductivity of the affected gland almost twofold. EIMs of 100% of the patients with diffuse (edematous-infiltrative) BC revealed typical general changes of electrical conductivity: electrical conductivity of the affected mammary gland is considerably lower than that of the healthy one as well as lower than that of the age norm. This results in the intense dark EIM and significant change of electrical impedance anatomy.

Conclusions:
The revealed peculiarities of the electrical impedance images during various forms of the infiltrating BC growth correlate with the pathological-physiological phases of the tumor development. The article is illustrated with electrical impedance mammograms (EIMs) and tables.

**Detecting Breast Cancer with Dynamic Diffuse Optical Tomographic Imaging.**

*Flexman ML, Kim HK, Lim E, Desperito E, Barbour RL, Hershman DL, Hielscher AH. Columbia University, New York, NY; State University of New York, Brooklyn, NY*

**Background:** Over the last decade diffuse optical tomography (DOT) has emerged as a novel medical imaging modality. Near-infrared light is used to non-invasively probe biological tissue, and three-dimensional (3D) maps of blood-dependent parameters can be obtained. Several studies are underway to show the clinical utility of DOT for imaging brain disease, joint disease, and breast cancer. Here we present the largest clinical study to date that uses hemodynamic effects caused by a simple breath hold to identify breast tumors using DOT.

**Methods:** We have designed and built a DOT breast imaging system that can acquire full 3D data sets within a fraction of a second. The system affords the ability to study fast hemodynamic effects in both breasts simultaneously. Using non-compressive imaging heads we measured the oxygenated and deoxygenated hemoglobin levels in the breasts of 15 patients whose mammogram showed a mass >1 cm (4 benign, 11 malignant) and 3 healthy controls. Data was acquired over the course of a 30-second breath hold and 30 seconds thereafter. In addition, a baseline measurement of 30 seconds prior to the breath hold was obtained. A multi-wavelength image reconstruction algorithm was used to create 3D maps of hemoglobin-dependent parameters (Δ[HbO2] and Δ[Hb]) in the breast every 0.58 seconds, over the course of the 90-second experiment. An image analysis algorithm identified regions of peak percentage change in [Hb] and [HbO2] in the breast and then computed the average hemoglobin levels in those regions.

**Results:** We observed an increase in the hemoglobin levels in all breasts during the breath hold. Upon resuming breathing, these hemoglobin levels returned to baseline. Tumor bearing breasts showed a statistically significant slower return to baseline than healthy breasts. In particular, we found that tumors can be detected by a substantially larger Δ[Hb] value as compared to normal tissue in images acquired 15 seconds following the end of the breath hold. In 10 of 11 patients the malignant tumor was identified using this technique, suggesting sensitivity over 90%. No regions of increased Δ[Hb] were seen in the healthy breasts, or in the breasts with benign masses. The peak percentage change in [Hb] at the 15 second post-breath hold time point was 10.0 ± 6.0% (n=11) in the malignant tumors compared to 1.4 ± 0.5% (n=3) (p=0.001) in healthy patients and 4.8 ± 1.9% in benign masses (n=4) (p=0.03).

**Discussion:** A breath hold impedes venous return to the heart, which causes pooling of blood in the breast. This is observed as an increase in [Hb] and [HbO2] using DOT. Tumor vasculature is known to be more disorganized, tortuous, and leakier than normal vasculature. Therefore, once the breath hold is released and blood is allowed to drain from the breast, blood accumulated in the tumor during the breath hold will drain more slowly than blood in healthy tissue. This study has shown that DOT allows us to visualize these hemodynamic effects and use them to detect tumors with a simple breath hold and compression-free imaging head. Future studies need to explore the detection limits and general clinical utility of this technique for screening, differentiating malignant from benign masses, and treatment monitoring.

**A Precision Comparison of Breast Ultrasound Images between Different Time Phases by Imaging Fusion Technique Using Magnetic Position Tracking System.**

*Nakano S, Fujii K, Yorozuya K, Yoshida M, Fukutomi T, Arai O, Mitake T. Aichi Medical University, Nagakute, Aichi-gun, Japan; Hitachi Medical Corporation*

**Purpose**
We developed a real-time virtual sonography (RVS) in which real-time ultrasound (US) images and reconstructive virtual US images of the same cross-section are synchronized based on US volume data obtained on the same monitor using magnetic position tracking system (US-RVS). The purpose of this study was to evaluate the accuracy of US-RVS to compare breast US images between different time phases.

**Materials and Methods**
Between March 2010 and April 2011, US-RVS was performed in 108 consecutive patients with 112 target lesions for US (mean lesion size: 12 mm, 54 malignant and 58 benign). We used US-RVS system which consisted of sonography equipment, magnetic field generator, magnetic sensor, and workstation. To assess the accuracy of the US-RVS, we analyzed the sonographic re-identification rate of target lesions in different time phases.

**Results**
Among the 112 target lesions, 105 (94%) lesions were re-identified by US-RVS. The remaining occult 7 (6%) lesions were included one DCIS and 6 fibrocystic changes in terms of the histological type, and one mass lesion and 6 nonmass like lesions in terms of morphological feature. US-RVS enabled us to precisely compare arbitrary cross-sections of US images in any direction between different time phases independent of the operator's skill.

**Conclusion**
US-RVS, which requires no contrast medium and involves no radiation exposure, can be a useful modality for temporally tracking regions of interest using US.

**P2-11-01**

**Validation of Predictive DNA Damage Response (DDR) Assay in Luminal B and Basal-Like Breast Cancers.**

*Rodriguez AA, Mao Y, Zhao H, Wong S, Chang JC. The Methodist Research Institute, Houston, TX*

**Background:** We previously published a 69-gene DDR microarray signature that predicted for pathologic complete response (pCR) to anthracycline chemotherapy in women with basal-like breast cancer in two clinical studies. Here, we sought to validate this predictive signature in independent data sets of breast cancers, selecting for...
basal-like and luminal B subtypes. We also customized a low density qRT-PCR array for use on formalin-fixed paraffin embedded tissue that will allow for prospective validation and clinical use.

Methods: Six independent validation sets were selected with known response to DNA damaging agents, containing either anthracyclines or cisplatin. One independent data set was known to response to the microtubulin agent docetaxel (non-DNA damaging) was used. Using PAM50 genes, the tumors were first classified according to the molecular subtype. The predictive value of the 69-gene DDR assay was then correlated with known pathologic response, and the receiver operating curve determined.

We then performed qRT-PCR of these 69 genes with 5 controls, and correlated the expression of these genes with microarray RNA values in an additional 50 basal tumors. The data for individual genes was normalized, combined, and then hierarchically clustered.

Results: In the 170 basal tumors treated with DNA damaging agents, a high score predicted response in basal-like tumors, A, p<0.05. Conversely, for a non-DNA-damaging therapy, a high score significantly predicted for lack of response. B. In the 116 luminal B cancers, the DDR-assay also predicted for response to DNA damaging agents containing regimens with AUCs ranging from 0.67 to 0.80. C.

N: number of patients, pCR: complete and near pathological response, AUC: area under the curve.

Microarray of the 69 DDR gene expression values was compared with Ct values by q-RTPCR, low density array for 50 paired samples. High concordance between these two platforms (48/50 samples) was observed.

Conclusion: We have identified a robust predictive DDR assay that predicts for response to the DNA damaging agents, doxorubicin, epirubicin, and cisplatin in multiple studies, but not for docetaxel therapy. Future studies are underway to test for prediction of benefit of PARP1 inhibitor in basal-like and luminal B breast cancer.

Brain-Derived Neurotrophic Factor Expression Is Associated with Poor Prognosis in Human Breast Cancer.

Patani N, Jiang WG, Mokbel K. The London Breast Institute, The Princess Grace Hospital, London, United Kingdom; University Department of Surgery, Cardiff University School of Medicine, Cardiff, United Kingdom; Brunei Institute of Cancer Genetics and Pharmacogenomics, Brunei University, London, United Kingdom

Background: Brain-derived neurotrophic factor (BDNF) belongs to the neurotrophin superfamily of polypeptide growth factors whose physiological roles primarily relate to the development and function of the vertebrate nervous system. However, BDNF is also expressed in non-neuronal tissues and has been implicated in breast cancer, in addition to several other human malignancies, including: neuroblastoma, myeloma, ovarian, lung, prostate, hepato-cellular, pancreatic, head and neck squamous cell carcinomas and pulmonary carcinoid tumours. Although increased neurotrophin and cognate receptor expression have been demonstrated in breast cancer, the emerging role of BDNF in tumour biology and its utility as a novel biomarker have yet to be fully elucidated. In this study, the mRNA and protein expression of BDNF are evaluated in women with primary operable breast cancer in a well annotated cohort with extended follow-up.

Methods: Breast cancer tissues (n=127) and normal/benign tissues (n=33) underwent RNA extraction and reverse transcription. Transcript levels of BDNF were determined using real-time quantitative PCR and protein expression was assessed using standardised semi-quantitative immuno-histochemical techniques. Expression levels in neoplastic tissues were compared with adjacent normal/benign samples and evaluated against conventional pathological parameters, including: tumour size, grade, nodal involvement, TNM stage, in addition to Nottingham Prognostic Index (NPI), disease free and overall survival over a 10 year follow-up period.

Results: BDNF was found to be expressed in both normal breast tissue and breast cancer specimens. Significantly greater BDNF expression was identified in neoplastic cells, compared to normal mammary epithelial cells. BDNF mRNA transcript levels were also found in breast cancers compared to normal samples (p=0.007). Increased BDNF transcript levels were found to be significantly associated with nodal positivity (p=0.047) and increased with NPI; NPI-1 vs. NPI-2 (p=0.009). Higher BDNF expression was significantly associated with local recurrence (p=0.0014), death from breast cancer (p=0.018) and poor prognosis overall (p=0.013), when compared to patients who remained disease free. Higher transcript levels were significantly associated with poorer overall survival (106 vs. 136 months, p=0.006) after a median follow up of 10 years.

Conclusion: Neurotrophins and their receptors are increasingly being implicated as novel mediators of carcinogenesis in neuronal and non-neuronal tissues. BDNF is overexpressed in breast cancer and significantly associated with adverse pathological parameters, including nodal positivity and increasing NPI. Higher BDNF expression was significantly associated with poorer clinical outcomes, including local recurrence, death, poor prognosis and reduced overall survival. The present study adds to the literature in support of the oncogenic function of BDNF in breast cancer and is the first to quantitatively evaluate expression in a large cohort. BDNF expression may offer prognostic utility as a biomarker and further mechanistic studies are warranted to explore the potential for targeted therapeutic manipulation.

P2-11-03
High Expression of CX3CL1 by Tumor Cells Correlates with a Good Prognosis and Increased Infiltrating CD8+-T Cells, Natural Killer Cells, and Dendritic Cells in Breast Carcinoma.

Lee JS, Park MH, Yoon JH. Chonnam National University Medical School, Gwangju, Republic of Korea

CX3CL1 is the only CX3C chemokine that can chemottract CD8+-T cells, natural killer (NK) cells, and dendritic cells (DCs). Although studies have reported that CX3CL1 regulates the host immune response, the roles of the CX3CL1 in breast carcinoma remain unknown. We evaluated the expression CX3CL1 in 198 surgical specimens of breast carcinoma and analyzed any association with the clinicopathological factors, including CD8+ T cells, CD56-
NK cells, and CD1a+ DCs, while also evaluating the impact on the prognosis. High CX3CL1 expression was found in 136 of 198 (68.7%) breast carcinomas. The numbers of stromal CD8+ T cells, intratumoral CD1a+ DCs, and stromal CD56+ NK cells were significantly increased in the high CX3CL1 expression group (19.3 ± 15.2, 0.3 ± 0.9 and 1.4 ± 1.7 per field, respectively) compared with the low expression group (10.2 ± 13.1, 0.0 ± 0.3 and 0.7 ± 0.8 per field, respectively). Patients with high CX3CL1 expression had a significantly better prognosis for disease-free and overall survival than those with low expression (P = 0.002 and P = 0.000, respectively). In a multivariate analysis, the CX3CL1 expression was identified as one of the independent prognostic factors for overall survival (odds ratio, 2.29; P = 0.002). These data suggest that CX3CL1 expressed in the tumor cells appears to enhance the recruitment of CD8+ T cells, NK cells, and CD1a+ DCs, thereby bringing about a better prognosis in breast carcinoma. CX3CL1 is a new prognostic biomarker and be a novel candidate for development of a more effective therapeutic strategy for breast carcinoma.

**P2-11-04**

**TMEPAI Is a Feedback Regulator of TGF-β Signaling during Breast Cancer Progression.**

Singha PK, Pandeswara S, De La Chapa JJ, Venkatachalam MA, Saikumar P. UT Health Science Center at San Antonio, San Antonio, TX

**Background:** Despite lack of hormone receptors (ER/PR) and HER2, many triple negative breast cancers (TNBC) depend on transforming growth factor beta (TGF-β) signaling activity for late growth and metastasis. Thus TGF-β signaling is a major potential target to treat TNBC patients. However, inhibition of TGF-β signaling pathway carries the risk of disturbing the tumor suppressive activity of TGF-β in normal tissues and early cancers. Hence, present study was undertaken with a goal to identify suitable markers which will enable to develop drugs that retard only the “oncogenic activity” of TGF-β while preserving its growth suppressive activities.

**Materials and Methods:** All cell lines were cultured according to the recommended standard procedures. Lentiviral mediated expression vector was used to stably knockdown endogenous TMEPAI expression. DNA transfections and luciferase assays were performed according to vendor instructions. Cell proliferation was performed according to vendor instructions. Cell proliferation was measured by quantitation of total cellular DNA. Immunoblotting and immunohistochemical analysis were performed using standard methods.

**Results:** Previously we have shown that Transmembrane prostate androgen-induced protein (TMEPAI), a TGF-β inducible gene has the potential to convert tumor suppressive TGF-β into a tumor promoter. In the present study, we show that Smad binding elements driven luciferase reporter activity, a measure of TGF-β signaling, was dramatically increased in TMEPAI knockdown cells. While wild type cancer cells showed transient raise in phosphorylation of Smad2 and Smad3 with TGF-β treatment, TMEPAI knockdown resulted in increased and sustained levels of phosphorylated Smad2 and Smad3. In normal mammary epithelial cells, continuous presence of TGF-β blocked their growth. In contrast, breast cancer cells showed a biphasic growth response (moderate inhibition up to 72h followed by strong growth stimulation) to TGF-β, while TMEPAI-deficiency blocked this response to TGF-β. Furthermore, exogenous expression of TMEPAI in normal mammary epithelial cells and TMEPAI-knockdown cells resulted in reduced TGF-β-dependent Smad activity. Additionally, we found that TMEPAI subverts tumor suppressive TGF-β dependent Smad signaling into tumor promotive non-Smad signaling through stimulation of stress activated protein kinases. Inhibition of stress kinases also reduced the growth of cancer cells similar to TMEPAI deficiency. To evaluate the translational importance of TMEPAI as predictive marker, immunohistochemical analysis on human breast cancer specimens revealed the gain of TMEPAI expressions in aggressive human breast tumor samples but not in normal human breast tissue specimens.

**Conclusions:** Our results show that TMEPAI, which subverts tumor suppressive Smad signaling, may serve as a novel prognostic and predictive marker for aggressive and TGF-β dependent of metastatic breast cancers. These studies will further provide new clues to develop an effective and decisive anti-TGF-β therapy against aggressive breast cancers without disturbing the growth suppression by TGF-β in normal tissues and early tumors.

**P2-11-05**

**Stromal Matrix Metalloproteinase-14 Expression Correlates with the Grade and Biological Behavior of Mammary Phyllodes Tumors.**

Lee JS, Park MH, Yoon JH. Chonnam National University Medical School, Gwangju, Republic of Korea

Phyllodes tumors (PTs) of the breast are rare biphasic tumors with the potential for invasion and metastatic spread. Matrix metalloproteases (MMPs) and their tissue inhibitors of metalloproteases (TIMPs) are involved in several key aspects of tumoral growth, invasion and metastasis, but little is known of their expression in PTs. The objective of this study was to assess the expression of MMPs and TIMPs in PTs and to determine their association with grade and clinical behavior of PTs. Eighty-two PTs (50 benign, 22 borderline, and 10 malignant) were studied. Automated immunohistochemical staining for MMP-1, -2, -7, -9, -11, -13, and -14 and TIMP-1, -2, and -3 was performed using tissue microarray blocks and the expression of MMPs and TIMPs was assessed in both the stromal components. There were no significant differences in the expression of stromal MMPs and TIMPs in the three groups of PTs, except for MMP-14. There was a significant increase in stromal MMP-14 expression with increasing PT grade (P < 0.01). The stromal MMP-14 expression in the borderline and malignant PTs was higher than that in benign PTs (P < 0.05 and P < 0.05, respectively). Furthermore, the expression of stromal MMP-14 was associated with a higher rate of recurrence (P < 0.05). Our results show for the first time that stromal MMP-14 expression is associated with the grade and clinical behavior of PTs of the breast.

**P2-11-06**

**PTEN Loss in Asian Triple Negative Breast Cancer Is a Frequent Event Associated with Basal Markers, Tumour Grade and Younger Age of Onset.**

Dean S, Rhodes A, Holly J, Perks C, Looi L-M, Mun KS, Taib NA, Tip CH. University of the West of England, Bristol, United Kingdom; University of Bristol, Bristol, United Kingdom; University of Malaya, Kuala Lumpur, Malaysia

Triple negative (TN) breast cancers are defined by their lack of expression of hormone receptors and HER2 and account for approximately 15% of all breast cancers. They are highly aggressive tumors for which there is currently no effective targeted therapy. PTEN is a tumor suppressor gene that shows loss or mutation in many types of cancer. PTEN functions by deactivating Akt signaling so cell growth is inhibited and apoptosis is promoted. PTEN has also been found to have an important role in DNA repair. Cancers with PTEN loss have been shown to be sensitive to PARP inhibitors that
prevent DNA repair and result in tumor cell death. In unselected breast cancer cohorts with the expected frequency of HER2 and hormone receptor positive cases, its loss appears to be a relatively rare event. Insulin-like growth factor binding protein-2 (IGFBP-2) regulates the anti-apoptotic and mitogenic effects of insulin like growth factors (IGF's) -I and -II and can also exert its own intrinsic effects on cell function; in vitro cell line models have shown that IGFBP-2 down regulates PTEN expression by interacting with the β-integrin receptor. The purpose of the current study was to investigate the extent of PTEN loss in an Asian series of TN breast cancers also to determine the association of PTEN loss with IGFBP2 expression and clinicopathological features. 122 TN breast carcinomas from the University of Malaya Medical Centre were immunohistochemically (IHC) stained for CK5/6, CK14, PTEN and IGFBP-2. The basal-like phenotype was defined as positivity for either one or both of CK5/6 and CK14, in invasive tumour cells. A modified Allred scoring system was used to assess the IGFBP-2 staining. PTEN was assessed for loss in both the cytoplasm and the nuclei; the surrounding stromal tissue and normal ducts had to be positive for the case to be assessable. Expression of basal CKs were present in the majority of cases, with 72.5% and 70.4% of TN cases staining positively for CK5/6 and CK14, respectively. Loss of nuclear and cytoplasmic IHC staining for PTEN occurred in 44.9% of TN cases. In those cases with PTEN loss, 88.4% were positive for CK5/6 compared to only 66% for cases without PTEN loss. (p=0.011). The median age of patients with tumors showing PTEN loss were 48 years old, compared with 56 years in those without PTEN loss (p=0.007). Of the cases showing PTEN loss, 35/40 (87.5%) were Grade 3 tumors; in comparison 28/46 (60.9%) of tumors without PTEN loss were Grade 3 (p=0.008). With respect to IGFBP2, 26.5% of cases were positive using the cut-off score of 6 or greater. However, there was no significant association between PTEN loss and IGFBP2 expression (p=0.542). Complete PTEN loss was a frequent event in a cohort of nearly one hundred TN breast cancers; this was significantly associated with younger age. PTEN loss can be readily and reliably assessed by an optimised IHC assay and validated PTEN antibody. The extent of PTEN loss occurring in TN breast cancers may well reflect a defect in DNA double strand repair and therefore, along with other suitable markers, may prove to be a valuable assay to identify those patients with TN breast cancers that are most likely to respond well to PARP inhibitors.

P2-11-07
Expression of Selected Predictive Markers in African American Women with Atypical Hyperplasia of the Breast.
Bandyopadhyay S, Cote M, Visscher DW, Ruterbusch J, Albashiti B, Alosh B, Frost MH, Hartmann LC, Fehmi RA. Wayne State University/KCI/DMC, Detroit, MI; Wayne State University/KCI, Detroit, MI; Mayo Clinic Cancer Center, Rochester, MN

Invasive breast carcinoma in African American (AA) women differs significantly from their Caucasian (CA) counterparts in its incidence, morphology and outcome. These tumors are more likely to be high grade, hormone receptor negative, present at a younger age and at a higher stage. Evaluation and a better understanding of precursor lesions may help delineate the mechanisms underlying the development of breast cancer in these two groups. Atypical hyperplasia (AH) in the breast has been associated with an increased risk of developing cancer (relative risk~4.0). Risk stratification of these women by identification of predictive biomarkers would be beneficial for optimal patient care. In our study we evaluated the expression of the following prognostic biomarkers: estrogen receptor (ER), Cyclooxygenase-2 (COX-2) enzyme and Ki-67 in AH in a cohort of AA women with benign breast biopsies. AA women with benign breast biopsies from years 1997-2000 were retrieved from our departmental database. Clinical and follow up data was obtained from the SEER database. The hematoxylin and eosin (H & E) slides for these cases were reviewed by 2 pathologists, who were blinded to the outcome, and those with atypia were included in this study. Paraffin blocks were retrieved for immunohistochemical (IHC) analysis and standardized scoring methods applied. A total of 1608 AA women had benign breast biopsies during the study period. We performed IHC analysis on 37 (2.3%) who were diagnosed with atypia (25 cases of atypical ductal hyperplasia (ADH) and 12 cases of atypical lobular hyperplasia (ALH)). Increased COX-2 expression was seen in 19 of 28 (67.8%) cases with AH. Of these, 13 of 19 cases (68.4%) were of ADH and 6 of 9 cases (66.7%) were of ALH. Twenty of 25 cases had a high expression of ER overall. Of these, 15 of 17 (88.2%) of the positive cases was in the ADH category and 3 of 7 (42.8%) was in the ALH group. Of 32 cases, only 3 cases showed a proliferation rate of > 2% (9.4%) with Ki-67 IHC stain. All of these cases belonged to the ADH (21) category. In summary, the majority of AH cases showed increased COX-2 expression, although no differences were observed between lobular and ductal lesions. In contrast, ADH lesions appeared to exhibit increased reactivity for ER compared to ALH. Similarly, although rare, more ADH cases showed an increased proliferation rate compared to ALH. From our data, COX-2 and ER might be of prognostic significance in AA patients with AH. Larger studies with follow up are needed to understand this disease further.

