Criteria of negative ALN metastasis are that minor axis of ALN is under 5 mm on CT images and fat tissue in the hilum of ALN does not disappear on ultra-sound images. In the case that hormone receptor expression is positive, pt was administered for 5 years. In the case of T1c or T2 under 70 years old, neoadjuvant and/or adjuvant anthracycline-based chemotherapies were administered. After surgery, patients without ALND with ALND received tangential irradiation at the region of breast. ALND and no ALND groups were compared for incidence of local, regional, distant recurrence, and overall survival.

Results: Patients with ALND (n=350) were compared with no ALND group (n=126). There were significant differences in primary tumor size, histology, nuclear grade, presence of LVI, ER/PgR/HER2 status between the two groups. Five years OS was 97.9% in ALND group, it was 98.0% in no ALND group (p<0.01). Further there was no significant difference between two groups in local, regional, and distant recurrence.

Conclusions: These results indicate that ALND is omissible for cT1/T2N0M0 breast cancer by a combination of hormone therapy, neoadjuvant/adjuvant chemotherapy, and irradiation.

Oncologic and Cosmetic Outcome in Breast Cancer Patients Who Underwent “Moving Window” Operation.

Ohno Y, Noguchi M, Nakano Y, Noguchi M, Kosaka T. Kanazawa Medical University, Japan

Background: An inappropriate skin incision on the breast reduces the cosmetic benefit of breast-conserving surgery (BCS).

Methods: To improve the cosmetic outcome, we have performed “Moving window” operation in which BCS can be performed via a periareolar incision (periareolar approach) and/or axillary incision (axillary approach) under direct visualization. Axillary lymph node dissection is also performed via an axillary incision.

Results: Periareolar approach was performed in 65 patients and axillary approach in 43 patients. Average operation time was 130 minutes in periareolar approach and 131 minutes in axillary approach. Average blood loss was 37 mL and 50 mL, respectively. Postoperatively, the surgical margin of breast tissue was histologically confirmed to be negative in 107 (99%) of 108 patients, while two patients underwent reoperation because of positive surgical margin. Fifty-two patients (85%) in periareolar approach and 37 patients (86%) in axillary approach had excellent or good cosmetic results.
With a mean follow-up of 36 months, one patient with DCIS developed in-breast recurrence, while 3 patients who had neoadjuvant chemotherapy developed in-breast recurrence. 

Conclusion: The moving window operation can improve a cosmetic outcome of the conserved breast without compromising the oncological safety. Moreover, it can reduce operating time and blood loss when compared with the endoscope-assisted BCS.

**P2-16-01**

A Multi-Centre Prospective Cohort Study Evaluating Health Related Quality of Life after Types of Immediate Latissimus Dorsi (LD) Breast Reconstruction.

**Introduction:** Evidence for the clinical effectiveness of breast reconstruction based on Patient Reported Outcome Measures (PROMS) is lacking. Methodology evaluating PROMS after types of breast reconstruction has been poor with respect to study design, statistics, missing data and absence of prospective documentation of pre-defined complication data in a systematic review of all studies since 1978. Furthermore, there is no reliable data on the effects of associated radiotherapy (RT) in this context. As a prelude to a proposed randomised trial in breast reconstruction, our aim was to conduct a 'robust' cohort study evaluating the effects of either implant-assisted LD (LDI) or tissue only (ALD) LD flap reconstruction in relation to key determinants including clinico-pathological parameters, complications and treatment schedules over a 36 month period.

**Methods:** An MREC approved prospective longitudinal cohort study involving 6 centres commenced in early 2007. Serial PROMS using the EORTC QLQ-C30, BR-23, FACT-B, BIS and HADS, were completed pre-operatively and at 3, 6, 12, 24 and 36 months after surgery. Data up to 12 months were included in this analysis as data were sparse beyond this point; follow-up is ongoing. Demographic and clinical data were compared between the surgical groups. Generalised estimating equations were used to investigate demographic and clinical predictors of HRQL over time.

**Results:** A total of 189 patients (107 – ALD, 82 – LDI) were recruited, with a mean age of 50 years (range 22-70). Baseline questionnaires were completed by 149 (79%) women, with 167 (88%) available surveys (51% response rate). MO and PS had similar overall knowledge scores (MO 59%, PS 56%, p=0.5). 23% of MO knew the correct treatments for breast skin necrosis, and 60% knew the correct treatment for seromas. 32% of PS knew the approximate duration of Her2-directed therapy, and 14% of PS identified the usual adjuvant treatment for patients who have had neoadjuvant chemotherapy. Providers from both specialties who primarily practice in a rural setting scored significantly lower on the knowledge portion of the survey than those practicing in an academic medical center or urban/suburban area (51% rural versus 59%, p=0.03).

The MO and PS agreed on the MO’s degree of responsibility for timely chemotherapy initiation (MO mean 4.6 versus PS mean 4.4 out of 5, p =0.2). However, they disagreed about the PS’s responsibility for timely chemotherapy initiation (MO mean 3.8, PS mean 3.0 out of 5, p=0.01). MO attributed low importance to a history of immediate breast reconstruction when planning chemotherapy treatment (mean 2.5 out of 10). PS placed little importance on the likelihood of post-operative chemotherapy when planning immediate breast reconstruction (mean 3.6 out of 10). Both MO and PS reported more frequent communication with each other about patients with complications (p<0.01 for various subscales). Significant improvements over time were noted for global QoL, role and social functioning, fatigue, pain and breast symptoms (p<0.001 for all).

**Conclusion:** There is increasing evidence of clinical equipoise between types of LD breast reconstruction and despite acknowledged cosmetic disadvantages the overall effects of PMRT on HRQL are minimal. The identification of important variables that may affect HRQL is crucial in all studies evaluating the effects of surgery on PROMS. Their integration into study results is essential for correct interpretation of clinically based assessments. This remains a challenging aspect in cohort studies, and emphasises the need for pragmatism in design of trials in the field.

**P2-16-02**

How Well Do Medical Oncologists and Plastic Surgeons Communicate about Their Patients?

Milucky JL, Deal A, Wu R, McNally RS, Anders C, Lee C. University of North Carolina at Chapel Hill, Chapel Hill, NC

**Background:** While complications of post-mastectomy breast reconstruction can affect the timing of adjuvant chemotherapy, chemotherapy can affect the wound healing process after reconstruction. Due to this interdependence, adequate communication between medical oncologists (MO) and plastic surgeons (PS) may be critical to optimize patient outcomes. In this study, we sought to evaluate the knowledge MO and PS have of each other’s fields, the roles they expect of each other, and how often they communicate in treating breast reconstruction patients.

**Methods:** A cross-sectional survey was conducted in a convenience sample of MO who treat at least one breast cancer (BC) patient per month and PS who perform at least one breast reconstruction per year. Surveys were distributed via email, US mail, and at two professional meetings. The survey included knowledge questions about reconstruction and chemotherapy, questions about provider and patient responsibilities for timely chemotherapy initiation, and questions about communication with other specialties. Fisher’s Exact and Wilcoxon Rank Sum tests were used to compare differences between groups.

**Results:** 53 medical oncologists and 23 plastic surgeons completed surveys (51% response rate). MO and PS had similar overall knowledge scores (MO 59%, PS 56%, p=0.5). 23% of MO knew the correct treatments for breast skin necrosis, and 60% knew the correct treatment for seromas. 32% of PS knew the approximate duration of Her2-directed therapy, and 14% of PS identified the usual adjuvant treatment for patients who have had neoadjuvant chemotherapy. Providers from both specialties who primarily practice in a rural setting scored significantly lower on the knowledge portion of the survey than those practicing in an academic medical center or urban/suburban area (51% rural versus 59%, p=0.03).

The MO and PS agreed on the MO’s degree of responsibility for timely chemotherapy initiation (MO mean 4.6 versus PS mean 4.4 out of 5, p =0.2). However, they disagreed about the PS’s responsibility for timely chemotherapy initiation (MO mean 3.8, PS mean 3.0 out of 5, p=0.01). MO attributed low importance to a history of immediate breast reconstruction when planning chemotherapy treatment (mean 2.5 out of 10). PS placed little importance on the likelihood of post-operative chemotherapy when planning immediate breast reconstruction (mean 3.6 out of 10). Both MO and PS reported more frequent communication with each other about patients with complications (p<0.01 for various subscales). Significant improvements over time were noted for global QoL, role and social functioning, fatigue, pain and breast symptoms (p<0.001 for all).

**Conclusion:** There is increasing evidence of clinical equipoise between types of LD breast reconstruction and despite acknowledged cosmetic disadvantages the overall effects of PMRT on HRQL are minimal. The identification of important variables that may affect HRQL is crucial in all studies evaluating the effects of surgery on PROMS. Their integration into study results is essential for correct interpretation of clinically based assessments. This remains a challenging aspect in cohort studies, and emphasises the need for pragmatism in design of trials in the field.

than about uncomplicated patients (mean 3.9 times over first 6 month for complications versus mean 1.6 over first 6 months for uncomplicated). This translated to communicating about 2.5 times as often for complicated patients (p<0.001).

Conclusion: Medical oncologists and plastic surgeons have substantial deficits in knowledge about each other’s fields and differ in their opinion regarding the burden of responsibility in ensuring timely chemotherapy initiation. While MO and PS increase their communication when complications arise, these data suggest room for improvement in communication and understanding, which could improve the care of BC patients who undergo reconstruction and chemotherapy.

**P2-16-03**

Outcomes of Nipple-Sparing Mastectomy (NSM) and Immediate Reconstruction.

Chidiester JR, Olson JR, Poruk KE, Marengo JJ, Matsen CB, Neumayer L, Agarwal J. Loma Linda University Medical Center; Loma Linda, CA; University of Utah School of Medicine, Salt Lake City, UT

**Background:** Nipple-sparing mastectomy (NSM) is the surgical removal of breast tissue that preserves the entire skin envelope including the nipple areola skin (NAS). We report our experience performing NSMs and immediate breast reconstruction for both high-risk breast cancer treatment and prophylaxis over a six-year period at The University of Utah and Huntsman Cancer Hospital.

**Methods:** A retrospective chart review was performed on patients undergoing NSM from April 2005 – April 2011. Data collection included: patient demographics, oncologic details, surgical information (including reconstruction timing and type), and complications (infection, hematoma, seroma, skin necrosis, NAS complication, skin flap loss, premature expander exchange/removal, and capsular contracture).

**Results:** 130 patients underwent 205 NSMs. Of these, 106 (81.5%) patients received mastectomy treatment for cancer while 24 (18.5%) patients were prophylactically treated. 102 NSMs (49.8%) were on breasts with biopsy-proven cancer, while 103 (50.2%) NSMs were on breasts for prophylaxis. All patients were female with a mean age of 44.7 years (range, 16 – 82 years). 119 (92.2%) patients were Caucasian, 3 (2.3%) were Asian, and 1 (0.8%) was Hispanic. The age of 44.7 years (range, 16 – 82 years). 119 (92.2%) patients were prophylactically treated. 102 NSMs (49.8%) were on breasts with cancer, while 103 (50.2%) NSMs were on breasts for cancer while 24 (18.5%) NSMs were for prophylaxis. Overall, complication rates are higher in breasts treated for cancer. Overall, complication rates are low in both cases of cancer and prophylaxis; this demonstrates that NSM and immediate reconstruction is a highly effective method of treatment for both groups.

Ochoa O, Chrysochou M, Nastala C, Ledex P, Pisan S. Plastic Reconstrucive and Microsurgical Associates of South Texas, San Antonio, TX

Introduction: Promoted by reports of decreased donor-site morbidity compared to traditional transverse rectus abdominis (TRAM) flap breast reconstruction, deep inferior epigastric perforator (DIEP) flaps have gained significant popularity. Increasing body mass index (BMI) is associated with poor flap-specific and donor-site outcomes in breast reconstruction using traditional techniques. The current study aims at defining flap-specific and donor-site complications with increasing BMI in patients undergoing DIEP flap breast reconstruction.

**Methods:** A retrospective analysis of 639 DIEP flaps in 418 consecutive patients between Jan 2006 to March 2008 was performed. Patients were stratified into five groups based on BMI: normal weight (≤ 24.9), overweight (25-29.9), obese (30-34.9), severely obese (35-39.9), and morbidly obese (≥ 40). Medical co-morbidities, adjuvant chemo-radiation therapy, timing of reconstruction, active tobacco use and surgical history were collected. Primary outcomes were compared between BMI groups.

**Conclusion:** When comparing NSMs in both patients and individual breasts with cancer to patients and breasts treated for prophylaxis, there is no significant difference in complication rates by case or breast, except for the capsular contracture rate, which was significantly higher in breasts treated for cancer. Overall, complication rates are low in both cases of cancer and prophylaxis; this demonstrates that NSM and immediate reconstruction is a highly effective method of treatment for both groups.
thrombotic and overall complications including flap failure were not significantly different between groups. Donor-site complications stratified by BMI demonstrated significantly increased delayed wound healing and overall complications among morbidly obese patients compared to other groups. Incidence of donor-site infection, acute or subacute hematomas, seroma formation, abdominal wall bulging, and hernia formation were not significantly different between groups despite increasing BMI.

Conclusion: Increasing BMI predisposes patients to delayed wound healing complications in both flap and donor-site locations. Nevertheless, overall flap complications remain similar across all BMI groups. Despite increased overall donor-site complications in patients with increasing BMI, abdominal wall stability was maintained during a follow-up period approximating 3 years. Given a similar flap complication profile and maintenance of abdominal stability, DIEP flaps are recommended in patients with increased BMI.

**Delay of Adjuvant Chemotherapy after Elective Mastectomy and Immediate Reconstruction in Breast Conservation Candidates: A Matched-Pair Analysis.**

Barry PN, Riley EC, Pan J, Crew JB, Lee K, Jain D, Kruse B, Quillo AR, Rai S, Dragan AE. James Graham Brown Cancer Center; University of Louisville School of Medicine, Louisville, KY

Background: To analyze factors that influence the timing of adjuvant chemotherapy in patients who are candidates for breast conservation therapy (BCT) but elect mastectomy with immediate reconstruction (M-IR).

Methods: Using data from the University of Louisville Cancer Registry, we identified 35 consecutively-treated patients with stage I or II breast cancer between 2004 and 2009 who underwent M-IR and adjuvant chemotherapy. These were matched for age and AJCC stage to 35 controls who underwent BCT and adjuvant chemotherapy. We examined the timing of initiation of chemotherapy from the date of surgery and assessed the probability of therapeutic delay using univariate logistic regression and McNemar’s test for matched pairs.

Results: For the 70 patients included in this study, the median age was 46y (range: 30-65y), and the distribution for stage I, IIa and IIb was 22.9%, 65.7% and 11.4%, respectively. The two groups were well balanced in terms of race, rural/urban status, smoking, diabetes, insurance coverage, and histology. The median time to initiation of adjuvant chemotherapy was 38 days (range: 25-103 days) for BCT and 55 days (range: 30-165 days) for M-IR. Patients undergoing M-IR were more likely to experience any delay (> 45 days; 74.3% vs. 25.7%, p < 0.001) and/or significant delay (>90 days; 20.0% vs. 2.9%, p < 0.001) than those choosing BCT. On univariate logistic regression analysis, the extent of surgery had a major impact on the likelihood of any delay in chemotherapy (OR= 8.35, 95% C.I. = 2.86-24.3, p <0.001). None of the other aforementioned factors predicted for delay.

Conclusion: The use of elective mastectomy with immediate reconstruction in breast conservation candidates independently predicts for delay in initiation of adjuvant chemotherapy. Further study is needed to qualify the underlying causes of and ultimate clinical significance of these delays.

**P2-16-06**

**A Systematic Review of Standardised Clinical Outcomes and Patient Reported Outcome Measures (PROMS) in Breast Reconstruction.**

Winters ZE, Chaudhry A, Benson JR. University Hospitals Bristol NHS Foundation Trust, Bristol, South West, United Kingdom; Cambridge University Hospitals NHS Foundation Trust, Cambridge, East Anglia, United Kingdom

**Introduction**

Failure to prospectively define and report surgical complications across a range of study designs is a confounding factor that fundamentally compromises the interpretation of data on health-related quality of life (HRQL) and PROMS. The UK National Mastectomy and Breast Reconstruction audit on 5000 breast reconstruction patients found higher than expected levels of complications (including rates of reoperation and levels of infection). We aimed to analyze the reporting of complications in a systematic review of all studies evaluating PROMS in breast reconstruction since 1978.

**Methods**

Efficace criteria for HRQL methodology were used to assess the inclusion eligibility for each study. Two out of 34 eligible studies were excluded due to overlapping patient datasets and small numbers (n<=5) of breast reconstruction cases. Two reviewers examined the reporting of complications. The study designs comprised: 2 randomised controlled trials (RCT); 10 prospective longitudinal studies (PLS) and 20 retrospective studies (RS). RCTs and PLSs were evaluated for predefined complications, their grading according to Clavien-Dindo and their integration into the evaluation of PROMS results. RS were evaluated for the reporting of complications and their statistical methodology.