P2-11-08
Schmitt M, Kiechle M, Schwarz-Boeger U, Langer R, Nakayama S, Matsushima T, Ishihara H. Technical University of Munich, Munich, Germany; Sysmex Corporation, Kobe, Japan

[Background] C2P is an assay measuring specific activities (SA; kinase activity compensated by its protein expression) of cyclin-dependent kinases CDK1 and CDK2 by examining a small piece of fresh-frozen tumor tissue. We reported previously that the C2P risk score given by CDK1SA and CDK2SA is a potent prognostic factor in node-negative breast cancer patients. Likewise, a uPA/PAI-1 ELISA test (FEMTELLER®, American Diagnostica Inc. Stamford, CT) quantitatively determines uPA (urokinase-type plasminogen activator) and PAI-1 (plasminogen activator inhibitor type-1) antigen levels in tumor tissue extracts, to identify patients with high or low risk of disease recurrence of node-negative breast cancer patients. These cancer biomarkers are recommended by the ASCO at the highest level of evidence (LOE-1) for therapy decision making in node-negative breast cancer patients. From the biological point of view, the above two assays can be placed into two categories: tumor cell proliferation for C2P and tumor cell invasion for uPA/PAI-1. This fact led us to examine the concept of combination of the two assays to better select breast cancer patients at risk. [Results] Fifty-nine cases of frozen primary breast cancer tissues were subjected to the C2P assay in a blinded manner. Twenty-one cases (40%) were categorized into “high risk”, 7 cases (14%) into “intermediate risk”, and 24 cases (46%) into “low risk”. Seven cases were judged as “not informative". The uPA/PAI-1 results and clinical information (26: recurrent cases, 30: non-recurrent cases, 1: stage IV, 2: unknown) were

provided by the TUM tumor bank, uPA/PAI-1 risk categories of 36 cases (61%) were classified “high” and 23 cases (39%) categorized “low”. C2P and uPA/PAI-1 showed statistically significant correlation to histological grading (Pearson correlation coefficient; 0.45 and 0.40, respectively). No significant correlation was observed between C2P and uPA/PAI-1. By Kaplan-Meier analysis for disease-free survival, in cases treated with endocrine therapy only, both C2P and uPA/PAI-1 showed a reproducible trend to the respective claimed performances as prognostic factors. In the combination analysis of the two parameters, where low/low was judged as “low” and the others as “high”, 11 cases (24%) were categorized into “low” and 34 cases (76%) into “high”. The sensitivity and negative predictive value for disease recurrence were 90% (19/20) and 91% (10/11), respectively. Strong statistical significance was observed between the risk categories by the log-rank test; \( p = 0.0089 \), and also by Cox proportional hazards regression analysis; \( HR = 9.18, \ p = 0.032 \). By multivariate analysis, also including tumor size and nodal status, the CP2 uPA/PAI-1 combination evolved as a significant, statistically independent parameter (HR: 6.51, \( p < 0.01 \)). [Conclusion] In this investigative study, the significance of the combination concept was strongly suggested for early breast cancer patients treated with endocrine therapy only. Yet, prior to implementation in the clinical setting, the practical performance of the combination assay should be validated by investigating an independent patient cohort.

### P2-11-09

#### EGFR Overexpression in Triple Negative Breast Cancer (TNBC) and Its Association with the Prognosis.

Liu W, Zhang L, Ma K, Han B, Li S, Xu G, Fan Z, Liu N, Shi A. The First Hospital of Jilin University, Changchun, Jilin, China; The 208 Hospital of People's Liberation Army, Changchun, Jilin, China; The Central Hospital of Siping, Siping, Jilin, China; The Second Hospital of Jilin University, Changchun, Jilin, China; The Siping Center Hospital, Siping City, Jilin Province, China

**Objective:** The aim of this study is to investigate EGFR expression in Triple Negative Breast Cancer (TNBC), and to find the relationship between EGFR overexpression and prognosis of TNBC, further to clarify the significance of EGFR in TNBC and provide valuable information for TNBC therapy.

**Methods:** 42 triple negative breast cancer patients (staging group) and 40 HER2+ breast cancer patients (control group) who underwent surgery from January 2000 to December 2005 were analyzed. 82 cases of paraffin-embedded specimens were detected by Immunohistochemistry (IHC), fluorescence in situ hybridization (FISH), and polymerase chain reaction (PCR) to investigate the overexpression, amplification and mutation of EGFR gene. The distant-free survival (DFS) and overall survival (OS) of these patients were used to investigate the relationship between EGFR overexpression and the prognosis of TNBC.

**Results:** 34 (43.9%) EGFR overexpression was observed in all cases, while gene amplification was only found in 7 (9.1%) cases. No EGFR gene mutation was found in all cases. Overexpression of EGFR occurring in 57.1% patients in TNBC group and 25.0% patients in HER2 group, and we didn’t find any correlation between EGFR overexpression and clinicopathology. 50 (61.0%) patients relapsed (TNBC 28, HER2 22) and 27 (32.9%) patients died (TNBC 18, HER2 9) were observed during the more than 5 years follow-up. The 5-year DFS was 57.1% and 77.5% respectively, the 5-year OS was 71.4% and 87.5% in TNBC and HER2 groups. In TNBC group, the survival of the EGFR-overexpressing group patients was significantly lower than that of the non-EGFR-overexpressing group patients (\( p = 0.018 \) for DFS, \( p = 0.026 \) for OS); In HER2 group, no statistical difference was found (\( p = 0.079 \) for DFS, \( p = 0.055 \) for OS).

**Conclusions:** This study showed that EGFR overexpression increased significantly in TNBC patients, which was no correlation with their clinicopathological data. EGFR gene amplification was much less frequent than its overexpression. It suggested that EGFR gene amplification may not be the unique mechanism of EGFR overexpression in TNBC. There may be other possible mechanisms and pathways that cause EGFR overexpression. In addition, it may suggest that gefitinib therapy is useless in TNBC patients because we did not find any mutations in the tested exons of TNBC. EGFR overexpression may associate with a poor outcome of TNBC patients which suggest it could be a significant prognostic factor for TNBC patients. EGFR may play important role for molecular-targeting therapy of TNBC.

### P2-11-10

#### Low Toll-Like Receptor 9 Expression Is Required for the Aggressive Behavior of Triple Negative Breast Cancer Cells in Hypoxia.

Selander KS, Tuomela J, Sandholm J, Karihtala P, Pressey C, Ilvesaro J, Vuopala K, Kauppila JH, Kauppila S, Harris KW, Graves D, Jukkola-Vuorinen A. University of Alabama at Birmingham, Birmingham, AL; Oulu University Hospital, Oulu, Finland; University of Oulu, Oulu, Finland

Toll-like receptor-9 (TLR9) is a cellular DNA-receptor and a member of the innate immune system which is widely expressed in breast cancers. Although synthetic TLR9-ligands stimulate breast cancer cell invasion in vitro, through down-regulation of tissue inhibitor of matrix metalloproteinase-3 (TIMP-3), the role of this protein in breast or other cancer pathophysiology is unclear. We discovered that low tumor TLR9 expression is associated with a significantly shortened breast cancer specific survival among patients with triple negative tumors, but not among those with ER+ tumors. We further discovered that hypoxia induces TLR9 expression in breast cancer cells in vitro and in vivo. Although the triple negative TLR9 siRNA MDA-MB-231 breast cancer cells (with lower TLR9 expression) were less invasive than control siRNA cells in normoxia, these cells became highly invasive in hypoxia. Hypoxia induces TLR9 expression in breast cancer cells in vitro and in vivo. Although the triple negative TLR9 siRNA MDA-MB-231 breast cancer cells (with lower TLR9 expression) were less invasive than control siRNA cells in normoxia, these cells became highly invasive in hypoxia. Although synthetic TLR9-ligands stimulate breast cancer cell invasion in vitro, through down-regulation of tissue inhibitor of matrix metalloproteinase-3 (TIMP-3), the role of this protein in breast invasion and pathways that cause EGFR overexpression. In addition, it may suggest that gefitinib therapy is useless in TNBC patients because we did not find any mutations in the tested exons of TNBC. EGFR overexpression may associate with a poor outcome of TNBC patients which suggest it could be a significant prognostic factor for TNBC patients. EGFR may play important role for molecular-targeting therapy of TNBC.
P2-11-11

IGFBP Ratio Confers Resistance to IGF Targeting and Correlates with Increased Invasiveness and Poor Outcome in Breast Tumors.
Becker MA, Hou X, Harrington SC, Carboni JM, Gottardis MM, Haluska P, Mayo Clinic, Rochester, MN; Bristol Myers Squibb Pharmaceutical Research Institute, Princeton, NJ

Purpose: To assess the role of insulin-like growth factor binding protein 5 (IGFBP-5) as a marker of relapse and survival in breast cancer tumors.

Experimental Design: Targeted regulation of IGFBP-5 was identified in MCF-7 cells resistant (MCF-7R4) to the IGF-1R/InsR inhibitor, BMS-536924 and examined by comparative microarray analysis, western and ELISA. Protein expression of IGFBP-5 was measured by immunohistochemistry in a cohort of 84 breast cancer patients to examine correlative associations with invasive tumor fraction and overall survival (OS). The expression ratio of IGFBP-5/IGFBP-4 (BPR) was determined in multiple breast tumor cohorts for univariate analysis.

Results: IGFBP-5 was markedly upregulated and highly localized to the membrane in MCF-7R4 resistant cells. When compared to pathologically normal reduction mammoplasty tissue, IGFBP-5 expression levels were upregulated in both invasive and histologically normal adjacent breast cancer tissue. In an independent cohort of breast cancer patients, IGFBP-5 protein levels correlated directly with invasion and OS. In univariate and multivariate modeling, metastasis-free survival, recurrence free survival (RFS) and OS were significantly associated with high IGFBP-5 expression. Prognostic power of IGFBP-5 was further increased with the addition of IGFBP-4 and tumors were ranked based upon IGFBP-5/IGFBP-4 expression ratio (BPR). Multiple breast cancer cohorts confirm that BPR (high vs. low) was a strong predictor of RFS and OS.

Conclusion: IGFBP-5 expression is a marker of poor outcome in breast cancer patients. An IGFBP-5/IGFBP-4 expression ratio may serve as a surrogate biomarker of IGF pathway activation and predict sensitivity to IGF-1R-targeted therapies.

P2-12-01

Immunohistochemical (IHC) BAG1 Expression Improves the Estimation of Residual Risk (RR) by IHC4 in Postmenopausal Patients Treated with Anastrozole or Tamoxifen: A TransATAC Study.
Dowsett M, Afentakis M, Pineda S, Salter J, Howell A, Buzdar A, Forbes JF, Cuzick J, Royal Marsden Hospital, London, United Kingdom; Wolfson Institute of Preventive Medicine, London, United Kingdom; Christie Hospital, Manchester, United Kingdom; MD Anderson Cancer Center, Houston; University of Newcastle, Newcastle, Australia

Aim: To determine whether the incorporation of BAG1 staining improves the estimate of RR after endocrine therapy in postmenopausal patients with ER+ve tumours treated with endocrine therapy.

Background: BAG1 encodes a protein (BCL2-associated athanogene 1) that binds to BCL2 and enhances its anti-apoptotic effects. BAG1 is included as a separate subgroup in the 21-gene OncotypeDX Recurrence Score (RS) that is used to assess RR after endocrine therapy in primary ER+ breast cancer. IHC4 is a 4-panel set of IHC markers (ER, PgR, HER2, Ki67) that was shown to provide as much prognostic accuracy as RS in the translational arm of the ATAC trial (TransATAC) of anastrozole versus tamoxifen alone or combined and subsequently independently validated (Cuzick et al, JCO, 2011, in press). Addition of extra markers such as BAG1 to IHC4 may improve the accuracy of the IHC4 and provide extra discriminatory power for oncologists.

Methods: Samples in triplicate TMAs from the TransATAC cohort were stained for BAG1 using the Genetex 3.10G3E2 antibody after validation using siRNA knockdown. Staining was scored separately as nuclear or cytoplasmic and categorized by intensity as 0, 1, 2 or 3. BAG1 IHC values were assessed for their correlation with BAG1 mRNA levels. The statistical analysis plan was pre-specified and tested possible additional information from BAG1 expression to the IHC4 in patients not treated with chemotherapy by change in the likelihood ratio chi-square (ΔLR-X2). Results were included only if there was also complete data for ER, PgR, Ki67 and HER2. Primary analysis was on the HER2-ve node-negative (N-neg) population; secondary analysis was on all N-neg patients. Follow-up was to 10 years and the primary end-point was time to distant recurrence (TTDR).

Results: Data on both nuclear and cytoplasmic BAG1 as well as the other 4 IHC parameters was available on 961 cases of which 855 were HER2-ve. There was a significant correlation between cytoplasmic and nuclear BAG1 (p=0.23, p=0.0001) but the nuclear staining correlated better with mRNA levels and was therefore considered further. Weak but significant correlations were also seen with ER, PgR and tumour grade. In the univariate analysis nuclear BAG1 was significantly associated with worse TTDR in HER2-ve and all N-neg cases (X2=7.91, p=0.005 and X2=10.63, p=0.001 respectively). Nuclear BAG1 also contributed significantly in multivariate analyses in the 2 populations firstly when added to the clinical model (X2=4.99, p=0.02 and X2=5.93, p=0.015 respectively) and secondly when subtracted from clinical plus the IHC4 parameters (X2=5.55, p=0.02 and X2=4.50, p=0.03 respectively).

Conclusions: Nuclear BAG1 expression has significant value for estimating RR that is independent of standard clinical and IHC parameters and it improves the prediction of TTDR in the TransATAC population beyond that with the validated IHC4 score. Unlike IHC4 markers, BAG1 is not commonly measured in pathology work-up of breast cancers. The clinical utility of its addition to IHC4 will be tested by measuring its discrimination of high and low risk patients in clinical practice.
trial. Pts were more likely to be older and postmenopausal (p=0.0001 for both). There was no significant association between BMI and ER/PR status (p=0.07) or histologic tumor grade (p=0.33). Obese pts were found to have significantly larger tumors ≥ 2 cm (p=0.002) and more positive lymph nodes (p=0.02). There was no significant difference in DFS within each intrinsic arm (A, B and C) between the obese and non-obese pts at 3, 5 or 7 yrs of follow up. However, pts in the non-obese group had significantly improved DFS in arm B and C compared to arm A (p=0.001 and p=0.0001 respectively). Also obese pts in arm C had significantly improved DFS compared to obese pts in arm A (p=0.008). There was a trend of improved DFS in the obese group in arm B compared to arm A, but this was not statistically significant (p=0.09). Pts in the normal weight and overweight groups did significantly better in arm B (p=0.02 for both) and arm C (p=0.01 and p=0.002 respectively) compared to arm A.

Conclusions: This analysis of data from the N9831 study confirms that obese pts with early stage HER2+ tumors have worse clinical outcome than pts with BMI < 30%. Adjuvant trastuzumab improved clinical outcome regardless of BMI. This study supports weight loss intervention for obese women with early stage HER2+ BC.

P2-12-03
A Prospective Study of the Prognostic Implications of Being a BRCA1 Carrier for Young Onset Breast Cancer Patients.
Eccles DM, Dent L, Gerty SM, Altman D, Copson ER, Simmonds PD, Duncan L, Ward D. University of Southampton, Southampton, Hampshire, United Kingdom; Oxford University, Oxford, United Kingdom; Southampton University Hospitals NHS Trust, Southampton, Hampshire, United Kingdom; Salisbury District Hospital, Salisbury, Wiltshire, United Kingdom

Background: BRCA1 gene carriers frequently develop triple negative breast cancer (TNBC) at young ages. Retrospective studies have reached conflicting conclusions about the prognostic implications of breast cancer diagnosed on a background of a constitutional BRCA1 gene mutation. Many studies have the disadvantages of retrospective design and small numbers or both. The Prospective study of Outcomes in Sporadic versus Hereditary breast cancer (POSH) recruited 3024 patients diagnosed before 41 years of age and treated for breast cancer in the UK between 2000 and 2007 (protocol published: Eccles et al, BMC Cancer 2008).

Aim: To investigate the effect of family history and BRCA1 gene mutation status on breast cancer survival in women aged younger than 41 years at diagnosis.

Methods: Cases in which the primary tumour pathology report was not available (2.8% of total) were excluded from this analysis. A completed family history questionnaire was available for 2907 cases (99% of total). The primary end point for this analysis was the development of distant metastases from breast cancer. All patients were younger than the starting age for screening in the UK except for known gene carriers of which there were only 8 in total, the remainder of identified gene carriers were tested after cancer diagnosis or as part of this study. Over 90% of patients received adjuvant or neoadjuvant chemotherapy with over 90% of these receiving an anthracycline based regimen. Kaplan Meier survival analysis and log rank test were used to assess survival differences.

Results: 2937 patients were included in the analysis. Mean and median age at diagnosis was 36 years and the cohort was followed prospectively for a mean and median follow up time of 50 months. Overall distant disease free survival in the whole cohort was only 75% at 5 years. The effect of family history on presentation was explored. Patients who reported a first or second degree relative with breast cancer presented with smaller tumours (20mm compared to 22.5mm, p= 0.006) but no difference in axillary nodal status (p=0.2605). Survival was however significantly better comparing the 499 patients who reported a family history of breast cancer compared with the rest of the cohort (p=0.0164). 539 patients had been tested for mutations in the BRCA1/2 genes and 176 high risk gene BRCA1/BRCA2 carriers were identified. We compared 118 patients with a known BRCA1 gene mutation (almost all diagnosed after the cancer) to the 465 patients with confirmed TNBC (p=0.0118). Survival was significantly better in the BRCA1 carriers (p=0.0118). After excluding 29 gene carriers whose primary tumour showed any of ER, HER2 or PR as positive, the same improved survival trend was seen although significant at the 10% level (p=0.07).

Conclusion: This prospective study indicates that BRCA1 gene carriers clearly do not have a worse prognosis when compared to triple negative breast cancers or young onset breast cancer overall and these early follow up data indicate an improved outlook in gene carriers.

P2-12-04
RACGAP1 mRNA Assay Outperforms Ki-67 as a Proliferation Marker in the FinHer Study Cohort.
Wirtz RM, Leinonen M, Bono P, Isola J, Kellokumpu-Lehtinen P-L, Kataja V, Turpeenniemi-Hujanen T, Jyrkkö S, Huang W, Eitd S, Joensuu H. STRATIFYER Molecular Pathology GmbH, Cologne, Germany; Pharma, Finland; Helsinki University Central Hospital and University of Helsinki, Finland; University of Tampere and Tampere University Hospital, Finland; Tampere University Hospital, Finland; Kuopio University Hospital, Finland; Oulu University Hospital, Finland; Turku University Hospital, Finland; Monogram Biosciences, Inc.; Institute of Pathology at the St-Elisabeth-Hospital, Germany

Background: Molecular subtyping of breast cancer has become an integral part of standard evaluation of breast cancer patients. Their assessment requires combining data from analyses on ER, PR, HER2 and cell proliferation markers. However, their immunohistochemical (IHC) testing carries an up to 20% risk of erroneous results. Similarly, assessment of cell proliferation by Ki-67 staining is hampered by lack of standardization of laboratory methods and agreement on cut-offs. Here we tested the prognostic value of objective quantitation of ESR1, PgR, HER2 and the proliferation markers RACGAP1 using RT-qPCR and compared the results with local and central IHC assessments.

Methods: RNA was extracted from FFPE tumor tissue of 917 patients who participated in the FinHer trial. ESR1, PgR, HER2 and the proliferation marker RACGAP1 using RT-qPCR and compared the results with local and central IHC assessments.

Results: HER2 mRNA expression increased in parallel with HER protein expression. The WHO BMI classification parameters of < 25%, 25-29% and ≥ 30% respectively were grouped into non-obese (BMI< 30) and obese (≥ 30) cohorts. DFS was estimated by the Kaplan-Meier method. Comparisons between arms A (chemotherapy alone), B (chemotherapy plus sequential trastuzumab) and C (chemotherapy plus concurrent trastuzumab) were performed using the Cox proportional hazards model, stratified by BMI.

Conclusions: This prospective study indicates that BRCA1 gene carriers clearly do not have a worse prognosis when compared to triple negative breast cancers or young onset breast cancer overall and these early follow up data indicate an improved outlook in gene carriers.
central IHC and CISH was good, while local IHC testing suffered higher false positive rates. RACGP1 mRNA expression was the greater the higher the histological grade. ESR1 and PgR mRNA correlated negatively with the histological grade (r=-0.38 and r=-0.33; p<0.0001), whereas HER2 and RACGP1 mRNA were correlated positively (r=0.10 and r=-0.49; p=0.002 and p=0.0001, respectively). RACGP1 mRNA was negatively associated with ESR1 and PgR mRNA (r=0.17 and r=-0.26, respectively; p=0.0001 for each). Molecular subtypes determined by RT-qPCR using predefined cut-off values were highly prognostic for overall survival (OS) (p<0.001). The 5-year OS rate for patients with luminal cancer was 94% and 86% for HER2-enriched cancer and 84% for triple-negative cancer. In the subset of luminal tumors, high expression of RACGP1 identified a population of patients who were at a high risk of death (5-year OS 82% versus 95%; p=0.0001). In a multivariate analysis RACGP1 mRNA expression, nodal status and chemotherapy type were independent prognostic factors, whereas IHC of ER, PgR, Ki-67 and histological grade were not significant.

Conclusion: Molecular subtyping of breast cancer by RT-qPCR using RNA isolated from FFPE tissue proved successfully in this large patient cohort. RACGP1 mRNA expression distinguished high and low risk luminal breast cancers. In a multivariate analysis mRNA-based molecular markers outperformed the immunohistochemical markers ER, PgR and Ki-67. Of note, quantitative assessment of the proliferation marker RACGP1 was superior to semi-quantitative assessment of Ki-67 from routine FFPE tissues using IHC. We conclude that quantitative assessment of ESR1, PgR, HER2 and RACGP1 mRNA by RT-qPCR is a robust and reproducible method to assess these key tumor biological factors from archival FFPE tumor tissue. RACGP1 is a novel cell proliferation marker in breast cancer that warrants further validation.

P2-12-05
Correlation between Quantitative HER2 Protein Expression and Risk of Brain Metastases in HER2-Positive Advanced Breast Cancer Patients Receiving Trastuzumab-Containing Therapy.

Duchnowska R, Biernat W, Szostakiewicz B, Sperinde J, Piette F, Hauck M, Paquet A, Lie Y, Czartoryska-Artukowicz B, Wysocki P, Jankowski T, Radecka B, Foszczyńska-Kłoda M, Litwinik M, Debska S, Weidler J, Huang W, Buyse M, Bates M, Jassem J. Military Institute of Medicine, Warsaw, Poland; Medical University of Gdansk, Gdansk, Poland; Monogram Biosciences, South San Francisco, CA; International Drug Development Institute, Louvain-la-Neuve, Belgium; Bialystok Oncology Center, Bialystok, Poland; Great Polish Cancer Center, Poznan, Poland; Lublin Oncology Center, Lublin, Poland; Opole Oncology Center, Opole, Poland; West Pomeranian Oncology Center, Szczecin, Poland; Poznan University of Medical Sciences, Poznan, Poland; Regional Cancer Center, Lodz, Poland; Cepheid, Sunnyvale, CA

Background. Patients with HER2-positive breast cancer are at particularly high risk for brain metastases; however, the biological basis is not fully understood. Within HER2-positive breast cancer tumors, it is possible to resolve a ~1.5-log range of HER2 protein expression using a novel quantitative HER2 assay (HERmark®). We investigated the correlation between quantitative HER2 protein expression in primary breast cancers and the time to brain metastases (TTBM) in HER2-positive advanced breast cancer patients treated with trastuzumab.

Methods. The study group included 142 consecutive patients who were administered trastuzumab-based therapy for HER2-positive metastatic breast cancer, defined as 3+ categorical staining by immunohistochemistry (IHC). HER-2/neu gene copy number was subsequently quantified as HER2/CEP17 ratio by central laboratory fluorescence in situ hybridization (FISH). HER2 protein was quantified as total HER2 protein expression (H2T) by the HERmark assay in formalin-fixed, paraffin-embedded primary tumor samples. HER2 variables were correlated with clinical features and TTBM measured from the initiation of trastuzumab-containing therapy. Results. H2T level (continuous variable) was correlated with shorter TTBM (HR=2.3; p=0.013), whereas HER2 gene amplification by FISH (p=0.28) and continuous HER2/CEP17 ratio (p=0.25) had no significant prognostic impact. The correlation between continuous H2T level and TTBM was confirmed in a multivariate analysis (HR=3.2; p=0.021). Controlling for the competing risk of death from causes other than brain metastases, continuous H2T remained a strong correlate of TTBM (HR=2.7; p=0.0009). In the subset of patients that was centrally-determined HER2 positive by FISH (117 patients), above-median H2T level was significantly associated with shorter TTBM (HR=2.4; p=0.005), whereas this was not true for median FISH/CEP17 ratio (p=0.4). In a multivariate analysis of this subset, continuous H2T (p=0.021) and a time dependent covariate capturing time to non-brain metastases (p=0.0044) were prognostic for TTBM, whereas FISH/CEP17, ER, PgR and grade were not.

Conclusion. These data reveal a strong relationship between quantitative HER2 protein expression levels and the risk of brain relapse in HER2-positive advanced breast cancer patients. Consequently, quantitative assessment of HER2 protein expression may inform and facilitate refinements in therapeutic treatment strategies for selected subpopulations of patients in this group.

P2-12-06
Nomogram To Predict Subsequent Bone Metastasis in Patients with Non Metastatic Breast Carcinomas.

Lousquy R, Delpech Y, Rouzier R, Glisovic J, Hsu L, Barranger E, Puzsztai L, Uzan S, Hori-bagyi GN, Costant C, Ibrahim NK, Lariboisiere Hospital, AP-HP, Paris, France, Metropolitan; Tenon Hospital, AP-HP, Paris, France, Metropolitan; The University of Texas M.D. Anderson Cancer Center, Houston, TX; Georges Francois Leclere Cancer Center, Dijon, France, Metropolitan

Background: Bone metastasis (BM) is one of the most common sites of distant metastasis for breast cancer. We hypothesized that its occurrence can be predicted if a clinical nomogram can be developed, thus allowing for selection of patients at high risk for BM.

Patients and Methods: Medical records of patients with non metastatic breast cancer were prospectively collected for the period between January 1997 and February 2007 at the M.D. Anderson Cancer Center (Texas, USA). A multivariate logistic regression analysis of selected prognostic features was done. Based on Cox proportional hazards regression model, a nomogram to predict BM was constructed and validated in an independent cohort of 579 patients with non metastatic breast cancer at time of diagnosis treated at the Tenon Hospital (Paris, France) between January 2003 and December 2005.

Results: Of 4175 patients with non metastatic breast cancer, 314 developed subsequent BM. Age, T stage, lymph node status, lymphovascular space invasion, breast cancer molecular subtype, adjuvant hormonotherapy were significantly and independently associated with subsequent BM. The nomogram had a concordance index of 0.69 (95% CI, 0.68 to 0.70) in the training set. The validation set showed a good discrimination with a concordance index of 0.65 (95% CI, 0.57 to 0.72). At 3, 5 and 7 years, the nomogram was well calibrated.
Conclusion: We have developed a robust tool that is able to predict subsequent BM in patients with non metastatic breast cancer. Selection of an enriched patient population at high risk for BM will allow to practice individualized therapeutic strategies, an adapted medical supervision and will facilitate the design of trials aiming at its prevention with the use of biphosphonate treatment.

P2-12-07
Pooled Analysis of Outcomes of T1a/bN0, HER2-Amplified Breast Cancer.
Amir E, Seruga B, OcanA A, Carlsson L, Bedard P, Princess Margaret Hospital, Toronto, Canada; Institute of Oncology Ljubljana, Ljubljana, Slovenia; Albacete University Hospital, Albacete, Spain

Background: Breast tumors with HER2 amplification have a worse prognosis than those with normal HER2 expression. This finding is independent of tumor size and other classical prognostic factors used in the adjuvant setting. The prognosis of node negative, sub-centimeter (T1a/bN0) tumors is usually excellent. However, little is known about the prognostic impact of HER2-amplification in this group. This study therefore, aimed to evaluate the relative and absolute prognostic impact of HER2-amplification in T1a/bN0 tumors.

Materials and Methods: Published data from studies assessing the outcomes of patients with HER2-amplified, node negative, T1a/bN0 tumors were included in a pooled analysis. Odds ratios (OR), 95% confidence intervals (CI) and absolute risks were computed for recurrence and distant recurrence at 5 years. Pooled hazard ratios (HR) for disease-free survival (DFS), were also assessed.

Results: A total of 3 case-control studies were included in the analysis and comprised 485 patients with HER2-amplified breast cancer (57.3% were also hormone receptor positive) and 1096 patients with HER2-normal disease (82.2% were hormone receptor positive). Among the HER2-amplified group, 4.1% received trastuzumab and 18.6% received chemotherapy. In the HER2-normal group, 4.3% received chemotherapy. Estimated median follow-up was 5.7 years. HER2-amplification was associated worse DFS (HR = 2.60, 95% CI 1.53-4.41, p<.001) and increased odds for recurrence at 5 years (OR =3.79, 95% CI 2.35-6.10, p<.001). There was a non-significant trend towards increased odds of distant recurrence at 5 years (OR = 2.51, 95% CI 0.82-7.67, p=.11). Compared with HER2-normal cancers, those with HER2-amplification showed lower absolute probability of recurrence-free survival at 5 years (90.1% vs. 94.6%, p<.001) and distant recurrence-free survival at 5 years (95.1% vs. 97.6%, p<.001). Among HER2-amplified cancers, tumor size 0.6-1.0cm (T1b) was associated with a trend for higher odds of recurrence at 5 years compared with those 0.5cm or smaller (T1a, pooled OR = 1.58, 95% CI 0.96-2.60, p=.07).

Conclusions: HER2-amplification is associated with worse outcome in T1a/bN0 tumors. However, recurrence-free and distant recurrence-free survival at 5 years is excellent in this group, particularly in those with T1a tumors. These data question the role of adjuvant chemotherapy and trastuzumab in these patients unless associated with other high risk factors. A differentially lower risk for distant recurrence suggests the possible role for more aggressive local therapy such as surgery and/or radiation therapy.

P2-12-08
Bcl-2 as a Prognostic Marker in Breast Cancer Patients Receiving Endocrine Therapy.
Larsen MS, Bjerre KD, Løkkhuseth A-V; Giobbie-Hurder A, Ejertsen B, Lyksesfeldt AE, Rasmussen BB, Herlev Hospital, Herlev, Denmark; Rigshospitalet, Copenhagen, Denmark; Dana-Farber Cancer Institute, Boston, MA; Danish Cancer Society, Inst of Cancer Biology, Copenhagen, Denmark

Background: In breast cancer patients with estrogen receptor (ER) positive tumors, endocrine treatment reduces recurrence. However, 30% of patients eventually relapse in spite of therapy. Additional markers to identify this group of therapy resistant, prognostically unfavourable patients are therefore needed. The expression of Bcl-2 has been shown to be a prognostic factor in breast cancer patients regardless of ER-status, but assessment of Bcl-2 by immunohistochemistry (IHC) needs to be standardized since different scoring systems and different cut-points have been used. In a pilot study comprising 258 ER positive tumors from tamoxifen-treated patients, a simple scoring system enabled us to find suitable cut-points, selecting patient-groups with poor prognosis. The aim of the current study was to validate these results in a similar population from a large randomised study.

Material and methods: Bcl-2 was assessed in 1082 (78%) of the 1396 postmenopausal Danish patients who in the BIG 1-98 trial were randomised to 5 years of tamoxifen (N=325), letrozole (N=335) or a sequence of these agents (N=422). Tissue microarrays were made from formalin fixed paraffin embedded primary tumors. An IHC score for expression of cytoplasmic Bcl-2 (clone 124, Dako) was performed according to both the number of positive cells (0%=0, 1-10%=1, 11-50%=2, 51-100%=3) and the intensity of the staining (weak, moderate, strong) as in the pilot study. The associations between Bcl-2 status and clinicopathological variables were assessed. The prognostic value of Bcl-2 according to cut-points determined in the pilot study was analysed by Cox proportional hazards models. The primary endpoint was disease free survival (DFS).

Results: Patients were divided into three subgroups according to predefined cut-points: Bcl-2 low (score 0 or 1 (n= 24)), Bcl-2 intermediate (score 2 or score 3/weak or moderate (n= 216)) and Bcl-2 high (score 3/strong (n= 842)). Bcl-2 expression was significantly associated with ER (P=0.0003) and progesterone receptor (PgR) (P<0.0001), and negatively associated with Ki-67 (P=0.0021) and tumor grade (P=0.005). In univariate analysis patients in the Bcl-2 low group had a bad prognosis compared to the Bcl-2 high group (HR=2.3; 95% CI: 1.2 to 4.1). In the multivariable analysis including ER, PgR, Ki-67, positive lymph nodes, age, tumor size and histological type and grading, association between Bcl-2 and DFS was not statistically significant (P=0.35).

Discussion: We found Bcl-2 to be a prognostic factor in the univariate analysis (P=0.024) but not to be an independent predictor of poor survival of ER positive patients treated with tamoxifen and/or letrozole. In this population a low or absent expression of Bcl-2 was uncommon (2.2 %), as expected since Bcl-2 is an ER regulated protein. The results of the pilot study could not be confirmed in this validation study. However, the strong positive relation to other prognostic factors like tumor grade and high proliferative index indicates that Bcl-2 could contribute to factors characterising a group of tumors with a bad prognosis.
P2-12-09
Prediction of Residual Risk of Recurrence for 5 Years of Follow-Up by Clinicopathologic Variables and 4 IHC Markers: A TransATAC Study.
Sestak I, Cuzick J, Dowsett M, Salter J, Quinn E, Zabaglo L, Howell A, Buzdar A, Forbes J, Queen Mary University of London, London, United Kingdom; Royal Marsden Hospital and Breakthrough Breast Cancer Centre, London, United Kingdom; Christie Hospital, Manchester; United Kingdom; University of Texas, Texas; University of Newcastle, Newcastle, NSW, Australia

Background: Adjuvant endocrine therapy beyond 5 years is known to be of benefit to some ER+ patients but it is unclear which patients have sufficient residual risk (RR) to merit this. We have previously shown that 4 immunohistochemical markers (ER, PgR, Ki67, HER-2), both alone and combined into the IHC4 score (Cuzick et al, JCO 2011) are significantly correlated with time to recurrence (TTR) in the overall follow up of a cohort of 1125 patients from the monotherapy arms of the Arimidex, Tamoxifen, Alone or in combination (ATAC) trial. We have now assessed the relationship of each of these parameters and common clinical variables (nodal status, grade, tumour size, age and treatment option) for predicting outcome beyond 5 years.

Material and Methods: We determined the univariate and multivariate prognostic value of clinical variables and the 4 IHC variables separately and as the IHC4 score for TTR separately in years 0-5 and 5-10 of follow up for all patients, separately for anastrozole and tamoxifen and only in the node-negative patients. Results: Results in years 5-10 are summarized in the Table. Nodal status, tumour size and grade were at least as strong in years 5-10 as in years 0-5. Ki67 and the overall IHC4 score were the only significant IHC biomarkers related to TTR univariately in this period, but both lost significance in a multivariate model including clinical variables. There were no significant interactions with treatment. Similar results were seen for the node-negative population. Conclusions: None of the IHC4 markers provided significant additional prognostic information in the 5-10 year period, but nodal status, tumour size and grade continued to be strong prognostic factors.

Table: Univariate and multivariate analyses of immunohistochemical markers and clinical variables in the 5-10 years follow-up period.

P2-12-10
Low TCR Diversity (Divpenia) Is a Prognosis Factor of Overall Survival in Metastatic Breast Cancer.

Background: We already showed that lymphopenia (<1000 lymphocytes/µL) or CD4+ T cell lymphopenia (<450/µL) detected before initiation of chemotherapy are prognostic factors for toxicity and death for metastatic breast cancer (MBC) patients. The goal of the present study was to identify the characteristics of the T cells in these lymphopenic patients. TCR diversity was investigated and tested as a prognostic factor for overall survival (OS).

Patients and methods: The ImmunTraCkeR® assay (ImmunID, Grenoble, France), which analyzes through semi quantitative multiplex-PCR the V-D-J combinatorial diversity of TCR-beta chain (TRB), was used to investigate diversity of T cell repertoire on cryopreserved blood samples from a retrospective cohort of MBC patients before chemotherapy administration (n=66). Univariate and multivariate analyses were performed. We then validated our score on a prospective cohort (n=67) using the same eligibility criteria (MBC patients before first line chemotherapy administration).

Results: Using a 33% cutoff for divpenia in our retrospective cohort (T cell diversity below 33%) (average diversity for healthy people is 70%), divpenia was associated with a median OS of 10 months vs 22 months for patients with diversity >33% (logrank p value=0.04). The NDLL score (Numeration Diversity Lymphocytes representation) that combines lymphocyte numeration with TRB diversity, demonstrated that lympho-divpenia (T cell diversity below 33% and lymphopenia below 1Giga/L) was associated with a poor OS compared to patients with either lymphocyte <1000/µL & diversity >33% or lymphocyte >1000/µL & diversity <3% or both lymphocyte >1000/µL & diversity >33% (p=0.015).

In multivariate analysis, including performance status (PS), hemoglobin level, polynuclear neutrophil count (PNN), age, and liver metastasis, NDLL score was identified as an independent prognostic factor for OS. In our prospective validation cohort, NDLL score was also identified as a prognostic factor for OS (p=0.007), as well as lymphopenia (<1000/µL) (p=0.0003), CD4+ lymphopenia (<450/µL) (p=0.04), menopausal status (p=0.02), hormonal receptor status (estrogen receptor p=0.02; progesterone receptor p=0.002) and lung metastasis (p=0.009).

In multivariate analysis, hemoglobin level was the only independent prognostic factor in this cohort.

Conclusion: We showed that Divpenia and NDLL score are prognostic factors for OS in MBC patients. In order to confirm these results, a prospective clinical trial is ongoing on a larger cohort of MBC and lung cancer patients.

P2-12-11
Clinical Relevance of a IL-8/B-Cell Gene Signature Identified from Triple Negative Breast Cancer (TNBC) in Intrinsic Breast Cancer Subtypes.
Rody A, Holtrich U, Ruckhaeberle E, Radosa J, Juhász-Boess I, Solomayer EF, Kaufmann M, Karrn T, Starland University, Hamburg, Germany; Goethe-University, Frankfurt, Germany

Background: As presented recently (SABCS 2010, #S5-5) a ratio of high B-cell and low IL-8 metagenes using gene expression analysis identified 32
% of triple negative breast cancers with good prognosis and was the only significant predictor in multivariate analysis including routine clinicopathological variables. However, the clinical relevance of this signature within the intrinsic breast cancer subtypes still remains unclear and is analyzed here.

**Methods**

Affymetrix gene expression data from n=2417 breast cancer patients have been assembled. We performed an unsupervised analysis to define metagenes that distinguish molecular subsets within TNBC (SABCS 2010, #S5-5). A high expression of B-cell metagenes was associated with good and high expression of IL-8-related metagenes were associated with poor prognosis. To identify intrinsic subtypes we used the method previously described by Hu et al. (2006) and the prognostic value within those subtypes was assessed by analyzing the event free survival of patients as function of high and low B-cell/IL-8 metagene ratio.

**Results**

Comparing ER positive with ER negative patients the B-cell/IL-8 ratio showed only in ER negative breast cancer a significant prognostic value (log rank p-value <0.0001). Within the entire cohort 37.8 % of patients could be assigned to luminal A, 35.2 % to luminal B, 7.4 % to erbB2 and 19.6 % to basal-like subtypes. Event free survival of patients with good or poor B-cell/IL-8 ratio showed only in basal-like breast cancer patients a statistical significant difference (p<0.0001). However, we could not observe any difference in prognosis in luminal A and B, as well as erbB2 tumors. No difference in the expression of the proliferation metagene was observed when samples of the intrinsic subtypes were stratified according to the prognostic predictor based on high expression of the B-Cell metagene and low expression of the IL-8 metagene.

**Conclusion**

The B-cell/IL-8 ratio is highly prognostic in basal-like/ TNBC and shows no association with proliferation status.

**P2-12-12**

**Prognostic Utility of Breast Cancer Index for Late Relapse in Patients with Early Stage Breast Cancer.**

**Schnabel CA, Zhang Y, Kesty NC, Erlander MG. bioTheranostics, Inc, San Diego, CA**

**Background:** Residual risk of relapse remains a substantial concern for breast cancer patients as greater than half of recurrences occur beyond the initial 5y of tamoxifen therapy. First generation multi-gene signatures provide further prognostic information to standard clinical and pathological factors, however, their utility is strongest for predicting early relapse (≤5y post-diagnosis), and they have limited prognostic value for late metastatic risk. Breast Cancer Index (BCI), a continuous risk index based on the combination of HOXB13/IL17BR (H1) and the molecular grade index (MGI), estimates the individual risk of recurrence in ER+, LN- breast cancer patients. In this study, the prognostic performance of BCI for predicting early versus late relapse (≥5y vs >5y post-diagnosis) was examined.

**Methods:** Gene expression profiling was performed on RNA extracted from FFPE tumor samples from untreated, postmenopausal, ER+ early stage breast cancer patients in the randomized Stockholm Trial. RT-PCR assay, pre-defined BCI score, H1 and MGI cut-points, and risk group categorization were done as previously described (Jerevall et al., Br J Cancer 2011). Association of gene expression data with the clinical endpoint of time to distant metastasis was assessed by Kaplan-Meier analysis using the log rank test; time-varying coefficient Cox proportional models were used to estimate the time-dependent hazard ratios (HRs).

**Results:** Analyses included 274 ER+, LN- patients (51% PR+, 87% HER2+, 63% grade 2, 17.7 y median follow-up) who did not receive adjuvant tamoxifen treatment. BCI was significantly associated with 10-year distant metastasis-free survival, with probabilities of 91% (86-96%), 82% (74-91%), and 65% (52-80%) for the low, intermediate, and high-risk BCI groups, respectively (HR high versus low-risk group = 4.31; 95%CI: 2.23-8.33; P=0.00001). Stratification for the first 5-y post-diagnosis using time-varying coefficient Cox models showed both MGI and BCI were significantly prognostic with HRs of 6.13 (95% CI: 2.11-17.8; P=0.0009) and 5.77 (95% CI: 2.16-15.39; P=0.0005). For prediction of late relapse in the subset of patients that remained distant metastasis-free for at least 5-y (N=221), MGI decreased in prognostic utility (HR 1.65, 0.76-3.56; P=0.2), consistent with other proliferation-based gene signatures. In comparison, both H1 and BCI were significantly associated with risk of late relapse [HRs 2.89 (1.31-6.36; P=0.009); 3.31 (1.3-8.39; P=0.012)].

**Conclusions:** This post-hoc analysis of a randomized clinical trial cohort demonstrates the prognostic utility of BCI to predict disease outcome for both early and late risk of relapse in untreated patients with early stage breast cancer. Given the significant need for predictors of late risk, the stability of BCI prognostic performance may have important implications for the type and duration of treatment for hormone-responsive breast cancer.

**P2-12-13**

**Topoisomerase 2 alpha (TOP2A) RNA Expression Provides Prognostic Information in Hormone Receptor Positive Breast Cancer That Is Complementary to a Simulated Algorithm for Recurrence Score.**

**Sparano JA, Goldstein LJ, Davidson NE, Sledge, Jr GW, Gray R. Albert Einstein College of Medicine, Montefiore Medical Center, Bronx, NY; Fox Chase Cancer Center, Philadelphia, PA; University of Pittsburgh, Pittsburgh, PA; Indiana University, Indianapolis, IN; Eastern Cooperative Oncology Group, Brookline, MA**

**Background:** We have previously reported that TOP2A RNA expression was prognostic in patients with operable estrogen receptor (ER) positive breast cancer treated with anthracycline containing adjuvant chemotherapy plus endocrine therapy in trial E2197, and provided complementary prognostic information in those who had a mid-range Recurrence Score (RS) (Sparano et al. Clin Cancer Res 2009; 15; 7693). The purpose of this analysis was to provide additional evidence regarding this observation.

**Methods:** We evaluated TOP2A RNA expression in 4 independent data sets and stratified patients with early stage breast cancer into low (≤ Median RS), intermediate (Median RS to 18 RS), and high RS (>18 RS) groups. Patients were also stratified by ER status, stage, grade, menopausal status, and type of adjuvant therapy (chemotherapy, tamoxifen, both). The impact of TOP2A expression on relapse-free survival was assessed using Cox proportional hazards models.

**Results:** TOP2A expression was associated with improved relapse-free survival in patients with ER positive breast cancer treated with adjuvant chemotherapy plus endocrine therapy. TOP2A expression was strongly associated with improved recurrence-free survival in patients with low RS (HR 0.3; 95% CI 0.2-0.5) and modestly improved recurrence-free survival in patients with intermediate RS (HR 0.6; 95% CI 0.4-0.9). TOP2A expression was not associated with improved recurrence-free survival in patients with high RS (HR 0.8; 95% CI 0.5-1.3). TOP2A expression was associated with improved relapse-free survival in patients with low RS, but not in patients with intermediate RS or high RS.
TOP2A expression was significantly associated with recurrence in all 4 datasets when evaluated individually (HR 1.56, p<0.001 in pooled analysis), and 2 of 4 datasets individually when adjusted for SimRS (HR 1.26, p=0.003 in pooled analysis). SimRS was significantly prognostic when adjusted for TOP2A individually in 3 of 4 datasets (HR 1.44, p<0.0001 in pooled analysis). For those with an intermediate SimRS, five year RFS rates were significantly higher in 2 datasets individually for high vs. low TOP2A expression (HR 1.82, p=0.007 in pooled analysis).

Conclusions: This analysis provides additional evidence that TOP2A expression provides prognostic information in patients with ER-positive, HER2-negative disease, a population known to have low incidence of TOP2A gene alterations. These findings also suggest that TOP2A expression provides information that is complementary to RS, and may be useful for identifying high risk subjects who have a mid-range RS. These findings require prospective validation in other prospective or prospective-retrospective trials using the actual rather than simulated RS.

P2-12-14
Prognostic Value of HER2 Positivity and Negative Hormonal Status in Patients with Small Tumor (<1cm) and Node-Negative Breast Cancer.
Meatini I, Livi L, Saieva C, Agresti B, Scotti V, Nori J, Sanchez LJ, Vezzosi V, Bianchi S, Cataliotti L, Bitt G. Florence University, Florence, Italy; Cancer Prevention and Research Institute, Florence, Italy

Introduction. Human epidermal growth factor receptor 2 (HER2) amplification has become the prototype biomarker to develop tailored biological treatment. Many studies suggested that HER2 positivity is an independent predictor of disease recurrence and breast cancer mortality. Trastuzumab has been introduced into clinical practice for high-risk HER2-positive patients who have completed the standard adjuvant treatment. However, small (<1cm), node-negative tumors remain a subgroup of HER2-positive patients who are currently ineligible for trastuzumab treatment, as clinically they have been deemed to have no requirement for standard adjuvant chemotherapy.

The aim of our analysis was to evaluate the prognostic factors of local and distant recurrence in patients diagnosed with T1a-b, node-negative, HER-2 positive breast cancer.

Materials and methods. A total of 704 patients were diagnosed at Florence University between November 1999 and December 2008 with node-negative, invasive BC that were 1 cm or smaller. Patients with ductal carcinoma in situ, with recurrent BC at presentation and patients that received adjuvant chemotherapy were excluded from analysis.

Results. Mean follow-up was 4.9 years (0.5 – 10.8 years); we recorded a total of 19 recurrences, including 10 distant recurrences. Mean time to local relapse occurrence was 3.8 years (0.4 – 7.3 years); mean time to distant metastases diagnosis was 4.4 years (1.4 – 7.6 years). Among all patients, the recurrence-free survival (RFS) was 93.7%.

The only parameter that emerged as significant predictor of events is the age (p=0.02).

The distant recurrence-free survival (DRFS) rate was 96.5%. Patients who had HER2-positive BC had worse DRFS than patients who had HER2-negative BC (92.0% vs 96.9%; p=0.045). In addition to HER2, also HR status was significantly associated with DRFS (p=0.026).

Patients who had HR negative status had worse DRFS than patients who had HR positive status (91.4% vs 97.4%; p=0.045).

Conclusions. Patients with T1a-b, node-negative, breast cancer have a low risk of distant and local recurrence. Women with HER2-positive and negative hormonal status have a significant risk of distant recurrence and should be considered for anti-HER2 adjuvant therapy.

P2-12-15
Dorairaj JJ, Wall D, Newell J, Blamey RW, Sweeney KJ, Ball G, Kerin MJ. National University of Ireland, Galway, Ireland; Breast Institute, Nottingham City Hospital, Nottingham, United Kingdom; Nottingham Trent University, Nottingham, United Kingdom

Introduction: Axillary lymph node status is an important predictor of overall survival (OS), hence its inclusion in clinical prognostic tools. The Nottingham Prognostic Index (NPI) which incorporates Lymph Node (LN) stage, tumor size and grade generates a score which predicts a percentage 10-year survival. Despite its status as a benchmark model for breast cancer prognosis, newer prognostic factors do exist. Lymph Node Ratio (LNR) is a superior prognostic indicator compared to absolute positive lymph node number, warranting re-evaluation of breast cancer prognostication. The aims of this study were threefold: identify the strength of LNR as a prognostic indicator compared to LN stage and NPI; establish a new prognostic index (Galway Index of Survival [GAINS]), taking into account the effect of LNR and breast cancer subtype on traditional clinicopathological features in breast cancer prognostication; and evaluate the prognostic efficacy of the new index compared to NPI.