**Results**

A total of 3213 patients were included in the 32 studies. The type of reconstruction was only recorded in 71% of patients. The majority of patients in these studies underwent abdominal flap reconstruction, compared to implant only techniques (32%), and less than 10% comprising Latissimus dorsi flaps. Only 19% of studies recorded complications with the majority (81%) failing to report any complications. Only 3 studies provided details of the numbers and level of complications amongst a total of 44 patients (1.4% of the total number of patients). Reported complications were graded and classified either as major (requiring surgical intervention) or minor comprising 55% and 45%, respectively. None of the RCT or PLS studies defined either the type or level of complications a priori, nor stratified complications based on risk factors such as age, body mass index, smoking and diabetes.

**Conclusion**

There is a significant under estimation of the contribution of complications to HRQL and PROMS reporting. This fact diminishes the current evidence on the effects of breast reconstruction on PROMS. There should be collective efforts to improve the standards of documentation for clinical outcomes in breast reconstruction. This together with standardized reporting of PROMS will consolidate clinical evidence upon which decision-making and provision of patient information can be confidently based.

P2-16-07
A Randomised Controlled Trial To Evaluate the Role of Tisseel, a Fibrin Sealant on Seroma Formation in Latissimus dorsi Breast Reconstruction.
Winters ZE, Llewellyn-Bennett R, English R, Turner J, Rayter Z, Greenwood R. University Hospitals Bristol NHS Foundation Trust, Bristol, South West, United Kingdom

Introduction
Donor site seromas are common complications following Latissimus dorsi breast reconstructions (LDBR), as shown in the UK National Mastectomy and Breast Reconstruction audit. Level I clinical evidence following the performance of an RCT supports ‘fixation’ of the back skin flaps by quilting sutures. Fibrin sealants (Tisseel) have been postulated to reduce seromas after simple mastectomy and axillary dissections, but their role in reducing donor site seromas after breast reconstruction has yet to be performed in a ‘robust’ clinical trial. The aim of this RCT was to compare Tisseel against Control (no Tisseel) on the incidence of seromas after LDBR.

Methods
In an ethics approved single centre, single-blinded study comprising 2 surgeons from 2005-2010; 106 women were randomised to either Control (52) or Tisseel (54) interventions after immediate or delayed breast reconstructions. Sixteen patients were excluded as follows due to incomplete data at 3 months or re-operations of the donor site for complications. The types of breast reconstructions comprised implant-assisted LD (LDI) in 45 women, 23 extended LD flaps (ELD) and 23 ELD with implant (ELDI). Immediate breast reconstructions (n=87) comprised the majority compared to only 4 delayed procedures. Intraoperative drains were placed to the breast, axilla and donor site (x two) as per standard practice. A 0.5% fibrinogen concentration was used in a hydraulic hand-held Tisseel spray application to the donor site chest wall over 60 seconds. Two stay sutures were pre-placed 2 cm adjacent to the donor wound skin edges above and below prior to the Tisseel application. In the control group, 2 drains only were placed.

The primary outcome measure was the total seroma volumes from all the sites over 3 months. This was used for the power calculation of the sample size and showed a requirement for a minimum of 95 women. Secondary outcomes included the volumes of the donor site seromas, and the frequency of post-drain removal donor site aspirations of all symptomatic seromas by patient self-report.

Results
The effect of Tisseel glue was to reduce the mean total drain (breast, axilla and back) volume from 2170ml to 1919ml (P=0.05, Mann-Whitney) within 7-10 days. The donor site seromas volumes were similar between the 2 groups over 3 months. The mean donor site total drain volumes (LD donor site drain volume and symptomatic donor site aspirations) were 5412ml in the Control group (840-6252), compared to the Tisseel group producing 4646ml (5384-738). There were no statistical differences between the frequencies or volumes of patient reported seromas aspirated post-drain removal between the two groups. This comprised a mean of 4 aspirations (range 0-13) in the Control group compared to a mean of 9 aspirations (range 0-11) after the use of Tisseel (P=0.548).

Conclusion
Tisseel glue may reduce the ‘early’ effect of seroma development, but has not shown any significant role in minimising the potential ‘shearing’ of the donor site skin flaps causing later seroma formation. Current evidence recommends quilting sutures as the gold-standard in reducing this complication.

Gath AA, Blechman K, Levowitz C, Small K, Axelrod D, Karp N, Choi M. NYU-Langone Medical Center, New York, NY; NYU-Langone Medical Center

Purpose: Nipple and/or areola-sparing mastectomy as a therapeutic or prophylactic procedure for breast cancer is rapidly gaining popularity as the literature continues to support it safety. The lateral inframammary fold (IMF) approach provides adequate exposure and eliminates visible scars on the anterior surface of the breast, making this incision cosmetically superior to radial or periareolar approaches.

Methods: We reviewed 58 consecutive nipple and/or areola-sparing mastectomies performed through a lateral IMF incision with immediate implant-based reconstruction, with or without tissue expansion, between June 2008 and February 2011. Prior to incision, breasts were lightly tumesced with dilute anesthetic solution with epinephrine. Sharp dissection, rather than electrocautery, was used as much as possible to minimize thermal injury to the mastectomy flap. When indicated, acellular dermal matrix was placed as an inferolateral sling. Subsequent fat grafting to correct contour deformities was performed in select patients. Three-dimensional (3D) photographs assessed changes in volume, antero-posterior projection, and ptosis. Retroareolar/nipple tissue underwent routine intraoperative frozen section analysis in cancer cases.

Results: Mean patient age was 44 years, and mean follow-up time was 14 months. Depending upon the judgment of the oncologic surgeon, 44 (76%) mastectomies were nipple/areola-sparing, and 14 (24%) were areola-sparing. Thirteen mastectomies (22%) were therapeutic, the remaining 45 mastectomies (78%) were prophylactic. Five of the nine sentinel lymph node biopsies (56%) were performed through the lateral IMF incision without the need for a counter-incision. Acellular dermal matrix was used in 44 (76%) breasts. Average permanent implant volume was 313 cc (range 170 to 750 cc), and average fat grafting volume was 90 cc (range 36 to 177 cc). Mastectomy flap necrosis, requiring operative debridement, occurred in three breasts (5%). One of these breasts required a salvage latissimus dorsi myocutaneous flap to complete the reconstruction. Of the 44 nipple/areola sparing mastectomies, three (7%) required operative debridement and reconstruction for partial nipple necrosis. No statistically significant differences existed between therapeutic and prophylactic mastectomies for developing partial skin or nipple necrosis (p = 0.65). Morphologic outcomes using 3D scan measurements showed reconstructed breasts were larger, more projected, and less ptotic (196 vs. 248 cc, 80 vs. 90 mm, 146 vs. 134 mm, p < 0.01 for each parameter).

Conclusion: Excellent results can be achieved with immediate implant-based reconstruction of nipple and/or areola-sparing mastectomy through a lateral IMF incision. NAC survival is reliable, and complication rates are low.

P2-16-10
Practice Variations in Post-Mastectomy Breast Reconstruction: What Are the Roles of Clinical Factors, Access Barriers, and Delayed Reconstruction?
Cox D, Milickey J, Dominik R, Lee C. University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: Breast reconstruction rates vary widely by race, income, and location. Proposed explanations have included clinical contraindications to reconstruction, access barriers, and patient or surgeon preference for delayed reconstruction. We sought to determine whether clinical contraindications (planned radiation, comorbidities) or access barriers (distance to care, surgeon) were associated with reconstruction and to estimate the frequency of delayed reconstruction over time.

Methods: A retrospective cohort study was conducted among women treated with mastectomy for Stage 0-IIA breast cancer between 2002 and 2007 at one institution. Demographics, stage, comorbidities, adjuvant therapy plans, and treatments were obtained from the medical record. Multivariable modified Poisson regression analyses were performed, with immediate and any reconstruction (immediate or delayed) as outcomes. Interaction terms were added to examine surgeon effects. Kaplan-Meier survival analysis was performed.

Results: Among 539 women, 18.9% had a plan for chemotherapy; 13.7% had a plan for radiation. Comorbidities were: obesity 17.1%, diabetes 11.9%, smoking 16.3%, heart disease 5.6%, immunodeficiency 2.2%. Most patients (59.8%) lived within 50 miles of the hospital. 33.8% had immediate reconstruction; 5.6% had delayed. Patients who had a plan for adjuvant therapy or comorbidity were less likely to have reconstruction. Patients who lived farther from the hospital were slightly more likely to have reconstruction, but this was not statistically significant (p<0.08). None of the associations varied significantly by surgeon. Few patients had reconstruction more than 2 years after mastectomy.

Role of Proper Patient Counselling in Combination with Effect of Socioeconomic Deprivation on the Rate of Immediate Breast Reconstruction after Mastectomy.
Chakrabarti M, Stallard S, Fitzgerald C, Obondo C, Weiler-Mithoff E, Doughty J, Romans, Jr L. Victoria Infirmary Glasgow; Glasgow Royal Infirmary; Western Infirmary Glasgow

Introduction: current guidelines in the United Kingdom suggest that the possibility of breast reconstruction should be discussed with all patients prior to mastectomy. However, the majority of patients are still treated with mastectomy alone and no reconstruction is carried out. It has also been suggested that women from more deprived areas are less likely to undergo immediate breast reconstruction (IBR). We investigated potential pitfalls in patient counselling and consequent decision making contributing to present IBR rate in combination with the effect of socioeconomic deprivation.

Methods: data from 89 consecutive mastectomy patients was prospectively collected in a single centre in Glasgow between August 2010 and March 2011. Each patient was scored for deprivation based on The Scottish Index of Multiple Deprivation. The patients were then divided into two groups: high and low deprivation levels. Consultations about IR and patients’ acceptance of counselling were analysed. For statistical calculations Fischer’s exact test was applied. Results: IBR was offered to 41 (46%) patients, but it was not to 42 (47%) (6 were excluded due to incomplete data). 25 patients accepted IBR, and of those 24 (27%) underwent IBR. 16 of 41 patients refused to undergo IBR due to lack of interest (10), not feeling ready for it (2), preference of delayed procedure (2) and fear of delaying
adjuvant therapy (2). Of 42 patients whom IBR was not offered, only 10 were documented in the notes, while there was no reference for discussing reconstruction in 32 (76%) cases. Reasons for not even discussing reconstruction were the following: age (15), co-morbidities (18), locally advanced cancer (2), co-morbidities with age (5), and locally advanced cancer with age (2). As regards to socioeconomic deprivation; 44 (49%) patients were from deprived areas and 39 (44%) from affluent areas. 41 patients were offered IBR and of these 23 (26%) were from affluent areas compared to 18 (20%). Of the 42 patients who were not offered IBR, 26 (29%) were from deprived while 16 (18%) from affluent areas (p<0.05). Of the 44 deprived patients, 18 were offered IBR but 26 were not. 15 of 25 patients, who accepted IBR, were from affluent areas. The 16 patients who refused IBR had equal distribution of deprivation.

Conclusions: while none of the reasons for not offering IBR represent absolute contraindication to IBR, decisions about refusal are based mostly on patients’ subjective intuitions. Further, a greater proportion of the patients who were not offered IBR were from more deprived areas, and it seems that patients from affluent areas are more likely to be offered and IBR compared to ones from deprived areas. However, confounding factors such as co-morbidities may contribute to the above. We believe, therefore, that detailed counselling about reconstruction of each patient requiring mastectomy is necessary, which is likely to further increase IBR rate.

Skin Reducing Nipple Sparing Mastectomy – A Treatment Option for Patients with Significant Ptois or Macromastia.

Ott Young A, Alizadeh K, Hodyl C, Pronovost M, Davenport T. Yale New Haven Health System, Fairfield, CT; Long Island Plastic Surgical Group, Garden City, NY; South Nassau Communities Hospital, Oceanside, NY

Background: With new data showing the oncologic safety of nipple sparing mastectomy with immediate reconstruction - nipple sparing mastectomies are now offered to an increasing number of mastectomy patients. Unfortunately cosmetically acceptable reconstruction of nipple sparing mastectomies is technically limited to women with perfect breast anatomy - where the skin envelope shows no or little redundancy and where the nipple areolar complex is located in the perfect location on the breast mount. Especially in countries with a high incidence of obesity and associated macromastia only a small percentage of women fall into this category. A high percentage of patients who would otherwise be good candidates for nipple sparing procedures are excluded based on their unfavorable breast anatomy. We describe a surgical technique that reduces the redundant mastectomy skin envelope in a breast reduction pattern and places the native nipple areolar complex as a free skin graft into proper anatomical position. This technique in conjunction with implant or autologous reconstruction combines the benefits of shorter better vascularized skin flaps with the cosmetic and emotional benefits of preserving the nipple areolar complex even in the anatomically difficult cases.

Methods: To investigate the safety and efficiency of this method we reviewed medical records of 40 patients who underwent 60 nipple preserving skin reducing mastectomies over the last 4 years. All procedures were performed by the senior author and follow up ranged from 4 weeks to 50 months.

The charts were analyzed for the occurrence of complications such as infection, seroma, hematoma, mastectomy flap necrosis, nipple-areolar loss and loco regional recurrence. All patients were asked to rate their reconstruction on a scale of poor-good-excellent.

Results: In 60 reconstructed breasts we encountered one case of seroma, four cases of limited mastectomy flap necrosis treated with local wound care and one case of partial areolar necrosis treated with local excision. No loco regional recurrences, hematomas or infections were encountered. Out of the group of 40 patients, 31 patients rated their result as excellent, 8 as good, and one as poor.

Conclusion: Our results compare favorably with data published in the literature. Patient satisfaction rates are high and complication rates are low in a patient population that historically has been a challenge for the breast surgeon, as well as, the plastic surgeon. The use of a skin reducing mastectomy in conjunction with a free nipple graft enables the breast surgeon to offer nipple sparing procedures for all patients who are good oncologic candidates regardless of their breast anatomy.

Life after Mastectomy without Breast Reconstruction – Are the Needs of Caribbean Women Different?

Morton-Gittens J, Ali R, Ajfan AM, Bovell P, Rampaul R. National Radiotherapy Centre, St James, Trinidad and Tobago

Aim: The standard of care in the United States and United Kingdom for women undergoing mastectomy is to be offered breast reconstruction surgery (BRS), either immediate or delayed. In Trinidad, for a variety of reasons, patients are not routinely offered this option. We undertook a study to determine the impact of breast surgery without reconstruction on their perception of sexuality, body image, relationships and quality of life. The aim is to establish a benchmark for the planning and incorporation of reconstructive options into the care pathway of patients requiring oncoplastic surgery in the Caribbean.

Method: A questionnaire was administered to post surgery breast cancer patients in a public oncology clinic in Trinidad. These patients had no BRS and had surgery at various institutions in Trinidad, where the primary surgical service was General Surgery. Data was collected prospectively and analysed using SPSS software.

Results: Of 130 questionnaires administered to date, 80(61.5%) of those collected were adequate for analysis. 46.1%(n=35) of patients were less than fifty years of age; 44%(n=24) were Afro-Caribbean and 55.6%(n=30) East Indian-Caribbean; 61.1%(n=44) had mastectomies and 38.9%(n=28) had breast conserving surgery (BCS). Of all patients, 90%(n=70) felt attractive, feminine and satisfied with their bodies before surgery, however postoperatively, all who had BCS remained satisfied with their bodies but a significant proportion of patients in the mastectomy group were dissatisfied (p=0.006) and found it harder to look at themselves naked (p=0.025) and be seen naked by their partners (42.9%, n=15). East Indian-Caribbean women felt less attractive after surgery compared to Afro-Caribbean patients (p=0.024). Among all patients, 19.2% felt shy to go out in public after surgery, 28.8% left their house less and 35% (n=25) had fewer social interactions. When analysed by ethnicity, East Indian-Caribbean women were more likely to avoid public events (p=0.003) and had fewer social interactions (p=0.028) than Afro-Caribbean patients. This effect persisted in mastectomy patients (p=0.007), especially in the East Indian-Caribbean group (p=0.0017). 69% of
patients were willing to undergo BRS, but it was offered to only 32.5% (n=13) of mastectomy patients. The interest in BRS was similar in all races, age groups and surgery types.

Conclusion: This study explores the experiences and needs of Caribbean women with breast cancer in Trinidad. We found from this data that their needs mirror those of women in other countries where BRS is incorporated into the core care pathway. Our data demonstrates that even with ethnic differences, there is deterioration in self esteem and femininity with breast cancer surgery, with lasting effects. Subtle differences appear to be present in body image perception amongst East Indian-Caribbean women versus Afro-Caribbean and may be a useful template when assessing patient needs with a view to how we individualize care in the Caribbean setting. This data also emphasizes the potential benefit in incorporating an Oncology-Plastic Surgery Team approach in our setting and supports the view that providing BRS to patients as early as possible can help to maintain a positive outlook in personal and social interactions.

P2-16-14
Skin Sparing Mastectomy and Immediate Latissimus Dorsi Flap Reconstruction: Patient Reported Outcome and Factors Affecting the Highest Patient Satisfaction.
Kim Z, Kang S-G, Lee J, Kim SY, Lim CW, Lee MH. Soonchunhyang University Hospital, Seoul, Korea

Background: Skin sparing mastectomy (SSM) and immediate breast reconstruction (IBR) with latissimus dorsi (LD) flap is a tailored surgical procedure for breast cancer patients. In this study the oncologic safety, morbidities, and aesthetic results of SSM and LD IBR, as regards to patient satisfaction, were assessed.