Methods: Two cohorts were used: Galway Cohort—a prospectively compiled cohort of 1668 cases with histologically proven Stage 1, 2 and 3 primary operable breast cancer treated between 1990-2010 in a single institute; and ONCOPOOL—a retrospectively compiled database of 16944 cases treated across 12 European breast cancer units between 1990-1999. A Cox Proportional Hazards model was fitted to evaluate the strength of LNR compared to LN stage (within the NPI model) in both cohorts. The effect of clinicopathological variables on OS was analyzed using multivariable analysis in the Galway cohort. Three models were created (Model 1: Traditional prognostic variables excluding NPI and LNR; Model 2: Model 1 and LNR; Model 3: Model 1 and NPI) and compared using Likelihood-ratio tests.

Model

</tr>
<tr>
<td>3</td>
<td>Variables in Model 1 and NPI groups</td>
</tr>
</tbody>
</table>

Stepwise variable selection was used to identify the best model to create a prognostic index and performance of the two indices was evaluated using Receiver Operating Curves (ROC).

Results: Controlling for tumor size and histological grade, LNR is a stronger prognostic factor than LN stage in both the Galway (β values of 1.2 and 0.3 respectively) and ONCOPOOL (β values of 1.3 and 0.3 respectively) cohorts, with LNR rendering LN stage non significant (p=0.135) in the former. In the Galway cohort, separate comparisons of Model 2 and 3 with Model 1 demonstrated that traditional clinicopathological variables in addition to LNR
HER2 Expression Is the Major Risk Factor for Recurrence in pT1a-b,N0 Breast Cancer: A French Regional Population-Based Study of 671 Patients.

Rouanet P, Daures JP, Roger P, Mathieu A, Romieu G, Cretin J, Barneon G, Granier M, Maran-Gonzalez A, Thibault S, Boissiere F, Bibeau F. Val d’Aurelle Cancer Institute, Montpellier, France; Montpellier 1 University, Montpellier; France; CHU Nimes, Nimes, France; ONCO LR Regional Network, Montpellier, France

Background
To evaluate the prognostic impact of HER2 overexpression in patients with pT1a-b, node negative, breast cancers.

Patients and Methods
A population of 1127 patients whose diseases were staged as pT1a-b, pN0 and who were treated in the Languedoc-Roussillon (ONCO LR Southern French regional network) from 1999 to 2004, was identified. 95% of patients had conservative management, no patient received adjuvant trastuzumab, 5% received chemotherapy and 80% anti-estrogen endocrine therapy. HER2 status was retrospectively assessed by immunohistochemistry in 671 patients (122 pT1a/549 pT1b). Kaplan-Meier method was used to estimate disease-free survival (DFS). Cox proportional hazard models were used to determine associations between HER2 status and disease-free survival adjusting on variables significantly linked to it.

Results
9-year Overall survival was 95%. HER2 overexpression (3+) was observed in 5.2% of the patients (n=35). HER2 3+ category was most frequently identified in the following sub groups: pT1a lesion (12.3% vs 3.6%; p=0.0001), mastectomies (14% vs 4.4%; p=0.023), Grade 2-3 (91% vs 50%; p=0.0001), estrogen receptor (ER) (negative (-) tumors (57% vs 30%; p<0.0001), progesterone receptor (PR) – tumors (74% vs 42%; p=0.0002). HER2 3+ was less frequent with adjuvant hormonal treatment (43% vs 80%; p<0.0001), 33 relapse (5%) were observed with a median follow-up of 6.4 years (range, 0.3 to 9.9 years). The 5-year DFS rates were 78% and 95% in patients with HER2-positive and HER2-negative tumors, respectively (p=0.017).

According to the immunohistochemical phenotype DFS5 were 95%, 94%, 85%, 73.6% for ER+/PR+/HER2- (n=502/75%), ER+/PR-/HER2- (n=124/20%), ER+/PR+/HER2 3+ (n=15/2%) and ER-/PR-/HER2 3+ tumors (n=20/3%), respectively (p=0.02).

In univariate analysis, HER2 positive tumors (p=0.017), phenotype classification (p=0.02) and adjuvant treatment (p=0.013) were significant prognostic factors. In multivariate analysis, only patients with HER2 3+ tumors had higher risks of recurrence (hazard ratio [HR], 2.41; 95% CI: [1.06-5.53]; p<0.05) than those with HER2 - tumors.

Discussion
Node-negative, pT1a-b, breast cancer patients overexpressing HER2 have a significant risk of recurrence at 6 years median follow-up. In our series of small breast tumors, HER2 status seems to be a better prognostic factor than ER status. In patients with hormone receptor–positive diseases, HER2 positivity is associated with a worse DFS despite an anti-estrogen treatment.
P2-12-18
A Prognostic Model Based on Node Status, Cathepsin-D and Ki-67
Predict the Outcome of Patients Failing To Achieve Pathological
Complete Response after Anthracycline-Based Neoadjuvant
Chemotherapy for Breast Cancer.
Chen S, Chen C, Yu K, Shao Z. Shanghai Cancer Hospital, Fudan
University, Shanghai, China

Background: Aim of this study was to evaluate factors which
could possibly affect the outcome of patients failing to achieve pathological
complete response (pCR) after anthracycline-based neoadjuvant
chemotherapy (NCT) for breast cancer, and built a prognostic model
to predict disease free survival (DFS) and overall survival (OS).

Material and Methods: We retrospectively collected data of
199 stage II-III breast cancer patients who had failed to achieve
pathological complete response after neoadjuvant chemotherapy in
Shanghai Cancer Hospital. The NCT regimens were NE (nabvblbine
25mg/m2, day 1, 8 and epirubicin 60mg/m2, day 1; every three weeks)
or CEI (cyclophosphamide 600 mg/m2, day 1; epirubicin 60 mg/m2,
day 1 and 5-fluorouracil 600 mg/m2, day 1; every three weeks) for a
median treatment course of 3 cycles. To develop the prognostic model,
variables at baseline(age, menopausal status, tumor size, node status,
ER, PR, and HER-2) and at surgery(tumor size, grade, histotype,
node status, vascular invasion, ER, PR, HER-2, Cathepsin-D, P53,
Topo-IIα, Nm-23, Bcl-2, BAX, MDR, GSTn, PS2, P27, Cyclin D1
and Ki-67) were investigated. Multivariate Cox regression model
and Kaplan-Meier method was used to build the model, and show the
discrimination of DFS and OS in different risk groups.

Results: By multivariate analysis, ≥4 lymph node metastasis (HR=1.9,
P<0.009), Cath-D positive (HR=2.5, P=0.006), and Ki-67 index≥20%
(HR=1.9, P=0.001) at surgery were independent predictors for lower
DFS and OS rate among non-pCR responders. We built a prognostic
scoring model on the basis of these variables, in which ≥4+ nodes,
Cath-D + or Ki-67 index≥20% would contribute 1 point separately
to the risk score. The 5-year DFS rates in low(0 point), intermediate-
low(1 point), intermediate-high(2 points) and high risk groups(3 points)
were 94%, 65%, 43%, and 28%, respectively (Log-rank test p<0.001). The 5-year OS rates in these four groups were 94%, 84%,
66%, and 34%, respectively (Log-rank test p<0.001). Conclusion:
Post-NCT node status, Cathepsin-D and Ki-67 were used to develop a
prognostic model which could simply discriminate patients with poor
prognosis among non-pCR responders after anthracycline-
neoadjuvant chemotherapy, and might help to tailor further individualized treatment strategies.

P2-11-19
Nomogram To Predict Recurrence and To Avoid Unnecessary
Adjuvant Chemotherapy Based on Ki67 Index and ER Status
in Hormone Receptor (HR)-Positive Breast Cancers with Low
Number of Nodal Metastases (≤3) (NCT101273415).
Park YH, Im S-A, Cho EY, Ahn JH, Kim S, Keam B, Han W, Park IA,
Center; Seoul National University College of Medicine

Background: Hormone receptor (HR) positive breast cancers
characterized with ER-associated genes are differentiated luminal B
from luminal A tumors mainly by proliferation genes. According to
NCCN guideline 2011, node positivity has been a main determinant
to decide adjuvant chemotherapy with category 1. However, the
experts’ panel at the St. Gallen Consensus in 2009 do not provides
definite indications to give or withhold chemotherapy in patient
group with intermediate criteria including low numbers (1-3, N1)
of involved lymph nodes. Thus, in cases of limited number of nodal
metastases, the role of biologic factors including Ki67 index needs to
be defined. The aims of this study are to evaluate of Ki67 index as a
useful surrogate marker to predict recurrence and to avoid unnecessary
adjuvant chemotherapy and to develop nomogram based on Ki67
index to determine adjuvant therapeutic options in HR-positive in
N0 and N1 breast cancers.

Patients and Methods: We retrospectively analyzed the
clinicopathologic characteristics and outcomes of 953 postoperative
HR-positive N0 and N1 breast cancer patients between 2004 and 2007
at the Samsung Medical Center. We constructed nomogram based
on Cox regression model using independent factors demonstrated
in multivariate analysis and validated externally in a cohort of 895
patients treated at Seoul National University Hospital.

Results: In Cox regression multivariate analysis, ER–ve/PgR+ve and
Ki67 index were identified as independent factors.

Nomogram base on Cox-regression model showed an AUC of 0.75
(95% CI, 0.72-0.77) in the training set. The validation set showed a
good discrimination with an AUC of 0.63 (95% CI, 0.60-0.66). We
defined low nomogram score as less than 53, and high nomogram
score as 53 or more from the cut-off value of the nomogram ROC
curve. Patients who received anthracycline-containing adjuvant
chemotherapy with high nomogram scores showed better DFS with
statistical significance than those who did not receive anthracycline-
containing adjuvant chemotherapy with high nomogram scores
(p<0.0001). In contrast, the patients with low nomogram scores
did not show any benefit from anthracycline-containing adjuvant
chemotherapy (p=0.804). When the patients with high nomogram
scores divided into two groups according to Allred ER scores (0-4 vs
5-8), the patients with high ER Allred scores (5-8) and high nomogram
scores did not show any benefit from anthracycline-containing
chemotherapy (p=0.283). Main benefit from adjuvant chemotherapy
is focused on the patients with low ER Allred scores (0-4) and high
nomogram score (p=0.022).

Conclusion: Ki67 index is useful as a valuable surrogate marker
to predict recurrence and to avoid unnecessary chemotherapy.
Nomogram based on Ki67 index is constructed and validated to
determine adjuvant therapeutic options in HR-positive N0 and N1
breast cancers.

P2-12-20
Adjuvant! Online is Overoptimistic in Predicting Survival of
Asian Breast Cancer Patients.
Blaho Pathy N, Yip CH, Hartman M, Saxena N, Taib NA, Bulgiba AM,
vander Graaf Y, Verkooijen HM. University of Malaya; University
Medical Center Utrecht; Ministry of Health Malaysia; National
University of Singapore; Karlinska Institute

Background: Adjuvant! Online is a free web-based tool which
dicts 10-year breast cancer outcomes and efficacy of adjuvant
therapy in patients with breast cancer. As its prognostic performance
has only been validated in high income Caucasian populations, the
model was validated in a middle income Asian setting.

Material and Methods: Within the University Malaya Hospital-Based
Breast Cancer Registry, all 631 women receiving standard
surgery for invasive non-metastatic breast cancer between 1993 and
2000 were identified. Calibration of Adjuvant! Online was evaluated
Adjuvant! Online performed fairly in terms of discrimination, with an area under ROC curve of 0.73 (95% CI: 0.69-0.77).

Conclusion: Even though Adjuvant! Online is capable of discriminating between good and poor survivors, it systematically overestimates survival. These findings suggest that the model requires adaptation prior to use in Asian settings.

### P2-12-21

**Impact of Recent Parity on Histopathological Tumor Features and Outcome of Young Women with Breast Cancer.**

Nagatsuma AK, Shimizu C, Tsuda H, Saji S, Hojo T, Sugano K, Fujiwara Y. National Cancer Center Hospital; Satama Medical University International Medical Center; Tochigi Cancer Center Research Institute

**Background:** Younger age has been associated with worse outcome in breast cancer patients (pts) and recent parity has been epidemiologically identified as worse prognostic factor among women with breast cancer. The objective of this study was to explore potential factors associated with worse prognosis in young breast cancer pts, and to demonstrate the impact of parity on the histopathological tumor feature and patient outcome.

**Materials and Methods:** We retrospectively analyzed 634 early breast cancer pts younger than 45 years old who underwent surgery between 2000 and 2009. For statistical analysis, Pearson’s and Fisher’s exact test were used. Survival analysis was performed only for pts diagnosed before 2006 in order to obtain a minimum follow up 5 years. **Results:** 108 women were diagnosed within 5 years since last parity (Group A), 216 were diagnosed > 5 years since last parity (Group B) and 310 were nulliparous (Group C). Median age at diagnosis was 37 (range 26-44), 41 (range 32-44), and 38.5 (range 22-44) and family history (FH) of breast and/or ovarian cancer within second degree was found in 23, 22, and 23% of the pts in Groups A, B, and C, respectively. In Groups A, B and C, clinical stage was III in 22, 10 and 12% (p = .025), ER was positive in 65, 69 and 70% (p = .650), PgR was positive in 64, 75 and 74% (p = .057), and HER2 was positive in 25, 14 and 14% (p = .017), respectively. In Group A had higher histological grade (grade 3: 60/44/47%, p = .019), higher nuclear grade (grade 3: 61/47/48%, p = .036) and more lymph vessel invasion (61/52/45%, p = .015) compared to those in Groups B and C, respectively. Median follow up time was 85.1 months (range 1.8-137.1 months) during which there were 61 deaths. In univariate analysis, age and FH were not correlated with overall survival (OS). OS in Group A was significantly lower than in Group B (hazard ratio (HR) 3.51, 95% confidential interval (CI) 1.80-6.84, p<.001) and in Group C (HR 2.42, 95% CI 1.36-4.29, p=.002), while OS did not differ significantly between Groups B and C. In the pts without FH, the HR of cancer death was more pronounced in Group A than in Group B (HR 4.25, 95% CI 1.97-9.14, p<.001) or Group C (HR 2.67, 95% CI 1.43-5.01, p=.002), while there was no significant difference among the groups in pts with FH. In multivariate analysis among the pts without FH, lymph vessel invasion (HR 4.51, 95% CI 1.89-10.76, p=.001), Group A women (HR 2.28, 95% CI 1.25-4.17, p=.007), histological grade 3 (HR 2.72, 95% CI 1.28-5.77, p=.009), PgR negativity (HR 2.23, 95% CI 1.19-4.18, p=.013) and clinical stage II and III (HR 2.92, 95% CI 1.04-8.21, p=.04) were significantly associated with poor prognosis, adjusting for age.

**Conclusion:** Recent parity was associated with worse histopathological features in breast cancer of women younger than 45. It was also associated with worse outcome, especially among pts without FH. Recent parity seems to be a confounding factor for the worse outcome in young breast cancer patients, which justifies further studies to elucidate underlying biology.

### P2-12-22

**A Prognostic Index Composed of Progesterone Receptor Status, Tumour Size and S-phase Fraction, Predicts Survival in Node-Negative Breast Cancer Patients in a Large Multicentre Prospective Cohort Study.**

Klintman M, Nilsson F, Bendahl P-O, Fernö M, Liljegren G, Emdin S, Malmström P. Clinical Sciences, Lund University and Skane University Hospital, Lund, Sweden; University of Umeå and Umeå University Hospital, Umeå, Sweden; Örebro University Hospital, Örebro, Sweden

**Background:** The importance of the added prognostic value of proliferation, either single factors such as Ki67 or flow cytometric S-phase fraction (SPF), or as the main common denominator in the majority of gene expression profiles, has been highlighted over the last years in node-negative breast cancer. There are however few published prospective studies. In an earlier retrospective study on node-negative breast cancer from our group, a prognostic index consisting of PR status, tumour size and a proliferation factor, SPF, identified one third of the patients as high risk, with a fourfold increased risk of distant recurrence. The present study was set up to validate this index in a large prospective multicenter cohort study with long term follow-up.

**Material and Methods:** 596 patients from 3 regions in Sweden were between 1991-1995 included in the study. Inclusion criteria were: 10mm≤tumour size≤50mm, node-negativity, ≥5 lymph nodes
removed, age <60 years, and radical surgery. Patients with bilateral breast cancer or previous malignancy were excluded. Prospective analyses of ER, PR, and flow cytometric SPF were performed. High-risk was defined as 2 or more of the following: 1. size ≥20mm 2. PR- (in the absence of PR status, ER-) and 3. high SPF (in the absence of SPF, Bloom Richardson grade 3). 82% of the patients received no adjuvant medical treatment. Cox proportional hazards regression, stratified for centre, was used to model the impact of the index on breast cancer specific survival (BCSS). Median follow-up was 16 years for the 452 patients alive at last follow-up. Analyses were done after 5 and 10 years follow-up, during which 42 and 95 patients, respectively, died of breast cancer. Results: 31% of the patients were identified as high-risk. In univariate analysis, the index was prognostic for BCSS after 5 years (HR 5.1, 95%CI: 2.7-9.8) as well as 10 years (HR 2.2, 95%CI: 1.5-3.4). The prognostic impact remained significant after adjustment for adjuvant medical treatment and age. The 5- and 10-year BCSS (95%CI) was 97% (94-98) and 87% (83-90) for low risk patients, compared with 85% (79-89) and 76% (69-81) for high risk patients. In the group with no risk factors (n=218), no patient died of breast cancer during the first 5 years. Proliferation was the strongest factor for BCSS followed by PR and tumour size, both in uni- and multivariate analyses. In multivariate analysis, adjusted for adjuvant treatment and age, the HR for proliferation was 7.5 (95%CI: 3.2-18) after 5 years and 2.5 (95%CI: 1.6-4.0) after 10 years. Discussion: This large prospective multicenter cohort study validates the results from an earlier retrospective study, that a prognostic index consisting of PR status, tumour size and a proliferation factor, SPF, reliably identifies one third of the node-negative patients with a high risk of relapse. The index also identifies an extreme low risk group; patients with no risk factors, with 100% 5-year survival. This group could be spared adjuvant medical treatment, especially chemotherapy. Taken together, this index may be clinically helpful for prognostic considerations and for selection of adjuvant treatment.

P2-12-23
How Should We Assess Tumour Size (T Stage) in Patients with Multicentric/Multifocal Breast Cancer? Results from the NCIC CTG MA.5 Randomized Trial of CEF vs. CMF in Pre-Menopausal Women with Node Positive Breast Cancer.

Bougamin N, Dong B, Hilton JF, Chapman J-AW, Arnaud A, O’Malley F, Nielsen T, Gelmon K, Verushalmi R, Levine M, Bramwell V, Whelan T, Pritchard KJ, Shepherd L, Clemons M, The Ottawa Cancer Center; Ottawa, ON, Canada; Queens University, Kingston, ON, Canada; The Ottawa Hospital, Ottawa, ON, Canada; Mount Sinai Hospital-University of Toronto, Toronto, ON, Canada; Vancouver Hospital and Health Sciences Center, Vancouver, BC, Canada; BC Cancer Agency-University of British Columbia, Vancouver, BC, Canada; Juravinski Cancer Center-McMaster University, Hamilton, ON, Canada; Tom Baker Cancer Center-University of Calgary, Calgary, AB, Canada; Odette Cancer Center-University of Toronto, Toronto, ON, Canada

Background: A common clinical conundrum in breast cancer management is whether pathologic T stage in women with multicentric or multifocal disease should be taken as the diameter of the largest focus or as the sum of all foci in the breast. Most staging systems, such as the American Joint Committee on Cancer (AJCC), simply use the largest tumour focus for staging. We examine here the impact of alternate methods of estimating tumour size including measures of total tumour size, volume and surface area.

Methods: NCIC CTG MA.5 is a randomized trial of CEF versus CMF in pre-menopausal women with node positive breast cancer. Median follow up is 10 years. Pathologically reported patient tumour dimensions for up to 3 foci were utilized to examine the effects of tumour size on Breast-Cancer-Free-Interval (BCFI). BCFI is defined as the time from randomization until recurrence: first local invasive or DCIS, regional, distant, contralateral invasive or DCIS. Tumour size was estimated as 1) pathologic T stage as per AJCC criteria; 2) largest dimension of largest tumour focus (cm); 3) sum of largest dimension(s) of tumour foci (cm); 4) sum of surface area(s) of tumour foci (cm²), and 5) sum of volume of tumour foci (cm³). Step-wise forward unstratified Cox regression was used to assess the different effects of tumour size.

Results: This study accrued 710 patients, 37% with T1 tumours, 52% with T2 tumours and 9% with T3 tumours; 61% had 1 to 3 positive lymph nodes. 59% hormone receptor positive. Higher pathologic T stage (p=0.001) and greater surface area (p=0.02) were associated with shorter BCFI, as was lymphovascular invasion (p=0.03), and # of lymph nodes involved (p=0.0001). Administration of anthracycline therapy led to significantly longer BCFI (0.003). The sum of largest tumour sizes (p=0.33) and sum of tumour volume (p=0.34) were not significantly associated with BCFI. Additionally, when the less complete locally reported tumour grade data were included, higher tumour grade was associated with shorter BCFI (p=0.0001).

Conclusions: Consideration of multicentric and multifocal disease was an important adjunct to standard pathologic tumour size as was estimation of tumour surface area in this chemotherapy trial of node positive premenopausal women. However, simply adding together the diameters of tumours in patients with multicentric or multifocal disease did not add any additional prognostic information in this high risk patient population.

P2-12-24
Resumption or Persistence of Menstruation after Cytotoxic Chemotherapy Is a Poor Prognostic Factor for Disease Free Survival in Premenopausal Patients with Early Breast Cancer.

Park IH, Han H-S, Lee KS, Kang HS, Lee S, Kim SW, Jung SY, Shin KH, Ro J. National Cancer Center, Goyang, Korea; Chungbuk National University, Korea

Background: We investigated the relationship between resumption or persistence of menstruation after chemotherapy and disease free survival (DFS) in premenopausal patients with early breast cancer.

Patients and methods: A total of 843 patients diagnosed with a stage I to III breast cancer between March 2001 and December 2006 were included in this study. All patients received cytotoxic chemotherapy after surgery; 411 (48.8%) with anthracycline based, 416 (49.3%) with anthracycline and taxane containing, and 16 (1.9%) with other regimens. We reviewed the medical records with a long term follow-up.

Results: The median age of patients was 41 years (range, 21-54 years) and the median follow-up duration was 6.2 years (range, 0.7-10.4 years).

</table>

Of all, 632 (75%) patients were hormone receptor (HR) positive who received tamoxifen therapy upon completion of chemotherapy. The chemotherapy induced amenorrhea (CIA) rate was 78.1% (n=658) and 52.4% (n=442) experienced the resumption of the long term follow-up. One hundred two (12.1%) patients had persistent menstruation without CIA. The disease free survival (DFS) was significantly affected by the young age (≤35 years) (HR=1.58, [95% CI, 1.10-2.70], P=0.014), advanced stage (stage 3) (HR=4.45, [95% CI, 3.17-6.25], P<0.001), HER negativity (HR=2.21, [95% CI, 1.57-3.12], P<0.001), HER2 positivity (HR=1.56, [95% CI, 1.04-3.24], P=0.032), and the resumption or persistent period (HR=2.03, [95% CI, 1.42-2.91], P<0.001). HR negativity (HR=2.03, [95% CI, 1.43-2.90], P<0.001), advanced stage (HR=4.40, [95% CI, 3.12-6.21], P<0.001), and the resumption or persistent period (HR=1.85, [95% CI, 1.24-2.77], P=0.002) were remained significant factors for DFS on multivariate analysis.

Conclusions

A considerable proportion of premenopausal patients treated by chemotherapy experienced resuming period after CIA. The resumption or persistence of menstruation was a poor prognostic factor for disease free survival in premenopausal patients with early breast cancer.

P2-12-25
Blinded Multi-Site Validation of a Pathology-Based Prognostic Marker Profile for Operable Hormone Receptor-Positive Breast Cancer.
Linke SP, Bremer TM, Man AK, Bloom KJ, Lawton TJ. Prediction Sciences, La Jolla, CA; Clarient, Inc., Aliso Viejo, CA; Seattle Breast Pathology Consultants, Seattle, WA

Background: We previously reported development and preliminary validation of a marker profile with a risk of recurrence algorithm for patients with operable hormone receptor (HR)-positive breast cancer using tissue microarrays. The profile includes ER, PR, HER2, EGFR, BCL2, and p53 (assessed by IHC) and MYC/Bq24 (assessed by FISH). It also directly incorporates the standard clinicopathologic risk factors tumor size, tumor grade, and nodal status to the extent that their prognostic value is not replaced by the molecular markers. Here, we demonstrate validation of the profile in a blinded multi-site study conducted on whole sections.