Material and Methods: Between March 2000 and February 2011, single surgeon performed SSM and IBR for 145 patients. Eighty-five patients completed the patient satisfaction survey, and 65 patients with SSM and LD IBR were included. The patients were divided into 2 groups according to their degree of satisfaction, and a stratified analysis was performed.

Results: The mean age of the patients was 48.4 years (range, 21-74), and the pathologic results were infiltrating ductal carcinoma (n=48, 73.8%), ductal carcinoma in situ (n=15, 23.1%), and others (n=2, 3.1%). After a mean follow-up of 34 months (range, 1.6-89.9) no local recurrence occurred, and there were no skin necrosis or LD flap loss. Donor site morbidities were seroma (n=8, 12.3%), scarring (n=8, 12.3%), and back pain (n=6, 9.2%).

Table: Post-operative complications and morbidities

<td>2 (7.7%)</td>
<td>0.726</td>
</tr>
</tbody>
</table>

Conclusion: The present study demonstrated that our SSM and LD IBR was oncologically safe, and was associated with low morbidity rates. LD flap per se, without a prosthesis implant, could sufficiently produce a high level of patient satisfaction. Accurate surgical techniques and careful consideration for breast symmetry and nipple cosmesis would be the key to meet the patient’s expectations and enhanced quality of life.

P2-16-15
Oncological Safety and Survival Rate According to Reconstructive Surgery in Advanced Breast Cancer after Neoadjuvant Chemotherapy.
Kim WW, Lee JJ, Nam KH, Jung JH, Chae YS, Yang JD, Lee YH, Park HY. Kyungpook National University; Hyesung Hospital

Purpose
Oncoplastic surgery has received attention according as the incidence of breast cancer is rising and quality of life including cosmetic result after surgery is regarded as important. The aim of this study is to compare combined reconstructive surgery with standard surgery regarding to oncological safety and survival rate in advanced breast cancer after neoadjuvant chemotherapy (CTx).

Method
Thirty-seven patients underwent neoadjuvant CTx and surgery with advanced breast cancer were analyzed from September 2007 to March 2010. Group A (n=12) received combined reconstructive surgery, group B (n=25) had standard surgery.

Results
There were no differences in age, size, metastatic LN, stage, ER/PR/Her-2 status, recurrence, metastasis and death between group A and B. Patients with good response in neoadjuvant chemotherapy (26 cases (72.9%)) had CTx-operation-radiation therapy (RTx), cases with poor response (10 cases (27.1%)) underwent CTx-RTx-operation. There was significant difference in order of treatment, eight patients among group A(66.6%) had CTx-RTx-operation, 22 cases in group B(88.0%) received CTx-operation-RTx (p=0.006). Mean follow up period was 22 months, 2 patients (5.2%) experienced local recurrences, 11 cases (34.3%) diagnosed with distant metastasis, and 4 patients (10.5%) expired with breast cancer.

Group 1: poor, fair, and good patient satisfaction. Group 2: excellent patient satisfaction

Conclusion: This study explored the experiences and needs of Caribbean women with breast cancer in Trinidad. We found from this data that their needs mirror those of women in other countries where BRS is incorporated into the core care pathway. Our data demonstrates that even with ethnic differences, there is deterioration in self esteem and femininity with breast cancer surgery, with lasting effects. Subtle differences appear to be present in body image perception amongst East Indian-Caribbean women versus Afro-Caribbean and may be a useful template when assessing patient needs with a view to how we individualize care in the Caribbean setting. This data also emphasizes the potential benefit in incorporating an Oncology-Plastic Surgery Team approach in our setting and supports the view that providing BRS to patients as early as possible can help to maintain a positive outlook in personal and social interactions.
Conclusion
Advanced breast cancer with poorly responded in neoadjuvant CTx could be actively treated with sequential CTx-RTx-reconstructive surgery. Combined reconstructive surgery was oncologically safe operation in advanced breast cancer.

Nipple Sparing Mastectomy and Immediate Breast Reconstruction: Critical Appraisal of Five Year, Single Centre Outcomes.
Westbroek D, Karat I, Min-Hui H, Gukas I, Daoud R, Laidlaw IJ. Frimley Park Hospital, Portsmouth Road, Frimley, Surrey, United Kingdom

Background:
Approximately 5,000 patients undergo breast reconstruction annually in the United Kingdom (2:1 ratio of immediate versus delayed respectively). Whilst skin sparing mastectomy is an accepted modality for local control in appropriately selected patients, nipple preservation remains controversial. In over 1,800 peer reviewed nipple sparing mastectomy (NSM) cases, the local event rate attributable to NAC preservation following NSM (therapeutic and prophylactic) is 0.16% with no evidence of deleterious impact on disease free survival. This study aims to evaluate in a selected cohort of patients, the oncological safety and aesthetic outcome of nipple- sparing mastectomy and immediate breast reconstruction (IBR). We highlight the surgical technique used and propose in/exclusion criteria.

Material and Methods:
Patients were identified retrospectively from our Institution’s electronic patient records and WinPath™ database by searching clinical codes corresponding to NSM & IBR, performed by the senior authors (IJL and RD) between January 2004 and December 2008. Pre-operative selection criteria included: 100% pre-operative lesion characterisation; 5mm margin acceptance; submission of separate nipple core specimens for paraffin block histological assessment and re-excision of all involved/ close margins. Follow-up data was verified from patients’ case notes, histo- pathological review and standardised photographic views. Endpoints include: local recurrence rate, disease free survival, peri-operative NAC subcutaneous tissue loss and validated aesthetic outcome measures.

Results:
84 patients underwent NSM & IBR for invasive disease. The mean age was 52.1 years and a median follow-up of 38 months. IBR utilised autologous tissue (latissimus dorsi or transverse rectus abdominus musculocutaneous flaps) with/ without implant prosthesis. There was one case of local recurrence (1.2%) in a patient who declined re-excision of close/involved margins and no recorded breast cancer related deaths. Peri-operative complication rates were within the national mastectomy breast reconstruction audit outcome guidelines.

Conclusion:
In this cohort of patients, nipple sparing mastectomy and immediate breast reconstruction achieves comparable oncological outcomes with excellent aesthetic relative to traditional ablative procedures for local control. Nipple preservation although not evaluated independently does enhance cosmetic outcomes.

*(Preliminary analysis)

P2-17-01
Coleman R, De Boer R, Eidiathmann H, Neven P, von Minckwitz G, Martin N, Modi A, Bandred N. University of Sheffield, Sheffield, United Kingdom; Royal Melbourne Hospital, Victoria, Australia; University Frauenklinik, Kiel, Germany; UZ Gasthuisberg, Leuven, Belgium; German Breast Group, Frankfurt, Germany; Novartis Oncology; East Hanover, NJ; University Hospital of South Manchester NHS Foundation Trust, Manchester, United Kingdom

Introduction: Bisphosphonates (BPs) combined with adjuvant endocrine therapy have been shown to prevent aromatase inhibitor-associated bone loss (AIBL) and improve outcomes in recent clinical trials in patients with hormone receptor-positive (HR+) early breast cancer (EBC). Accelerated bone turnover (a common phenomenon during AIBL) has been associated with increased risk of bone metastasis in EBC (Lipton A, et al. St. Gallen 2009. abs #224), but little is known about the effect of BPs on the disease course in women with EBC and progressing AIBL. We have previously demonstrated that adding ZOL to adjuvant therapy significantly improved bone mineral density (BMD) and prolonged disease-free survival (DFS) vs delayed ZOL (de Boer R, et al. SABCS 2010. P5-11-01). We report here the prognostic factors for DFS and the effect of ZOL initiation in the delayed ZOL (DZOL) arm of the ZO-FAST trial at 5 years’ median follow-up.

Methods: The ZO-FAST trial randomized postmenopausal women with HR+ EBC initiating letrozole (LET; 2.5 mg qd × 5 years) with a BMD T-score ≥–2 (N=1,065) to immediate (IMZOL; 4 mg q 6 months) or DZOL (initiated for post-baseline T-score <–2, or nontraumatic/asymptomatic fractures). The primary endpoint was change in BMD at 12 months; patients were followed for disease recurrence and overall survival for 5 years (secondary endpoints). Exploratory Cox regression analyses were performed to identify prognostic factors for DFS in the DZOL arm.