Material and methods: The study was conducted in a blinded fashion using an independent data management firm (Synteract, Carlsbad, CA). Eligible patients were females diagnosed between 1985 and 1997 with HR-positive stage I-IIIA breast cancer treated only with hormone therapy after definitive surgery for whom sufficient tumor samples were available for testing. Slides with FFPE tumor tissues and associated clinicopathologic, treatment, and outcome data were provided by four clinical sites through the NCI-funded Cooperative Breast Cancer Tissue Resource program: Fox-Chase Cancer Center (Philadelphia, PA) (n=106), Kaiser Permanente Northwest (Portland, OR) (n=165), University of Miami (FL) (n=55), and Washington University St. Louis (MO) (n=74). Marker assays, scoring, and calculation of risk scores using a predefined algorithm were conducted at Clarient, a CLIA-certified laboratory. The algorithm assigned a risk score to each patient on a scale of 0 to 10+, and a predefined threshold of 3.8 was used to separate patients into low and high risk groups.

Results: Complete data for all seven markers was obtained in 349 of the 400 patients. The algorithm defined 28% of the patients (n=99) as high-risk and 72% of the patients (n=250) as low-risk. The high-risk and low-risk patient groups had 10-year distant metastasis rates of 34% and 9%, respectively, resulting in a hazard ratio of 4.7 (95% CI, 2.3-7.8, p<0.0001) through 10 years without an intermediate-risk group. Similar results were achieved when using disease-specific survival (death with evidence of breast cancer recurrence) as the outcome. Using a standard threshold score of 3.4, the Nottingham Prognostic Index (NPI) also stratified the patients (n=349) into low and high risk groups (p=0.03), but only 10% of the patients were in the low-risk category, and the profile further risk stratified patients in the NPI intermediate and high risk categories similar to the overall patient set (p<0.001). In multivariate Cox proportional hazards analysis with clinicopathologic factors, only the profile and tumor size were significant (Wald statistic p=0.001 for both).

Discussion: This blinded study, using a predefined algorithm and threshold, validates the prognostic and clinical utility of the multi-marker profile to help guide the appropriate level of adjuvant treatment in breast cancer patients.
P2-12-26

Rezai M, Eiermann W, Kümmel S, Kühn T, Warm M, Friedrichs K, Schneeweiss A, Markmann S, Eggemann H, Hilfrich J, Jackisch C, Witzel I, Eidmann H, Kaufmann M, Blohmer JU, Lüsenkranzhaus, Düsseldorf, Germany; Rotkreuzklinikum, München, Germany; Klinikum Essen-Mitte, Essen, Germany; Klinikum Esslingen, Esslingen, Germany; Krankenhaus Holweide, Köln, Germany; Brustzentrum, Hamburg, Germany; Universitätsklinikum, Heidelberg, Germany; Universitätsklinikum, Rostock, Germany; Universitätsklinikum, Magdeburg, Germany; Eilenriedeklinik, Hannover, Germany; Klinikum Offenbach, Offenbach, Germany; Universitätsklinikum Eppendorf, Hamburg, Germany; Universitätsklinikum, Kiel, Germany; Universitätsklinikum, Frankfurt, Germany; Sankt Gertrauden-Krankenhaus, Berlin, Germany

Background: Oncotype DX® has become part of clinical routine in the diagnosis and decision-making progress in early breast cancer (EBC). Prospective data on its clinical use and impact on treatment decisions in ER-positive (ER+) node negative (N0) disease from various controlled clinical trials in different countries have been published recently. The Recurrence Score® (RS) has also been validated as a prognostic and predictive marker for patients with ER+ node positive (N+) disease. As of today no prospective data have been reported on its impact on decision making in these patients. We performed a large prospective study to evaluate RS-guided adjuvant therapy in N0 and N+ ER+ EBC.

Material and Methods: Patients (pts) with ER+, HER2-negative N0 and N+ (1-3 positive lymph nodes) EBC and no contraindication for adjuvant chemotherapy were included in the study. Physicians’ adjuvant treatment recommendations and their confidence in these as well as patients’ decisional conflicts were assessed before and after knowledge of the results of the test using standardized questionnaires. Actual treatment data were collected to perform pharmacoeconomic analyses. Analyses were performed on the per-protocol population for whom a Recurrence Score result and treatment recommendations pre and post-test were available.

Results: Overall 379 pts were recruited. In 11 pts Oncotype DX could not be performed and 2 pts dropped out leaving 366 pts in the per protocol population. Of these, 244 (66.7%) were N0 and 122 (33.3%) N+. Median age was 56 years (Range 25-85). Overall, 54.1% had low, 38.0% intermediate and 7.9% high RS values. For N0 disease, the distribution of RSs was 53.7%, 38.9%, 7.4% and for N+ disease 54.9%, 36.9% and 9.0%, respectively.

Initial treatment recommendation changed in 33.1% of all cases; 30.3% in N0 and 38.5% in N+ disease, and in 36.4% for pts with low, 30.9% with intermediate and 20.7% with high RSs. In 21.6% of all pts a recommendation for adjuvant chemotherapy was changed from HT to CHT. For N0 disease change rates were 18.4% from CHT to HT and 11.5% from HT to CHT. For N+ disease 27.9% of recommendations changed from HT to CHT and 9.0% of recommendations changed from CHT to HT. In 25% of all, 22% of N0 and 39% of N+ pts initially recommended HT the post-RS recommendation changed to CHT; in 32% of all, 39% of N0 and 37% of N+ pts initially recommended CHT the recommendation changed to HT.

Overall, physicians’ confidence increased in 45.1% of all (p=0.047) and 44.7 of N0 and 45.9% of N+ cases, respectively. There was a moderate decrease of the decisional conflict score in all pts and subgroups that reached statistical significance for all pts (p=0.029) and the low RS subgroup (p=0.003).

Conclusions: Results of this large prospective study show an impact of the RS on adjuvant treatment decision making in German clinical practice for patients with ER+ EBC. Recommendations were predominantly changed from chemoendocrine to endocrine adjuvant therapy resulting in a net reduction of chemotherapy usage. This effect was more pronounced for patients with 1-3 positive nodes.

P2-12-27
Simply Adding Together the Diameters of Tumor Foci in Patients with Multicentric or Multifocal Disease Does Not Add Any Additional Prognostic Information: An Analysis from NCIC CTG MA.12 Randomized Placebo-Controlled Trial of Tamoxifen after Adjuvant Chemotherapy in Pre-Menopausal Women with Early Breast Cancer.

Hilton JP, Dong B, Bouganin N, Chapman J-AW, Arnaout A, OMalley F, Nielson T, Gelmon K, Yerushalmi R, Levine M, Bramwell V, Whelan T, Priehardt KI, Shepherd L, Clemmons M, Queens University, Kingston, ON, Canada; The Ottawa Hospital, University of Ottawa, Ottawa, ON, Canada; Mt. Sinai Hospital, University of Toronto, Toronto, ON, Canada; Vancover Hospital and Health Sciences Centre, University of British Columbia, Vancouver, BC, Canada; BC Cancer Agency, University of British Columbia, Vancouver, BC, Canada; Juraviski Cancer Centre, McMaster University, Hamilton, ON, Canada; Tom Baker Cancer Centre, University of Calgary, Calgary, AB, Canada; Odette Cancer Centre, University of Toronto, Toronto, ON, Canada

Background: A common clinical conundrum in breast cancer management is whether pathologic T stage in women with multicentric or multifocal disease should be taken as the diameter of the largest focus or as the sum of all foci in the breast. Most staging systems, such as the American Joint Committee on Cancer (AJCC), simply use the largest tumor focus for staging. We examine here the impact of alternate methods of estimating tumour size including measures of total tumor size, volume and surface area.

Materials & Methods: NCIC CTG MA.12 is a randomized placebo-controlled trial of tamoxifen after adjuvant chemotherapy for pre-menopausal women with early breast cancer. Median follow up is 9.7 years. Pathologically reported patient tumor dimensions for up to 3 foci were utilized to examine the effects of tumor size on Breast-Cancer-Free-Interval (BCFI), defined as the time from randomization until recurrence (defined as first local, regional, distant, or contralateral invasive tumor or DCIS). Tumor size was estimated as 1) pathologic T stage as per AJCC criteria; 2) largest dimension of largest tumor focus (cm); 3) sum of largest dimension(s) of tumor foci (cm²); 4) sum of surface area(s) of tumor foci (cm²), and 5) sum of volume of tumor foci (cm³). Step-wise forward unstratified Cox regression was used to assess the different effects of tumor size.

Results: This study accrued 672 patients, 43% with T1 tumors, 51% with T2 tumors, and 6% with T3/T4 tumors; 25% were node negative and 56% had 1-3 positive lymph nodes. 75% were locally determined to have hormone receptor positive tumors. A higher number of involved lymph nodes was associated with significantly shorter BCFI (p<0.0001). None of pathologic T stage (p=0.14), largest dimension of largest tumor size (p=0.14), sum of largest dimension(s) of tumor foci (cm); 4) sum of surface area(s) of tumor foci (cm²), and 5) sum of volume of tumor foci (cm³). Step-wise forward unstratified Cox regression was used to assess the different effects of tumor size.

Discussion: In the MA.12 population of pre-menopausal women randomized to either tamoxifen or placebo, the sole factor significantly
associated with BCFI was nodal status. No measure of tumor size in unifocal or multicentric/multifocal tumors impacted BCFI. The findings of this mature data set suggest that simply adding together the diameters of tumors in patients with multicentric or multifocal disease did not add any additional prognostic information.

P2-12-28
Studies of a Malignancy-Associated Protein, Osteopontin, in NCIC CTG MA.14, a Randomized Trial of Tamoxifen Versus Combined Tamoxifen and Octreotide LAR in Adjuvant Treatment of Women with Early Breast Cancer.
Bramwell VH, Tuck AB, Chapman J-A, Anborgh PH, Postenka CO, Shepherd L, Pritchard KJ, Han L, Wilson C, Pollak M, Chambers AF. Tom Baker Cancer Centre, Calgary, AB, Canada; London Regional Cancer Program, London, ON, Canada; NCIC Clinical Trials Group, Kingston, ON, Canada

Background: We have shown, in women with metastatic breast cancer (BC), that high baseline plasma osteopontin (OPN) levels and increases over time are associated with poor survival. In primary BC, increased immunohistochemical (IHC) expression of OPN in tumour is associated with poorer survival and is elevated in lymph node metastases relative to primary tumour. Our current study evaluates tumour and baseline/serial plasma OPN levels after resection of primary BC.

Methods: In NCIC CTG MA.14, 667 postmenopausal women post surgery received 5 yrs Tamoxifen (T) +/- 2 yrs monthly Octreotide LAR. There were no differences in survival outcomes between arms. OPN was assayed by IHC in primary BC. OPN was measured in plasma at baseline (up to 4 mos post randomization) and serially in recurrent (18 mos time window) versus non-recurrent cases, by ELISA. Statistical Analysis: IHC and plasma OPN had Box-Cox variance stabilization transformations (power 0.5; logarithm). Descriptive characterization of both OPN measurements is provided for all patients, by baseline patient and tumour characteristics, and by recurrence status. Univariate stratified log-rank statistics and hazard ratios with 95% CI were generated for intention to treat (ITT), event for free survival (EFS), relapse fee survival (RFS), overall survival, and for other clinical and pathological potential covariates by Cox regression was used, with factor added if p<0.05.

Results: From 667 MA.14 patients, 647 patients were assessed for OPN: 462 (69%) by IHC; 387 (58%) at baseline in plasma (with 2,542 samples total from serial sampling), IHC % tumor positivity had mean 33.9% (95% CI 30.2%-37.9%), while baseline plasma OPN was mean 46.1 (44.6-47.6) ng/ml. In 80 women with recurrence, mean OPN during the recurrence window was 60.7 (52.8-69.8) ng/ml. Neither baseline IHC or plasma OPN levels were significantly associated with any of the endpoints in either univariate or multivariate analyses. Older age (p=0.02), greater nodal involvement (p=0.001), higher baseline body mass index (p<0.0001), and higher tumour grade (p=0.0001) were multivariately associated with shorter EFS. Baseline plasma OPN was not correlated with IHC OPN (Pearson 0.02, p=0.73).

Discussion: Mean baseline OPN plasma level 46.1 ng/ml (median 45 ng/ml) in MA.14 was similar to our previous findings in healthy women (median 47 ng/ml). In contrast, we previously showed that 63% of 158 women with a new diagnosis of metastatic BC had elevated OPN levels with median value 177 ng/ml. Our results thus far suggest that tumor and plasma levels, while associated with prognosis in metastatic BC, may not be so in primary BC following surgery. However, in MA.14, the 80 women with recurrent BC had significantly higher mean OPN in the recurrence window, 60.7 ng/ml, than at baseline. We will present further analyses exploring this finding.

Pre-Operative Haematological Markers and Prognosis in Early Breast Cancer.
Cordiner RL, Mansell J, Obondo C, Angerson WJ, Lannigan A, McMillan D, Wilson CR, Doughty JC, Western Infirmary, Glasgow, United Kingdom; Wishaw General Hospital, Wishaw, United Kingdom

Background: Systemic inflammation may influence survival in women with breast cancer. Both the platelet lymphocyte ratio (PLR) and the neutrophil lymphocyte ratio (NLR) have been shown to be associated with survival in a number of solid tumours. The aim of this study was to assess the role of PLR and NLR in survival of women with early breast cancer.

Methods: Women diagnosed with early breast cancer at two centres between 2003 and 2006 were included. All women had measured white cells, neutrophils, lymphocytes and platelets. NLR and PLR were calculated. Cox regression survival analysis was performed with breast cancer specific survival used as the primary end point. Significant associations of NLR and PLR with pathological variables was assessed using the Chi squared test.

Results: 707 women were included with a median follow up of 3.7yrs. On univariate analysis neither NLR (HR 1.08, 95% CI 0.66-1.79) or PLR (HR 0.96, 95% CI 0.58-1.59) were significantly associated with breast cancer specific survival. An increased PLR was found to be associated with significantly fewer grade 1 tumours (P<0.05) but no other significant associations with pathology was demonstrated for either PLR or NLR.

Conclusions: This study would suggest that the NLR and PLR are not prognostic of survival in women with early breast cancer.

P2-12-31
Moderate Immunohistochemical Expression of HER2 (2+) without HER2 Gene-Amplification Is a Negative Prognostic Factor in Early Breast Cancer.
Rossi V, Sarotto I, Maggiorettro F, Tomasi Cont N, Redana S, Aglietta M, Ponzone R, Montemurro F, Institute for Cancer Research and Treatment IRCC, Candiolo, Turin, Italy

Purpose
We sought to evaluate whether moderate HER2 immunohistochemical (IHC) expression (2+ and no HER2/amplification) identifies early breast cancer (EBC) with a distinct prognostic profile.

Methods
A total of 1295 women (median age 58, range 22-94) undergoing surgery for EBC from Jan 1995 to Sept 2009 were retrospectively reviewed. All patients had undergone HER2 testing by the HercepTest and, when needed, by fluorescence in-situ hybridization (FISH). All tests were carried out at our Institutional Surgical Pathology laboratory. The impact of HER2 status on disease-free survival (DFS) was corrected for other clinical and pathological potential covariates by Cox Proportional Regression Analysis.

Results
A total of 494 (38%), 486 (38%), 119 (9%) and 196 (15%) of the patients had HER2 0+, 1+ 2+ and positive (3+ or FISH+) tumors, respectively. Sixty-one of 196 patients with HER2-positive EBC received adjuvant trastuzumab. A total of 298 DFS events occurred at median follow-up of 59 months (4-137 months). By using HER2 0+ status as reference, multivariate analysis revealed that HER2 2+ expression was associated with a significant increase in the risk of
a DFS event (HR 2.303, 95% CI 1.501-3.533, p<0.001), whereas HER2 1+ was not (HR 0.976, 95% CI 0.698-1.365, p=0.889). We performed exploratory two-group comparisons by further classifying tumors according to hormone-receptor status (cutoff for ER and PgR positivity ≥10% of stained cells). Results are summarized in the table. HER2 2+ expression was associated with worse prognosis in both ER and/or PgR positive and ER/PgR negative tumors. In the latter group, HER2 2+ expression was associated with a particularly high rate of DFS events, with a 60-month projected DFS of 20%. Furthermore, while DFS curves plateaued at 60 months for HER2-positive tumors (with and without adjuvant trastuzumab) and for ER/PgR negative tumors with HER2 0/1+ expression, hormone receptor positive/HER2 2+ tumors displayed a particularly high rate of late relapses (beyond 60 months). Results did not change using a 1% cutoff to define ER and PgR positivity.

Conclusion

Moderate HER2 positivity (IHC 2+/FISH negative) identifies EBC and PgR positivity.

Her2 2+ tumors displayed a particularly high rate of late relapses (beyond 60 months). Results did not change using a 1% cutoff to define ER and PgR positivity.

P2-12-32

Association between Progranulin (GP88) Expression and Recurrence Risk for Breast Cancer Patients with Estrogen Receptor Positive Invasive Ductal Carcinoma.

Serrero G, Hawkins DM, Joffe O, Bejarano P, Phillips JT, Head JF, Elliott RL, Godwin AK, Weaver J, Yue B. A&G Pharmaceutical Inc, Columbia, MD; University of Minnesota, Minneapolis, MN; University of Maryland, Baltimore, MD; University of Miami, Miami, FL; EEH Breast Cancer Research and Treatment Center, Baton Rouge, LA; University of Kansas Medical Center, Kansas City, KS; Fox Chase Cancer Center, Philadelphia, PA.

Purpose:

GP88 (progranulin) is a critical player of breast tumorigenesis for estrogen receptor positive (ER+) breast cancer. Pathological studies showed that GP88 was expressed in invasive ductal carcinoma (IDC), but not in normal mammary tissue, benign lesions or lobular carcinoma. The present study examines GP88 prognostic significance in association with recurrence risk for patients with ER+ IDC.

Patients and Methods:

Two retrospective multi-site clinical studies examined GP88 expression by immunohistochemistry (IHC) analysis in paraffin-embedded tumor tissues in correlation with patients’ survival outcomes. The training study established a GP88 cut-off value associated with decreased disease-free (DFS) and overall (OS) survivals. The validation study verified the GP88 cut-off value and compared GP88 prognostic information with other prognostic factors in multivariate analysis.

Results:

GP88 expression is associated with a statistically significant increase in recurrence risk for ER+ IDC patients. The training study established that GP88 3+ score by IHC analysis was associated with decreased DFS (p=0.0004) and OS (p=0.0036). The independent validation study verified that GP88 3+ score for the high risk group and demonstrated that GP88 3+ score was associated with a 5.9-fold higher hazard of disease recurrence and a 2.5-fold higher mortality hazard compared to patients with tumor GP88≤3+. GP88 remained an independent risk predictor after considering age, nodal status, tumor size, tumor grade, progesterone receptor expression, treatment and disease stage.

Conclusion:

Our training and validation studies demonstrate that the survival factor GP88 is a prognostic biomarker, predictive of recurrence risk and increased mortality for ER+ IDC patients, independent from other prognostic factors. These results provide support for measuring GP88 tissue expression for newly diagnosed early stage breast cancer patients.

Gene Profiling of Whole Blood May Identify Patients with BRCA Mutations.

Mina LA, Gokmen-Polar Y, Goswami C, Storniolo AM, Li L, Badve S, Sledge GW. Indiana University School of Medicine, Indianapolis, IN.

Background: The BRCA1 and the BRCA2 proteins play a role in DNA repair and confer genomic stability to the cell. Identifying BRCA mutation carriers has become an important tool for prevention as well as guiding therapy in cancer patients. We proposed to test the hypothesis that gene expression analysis of peripheral whole blood can reliably detect these mutations.

Materials and methods:

Following IRB approval, 10cc of blood was collected from 36 women (BRCA1 (n=8), BRCA2 (n=9), Hereditary breast cancer without BRCA (FAM) (n=7), sporadic breast cancer (SPO) (n=11)). 3 of BRCA1 and 5 of BRCA2 samples were from women without cancer. Following RNA extraction (using the method described by Beckman et al) and quality assessment, Illumina® Whole-Genome DASL™ microarray (Human Ref-8 BeadChips) analysis was performed. The raw data was normalized and analyzed using Partek® Genomic Suite. Differentially expressed genes were identified using ANOVA analysis. Geneset specific supervised analysis was performed to visualize the inherent similarities and differences in the gene expression amongst different groups for 1) DNA repair and 2) Immune-system-related genes. Ingenuity Pathway Analysis (IPA) was performed to interpret the data in the context of biological processes, pathways and networks.

Results:

Twenty-nine of the 87 immune-related genes were up-regulated in BRCA1 and BRCA2 groups compared to SPO or FAM groups; these included IL7R, CD53, CD2, CD48 and HLA-DRA. Twenty-five of the 79 DNA repair genes were up-regulated in BRCA1 and BRCA2; these included FANCC, RAD51L3, MSH2, MSH6 and PCNA. In IPA analysis, the comparison of BRCA1 vs. REST (BRCA2 + FAM + SPO) showed a strong immunologic signal, with the top altered biological processes including “Immunologic disease”, “Infection mechanism”, “Immune cell trafficking” and “cell-mediated immune response”. The top 5 canonical pathways also reflected a similar pattern and included “ICOS-ICOSL Signaling in T Helper Cells”, “OX40 Signaling Pathway”, “Calcium-induced T Lymphocyte”, “Apoptosis Regulation of IL-2 Expression in Activated and Anergic...”
T Lymphocytes” and “Protein Ubiquitination Pathway”. When BRCA2 was compared with the REST (BRCA1 + FAM + SPO), a much weaker signal was noted with none of the canonical pathways being significantly altered. PAM analysis showed that a set of 16 genes could differentiate the BRCA patients from the rest with an error rate of 5%. Further validation of this genaset is being performed.

Conclusion:
Gene profiling in whole blood may offer an easy, reliable and inexpensive way to identify patients with BRCA mutation. Further studies are currently underway to validate our results in a larger patient population.

P2-13-02
Parent of Origin of BRCA Mutation May Determine Age at Breast Cancer Diagnosis.
Shapira I, Budman DR, Akerman M, Weiselberg L, Vinciguerra V, D’Olimpio J, Devoe C, Cheng KL, Donahue L, John V, Cohen S. Hofstra North Shore LIJ School of Medicine, Lake Success, NY; Feinstein Institute for Medical Research, Manhasset, NY

Background
Genetic diseases may display parent-of-origin effects. In such cases, the risk depends on the specific parent or origin allele. Imprinting effect is evident in autosomal dominant hereditary paraganglioma leads to tumors only if inherited from paternal germline. Cancer penetrance in mutations carriers may be determined by the parent origin of BRCA mutation.

Methods
From 2007-2010 we analyzed 1889 consecutive (136 ovarian + 1753 breast) breast (BrCa) or ovarian cancer (OvCa) patients presenting for treatment at our outpatient facility. In 130 patients with BRCA 1 or 2 mutations the parent of origin for the mutation was known. Of the 130 patients 2 had both BRCA1 and BRCA2 mutated paternal inherited and were excluded from this analysis. Of the breast cancer patients: 28 patients had paternal and 29 had maternal BRCA1 mutations, 24 had paternal and 21 had maternal BRCA2 mutations. Of the ovarian cancer patients 6 had paternal and 10 had maternal BRCA1 mutations, 7 had paternal and 3 had maternal BRCA2 mutations. In carriers of BRCA mutations the mean age at diagnosis for ovarian cancer was 51 (range 21-70) and for breast cancer was 43 (range 24-78).

Two-sample t-test was used to compare the mean age at diagnosis in patients with BRCA 1 or 2 mutations of paternal or maternal inheritance.

For breast cancer maternal allele versus paternal allele 2-sample t-test and p-value were compared for the age at first diagnosis. For breast cancer patients BRCA1 maternal inheritance (mean±SD yrs) 45.73±11.22 versus paternal inheritance 38.04±7.14 2-sample t-test p-value p<0.0020. For breast cancer BRCA2 maternal inheritance (mean±SD yrs) 50.65±10.44 versus paternal inheritance 41.68±6.16, 2-sample t-test p-value p<0.0008.