Results: At 60-months follow-up, IMZOL significantly reduced the risk of a DFS event by 34% vs DZOL (42 vs 62 events; >80% distant recurrences and 20% local; hazard ratio [HR]=0.66; 95% confidence interval [CI], 0.44-0.97; P=.034) in the intent-to-treat population (N=1,065; n=532 IMZOL; n=533 DZOL). In exploratory analyses of the DZOL arm (n=535; safety population), patients who initiated DZOL treatment (n=144) had significantly improved DFS (10 events; HR=0.462; 95% CI, 0.23-0.94; P=0.033) compared with DZOL arm patients who never initiated ZOL (53 events; n=391). Other significant prognostic factors for DFS events in the DZOL arm were age ≥65 years at study entry (HR=1.949; 95% CI, 1.09-3.47; P=.024 vs age <65 years) and cancer T-stage ≥2 (HR=2.155; 95% CI, 1.03-4.51; P=.042 vs T-stage <2).

Conclusions: Exploratory analyses of the ZO-FAST database revealed significant DFS benefits from initiation of ZOL treatment for post-baseline fractures or T-scores <–2, suggesting that ZOL (even if initiated late) can positively influence the disease course in patients with AIBL. Together with other studies showing DFS benefits from ZOL in patients with complete ovarian suppression/postmenopausal status (Coleman RE, et al. SABCS 2010. abs #S4-5; Gnant M, et al. NEJM 2009;360:679-691), these data suggest that treating (and ideally, preventing) AIBL may also improve DFS in patients with HR+ EBC.
P2-17-02
Increased Progression Free and Overall Survival in Breast Cancer Patients with Menopausal Symptoms or Arthralgia/Myalgia during Adjuvant Treatment with Exemestane or Tamoxifen – Results of the German TEAM Trial.

Hadjii P, Kieback DG, Hasenburg A, Tams J, Ziller M. Phillipps University, Marburg, Germany; Elbländkliniken, Meissen, Germany; University Hospital Freiburg, Freiburg, Germany; ICRC-Weyer GmbH, Berlin, Germany

Background:
Previous studies have suggested a correlation between the occurrence of vasomotor or joint symptoms during tamoxifen or aromatase inhibitor treatment and improved clinical response. We assessed if there was any correlation between treatment-emergent adverse events during exemestane or tamoxifen treatment and clinical response.

Methods:
A retrospective analysis of the German cohort of the TEAM trial was performed to assess progression-free survival and overall survival in patients with and without menopausal symptoms or arthralgia/myalgia during adjuvant treatment with exemestane or tamoxifen.

Results:
A total of 1502 patients were included in this analysis; 739 patients received tamoxifen and 763 received exemestane. Patients reporting menopausal symptoms and patients reporting arthralgia/myalgia during tamoxifen or exemestane treatment had significantly longer overall survival and progression-free survival. The effect on overall survival was irrespective of treatment. Progression-free survival was significantly improved in exemestane-treated patients reporting menopausal symptoms or those reporting arthralgia/myalgia versus those not reporting these adverse events. There was no significant difference in progression-free survival between tamoxifen-treated patients reporting these symptoms versus those who did not. A combined analysis of patients reporting either menopausal symptoms or arthralgia/myalgia showed that overall survival and progression-free survival was significantly improved in patients reporting one of these symptoms versus those not reporting either symptom. In this analysis, the effect on overall survival and progression-free survival was irrespective of treatment.

Conclusions:
Our results suggest that the occurrence of menopausal symptoms or arthralgia/myalgia during treatment with tamoxifen or exemestane is associated with significantly improved overall survival.

P2-17-03
Incomplete Uptake and Diminished Adherence to Endocrine Therapy in Women with Hormone Receptor Positive Breast Cancer 4 Years from Diagnosis: An Australian Cohort Study.

Bell RJ, Fradin P, Schwarz M, Davis SR. Monash University, Melbourne, VIC, Australia; Alfred Health, Melbourne, VIC, Australia

Background: Tamoxifen(T) and the aromatase inhibitors (AIs) are associated with side effects which impair adherence to therapy. Our aim was to investigate the uptake of, and adherence to, endocrine therapy (ET) in a cohort of women with invasive breast cancer (BC) nearly 4 years post-diagnosis.

Materials and Methods: The BUPA Health Foundation Health and Well being After Breast Cancer study is a prospective questionnaire-based cohort study of 1684 women with their first episode of invasive BC recruited between 2004 and 2006 through the Victorian Cancer Registry (VCR), Australia. An enrolment questionnaire (EQ) was completed within 12 months of diagnosis, with questionnaires every 12 months thereafter (FQ1-FQ3). Tumor pathology was provided by the VCR. FQ3 was completed on average 3.8 years from diagnosis. Active disease included a new primary BC, local recurrence or metastatic disease.

Results: Of 1684 recruits, 1370 were HR+. At diagnosis, average age was 58 years and 50% were stage 1. The table shows the number of HR+ women retained in the analysis at each questionnaire, the average time of each questionnaire from diagnosis and the proportions of women at each questionnaire on any ET on T, an AI or on no ET.

</tbody>
</table>

Switching of ET from T to AI was predominantly a clinician decision. Cessation of T was patient initiated, mainly for vasomotor symptoms and vaginal bleeding. For the change from an AI to T, or cessation of an AI, the main reason was joint pain.

At FQ3, nearly 4 years from diagnosis, 215 (18%) women were not on any ET. Compared with women on ET at this time, these 215 women were more likely to have been stage 1 (rather than > stage 1) at diagnosis, have active disease by FQ3, be seeing an alternative therapist (all p<0.01) and were less likely to be seeing an oncologist (p<0.001).

Discussion:
By nearly 4 years from diagnosis, an increasing proportion of women with HR+ BC are not on ET, despite the evidence for the benefit of therapy for at least 5 years. Differences between ET users and non-users at this stage are not simply explained by previous users not continuing ET, with or without active disease. There is a small (8.2%) but important subgroup who appear to have never been on ET, which raises serious concerns.

P2-17-04
Induction of Tamoxifen Metabolism by Rifampicin: A Worrying Drug-Drug Interaction.

Binkhorst L, Loos WJ, de Jongh FE, Hamberg P, Ghobadi Moghaddam-Helmantel IM, Jager A, Sneyaeye C, Verweij J, van Gelder T, Mathijssen RH. Erasmus University Medical Center, Rotterdam, Netherlands; Erasmus University Medical Center - Daniel den Hoed Cancer Center, Rotterdam, Netherlands; Iakuzia Hospital, Rotterdam, Netherlands; Sint Franciscus Gasthuis, Rotterdam, Netherlands

Background: Tamoxifen (Tam) undergoes extensive biotransformation into several metabolites, including the highly active metabolite endoxifen. Differences in metabolism, influenced by both genetic and environmental factors, largely contribute to the inter-individual variability in endoxifen plasma concentrations, potentially affecting the efficacy of Tam. Conflicting results between CYP2D6 genotype/phenotype and endoxifen concentrations have been observed. A reason for this discrepancy may be that CYP3A4 may have a more crucial role in the formation of endoxifen than previously thought (de Graan et al, JCO, in press). Hypothesizing that induction of CYP3A4 and CYP2D6 could lead to increased endoxifen levels, a prospective

Cancer Res; 71(24 Suppl.) December 15, 2011 326s Cancer Research
study was activated evaluating the effects of enzyme induction by rifampicin (Rif) on the plasma pharmacokinetics (PK) of Tam and its metabolites.

Methods: A randomized cross-over study design was used, with each patient serving as her own control. Breast cancer patients on steady state Tam therapy (20 or 40 mg once daily) were included. Patients underwent two periods of plasma sampling covering 24 hrs each, once using Tam alone, and once after 15 days of oral Rif (600 mg daily) taken in combination with Tam. Patients were randomized for sampling sequence 1) Tam alone followed by Rif/ Tam versus 2) Rif/Tam followed by Tam alone. PK sampling in sequence 2 was performed after a 30-day wash-out period of Rif. Tam and its main metabolites ND-Tam, 4-OH-Tam and endoxifen were quantitated by a validated LC-MS/MS method. PK parameters, including area under the plasma-concentration time curve (AUC) and maximum concentration (Cmax) of all four compounds were calculated (WinNonLin program) and compared (with or without Rif) using a two-sided paired t-test. For safety reasons an interim-analysis was performed after 4 patients.

Results: The interim-analysis showed that concentrations of Tam and its metabolites were significantly decreased during Rif/Tam co-administration as compared to Tam administration alone (see table). Especially endoxifen exposure was decreased by a mean of 69%. Based on these data it was decided to stop further enrollment in this study.

Conclusions: Concentrations of Tam and its main metabolites decreased significantly after induction by rifampicin. Potentially contributing factors include further metabolism of Tam-metabolites into other inactive metabolites or conjugates (i.e. glucuronides) or a decreased oral availability of Tam. Further pharmacokinetic analyses, including the analysis of glucuronides and other metabolites, will be performed to better understand the mechanism behind these findings. Based upon these data, combining rifampicin with Tam should be avoided. Similar drug-drug interactions may exist between Tam and other strong CYP inducers, such as St John’s wort and phenytoin.