Results:
Significantly younger age at breast cancer diagnosis was observed in paternal vs. maternal inheritance of BRCA1 mutation (38 vs 46, respectively, p=0.0020) and BRCA2 mutation (42 vs 51 respectively, p<0.0008). There was no significant difference between paternal and maternal age of ovarian cancer diagnosis of BRCA1 (p=0.1415) or BRCA2 mutation (p<0.3470).

Conclusion:
The restrospective nature of the study may introduce ascertainment bias. However, the breast and ovarian cancers cases in BRCA1 & 2 carriers with maternal or paternal inheritance mirror the Mendelian autosomal dominant pattern in our unselected consecutive cohort of patients. Maternal and paternal inherited BRCA alleles may not be exchangeable. Women with paternally inherited mutations in BRCA gene mutations develop breast cancer at younger age compared with women who inherit the gene mutations from their mothers. In this small sample, clear differences at age of cancer diagnosis are apparent in paternal inheritance of BRCA gene mutation. If this observation duplicates in larger cohorts results will have important implications for recommendation of surgical risk reduction in BRCA mutation carriers.

Beattie MS, Ganschow P, Gabram-Mendola S, Wilson A, Joseph G, Lee R, Loranger K, Stanislav C, Seelaus C, Farrell R, Trim L, DelPozo S, Luce J. University of California, San Francisco, CA; San Francisco General Hospital, San Francisco, CA; Stroger Hospital of Cook County, Chicago, IL; Rush University Medical Center, Chicago, IL; Emory University, Atlanta, GA; Grady Memorial Hospital, Atlanta, GA

Background: Underserved women at risk for Hereditary Breast and Ovarian Cancer (HBOC) are confronted with many unique challenges, such as barriers to accessing appropriate genetic testing and counseling services and decreased resources, that place them increased cancer risk. It is unclear whether these high-risk women are appropriately referred for genetic counseling and what their genetic test results demonstrate due to minimal practice-based evidence. To study this population, and to establish an infrastructure to further explore long-term outcomes, we formed the Consortium of Underserved BRCA testers in October 2010 from: San Francisco General Hospital (SF), Stroger Hospital of Cook County (Chicago), and Grady Memorial Hospital (Atlanta).

Methods: Using common clinical and research protocols and mixed methods analysis, we examined and compared referral patterns, demographics, and BRCA test results between sites. We used chart reviews and common data collection instruments to gather and pool data. Using descriptive and comparative statistics, we examined similarities and differences between Consortium sites.

Results: SF’s program began 9 years ago, Chicago’s began 6 years ago, and Atlanta’s began 3 years ago. Medicaid funding for BRCA testing has been available in SF since 2011, in Chicago since 2009, and is not yet available in Atlanta. P values were all <0.05 for comparing referral sources between sites. Each site uses unique referral tools and systems. For example, in SF, a family history screening questionnaire is administered during mammography; in Chicago, an extensive primary care network has been educated to refer patients for genetic counseling and what their challenges, such as barriers to accessing appropriate genetic testing and counseling services and decreased resources, that place them at increased risk of breast cancer. It is unclear whether these high-risk women are appropriately referred for genetic counseling and what their genetic test results demonstrate due to minimal practice-based evidence. To study this population, and to establish an infrastructure to further explore long-term outcomes, we formed the Consortium of Underserved BRCA testers in October 2010 from: San Francisco General Hospital (SF), Stroger Hospital of Cook County (Chicago), and Grady Memorial Hospital (Atlanta).

Conclusions: Despite differences in referral patterns and Medicaid funding, underserved women at all 3 public hospital sites had similar BRCA positive rates, which are in line with positive rates from University Cancer Centers. We believe this relates to the availability of genetic counseling services and a similar testing threshold at each site. The large and ethnically diverse population of this Consortium can serve as a valuable resource for researchers and clinicians. We plan to follow this cohort prospectively to study clinical outcomes and medical decisions after BRCA testing in underserved families at risk of HBOC.

**P2-13-04**

Turco DL, Elsayegh N, Litton J, Hortobagyi GN, Arun B. M.D.

Anderson Cancer Center, Houston, TX

Background: Infiltrating lobular carcinoma (ILC) is the second most common type of invasive breast cancer behind infiltrating ductal carcinoma (IDC). ILC makes up approximately eight percent of all invasive lesions. In addition, the mixed ductal and lobular carcinoma histology makes up approximately seven percent of all invasive diagnoses.

There are several biologic differences that are demonstrated by ILC compared to other common pathologies. They are more frequently bilateral and multicentric. They tend to be seen in women slightly older than the average age of diagnosis and are usually ER positive. It is also known that individuals with a genetic predisposition have an increased risk to develop breast cancers. Women with a mutation in their CDH1 gene have up to a 39% chance to develop ILC. The majority of hereditary breast cancer is caused by germline mutations in the BRCA1 and BRCA2 genes. Women with a mutation in their BRCA1 or BRCA2 gene have up to an 87% risk to develop an invasive breast cancer, however, the presence of ILC in this population has not been well defined. Therefore, the aim of this study is to evaluate the rate of germline BRCA mutations in a cohort of patients both with pure ILC, as well as mixed ILC/IDC.

Methods: A retrospective chart review revealed one hundred and sixty nine women with ILC and mixed ILC/IDC who underwent genetic testing for mutations in the BRCA1 and BRCA2 genes through the Clinical Cancer Genetics Program at M. D. Anderson Cancer Center. Women were referred for genetic testing using referral guidelines based on the NCCN guidelines, this usually involves a personal history of early onset breast cancer and/or a family history of breast and/or ovarian cancer.

Results: Out of the 169 patients, 19 (11.24%) were found to have a germline mutation in their BRCA1 or BRCA2 gene. A significant majority (73.7%) of these patients were BRCA2 positive. Five women tested for a variant of uncertain significance. The average age of diagnosis for the cohort was 55.6 years (range 30-87); while the average age of diagnosis for a positive patient was 49.4 years (range 30-72). Of the 62 women with pure ILC, 5 (8.06%) were positive for a BRCA gene mutation. Historically, out of all the patients with breast cancer referred and tested through the Clinical Cancer Genetics Program, approximately 15% test positive, and research shows that in the general population, 7-10% of breast cancer patients will test positive.

Conclusions: while the positivity rates between the cohorts are not statistically significant, we have shown that patients with a BRCA mutation can develop ILC in addition to the more commonly seen IDC. We suggest that patients continue to be referred for genetic counseling according to the NCCN guidelines, regardless of the pathology of their tumor.

**P2-13-05**

Breast Cancer, BRCA Mutations and Attitudes Regarding Pregnancy and Preimplantation Genetic Diagnosis.

Litton JK, Etzel CJ, Jackson MA, Muse KI, Turco D, Schover LR, Theriault RL, Mattair D, Lu KH, Hortobagyi GN, Arun BK. The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Breast cancer is associated with treatment-related infertility and has been demonstrated to be a major concern for premenopausal survivors. Detection of a BRCA deleterious mutation may also affect attitudes regarding future childbearing. Preimplantation genetic diagnosis (PGD) allows women to use in vitro fertilization (IVF) to implant only those embryos without a BRCA mutation. The ability to test the fetus for BRCA mutations is also available through amniocentesis and chorionic villus sampling (CVS). The objective of this study was to evaluate attitudes about childbearing and fertility in women being evaluated for a BRCA mutation. Methods: Women with childbearing potential who were referred to the Clinical Cancer Genetics Clinic to be evaluated for a BRCA mutation were invited to participate in this survey. The questionnaire was administered prior to genetic counseling. A follow-up was administered after the BRCA results were disclosed. The survey queried participants regarding their attitudes on fertility, pregnancy as it may relate to cancer and the potential of a BRCA mutation. Other questions detailed attitudes regarding IVF, PGD, and CVS in these instances. Descriptive statistics were used. Results: One hundred and twenty-eight women completed pre-questionnaires and to date 76 have completed post results disclosure questionnaires. The mean age was 33 (range 21-44) with 69.5% with a diagnosis of breast cancer, 39.8% received chemotherapy and 60.9% already had at least 1 biological child. A future child was desired by 45.3% although 53.1% worried that their children would have an increased risk of cancer. Regarding PGD, although only 30.9% (38/123) said that they would use PGD, 80.2% felt that the testing should be available to families with inherited cancers. Regarding fetal testing via amniocentesis or CVS, 29.7% would have the fetus tested and 7% would consider termination if a genetic mutation was identified. Additionally, 69.5% felt it was important to receive fertility counseling and treatment at the same place where they receive their cancer care. To date 8 women have been diagnosed with a BRCA1 mutation and 4 with a BRCA2 mutation. When asked similar questions after their genetic results were disclosed, 2 women who had previously stated they would not use PGD changed their mind. Conclusions: Future pregnancies are important to many breast cancer survivors. BRCA mutation carriers have the option to have children without passing on their genetic risk for cancer. Although few would use these interventions, a large majority felt it was important to have information about these choices and to have options for fertility preservation options addressed at the

Background: Patients with BRCA1-BRCA2 germline mutation who developed a first breast cancer (BC) have a high risk to develop a second BC, especially if aged less than 40 at first diagnosis. Thus, a positive BRCA test may influence the therapeutic management and orient towards non-conservative surgery to reduce new BC occurrence. We set up a fast-track process to get BRCA1/2 and sometimes p53 mutation results within the shortest possible interval, in recently diagnosed BC patients whose probability to be mutation carriers was high (>20%).

Methods: Between 05/02/2009 and 03/01/2011, 61 patients diagnosed with localized BC requesting neo-adjuvant or adjuvant chemotherapy and whose personal or familial history fulfilled BRCA1/2 or P53 genetic testing criteria, were proposed genetic counselling. After a first multidisciplinary team meeting (MT), genetic testing was proposed and performed according to usual genetic counselling rules. Psychological support was offered at every step of the process. Patients were informed that their test would be analysed as part of a fast-track process and were aware of the potential consequences of a positive test. Results were communicated and discussed during a second MT, when initial therapeutic plan was eventually changed.

Results: All women who were referred to the genetic clinic for fast-track testing accepted the analysis. The mean age at diagnosis was 38 (range 26-55). The whole process (from 1st genetic consultation till disclosure consultation) was completed in a median interval of 99 days (range 19-245). All pts received appointment within 5 days, when results were available. 50% pts postponed for more than 15 days their disclosure appointment (range 0-113 days). One patient (pt) declined result disclosure. 18 pts (30%) were found to be carriers of a deleterious mutation (13 BRCA1, 4 BRCA2, 1 p53). Variants of unknown significance (UV) in BRCA1 or BRCA2 genes were identified in another 4 patients. In 18 cases, surgery type initially proposed was changed because of the presence of the germline mutation: all pts were proposed ipsilateral mastectomy eventually associated to immediate reconstruction as often possible, as well as contralateral mastectomy. Final surgery turned to bilateral mastectomy in 3 patients with deleterious BRCA mutation and in one suspect UV. 14 patients with mutation accepted the change, but four BRCA2 and one BRCA1 mutation carriers refused mastectomy or bilateral mastectomy. Radiotherapy was cancelled in a p53 mutation carrier.

Conclusion: This data show that genetic testing might be considered as part of therapeutic decision. Moreover, 22% (4/18) opted for a simultaneous contralateral prophylactic mastectomy. On the other hand, some women did not change their mind with mutation knowledge (4/18, 22%). Psychological impact of this procedure is currently retrospectively assessed by a self-questionnaire, fulfilled by mail. Analyses will be available for the meeting.

Prevalence of Germline BRCA1 and BRCA2 Deleterious Mutations in Brazilian Patients with High-Risk of Breast and Ovarian Cancer.

Diz MDPE, Escobar KA, Guindalini RSC, Pasini FS, SnitkowskI IMI, Maistro S, Hoff PMG, Federico MHII, Instituto do Cancer do Estado de Sao Paulo, Sao Paulo, Brazil; Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil

Background: Germline mutations in the BRCA1/2 genes account for the majority of hereditary breast ovarian cancer (HBOC). Distribution and prevalence of clinically relevant mutations in BRCA1/2 differ among different populations. All of the Brazilian studies published to date have not performed complete sequencing of both genes, restricting their analyses to selected exons. In addition, a highly heterogeneous mutation spectrum was observed. The lack of data concerning the prevalence and profile of BRCA1/2 deleterious mutation and the appropriated screening criteria for DNA sequencing in the Brazilian population complicates the design of screening strategies.

Objective: To accurately determine the contribution of BRCA1/2 germline mutations in a well characterized sample of Brazilian breast and ovarian high-risk pts.

Methodology: A total of 73 unrelated pts attending a Brazilian public hospital from September 2005 to July 2006, with HBOC risk ≥10% according to Frank, Evans or BRCAPRO algorithms, underwent complete sequencing and MLPA analysis of BRCA1/2 genes. Demographic data and tumor pathological features were extracted from prospectively registered medical records.

Results: Mean age, median of cancer cases in families and median score by Frank, Evans and BRCAPRO algorithms were respectively 48y (24-78), 4 (0-13), 11.2 (0-56.3), 13.4 (0,1-100) and 16 (2-75). A total of 79 unknown clinical significance mutations were identified: 44 in BRCA1 and 35 in BRCA2. Known deleterious mutations were identified in 8 pts. Four in BRCA1: R71G at exon 5, 5382insC at exon 20 (2 patients) and R1751X at exon 20; and four in BRCA2: R2318X at exon 13, R3128X at exon 25, 5844del5 and 663del5 at exon 11. Several polymorphisms were found in all pts. No mutation was detected by MLPA technique. One novel frameshift deleterious mutation in BRCA2: 6610insTT at exon 11 which results in a stop codon was detected in a breast cancer patient and in four of her relatives from a family with high-risk of HBOC. Taking into account the novel mutation, the prevalence of BRCA1/2 mutation in high-risk pts in our cohort is 12.3%. Pts characteristics presented in [Table 1].

Conclusion: To the best of our knowledge, the study represents the first report of the complete sequencing and MLPA analysis of BRCA1/2 genes in large Brazilian series of HBOC high-risk pts. The prevalence of germline mutations found in the present study was similar to the reported by other studies examining high-risk populations.

Kwong A. Chu ATW. The University of Hong Kong, Hong Kong; The Hong Kong Hereditary Breast Cancer Family Registry, Hong Kong

Background: Research in the West has shown that the uptake rates of surveillance and prophylaxis may be different in BRCA mutation carriers and non carriers and this may vary between different ethnicities. To date there is limited comprehensive data available for the behavioural pattern of Asian cohorts. The present on-going study is the first to investigate the behavioural impact and medical compliance of Chinese high risk females who had undergone BRCA1/2 genetic testing up to 1.5 years after genetic testing.

Methods: 88 females with personal or family breast and/or ovarian cancer history who had BRCA1/2 genetic testing performed by the Hong Kong Hereditary Breast Cancer Family Registry were surveyed by a face-to-face or telephone interview. Sociodemographic information, genetic test results, pre-and post-testing surveillance practice, chemoprevention methods used and attitudes towards clinical management were obtained. Retrieval of medical records was performed using a prospective database.

Results: 39 carriers and 49 noncarriers of a BRCA 1/2 mutations were interviewed. 82.1% of carriers and 79.6% noncarriers had breast and/or ovarian cancer prior to testing. The uptake rate of breast surveillance by eligible carriers (85.2%) and noncarriers (71.1%) remained high after knowing the test results. 12.8% and 15.4% of the eligible carriers had prophylactic contralateral mastectomy and salpingo-oophorectomy respectively, while 5.1% chose to have both procedures within 1.5 years of knowing the genetic test result. Significantly more carriers (85.7%) than noncarriers (49%) underwent ovarian surveillance (p=0.004). 25.6% of carriers and 26.5% of noncarriers with breast cancer history chose Western chemoprevention methods, while no carriers without breast cancer history chose such methods. 34.7% of carriers (30.8% of noncarriers) used Chinese herbal medicine as complementary prevention treatment after knowing the genetic test result. Clinicians’ advice was perceived as the major reason of choosing a particular surveillance or preventative strategy.

Conclusions: As population-based breast screening is unavailable in Hong Kong, the relatively high uptake rate of breast screening among noncarriers may be the result of enhancement in health-consciousness due to prior personal or family cancer experience. Proper education by clinicians is crucial to increase uptake of high risk screening. Traditional Chinese herbal medicine methods are commonly used as a form of prevention. A longitudinal prospective study will contribute to the understanding of attitude-change towards clinical management of this Chinese population who may have different cultural beliefs.

P2-13-09
First Statewide Experience with Telephone Delivery of Cancer Genetic Counseling.

Background: National guidelines and multiple professional medical societies recommend genetic counseling as the standard of care for women with a personal and/or family history suggestive of a hereditary cancer syndrome. In addition, the ability to provide risk assessment and genetic counseling is a requirement for accreditation of breast centers by organizations such as the National Accreditation Program for Breast Centers (NAPBC) and the Commission on Cancer. However, there is clear evidence that this standard is not being achieved. Many individuals are undergoing genetic testing for these syndromes without adequate pre- and post-test counseling and, on the other hand, many individuals who are appropriate for genetic testing are not being identified and referred for genetic counseling and therefore not receiving potentially life-saving genetic information and services. A number of factors have been identified as contributors to these poor public health outcomes, including a lack of available genetic counseling services due to a limited number of trained genetics professionals and their limited geographic distribution. Research has demonstrated the effectiveness of cancer genetic counseling delivered by telephone, but to date, almost no real-world experience has been reported. We provided statewide access to board-certified genetic counselors via telephone in Michigan beginning in February 2010 and report our experience with the first 200 patients at risk for hereditary breast and ovarian cancer.

Materials and Methods: Baseline data were analyzed for all Michigan patients undergoing telephone genetic counseling through Informed Medical Decisions since service delivery began in February 2010. Variables include demographics, geographic location, personal cancer history, family cancer history, Gail risk and test appropriateness criteria.

Results: Analysis has been completed on the first 200 patients referred for consideration of hereditary breast and ovarian cancer. Outcomes include testing, results and, where applicable, reasons testing was not pursued, patient and provider satisfaction, as well as trends over time in patient volumes, providers using the service and uptake by geographic location.

Conclusion: Based on statewide experience in Michigan, telephone cancer genetic counseling is a viable method for service delivery in the real world. The Michigan experience can serve as a cost-effective model for improving genetic services in other locations with limited access to genetic experts.

P2-13-10
Detection, Visualization and High Resolution Physical Mapping of Large Rearrangements by Molecular Combing in the Hereditary Breast Cancer Genes BRCA1 and BRCA2.

The BRCA1 and BRCA2 genes are involved, with high penetrance, in breast and ovarian cancer susceptibility. About 2% to 4% of breast cancer patients with a positive family history who are negative for BRCA1 and BRCA2 point mutations can be expected to carry large genomic alterations (deletion or duplication) in one of the two genes, and especially BRCA1. However, large rearrangements are missed by direct sequencing.

Molecular Combing is a powerful FISH-based technique for direct visualization of single DNA molecules, allowing the entire genome to be examined at high resolution in a single analysis. We have developed a novel genetic test based on Molecular Combing. For that purpose, we designed specific BRCA1 and BRCA2 “Genomic Morse Codes” (GMC), also covering the non-coding regions and including large genomic portions flanking both genes. We developed a measurement strategy for the GMC signals, and validated our approach by blindly testing 10 breast cancer patients with a positive family history and 10 control patients. Large rearrangements, corresponding to deletions and duplications of one or several exons and with sizes ranging from 3 kb to 40 kb, were detected on both genes, including the characterization
of 4 new mutations (for BRCA1: Del ex 3, Del ex 24 and Dup ex 3; for BRCA2: Dup ex 17-20). The identified mutations confirmed the results obtained with high-resolution zoom-in aCGH (11 k) in the same patients, with a resolution in the 1-2 kb range. Importantly, the developed GMC allowed to unambiguously localize several tandem repeat duplications on both genes, and to precisely map large rearrangements in the problematic Alu-rich 5’-region of BRCA1.

We propose the developed Molecular Combing genetic test as a valuable tool for the screening of tandem repeat duplications, CNVs, and other complex rearrangements in BRCA1 and BRCA2, such as translocations and inversions, to be combined in clinical settings with an essay that allows the detection of point mutations. We see the main application of the developed molecular diagnostic tool as a predictive genetic test. However, we envisage to extended the application of the developed tool as a companion diagnostic test, for instance in the screening of BRCA1-mutated cells in the context of the development of PARP inhibitors. Thus, the genetic test may be applied not only to clinical blood samples, but also to circulating cells and heterogeneous cell populations, such as tumor tissues.

P2-13-11
Follow Up of BRCA1/2 Carriers: The Spectrum of Cancer Diagnoses in Healthy at Risk Individuals (HTR), and in Cancer Survivors (CS).

Introduction and Objective: Data from long term follow up of BRCA1/2 carriers is scarce and is mainly related to BRCA1 women. Our multidisciplinary program targets both women and men for counselling towards BRCA1/2 screening and inclusion in clinical follow up. In here we review all cancer diagnoses observed in our BRCA1/2 cohort during follow up.

Methods: Review of individual records of BRCA1/2 carriers registered from January 2000 to December 2010. Follow up was calculated since BRCA1/2 post-test counselling until the last visit to the Clinic. All new cancer diagnoses and preventive surgeries were registered.

Results: Two-hundred and fifty nine BRCA1/2 carriers (206 females and 53 males) were diagnosed with BRCA1/2 mutations (42 BRCA1 and 217 BRCA2). Medium follow up for all population is 25 months (1-98). At the date of initial BRCA1/2 diagnosis 99 women and 14 men were CS.

Female population: Eighty-eight female CS had been previously diagnosed with breast cancer (18 bilateral cases), 18 with ovarian cancer, and 1 with biliary tract cancer. Preventive surgeries in the CS female population were: bilateral adnexectomy (33 pts) and prophylactic contralateral mastectomy (10 pts). In this CS female population, new cancers, during follow up were: Contralateral breast cancer (4 cases), peritoneal cancer (2 cases in pts with previous prophylactic surgery) and skin non-melanoma cancers (2 cases). In female HTR, 23 preventive bilateral adnexectomies and 20 bilateral mastectomies were performed. Cancer diagnoses during follow up were: breast (11), peritoneum (1 in pt with previous prophylactic surgery), gastric (1) and M3 leukemia (1). Global failure of prophylactic adnexectomy, so far (CS+HTR): 3/56 (5%).

Male population: The medium age for male CS is 73 yrs and for male HTR is 52 yrs. Male CS had mostly been previously diagnosed with BC (12; 4 bilateral) and prostate cancer (4). Other previous cancers: gastric (2), skin (2: 1Melanoma, 1 non-Melanoma), colorectal (1). One BRCA2 man with gynecomasia and prostate cancer was submitted to reduction mastectomy, as a preventive surgery. During follow up, we diagnosed second and third cancers in male CS: breast (2), prostate (6) and gastric (1). Only 1 male HTR was diagnosed with cancer: skin non-melanoma.

Conclusion: The proportion of second and third cancer diagnoses in the male BRCA2 CS population is higher than in the female BRCA1/2 CS population. Small numbers and the availability of preventive surgery for women influence this observation. No data from preventive mastectomy exists for males (we have one case). The low frequency of cancer in male HTR may be due to younger age and other unknown modifier factors. Longer follow is needed.

P2-14-01
Race, Response to Chemotherapy, and Outcome within Clinical Breast Cancer Subtypes.
Tichy JR, Deal AM, Anders CK, Carey LA. UNC, Chapel Hill, NC

Introduction: Racial disparity in breast cancer (BC) outcome has been attributed to access to care, socioeconomic factors, and biologic factors. In particular, the prevalence of triple negative BC is significantly higher among African-American (AA) women than white women (non-AA). However a recent population-based study suggests that racial disparities persist even if stratified by subtype, although it is possible that bias in stage at presentation may have influenced these results. In this study, we examined 464 women of uniform clinical stage II-III breast cancer, all treated with neoadjuvant chemotherapy, and examined pathologic complete response (pCR), recurrence-free survival (RFS), and overall survival (OS) to see if racial disparity exists within a more homogeneous stage and treatment cohort. Methods: The UNC Neoadjuvant Breast Cancer Database is a prospectively maintained cohort with clinical and outcome annotation. We identified women diagnosed between 1991-2011 and assigned BC subtype by clinical assay for estrogen receptor and progesterone receptor (hormone receptors, HR) and HER2. Fisher’s Exact and Wilcoxon Rank sum tests compared characteristics between AA and non-AA. The Kaplan-Meier method and Log Rank test compared OS and RFS curves.

Results: 142 (31%) of 464 women were AA, 294 (63%) were white, and 28 (6%) were other races (for analysis white and “other” were categorized as non-AA). 191 (41%) were clinical stage II and 273 (59%) stage III at diagnosis. Stage at diagnosis did not differ between AA and non-AA (p=0.07). AA were slightly older (median age 49 v 45, p=0.01) and were more likely to be HR-/Her2- (44% v 25%, p=0.003). All patients received preoperative chemotherapy. AA received less biologic therapy such as trastuzumab or on-protocol bevacizumab (10% v 18%, p=0.03) and received significantly less endocrine therapy (46 v 59%, p=0.01) than non-AA patients. 102 (22%) of patients had a pCR to neoadjuvant chemotherapy; pCR rates did not differ significantly by race (p=0.7) or within subtype by race (all p>0.14). At a median follow-up of 4.5 years, 20% (126) of patients have died. Among HR-/HER2- (n=114) and HR-/HER2+ (n=47) patients, OS and RFS did not differ between AA and non-AA (all p>0.5). Conversely, among HR+/HER2- patients (n=159) AA had worse OS (p=0.01) and RFS (p=0.03) and among HR+/HER2+ patients (n=53), AA had worse OS (p=0.0004) and RFS (p=0.005).

</tbody>
</table>

Conclusion: In this cohort of clinical stage II-III BC patients, AA women were over 75% more likely to have triple negative BC than non-AA patients. Pathologic reponse to chemotherapy did not differ
between AA and non-AA patients. Examining the entire cohort, AA women had worse DFS and OS, however there was no difference among ER-negative subtypes. The difference in DFS and OS was driven by worse outcome among women with ER or PR+ tumors (regardless of HER2). It is possible that this racial disparity in outcome among hormone receptor-positive BC patients reflects unknown biologic differences by race, or differences in access to or receipt of endocrine therapy.

**P2-14-02**

NCIC CTG MA.27: Clinical Tolerability and Overall Survival of Racial and Ethnic Minority Women on Aromatase Inhibitor Therapy.

Moy B, Shepherd LE, Chapman J-AW, Le Maitre A, Gelmon KA, Elliott C, Ingle JN, Goss PE. Massachusetts General Hospital, Boston, MA; National Cancer Institute of Canada Clinical Trials Group, Kingston, ON, Canada; British Columbia Cancer Agency, Vancouver, BC, Canada; Mayo Clinic, Rochester, MN

**Background:** Aromatase inhibitors (AIs) are standard adjuvant therapy for postmenopausal women with hormone receptor-positive breast cancer. We previously reported that racial/ethnic minority women receiving an AI in NCIC CTG MA.17 experienced fewer hot flashes, fatigue, and arthralgias than Caucasians (Moy B et al. Ann Oncol 2006;17:1637). Here we examined whether race affected clinical outcomes in the MA.27 AI trial comparing exemestane (E) with anastrozole (A). Methods: Fisher’s exact test was used to compare observed side effects (0 vs grades 1-5) between minority and Caucasian women. Adverse events (AE), including menopausal symptoms, were assessed according to the Common Terminology Criteria of the National Cancer Institute (version 3.0). ITT univariate test of race effects on overall survival (OS) was determined with a stratified log-rank test, while multivariate testing was with stratified Cox regression. Results: Among 7312 for whom race was known, distribution was: Caucasian (n=6939; 95%); black (n=235; 3%); Asian/Native Hawaiian/Pacific Islander (n=93); 1%; American Indian (n=39; 1%); and mixed race (n=6). Among women treated with E, minorities reported a significantly lower incidence of hot flashes (45% vs. 56%; p=0.003) and fatigue (34% vs. 46%; p=0.001) compared to Caucasians. Similarly with A, minority women reported significantly fewer hot flashes (47% vs. 58%; p=0.002) and lower cholesterol (12% vs. 18%; p=0.01); however, they reported more headaches than Caucasians (16% vs. 10%; p=0.01). Caucasian women were more likely to discontinue therapy due to AE or side effects (32% vs. 24%). There was a significant OS interaction (p=0.02) between race and treatment with minority women on E having fewer deaths than those on A. Caucasian women had HR of E vs A of 0.98 (95% CI 0.81-1.20, p=0.85, while minorities had HR of E to A of 0.72 (95% CI 0.33-1.58, p=0.41. Conclusions: Minority women tolerated AIs better and were also more compliant than Caucasians, supporting our previous findings. A significant interaction between race and type of AI therapy for OS was seen, favoring exemestane in minority women. Replication of these findings in larger cohorts is necessary. Since race/ethnicity may serve as a surrogate for genetic differences, our findings suggest pharmacogenomic differences which require further research.

**P2-14-03**

A Comparison of Biologic Differences in Tumors in a Matched Cohort of Hispanic and Caucasian Women with Early-Stage Breast Cancer Using the 21-Gene Recurrence Score Assay.

Lim EA, Hershman DL, Greenlee H, Crew KD, Mauer MA, Hibshoosh H, Kalinsky K. Columbia University Medical Center, New York, NY; Mailman School of Public Health, New York, NY

**Background:** Several studies demonstrate that Hispanic women have a higher mortality rate and lower incidence of breast cancer (BC) as compared to Caucasian women. This survival pattern has also been observed in Hispanic women with untreated, early-stage BC. The Hispanic population should be considered a heterogeneous group, however, given the various racial and national backgrounds that comprise this entity. As African American (AA) similarly demonstrate a worse survival as compared to Caucasian women, a retrospective analysis of 27 tumor from AA patients (pts) showed a significantly higher expression of the 5 proliferation genes in the 21-gene recurrence score (RS) assay (Oncotype Dx) as compared to other races, with no significant difference observed in the 21-gene RS. The primary aim of this analysis is to investigate biologic differences between Hispanic women in a primarily Dominican Republic population, as compared to Caucasian women, as determined by indices in the 21-gene RS assay.

Methods: We collected data from women with early-stage breast cancer who underwent RS assay testing between 2005 and 2011. Pt charts were reviewed for ethnicity (Hispanic or other), country of origin, RS, 10-year risk of distant recurrence, and breast tumor ER/PR/HER2 expression by Oncotype Dx. Hispanic pts were matched to Caucasians in a 1:2 fashion based on age (+/- 10 years), tumor stage, and presence of lymph node metastases. Prognostically important clinicopathologic features were collected, including lymphovascular invasion (LVI) and grade. Descriptive statistics were computed. Two Sample t-testing was used to evaluate if RS was equal across by ethnicity groups.

Results: Of 214 pts who underwent RS testing, 30 (13.5%) were Hispanic: 18 from the Dominican Republic, 5 from Puerto Rico, and 1 from various Central and South American populations. The 30 Hispanic women were matched to 57 Caucasians: total population 87 pts. The mean RS for Caucasian women was 18.3 (range: 0-54) and for Caucasians: 15.5 (range: 1-38). By two Sample t test, no statistically different differences were observed between Hispanic and Caucasian women in regards to the RS (p= 0.2828) or 10-year distant recurrence score after 5 years of anti-estrogen therapy (p=0.4218). No differences were observed in median ER expression (9.4% vs. 10.1%; Hispanic vs. Caucasian), PR (7.2% vs. 7.7%), or HER2 (9.2% vs. 9.0%). LVI was numerically more frequently identified in Hispanic pts [7/30 (23.3%) vs. 8/57 (14.0%)], as were grade III tumors [7/30 (23.3%) and 4/57 (7%)].

Conclusions: Similar to the findings with AA pts, there was no significant difference in RS between Hispanic and matched Caucasian women with early-stage BCs. A numerical trend to a higher RS was seen in this Hispanic population of primarily pts from the Dominican Republic. We will evaluate for differences in the 5 genes involved in proliferation (CCNB1, MKI17, MYBL2, BIRC5, AURKA). Also, further analyses will be conducted with additional pts to determine if the numeric differences in RS, LVI, and grade are observed in a larger cohort.
P2-14-04
The Influence of Demographic, Psychosocial and Emotional Barriers to Screening for Colorectal and Ovarian Cancer among Latina Breast Cancer Survivors.
Ramirez AG, Holden AE, San Miguel SL, Gallion KJ. UT Health Science Center at San Antonio, San Antonio, TX

Background Ten percent of all new cancers are diagnosed in cancer survivors and second cancers are the sixth leading cause of cancer deaths. Breast cancer survivorship brings to the fore concern that survivors obtain thorough preventive health screening services. In two previous studies, we observed that Latina women are unable to comply with recommendations for breast cancer care due in part to psychosocial barriers including ability to understand physicians and fear of recommendations. Affective influences, particularly depression may also contribute to noncompliance via its inhibitory effect on vigilance. Here we test a hypothesis that similar barriers in addition to depression level restrict breast cancer survivor screening for colorectal and ovarian cancer.

Methods We conducted a cross-sectional study of 117 Latina breast cancer survivors using self-report data. Proportions of respondents compliant and noncompliant with recommended screening protocols were compared. Reasons were coded “yes”-“no”; depression was measured with the Center for Epidemiologic Studies (CESD) instrument dichotomized at the usual cutoff of 16 points or higher signifying depression. Cancer screening compliance was determined by published NCI guidelines. Associations were determined via chi-squared analysis. Multivariate analysis was conducted using logistic regression.

Results Only 5 (4.2%) of participants were screened for both cancers, 43 (36.8%) for either cancer, and 69 (59.0%) were screened for neither cancer. Reported barriers to cancer care were generally high with respect to screening for other cancers, but only “cannot understand English” (66% v 53%, p=0.05) and “care is too expensive” (84% v 71%, p=0.05) were associated with lack of ovarian cancer screening and none were associated significantly with lack of colorectal screening. Thirty-two percent of the sample met CESD criteria for depression, nearly twice the general population rate; it is associated with ovarian but not colorectal screening noncompliance. Factors including unemployment (74% v 57%, p=0.03) and no familial history of cancer (75% v 53%, p=0.02) are related to non-compliance with ovarian screening, but only unmarried status is related to colorectal screening (54% v 20%, p<0.01). Separate multiple logistic regression analyses confirmed the independent significant association of these factors with ovarian and colorectal screening compliance, indicating good model fit and significant proportions of variance explained by the models.

Discussion There are significant impediments to cancer screening among Latina breast cancer survivors. They derive from multiple domains (demographic factors, psychosocial barriers, and affective states). For this reason they require further research to clearly identify them. Moreover we must develop an equally broad-based preventive strategy that addresses each of these domains to promote vigilance and increase healthy behaviors among Latina women.

Racial Differences in the Use of Adjuvant Chemotherapy for Breast Cancer in a Large Urban Integrated Health System.
Simon MS, Lamartine L, Krajenta R, Boza J, Ruterbusch J, Kunz S, Schwartz K. Karmanos Cancer Institute at Wayne State University, Detroit, MI; Henry Ford Health System, Detroit, MI; Wayne State University, Detroit, MI

Background: Despite improvements in breast cancer treatment, there continues to be a gap in survival between African American (AA) and White women with breast cancer, which may be due at least in part to racial differences in the patterns of care. In order to better understand breast cancer survival disparities, we evaluated racial differences in the receipt of adjuvant chemotherapy among women treated at a large integrated health care system in Southeastern Michigan. Materials and Methods: The study population included 2,234 women (33 % AA) with stage I through III breast cancer treated at the Henry Ford Health System (HFHS) from 1996 through 2005. Linked datasets from the HFHS, the Metropolitan Detroit Cancer Surveillance System (MDCSS) and the U.S. Census Bureau were used to obtain socio-demographic and clinical information. Co-morbidity was assessed by the Charlson co-morbidity index (CCI), and economic deprivation was categorized using a neighborhood deprivation index (DI). Results: AA women were significantly more likely than Whites to have larger tumors (40% vs. 31% > 2 cm), as well as more aggressive tumors (29% vs 19% estrogen and progesterone negative). AA women were also significantly more likely than Whites to have other co-morbid conditions (15 % vs. 8% with a CCI of 2+) and to reside in a more economically deprived area (45% vs. 5% reside in the most deprived area). While AA women were more likely to receive adjuvant chemotherapy (47% vs. 43%, p=0.0278), they were also more likely to have a delay in initiation of treatment (57% vs 45% delayed beyond 60 days from diagnosis, p=0.0004). After multivariable adjustment for age, DI, CCI, insurance and surgery, there were no racial differences in treatment delay (Odds Ratio 1.20, 95% confidence interval, 0.82-1.77). Discussion: In a large urban integrated health care system, racial differences in the delay in receipt of adjuvant chemotherapy for breast cancer can be explained by clinical and socioeconomic characteristics.

P2-14-06
Loch MM, Ross AA, Rosenberg C, Blanchard RA. Boston University Medical Center, Boston, MA; Boston University, Boston, MA

Background: There is limited literature regarding Haitian women and breast cancer. What exists is based on screening with no literature on clinical or pathologic subtypes of breast cancer. We examined patient and tumor characteristics in Haitian born women with invasive breast cancer in our ethnically diverse tertiary care hospital.

Methods: We expanded a pre-existing database to include all women diagnosed with breast cancer from 1998-2011. From the electronic medical record we documented age, body mass index (BMI), place of diagnosis, with mean age 55.1 vs. 59.4 overall p=0.04. Mean age W: 60 days from diagnosis, p=0.0004). After multivariable adjustment for age, DI, CCI, insurance and surgery, there were no racial differences in treatment delay (Odds Ratio 1.20, 95% confidence interval, 0.82-1.77). Discussion: In a large urban integrated health care system, racial differences in the delay in receipt of adjuvant chemotherapy for breast cancer can be explained by clinical and socioeconomic characteristics.
The frequency of HER2-overexpressing breast cancer did not differ among Chinese, Malay, and Indian pts. Indian pts were more likely to have TNBC compared with Chinese (p=0.005) and 50% among Indians (p=0.11, ns). Malay and Indian pts had higher BMI compared to Chinese pts (26.4 and 26.2 vs 22.8, p<0.001 and <0.001 respectively). Malay pts also had lower 5-yr DFS at 59% and 5-yr OS at 76% compared with 76% (p=0.001) and 84% (p=0.04) in Chinese pts. Survival analyses on Indian pts were limited by the small numbers. Full multivariate analyses will be tabulated.

Conclusions: There are significant differences in the frequency of various subtypes of breast cancer among the Chinese, Malays and Indians in Singapore. The disparities in survival outcomes between the Chinese and the Malays may be related to more aggressive tumor biology, more advanced stage at diagnosis and host factors such as higher BMI. The full impact of ethnicity on breast carcinogenesis is still unknown but is increasingly relevant with the development of therapies that target specific molecular pathways.

P2-14-08
Hormone Receptor Status and Breast Cancer Survival among Hispanic and Non-Hispanic White Women over 10 Years of Follow-Up.

Introduction: The joint presence or absence of expression of estrogen receptor (ER+/−), progesterone receptor (PR+/−), and Her2neu (Her2+/−) is now widely used to define the hormone receptor (HR) phenotype of breast tumors. HR phenotype influences breast cancer etiology, response to treatment and survival, which may vary by ethnic group. The triple negative phenotype (TNT: ER-/PR-/Her2-) is associated with the poorest survival and is more common in African American than white women. Few studies have assessed how HR status differs by Hispanic (H) versus non-Hispanic white (NHW) ethnicity in relation to survival.

Methods: We analyzed data from the New Mexico site of the ‘Health, Eating, Activity and Lifestyle’ (HEAL) study for breast cancer mortality over 10 years of follow-up by HR phenotype and ethnicity for 126 H and 408 NHW women with invasive (I-IIIA), first primary breast cancer. Kaplan Meier curves were used to describe differences in breast cancer survival by HR and ethnicity, adjusting for age at diagnosis, stage, and diagnosis of another cancer (yes/no).

Results: Kaplan Meier (KM) analysis indicated that the TNT phenotype was associated with poorer survival, particularly during the first 5 years, although the difference was not statistically significant after 10 years of follow-up (p=0.36). The prevalence of TNT was higher in H (10.3%) than NHW (6.6%) women, and H also tended to poorer survival than NHW women (p=0.17). In multivariate-adjusted models, women with a TNT phenotype had a 26% increased risk of death (HR=1.26 95% CI 0.62-2.6). In NHW women, the risk was 12% (HR=1.12 95% CI 0.43-2.9). Among H women, those with a TNT phenotype had a 17% increased risk of death (HR=1.17 95% CI 0.35-3.8) while those with ER-/PR-/Her2+ had a 46% increase (HR=1.46 95% CI 0.40-5.3).
Discussion: Although this analysis is limited by small numbers, the results suggest that Hispanic women may have worse 10-year survival rates than non-Hispanic women and that women with TNT have a higher risk of death regardless of ethnicity. These differences in survival could be due to a higher rate of recurrence or issues related to treatment. This study suggests that there is an ethnic disparity in survival by HR subtypes that should be examined in a larger population based study.

P2-14-09
Comparison between Spanish and Peruvian Patients with Early Breast Cancer.
Castaneda CA, Gomez HL, Vallejos C, Cortes-Funes H, Castellano D, Andrés E, Cruz W, Ciruelos EM. Instituto Nacional de Enfermedades Neoplásicas, Lima, Peru; Hospital Universitario 12 de Octubre, Madrid, Spain

Purpose: Breast Cancer (BC) is a genetic, heterogeneous disease and has a remarkable variability according to racial factors. Hypothetical explanations for these disparities include differences in tumor biology. The present study was designed to compare clinical and pathological features between Peruvian Latinas and Spanish women with BC; interest of this analysis increases if we take into account the relationship among historic ancestries of both ethnic groups (Incas emporium and Spanish conquers).

Methods: Information was retrospectively reviewed from patients files and pathologic reports from Instituto Nacional de Enfermedades Neoplásicas (INEN) in Lima- Peru, and Hospital Universitario 12 de Octubre in Madrid- Spain. In order to produce comparative information and avoid subjective clinical measurements we selected only non-metastatic and non-bilateral invasive BC cases that underwent surgery as initial therapy. BC cases were classified as molecular subtypes: Luminal A [RE+ and/or RP+, HER2-], Lum B [RE+ and/or RP+, HER2+], triple negative (TN) [RE-, RP-, HER2-] and HER2 [RE-, RP-, HER2+]. Variables were compared with the X2 test and survival curves were evaluated with Kaplan-Meier method.

Results: The study included 3765 BC cases. The Spanish cohort involved 1539 (40.9%) women consecutively diagnosed between 1997 and 2007 (median follow-up of 7.9 years). The Peruvian cohort involved 2226 (59.1%) women consecutively diagnosed between 2000 and 2006 (median follow-up of 6.3 years).

In terms of pathological features, grade 1 tumors were more frequent in Spanish (16.2%) than Peruvian women (9.6%) (p<0.001). Higher rates of lobular histology were also found in Spanish (16.2%) than Peruvian (6.0%) women (p<0.001). Spanish cases presented at earlier stages when evaluated by lymph node status (N0 in 58.9% vs 47.1%) (p<0.001) or by tumor size (T1 in 37.9% vs 17-2%). Conservative surgery were more frequent among Spanish cases (50.6% vs 16.8%) (p<0.001). TN molecular subtype were more frequent among Peruvian cases (22.5% vs 12.4%) (p<0.001).

Brain (10.4% vs5.3%), and skin and subcutaneous (7.1% vs 2.4%) metastases were more frequently found in Peruvian patients. On the other hand, contralateral breast cancer was more frequent among Spanish patients (12.2% vs 2.8%). And when evaluated by molecular subtype, bone metastases in TN were more frequent among Spanish (25.4%) than Peruvian (18.5%) cases.

Disease-free survival rates at 7 years were similar between Spanish and Peruvian patients (80.3% vs 79.6%, p=0.197). However, overall survival at 7 years was better in Spanish women (90.4% vs 82.6%, p<0.001).

Conclusion: Epidemiologic differences in terms of histological features, clinical stage at diagnosis, molecular subtypes distribution, recurrence patterns and prognosis were found among Spanish and Peruvian BC patients in this retrospective analysis.

Are There Variations in Invasive Tumour Characteristics between Different Ethnic Groups?
Hariri B, Lo M, Gandomiwillja T, Lewis J, Hogben K. Imperial College Healthcare NHS Trust, Charing Cross Hospital, London, United Kingdom

Introduction: Studies have shown that ethnic minorities with breast cancer are more likely to present at a younger age and with more aggressive tumours. The aim of this study was to examine the variation in tumour characteristics and surgical outcomes in different ethnic groups in our breast unit over a 12-month period.

Methods: A retrospective study was performed on all patients with a new diagnosis of breast cancer, either screen-detected or symptomatic, between January to December 2009. Using our Trust databases, data on patient demographics, tumour characteristics, and ethnicity were collected. Where ethnicity was not documented, patients were contacted by telephone to complete the database. Those unable to be contacted were excluded from the study. Other exclusion criteria include those with recurrent ipsilateral breast cancer.

Results: A total of 270 patients (265 females) were included in our study, of which 235 (87%) had invasive cancers (ductal carcinoma, lobular carcinoma, tubular carcinoma, mucinous carcinoma, cribriform carcinoma, papillary carcinoma, sarcoma) and the remaining 35 patients (13%) had non-invasive cancers (ductal carcinoma in-situ, lobular carcinoma in-situ, papilloma, columnar cell hyperplasia). We were unable to contact 23 (8.5%) patients to ascertain their ethnicity, and therefore these have been excluded from our results.

Discussion: Although this analysis is limited by small numbers, the results suggest that Hispanic women may have worse 10-year survival rates than non-Hispanic women and that women with TNT have a higher risk of death regardless of ethnicity. These differences in survival could be due to a higher rate of recurrence or issues related to treatment. This study suggests that there is an ethnic disparity in survival by HR subtypes that should be examined in a larger population based study.

Conclusion: We found that the age of breast cancer presentation was lowest in Black and Asian patients (mean age 52 years and 54 years, respectively), compared to White (mean age 59 years). Furthermore, compared to white patients, tumours in Asian patients were larger (62.5% vs 47.2%), of higher grade (83.3% vs 75.2%), more likely...
to be ER negative (16.7% vs 12.4%), and tended to be lymph node positive (41.7% vs 34.2%). These may explain the higher mastectomy rate in Asian patients (n=12, 50%).

The reason for the younger presentation age in the ethnic Asian group is unclear. However, it is possible that their cancer may have different tumour biology. Other studies have suggested reasons such as birth cohort effect and obesity.

Reflecting the United Kingdom’s population the majority of patients that present to our breast unit are White and the number of Asian patients remains small. An increase in the sample size may strengthen our results.

**Surgical Patterns of Care after Magnetic Resonance Imaging in the Academic Setting in Patients with Operable Breast Cancer Treated with Neoadjuvant Systemic Therapy: A Secondary Analysis of TBCRC 017.**

De Los Santos J, Cantor A, McGuire K, Golshan M, Meric-Bernstam F, Horton J, Nanda R, Amos K, Forero A, Hudis C, Meszoely I, Hwang S, University of Alabama at Birmingham, Birmingham, AL; University of North Carolina Chapel Hill, Chapel Hill, NC; Dana-Farber Cancer Institute, Boston, MA; Duke University Medical Center, Durham, NC; Memorial Sloan Kettering Cancer Center, New York, NY; University of Pittsburgh Medical Center, Pittsburgh, PA; MD Anderson Cancer Center, Houston, TX; Vanderbilt University, Nashville, TN; University of Chicago, Chicago, IL; University of California at San Francisco, San Francisco, CA

Background: Neoadjuvant chemotherapy is increasingly used to downstage locally advanced tumors, test new regimens, and improve chances of breast conservation. In parallel, use of breast MRI for surgical planning and as a potential response biomarker has also increased along with an observed increase in mastectomy rates. This secondary analysis reports surgical patterns of care across 8 NCI comprehensive cancer centers in women receiving both neoadjuvant therapy and breast MRIs.

Methods: 770 women from 8 institutions were retrospectively identified as having received neoadjuvant systemic therapy with MRI done before and after systemic treatment. Univariate and multivariate analyses of covariates associated with surgical management were performed. Within MRI complete response or not, the Jonckheere-Terpstra Test (JTT) was used to test for a trend in mastectomy rate by T stage.