**Antiprogestin Proellex Suppresses Proliferation of Aromatase Overexpressing and Letrozole Resistant T47D Breast Cancer Cells.**

**Background:** Aromatase is a cytochrome P450 CYP19A1 enzyme responsible for the conversion of C19 androgens to C18 estrogen. Aromatase overexpression leads to increased in local estrogen concentration in post menopausal women diagnosed for breast cancer. Aromatase inhibitors (AI) are used as one of the first line therapies for the treatment of ER+PR+ breast cancers. However, many patients acquire resistance to AI treatment. Therefore alternative approaches are being sought for patients with AI resistance. Previous reports suggest that upregulation of progesterone receptor can lead to enhanced expression of EGFR/ERK/MAPK involved in acquiring resistance. In this study, we evaluated the effect of a selective progesterone receptor modulator, CDB4124 (Proellex) with low glucocorticoid activity on aromatase overexpressing and Letrozole resistant T47D cells.

**Methods:** Aromatase overexpressing T47D (T47Darom) and respective control (T47Dcon) breast cancer cell lines were generated by stable transfection with plasmid containing CYP19A1 coding region, or empty vector respectively. Letrozole resistant cell line (T47DaromLR) was generated by incubating T47Darom for 75 weeks in the presence of 10µM Letrozole. Cell proliferation was determined by MTT or Crystal violet assays. Gene expressions were quantitated by qRT-PCR whereas proteins were identified by western blot analyses, flow cytometry and immunofluorescence staining. Aromatase activity was determined by estradiol ELISA. The effects of Proellex on anchorage independent growth were measured by soft agar colony formation. Statistical differences between the various groups were determined by Student’s ‘T’ test or ANOVA followed by Bonferroni’s post hoc test. Results: T47Darom and T47DaromLR cell lines had significantly higher aromatase expression (mRNA and protein) and as a result exhibited increased conversion of testosterone to estradiol as compared to T47Dcon. Both these cell lines showed enhanced growth in the presence of Testosterone. In T47Darom cells increased PR-B and EGFR expression as compared to T47Dcon cells was observed. Proellex, Letrozole and other known AI (Anastrozole, Exemestane) inhibited testosterone induced cell proliferation and anchor age independent growth of T47Darom cells. The inhibition of cell proliferation was significantly greater when cells were treated with Proellex in combination to other AIs. Proellex inhibited mRNA and protein levels of PR-B, reduced PRB/p300 complex formation in the nuclei and significantly reduced EGFR expression in T47Darom cells. Our results in the present study indicate that antiproliferative effect of Proellex may be due to PR-B / EGFR modulation in ER+PR+, aromatase overexpressing cells. Conclusion: Overall these results suggest that antiprogestin, Proellex could be developed as a possible treatment strategy for aromatase overexpressing ER+/PR+ breast cancer patients as well as for AI resistant breast cancer patients.

### P2-17-06

**Patterns of Bone Density Evaluation in a Community Population Treated with Aromatase Inhibitors.**

*Ligibel JA, O’Malley AJ, Fisher M, Daniel GW, Winer EP, Keating NL. Dana-Farber Cancer Institute, Boston, MA; Harvard Medical School, Boston, MA; HealthCore*

Aromatase inhibitors (AIs) lead to an increased risk of bone loss and fracture. Fracture rates in adjuvant AI studies have ranged from 2.3% to 11%, with higher rates seen in studies with longer duration of AI therapy and longer follow up. The American Society of Clinical Oncology recommends baseline bone density testing upon initiation of AI therapy and repeat testing every 1-2 years while on therapy. There are few data regarding the incorporation of these guidelines into clinical practice. We sought to evaluate patterns of bone density testing in a community-based cohort of breast cancer patients treated with AIs.

**Methods:** We obtained encounter and pharmacy data from the HealthCore Integrated Research Database, a fully integrated commercial payer dataset including patients enrolled in WellPoint insurance plans. We identified 9138 women aged ≥50 years who had at least 2 diagnosis codes for breast cancer between 2001 and 2007 (followed through 2008), and who filled at least 1 prescription for an AI. We identified
bone density testing using encounter data and used logistic regression to assess patient demographic and clinical characteristics associated with baseline bone density testing (any test from 6 months before through 6 months after the first prescription for AI). Among 2038 women who continued AI therapy for ≥2 years, we used logistic regression to assess factors associated with receipt of any bone density during the 2-year period.

**Results**

Overall, 41.6% of women underwent baseline bone density testing. Rates of bone density testing increased over time, from 26.6% in 2002 to 44.7% in 2008 (adjusted odds ratio [AOR] for 2008 vs. 2002=2.02, 95% confidence interval [CI]=1.53-2.68). Older women were less likely to undergo baseline bone density testing (AOR for women age ≥69 vs. 51-59=0.64, 95% CI=0.56-0.72). Women taking proton pump inhibitors, which have been linked to bone density loss, were also less likely to undergo baseline bone density testing (AOR=0.86, 95% CI=0.73-1.00). Women living in areas of lower education (p<.001), and areas with a higher proportion of blacks (p=0.02) or Hispanics (p<0.001), as well as women who were previously treated with tamoxifen (p=0.02), were all less likely to undergo baseline bone density. Women receiving bisphosphonates in the year before initiation of an AI were more likely to undergo baseline bone density testing (AOR=1.33, 95% CI=1.16-1.51).

Among women on AIs for at least 2 years, 59.9% of women underwent a bone density within 2 years of starting treatment. In adjusted analyses, earlier year of AI initiation (p<.001), living in areas with lower education levels (p<.001), and having been previously treated with tamoxifen (p<.001) were all associated with a decreased likelihood of undergoing bone density testing.

**Conclusions**

Despite the increased risk of fracture in women treated with AIs and guidelines recommending regular bone density evaluation, 58.4% of women starting an AI and 40.1% of women on long-term therapy did not undergo bone density evaluation in this community-based population. Older women, who might be especially vulnerable to bone loss and fracture, were less likely to undergo baseline bone density evaluation. More attention is needed to ensure that preventable fractures are avoided in patients taking AIs.

**P2-17-07**

**Construction of a Predictive Model of Probability of Ovarian Function Recovery in a Series of Premenopausal Breast Cancer Patients with Chemotherapy-Induced Amenorrhea Switched to an Aromatase Inhibitor (AI) after Adjuvant Tamoxifen.**

Perez-Fidalgo JA, Bermejo B, Pons V, Guzman C, Bosch A, Lluch A. Hospital Clínico Universitario, Valencia, Spain; Pfizer Spain, Alcobendas (Madrid, Spain).

Introduction: AI therapy is not recommended in breast cancer patients with conserved ovarian function as AI decreases estrogenic feedback leading to an increased of FSH and LH. In patients older than 40 and with prolonged amenorrhea, switching to an AI after tamoxifen therapy is a controversial approach but with an adequate follow-up for early detection of potential menopause renewal it might be feasible. Several factors have been identified in the literature as clinical defining variables of CIA while other factors have been associated with high probability of permanent CIA. Among clinical defining variables are time from last menses date (LMD) and low estradiol (E2) levels. Risk variables for permanent CIA are chemotherapy schedule administered and advanced age. We aimed to construct a predictive model to identify high risk of renewal of menses after switching to AI in premenopausal patients with CIA lasting at least 1 year.

Methods: Based on defining and prognostic variables of CIA, a predictive model of high probability of permanent amenorrhea was constructed by assigning a score as follows:

1) Time from LMD to switching date ≥3 years: 1 point, < 3 years: 0 points
2) E2 levels ≤20 ng/ml: 1 point, >20 ng/ml: 0 points
3) Age ≥45 years: 1 point, < or = 45: 0 points
4) Chemotherapy regimen administered: dose dense or high doses: 2 points, conventional doses regimen with anthracycline and taxanes: 1 point, conventional doses only anthracycline-based or other: 0 points.

Final score obtained from 0 to 5 points was classified in two groups:

- Low-probability of permanent amenorrhea: score 0-2, and high probability of permanent amenorrhea: score 3-5.

To validate this probability model we retrospectively analysed data from a prospective maintained database of early breast cancer patients, clinically premenopausal at diagnosis that were treated in our institution from May 2004 to December 2009. All patients had histologically confirmation of hormone-sensitive breast carcinoma at stage I-III.

Therapy included in all cases adjuvant or neoadjuvant chemotherapy and adjuvant tamoxifen and all patients referred a CIA lasting at least 1 year. Since 2006, in most patients E2 levels before switching were determined.

**Results:** Validation of probability model was performed in our series of 102 premenopausal patients of whom 9 recovered ovarian function (prevalence ratio: 0.088).