Results: Surgical data was available on 763/770 patients. Table 1 lists MRI response by pretreatment imaging size and final breast surgery. Table 2 lists demographics, tumour characteristics and reasons for mastectomy.

**Are We Performing More Mastectomies on Women Diagnosed with Invasive Breast Cancer?**

Lo MCI, Hariri B, Gandamahirdja T, Lewis J, Hogben K. Imperial College Healthcare NHS Trust, Charing Cross Hospital, London, United Kingdom

**Introduction**

Surgical management of breast cancer has changed over the past several decades; breast-conserving surgery has become widely accepted. Mastectomies, however, are still being performed as part of the management of breast cancer. The aim of this study was to investigate the indications for mastectomy in women with invasive breast cancer within our institution.

**Method**

A systematic review of all new patients with invasive breast cancer treated with surgical intervention at our breast unit in the years 2000, 2005 and 2009 was performed. Using our databases, patient demographics, tumour characteristics and reasons for mastectomy were examined. Screen-detected and symptomatic patients were included in the study. Patients excluded were those with incomplete data and recurrent breast cancer.

**Results**

A total of 584 patients (F:M, 576:8); with cancer types which included invasive ductal carcinoma (n=501, 84%), invasive lobular carcinoma (n=51, 9%), invasive tubular carcinoma (n=27, 5%) and sarcomas (n=5, 1%) were studied.

Conclusion
In our institution, the majority of patients with screen-detected invasive breast cancer fulfilled the criteria to have breast-conserving surgery; mastectomy rate for screen-detected cancers remained stable. However, we found that in the symptomatic patient group, there was an increase in mastectomy rate from 16% (n=170) in 2000 to 52% (n=225) in 2009. Despite this trend, our results were still in keeping with the national standard as illustrated by the National Cancer Intelligence Network, where they noted that in 2006, 52% of symptomatic patients with invasive breast cancer underwent mastectomy in the United Kingdom.

The reason for a higher mastectomy rate in symptomatic patients compared to screen-detected patients in 2009 is multifactorial. We found that a larger proportion of symptomatic patients presented with larger tumours and tumours which were multifocal in nature. Other factors which may have contributed included more accurate estimation of tumour size by imaging (e.g. MRI) and patient choice.

Sakurai T, Sakurai T, Umemura T, Jinta E, Suzuma T, Yoshimura H, Ohsumi S, Iwase T, Inaji H, Mitzutani M, Nishimura R, Mukai H, Niigata Cancer Center Hospital, Niigata, Japan; National Hospital Organization Shikoku Cancer Center, Matsuyama, Japan; Cancer Institute Hospital Tokyo, Japan; Osaka Medical Center for Cancer and Cardiovascular Diseases, Osaka, Japan; National Hospital Organization Osaka National Hospital, Osaka, Japan; Kansai Medical University, School of Medicine, Osaka, Japan; Osaka Medical Center for Cancer and Cardiovascular Diseases, Osaka, Japan; National Hospital Organization Osaka National Hospital, Osaka, Japan; Kumamoto City Hospital, Kumamoto, Japan; National Cancer Center Hospital East, Kashiwa, Japan

[Introduction] Mastectomy has been conducted in general for cases in which breast conservation is inapplicable. Since Nipple-sparing Mastectomy (NSM) conserves nipple-areola, it is not only more advantageous in an aspect that nipple-areola reconstruction isn’t required in case of breast reconstruction compared with mastectomy but also significantly meaningful because the sensation of nipple-areola is preserved in about 70% cases by skin flap preparation based on thick flap method we have adopted. On the other hand, NSM is controversial relating to complication of surgery and recurrence as well.

[Objective] We’ve made (1) review of safety in NSM surgical technique, (2) discussion over recurrence and prognosis comparing with those in mastectomy, and (3) consideration of performance in immediate reconstructions.

[Result] (1) Of all cases of NSM, the number of cases in stage 0, 1, 2A, 2B, 3 and 4 was 21, 305, 239, 123, 112 and 6 respectively. During 104 months of follow-up period in average, total of seven complication cases (0.9%) were observed, including two flap necrosis cases and five postoperative bleeding cases, but no nipple necrosis case was recorded. Although nipple-areola recurrence rate (%) in stage 0, 1, 2A, 2B and 3A was 0, 2.9, 4.6, 2.4 and 5.3 respectively, prognosis of nipple-areola recurrence cases was good showing no difference between stages (OS: 60M; 93%, 100M; 84%). Skin flap recurrence rate (%) in stage 0, 1, 2A, 2B and 3 was 0, 3.2, 3.3, 4.0 and 14.2 respectively, and prognosis of skin flap recurrence cases was significantly worse in stage 2B and 3 compared with that in stage 1 and 2A (p < 0.001).

(2) We analyzed local recurrence rate, recurrent free survival and overall survival between 806 of NSM cases and 200 of mastectomy cases which had been performed during the same period, and the result showed no significant difference in those rates between NSM and mastectomy cases.

(3) Infectious complication was observed in one out of 18 immediate reconstruction cases using free dermal fat graft. Among 124 immediate reconstruction cases using implant, complications were observed in five postoperative bleeding.

[Conclusion] NSM was excellent in cosmetic aspect showing equivalent results in local recurrence rate and prognosis compared with those in mastectomy cases. Besides, patient’s satisfaction was also higher in those who had had NSM alone without reconstruction. Our long term follow-up data shows that NSM may be considered as an alternative option for mastectomy in cases in which breast-conserving surgery is inapplicable in breast cancer patients.

Clinical Significance of Resection with Curative Intent for Isolated Pulmonary Metastases from Breast Cancer. Multi-Institutional Study in Japan.
Sato N, Ohsumi S, Iwase T, Inaji H, Mitzutani M, Nishimura R, Mukai H, Niigata Cancer Center Hospital, Niigata, Japan; National Hospital Organization Shikoku Cancer Center, Matsuyama, Japan; Cancer Institute Hospital Tokyo, Japan; Osaka Medical Center for Cancer and Cardiovascular Diseases, Osaka, Japan; National Hospital Organization Osaka National Hospital, Osaka, Japan; Kumamoto City Hospital, Kumamoto, Japan; National Cancer Center Hospital East, Kashiwa, Japan

OBJECTIVE: Although resection of isolated pulmonary metastases is a common treatment in other primaries such as colon cancer, the role of lung metastasectomy of breast cancer is still unclear. The objective of the present study was to investigate the clinical outcome of our operated patients with isolated pulmonary breast cancer metastases and discuss the clinical implication of resection with curative intent for them.

METHODS: We retrospectively analyzed 86 female patients with histologically proven isolated pulmonary metastases from breast cancer who were treated with surgery of curative intent between January 1980 and September 2010 at 7 Japanese hospitals. The mean age of them was 50 years, the median disease free interval (DFI) from the definitive surgery for the primary breast cancer was 4.6 years (range: 0.5 - 20.4 years) and the median follow-up after lung metastasectomy was 4.1 years (range: 0.3 - 30.9 years).

RESULTS: Lung metastasectomy was performed by thoracotomy in 22 patients and by video-assisted thoracoscopic surgical resection in 64 patients. The number of metastatic foci resected was one for 79 patients, two for 6, and unknown for 1. Lymph node resection was performed for 12 patients, was not done for 69, and unknown for 5. Five-year survival rates after lung metastasectomy were 68% in the patients. The main prognostic factor was the DFI. Five-year survival rates for patients with DFI of longer than 2 years (n = 72) and those with DFI of shorter than 2 years (n=14) were 74.5% and 33.8%, respectively (p = 0.0006). Five-year survival rates after lung metastasectomy were 68% in patients without macroscopic residual pulmonary tumor after lung metastasectomy (n = 69) and 34% in those with macroscopic residual tumor (n = 12) (p = 0.023). Five-year disease free survival after lung metastasectomy for patients without macroscopic residual tumor was 51 %. Five-year survival rates were 78% in patient with endocrine hormonal therapy following lung metastasectomy (n = 51) and 53% in those without endocrine hormonal therapy (n = 35) (p = 0.045). No prognostic influence could be demonstrated for age, number of initial axillary node metastases, primary tumor size.

CONCLUSION: The prognosis of the breast cancer patients with isolated pulmonary metastases who underwent metastasectomy with curative intent was good. It was affected by the biological aspects
of the primary tumor, “curativity” of the resection, and systemic treatments after lung resection. It may be expected that some of those patients will be cured by surgery with curative intent.

P2-15-05
Excision of the Primary Tumour in Patients with Metastatic Breast Cancer – Will E2108 Provide the Definitive Answer?

Background: Approximately 10% of new breast cancer patients will present with overt synchronous metastatic disease. Controversy exists about the optimal local management of these patients. While several series suggest that removal of primary tumour is associated with a survival benefit, the retrospective nature of these studies raises considerable methodological challenges. We decided to evaluate the experience at our centre around the impact of surgery in patients with synchronous metastasis.

Method: Case records of all patients seen with primary breast cancer and concurrent distant metastases between 2005 to 2007 were reviewed. Demographic and treatment data was collected. The study endpoints compared both overall survival and symptomatic local progression rates between patients who had breast surgery and those who did not.

RESULTS: 111 patients were identified. Median follow-up 40 months (0.6-71 months). Patients were divided into two groups: those patients who underwent breast surgery (n=48; 29/48 had surgery immediate prior to metastatic diagnosis) and those that did not have surgery(n = 63). The surgical group were less likely to present with T4 tumours (20% vs 36%), N3 nodal disease (8% vs 19%) and visceral metastasis (67% vs 73%) when compared with non-surgical group. Improved overall survival (49 months vs 33 months; p=0.01) and less symptomatic local progression rates (15% vs 43%, p < 0.001) were seen in the surgical group compared to the non-surgical group.

CONCLUSIONS: The optimal local management of patients with metastatic breast cancer is unknown. Despite the surgery group demonstrating an improved overall survival and symptomatic local control, this group had less aggressive disease at presentation. These results confirm the need for prospective randomized studies. E2108, an ongoing Phase III Trial, was designed to assess the effect of breast surgery in metastatic patients responding to first line systemic therapy. If excision of the primary tumour is associated with a survival benefit, then the pre-selected subgroup of patients that have responded to initial systemic therapy is the desired population to put this hypothesis to test.

Breast Cancer Liver Metastases – Possibilities and Limits of Surgical Treatment.
Narsanska A, Treskova I, Treska V, Skallicky T, Sutnar A. University Hospital and Medical Faculty Pilsen, Charles University Prague, Pilsen, Czech Republic

Background: Breast cancer liver metastases (BCLM) are often considered as a sign of a systemic disease with little hope of therapeutic success. The aim of study was to assess the possibilities and determine the limits of the surgical treatment of BCLM.

Method: 646 patients were operated for malignant and benign lesions of the liver between 1999 and 2010. Liver surgery for BCLM was performed in 21 women of the average age of 48.5 years (33-71). The average time from the primary surgery for breast cancer till BCLM diagnosis was 4.7 years (2 months - 9 years). BCLM were solitary in 17 and in four cases multiple. Patient selection for liver surgery was based on sufficient future remnant liver volume, the absence of systemic non-resectable tumor dissemination and response to chemotherapy. The authors performed six right-sided hepatectomy, four segmentectomies, three left lobectomies, one metastasectomy, six radiofrequency ablations (RFA), one combined procedure - liver resection and RFA. Histological examination revealed ductal carcinoma in fourteen and lobular carcinoma in seven cases. All patients were treated with the curative adjuvant chemotherapy after surgery. The data were statistically evaluated by statistical software Statistica 9.0.

Results: 30 – days mortality rate was 0%. One patient had a complicated hepatectomy with iatrogenic bile duct injury. According to statistical analysis the probability of patients survival twelve, resp. thirty months after surgery was 100, resp. 66.7% and the probability of the tumor relapse anywhere in the body was at the same time intervals 0, resp. 71. 5%.

Conclusion: Liver surgery combined with the adjuvant chemotherapy are a therapeutic methods of choice for highly selected patients with metastases limited to the liver and objective response to neoadjuvant chemotherapy.

The study was supported by the research projects IGA MZ NS 9727 and IGA MZ NS 102 40.

The Need for Additional Surgeries to Adequately Excise Early Breast Cancers May Have a Negative Impact on Local Recurrence.
Warburton R, Alriyees L, Wang DY, Wong SL, Leong W. University Health Network, University of Toronto, Toronto, ON, Canada

Background: Breast conservation surgery (BCS) is considered the standard of care for the treatment of early stage breast cancer (ESBC, AJCC stage 1 and 2). 20 to 50% of patients will require further surgery for positive or close margins. There is recent data suggesting that re-operation can have a negative impact on local and distant recurrences. Our aim is to examine the effects of multiple surgeries to obtain adequate margins on breast cancer recurrence, metastatic disease and survival.

Methods: We reviewed a prospectively maintained breast cancer database at the University Health Network and included all women who had BCS for their first diagnosis of ESBC between January 2004 and December 2007. Patients with neoadjuvant chemotherapy were excluded. We collected patient demographics, surgical pathology, adjuvant therapy and follow up outcome data, which included local recurrence, distant recurrence, cancer-specific survival and overall survival. Clinical and pathologic features were compared using chi-square analyses. Patients who had one lumpectomy were compared to those who had multiple surgeries by using Kaplan-Meier survival curves and log rank test.

Results: Of a total of 744 patients (8 patients had bilateral cancer) 577 (77.6%) had one lumpectomy only (Group 1). 167 (22.4%) patients required further surgery (group 2 = LR+LM+LRM); 83 (11.1%) had a re-excision (LR), 69 (9.3%) had mastectomy (LM) and 15 (2%) had a re-excision followed by a mastectomy (LRM). Thus, a total of 85 (11.4%) patients had mastectomy to achieve adequate margins. All clinicopathologic factors and adjuvant systemic treatments were similar between the two groups except for age and use of adjuvant radiotherapy, which was related to that fact that many of those in group 2 had mastectomy. We observed a difference in disease-free survival favoring patients with lumpectomy only (group 1- 3.4% vs. group 2 - 8.1%, p= 0.01) but there was no difference in distant
metastasis (4.5% vs. 5.6%, p=0.56), cancer-specific survival (97.6% vs. 95.6%, p=0.20) and overall survival (6.9% vs 6.3%, p= 0.76) at a median follow up of 4.54 years.

Conclusion: Despite having similar stage, grade, receptor status and adjuvant systemic therapies, having multiple surgeries for primary breast cancer appeared to be associated with decreased disease-free survival but had no difference in rates of distant metastatic disease, cancer-specific survival and overall survival.

**New Trends for Surgical Treatment of Large Breast Tumors.**

Zucca Matthes AG, Vieira RAC, Kerr LM, Matthes ACS, Folgueira MAAK, Uemura G. Barretos Cancer Hospital, Barretos, SP, Brazil; School of Medicine of Botucatu - UNESP, Botucatu, SP, Brazil; USP, Sao Paulo, SP, Brazil; University Barão de Mauá, Ribeirão Preto, SP, Brazil

**Introduction:** The locally advanced breast cancer is still common in developing countries. The neoadjuvant chemotherapy (NC) allows converting large tumor into operable one. Oncoplastic surgery (OS) adds new techniques to breast conservative treatment (BCT). The association between NC and OS provides the resection of large amount of breast tissue, including skin, with satisfactory aesthetic results.

**Objective:** Evaluate the possibilities to indicate oncoplastic techniques to determine BCT after NC for large breast tumors.

**Material and Methods:** A prospective clinical trial (www.clinicaltrials.gov; NCT00820690) study with women breast cancer patients, clinical stage III, no extent skin involvement, submitted to NC, based on four cycles of doxorubicin 60mg/m2 + cyclophosphamide 600 mg/m2 and 4 cycles of paclitaxel 175mg/m2. Preoperative tattoo was realized for all patients to determine the clinical dimensions of the tumor. Tumor size was controlled by physical and radiological exams. The oncoplastic surgeries were offered in accordance to clinical-imaging previous to NC, final response to chemotherapy, tumor localization, tumor size, breast size, oncologic security, patient comorbidities and experience of the surgeon. The skin-sparing mastectomy with immediate breast reconstruction was also considered an oncoplastic technique. The surgical planning has involved the whole area previously marked by the tattoo regardless of tumor response. A detailed analysis of the pathological specimen was provided to confirm the oncologic safety of the treatment. All patients were followed by radiotherapy after surgery.

**Results:** 50 patients were enrolled. PE tumor median measurement was 6.5 cm (3.0 to 14.0 cm) and pathologic median tumor was 4.0 cm (0 to 14.5cm). Pathologic response was rated as stable disease, progressive disease, partial response and complete response in 18%, 10%, 68% and 4% of the cases, respectively. Pathologic responses were diverse and included tumor micro-fractionation and macro-fractionation. PE tumor size before chemotherapy correlated best with MRI (rcc 0.588, p <0.001), as well as pathologic tumor size measured after chemotherapy correlated best with MRI (rcc 0.738, p <0.001). The surgical approach allowed BCT in 34% (17) of patients. Skin involvement was presented in 38% of pathologic specimen regardless previous clinical exam noticed.

**Conclusion:** Oncoplastic techniques increase the rates of BCT for selected patients in spite of large locally advanced tumors. The surgical planning is fundamental to this approach. This study recommends the full resection of the tumoral area previous to NC, including marked skin, regardless the response to neoadjuvant treatment. Follow-up of these patients will be important for additional information in the future.

**Prospective Randomized Comparison of Conventional Instruments and the Harmonic Focus® Device in Breast-Conserving Therapy for Primary Breast Cancer.**

Böhmer D, Kubitsa A, Lebrecht A, Schmidt M, Köbl H. University Medical Centre, Mainz, Germany

**Background:** In recent years, surgeons have utilized Harmonic instruments to perform breast cancer resection. Retrospective and prospective studies have demonstrated that the use of this surgical device for mastectomy and axillary dissection can reduce perioperative blood loss, seroma formation, and duration and total amount of drainage. No study has analyzed the feasibility of Harmonic instruments in breast-conserving surgery. We conducted a prospective, randomized clinical trial comparing Harmonic instrument and conventional surgery in the performance of breast conserving surgery and axillary procedures to determine differences in surgical procedures, postoperative outcome, and complications.

**Methods:** One hundred and forty seven patients with operable breast cancer who underwent breast-conserving surgery at a single institution between December 2009 and March 2011 were included in the analysis. Surgery was performed in 73 patients with the Harmonic Focus® device and in 74 with scissors and electrocautery. Charts were reviewed for patient demographics, histopathologic reports, surgical procedures, length of stay, volume and duration of postoperative drainage, complications such as seroma and hematoma formation, and postoperative pain.

**Results:** We found a statistically significant difference in size of resected breast tissue (p=0.001), postoperative serum hemoglobin (p=0.001), volume (p<0.001) and duration (p=0.001) of breast drainage, volume (p<0.001) and duration (p=0.001) of axillary drainage, intramammary (p=0.04) and axillary (p=0.006) seroma formation, subjective (p=0.012) and objective (p=0.001) postoperative pain, and length of hospital stay (p=0.002) in favor of the Harmonic surgical device.

**Discussion:** This is the only study comparing the Harmonic instrument with traditional surgery in both breast conserving surgery and axillary procedures. From this study, we conclude that despite higher costs, the Harmonic device is safe to use and provides key benefits in intraoperative technique, postoperative outcome, and rate of complications in breast cancer surgery.

**P2-15-10**

**Do Patients with Incurable Advanced Breast Tumor and Distant Metastasis Derive Any Benefit from Primary Tumor Resection?**

Takahashi M, Shibasaki S, Jotoku H, Watanabe K-I. Hokkaido Cancer Center, Sapporo, Hokkaido, Japan

**Background:** Metastatic breast cancer (MBC) is considered incurable. Surgical removal of primary tumors has not been established as a standard treatment for MBC because it is generally accepted that local therapy provides no survival advantage once metastases have occurred. Additionally, tumor excision may further stimulate metastasis. Therefore, primary tumor resection in patients with MBC is usually only applied as a palliative treatment for symptomatic wound complications such as bleeding, ulcer formation, unpleasant smell, and purulent discharge. In recent years, however, some retrospective studies have reported advantages of debulking surgery in terms of improving patient outcome. We retrospectively analyzed the surgical benefits and prognostic factors for patients with MBC who were treated at our center.

**Methods:** We retrospectively reviewed individual medical records from the Hokkaido Cancer Center. In this study, incurable advanced
breast cancer is defined as the presence of a tumor, larger than 5 cm, and shows either (invasion to chest wall or skin or is an inflammatory carcinoma) and at least one metastatic site, including distant lymph nodes, bone, or visceral organs (lung, pleura, mediastinum, liver, and brain) at diagnosis. Between January 2000 and June 2010, 92 women were diagnosed with incurable advanced breast cancer at our institute. The effect of surgical treatment on survival was evaluated. Patient demographics and tumor characteristics were also investigated.

**Results:** Thirty-six patients had surgery for resection of primary tumors. There were no substantive differences between individuals, or between tumor characteristics, for patients who underwent surgery versus patients who did not. The median survival time for surgically treated patients was 25.0 months versus 24.8 months for patients who did not undergo surgical resection (P=0.352). Only three patients relapsed within three months of surgery. For the remaining majority of patients, primary tumor resection gave some relief from the often severe symptoms that come from harboring a large tumor for an extended time. In univariate and subsequent multivariate analyses of predictive indicators, a diagnosis of triple-negative breast cancer and/or metastasis to more than three sites was significantly associated with a severe prognosis.

**Conclusion:** Primary tumor resection failed to prolong overall survival times in patients with incurable advanced breast cancer that was greater than 5 cm. However, surgery did improve the quality of life in patients who were expected to have a relatively long prognosis.

**P2-15-11**

Outcomes of Corrective Procedure with Vicryl Mesh as an Oncoplastic Surgery of the Breast.

Lim YA, Lee YO, Kim JH, Kim HS, Kang HJ, Kim LS. Hallym Sacred Heart Hospital, College of Medicine, Hallym University, Anyang, Gyeonggi-do, Korea

Background: Both cosmetic and oncologic outcomes are becoming more important for breast cancer patients. Breast-conserving surgery (BCS) has an acceptable cosmetic result compared with mastectomy, but BCS is also associated with cosmetic failure. In this study, we evaluated the cosmetic outcome of reconstructive surgery with the absorbable implant vicryl mesh after BCS compared with the outcome of BCS alone.

Methods: From May 2007 to December 2009, 101 patients were involved in this study at Hallym University Sacred Heart Hospital. We used absorbable implants made of folding vicryl mesh and wrapped them with Interceed. In 79 cases, BCS with vicryl mesh implantation was performed; in the other 56 cases, only BCS was performed. Patient satisfaction with cosmetic outcomes was evaluated. We also analyzed other factors that affected cosmetic outcomes, including patient age, body mass indices, tumor locations, and removed breast tissue.

Results: In the vicryl mesh implantation group, 65 of 79 patients (82.3%) were satisfied; in the BCS-only group, 24 of 56 patients (43%) were satisfied (P < 0.05). In the vicryl mesh implantation group, patient ages, body mass indices, and removed breast tissue did not affect cosmetic outcomes. When the tumor was located in the upper outer quadrant, the patients were more satisfied (P < 0.05).

Conclusions: Reconstructive procedures with vicryl mesh are simple, safe, and less expensive than other plastic reconstruction techniques. This study suggests that the procedure was superior to BCS alone in cosmetic outcomes. We believe that the procedure could become a favorable technique in oncoplastic surgery.

**P2-15-12**

Management Strategy of Early-Stage Breast Cancer Patients: With or without Axillary Lymph Node Dissection.

Yamamoto D, Tanaka K, Tsubota Y, Yosida H, Kanematsu S. Kansai Medical University, Hirakata, Japan; Ribon-Roze Tanaka Kanji Clinic, Osaka, Japan

Background: The sentinel lymph node (SLN) biopsy has steadily replaced axillary lymph node dissection (ALND) for staging clinically node-negative breast cancer. However ALND remains the standard management of the axilla when a tumor-positive sentinel lymph node (SLN) is identified. The aim of this study was to evaluate the ALND in local, distant recurrence, and overall survival (OS) in breast cancer patients.

Methods: We identified 350 patients with breast cancer (clinically T1/T2N0M0) from the prospective database from five institutions from July 1999 and April 2004. All patient age ranged from 26 to 81 (median 49) years. All patients underwent mastectomy or breast conserving surgery (BCT) combined with either ALND or no ALND.