<table>

<td>6</td>
<td>55</td>
</tr>
<tr>
<td>total</td>
<td>9</td>
<td>95</td>
</tr>
</tbody>
</table>

Test sensibility of the model was 100% and specificity 56.99%. Positive predictive value was 18.4% and negative predictive value 100%. Positive likelihood ratio was 2.32 and negative likelihood ratio was 0.

**Conclusions:** Our model of probability of ovarian function recovery is a highly sensitive test that might become a useful tool to identify premenopausal patients with CIA that could be safely switched to AI after tamoxifen. Further validation in a prospective series including more accurate E2 monitoring and follow-up is warranted.

**P2-17-08**

**Prospective Study of Aromatase Inhibitor Induced Bone Loss and Lipid Levels in Early Postmenopausal (PM) Hormone Receptor Positive (HR+) Breast Cancer (BC) Patients Treated with Adjuvant Letrozole Extended beyond 5 Years (yrs).**

Introduction/Aim: Adjuvant treatment with aromatase inhibitors (AI) is associated with accelerated bone loss and increase in lipid levels. The effectiveness and tolerance of extended treatment with AI beyond 5 years is currently under investigation. In the SOLE study, five years of continuous (C) extended letrozole is compared to interrupted therapy (9 months on, 3 months off letrozole) after 5 yrs of tamoxifen, AI or sequential hormonal therapy. We have evaluated the bone mineral density and lipid levels during the extended use of letrozole beyond 5 yrs in a cohort of patients included in the SOLE study.

Patients and methods: Postmenopausal women with HR+ BC, receiving extended continuous (C) or intermittent (I) letrozole for 5 yrs after 5 yrs of tamoxifen, 5 yrs of an AI, or switch therapy within...
Background: Invasive lobular carcinoma (ILC) represents the second most common BC subtype and is often characterized as hormone responsive to trastuzumab in patients with advanced HER2+ lobular breast carcinoma. In addition, we sought to describe the pattern of hormone receptor positivity in the subsets of ILC and invasive ductal carcinoma (IDC).

Metzger O, Procter M, de Azambuja E, Viale G, Leyland-Jones B, Dowsett M, Gelber R, Gresko E, Loi S, Sotiriou C, Piccart M. Institut Jules Bordet, Université Libre de Bruxelles, Brussels, Belgium; Frontier Science (Scotland) Ltd, Kincraig, Kingussie, United Kingdom; European Institute of Oncology, Milan, Italy; Emory University, Atlanta; Royal Marsden Hospital and Institute of Cancer Research, London, United Kingdom; Dana-Farber Cancer Institute, Boston; Roche, Basel, Switzerland.

Background: Invasive lobular carcinoma (ILC) represents the second most common BC subtype and is often characterized as hormone receptor positive and HER2-negative. However, a small subset of ILC is found to be HER2+. Isolated case reports have demonstrated high responsiveness to trastuzumab in patients with advanced HER2+ ILC. The HERA trial comprises 1 or 2 years of trastuzumab treatment with observation and 1 versus 2 years of trastuzumab treatment after standard chemotherapy in women with HER2+ breast cancer. We sought to evaluate the incidence of HER2+ ILC and the magnitude of trastuzumab benefit in HER2+ ILC in the context of the HERA trial. In addition, we sought to describe the pattern of hormone receptor positivity in the subsets of ILC and invasive ductal carcinoma (IDC) as well as the pattern of hormone receptor positivity among ILCs.

Methods: The database used in the analysis had a clinical cut-off date of 9th June 2008 and 4-year median follow-up (Gianni et al., 2011). Patients randomized to the 1-year trastuzumab and observation group were included in the preliminary study. 18% of ILC-users discontinued their treatment due to musculoskeletal symptoms compared with none of the tamoxifen-users. 62% of patients on AI and 35% of tamoxifen patients complained of new or worsened joint pain. Table 1 shows the proportion of patients that attribute their complaints to their endocrine therapy. Grip strength significantly decreased over time (p<0.03), with patients under AI treatment having a larger loss of grip strength than patients under tamoxifen treatment (p=0.04).

We confirm our previously reported results on the shape of the curve “BMI AI-induced loss of grip strength”. Years past menopause and age showed a significant effect on grip strength (p<0.001 and p=0.0007, respectively), whereas no significant relationship was found between WHR with grip strength or joint pain. Detailed results will be presented.

Conclusion Our preliminary results confirm that a majority of patients treated with an AI experience musculoskeletal problems, which are considered due to the therapy by most patients. Grip strength decreased over time, with a significantly larger loss of grip strength in the AI-users compared with the tamoxifen-users. AI-induced loss of grip strength and baseline BMI showed an inverse relationship, although differences between quartiles were small. Further results should be awaited as this is only a preliminary analysis.

Conclusion: This is the first prospective BMD and lipid follow-up study during adjuvant letrozole extended beyond 5 years in PM early breast cancer patients. After the first year of extended intake of continuous letrozole, patients will be presented. After one year no differential effect on cholesterol levels has been observed.

P2-17-09

A Prospective Assessment of Loss of Grip Strength by Baseline BMI in Breast Cancer Patients Receiving Adjuvant Aromatase Inhibitors or Tamoxifen.

Background: The 3rd generation aromatase inhibitors (AIs) induce or enhance musculoskeletal problems. Underlying mechanisms are probably multiple, but remain unknown. We have previously reported that loss of grip strength together with tenosynovial abnormalities are more important in AI- than in tamoxifen-users (Morales et al, JCO 2008) and that musculoskeletal changes in AI-users are more pronounced in women with extremes in baseline BMI (Lintharms et al, Ann Oncol 2011) We here report preliminary results from a larger population and plan to validate findings in patients from University of Michigan.

Patients and methods: In this prospective observational study, postmenopausal early breast cancer patients scheduled to start adjuvant hormonal therapy with any of the third generation AIs or tamoxifen were recruited. After providing informed consent, a modified sphygmomanometer was used to assess and a rheumatological questionnaire was completed at each visit. Results: Ninety-four (79 AI; 15 tamoxifen) of the planned 200 patients were included in this preliminary study. 18% of AI-users discontinued their treatment due to musculoskeletal symptoms compared with none of the tamoxifen-users. 62% of patients on AI and 35% of tamoxifen patients complained of new or worsened joint pain. Table 1 shows the proportion of patients that attribute their complaints to their endocrine therapy. Grip strength significantly decreased over time (p<0.03), with patients under AI treatment having a larger loss of grip strength than patients under tamoxifen treatment (p=0.04).

We confirm our previously reported results on the shape of the curve “BMI AI-induced loss of grip strength”. Years past menopause and age showed a significant effect on grip strength (p<0.001 and p=0.0007, respectively), whereas no significant relationship was found between WHR with grip strength or joint pain. Detailed results will be presented.

Conclusion: This is the first prospective BMD and lipid follow-up study during adjuvant letrozole extended beyond 5 years in PM early breast cancer patients. After the first year of extended intake of continuous or intermittent letrozole a possible difference in bone mineral density between the two arms is emerging, but the two groups are too small to make final conclusions. An updated longer follow-up on more patients will be presented. After one year no differential effect on cholesterol levels has been observed.

P2-18-01

The Magnitude of Trastuzumab Benefit in HER2-Positive (HER2+) Lobular Breast Carcinoma (BC): Results of a HERA Trial Sub-Group Analysis.

Metzger O, Procter M, de Azambuja E, Viale G, Leyland-Jones B, Dowsett M, Gelber R, Gresko E, Loi S, Sotiriou C, Piccart M. Institut Jules Bordet, Université Libre de Bruxelles, Brussels, Belgium; Frontier Science (Scotland) Ltd, Kincraig, Kingussie, United Kingdom; European Institute of Oncology, Milan, Italy; Emory University, Atlanta; Royal Marsden Hospital and Institute of Cancer Research, London, United Kingdom; Dana-Farber Cancer Institute, Boston; Roche, Basel, Switzerland.

Background: Invasive lobular carcinoma (ILC) represents the second most common BC subtype and is often characterized as hormone receptor positive and HER2-negative. However, a small subset of ILC is found to be HER2+. Isolated case reports have demonstrated high responsiveness to trastuzumab in patients with advanced HER2+ ILC. The HERA trial comprises 1 or 2 years of trastuzumab treatment with observation and 1 versus 2 years of trastuzumab treatment after standard chemotherapy in women with HER2+ breast cancer. We sought to evaluate the incidence of HER2+ ILC and the magnitude of trastuzumab benefit in HER2+ ILC in the context of the HERA trial. In addition, we sought to describe the pattern of hormone receptor positivity in the subsets of ILC and invasive ductal carcinoma (IDC) as well as the pattern of hormone receptor positivity among ILCs.

Methods: The database used in the analysis had a clinical cut-off date of 9th June 2008 and 4-year median follow-up (Gianni et al., 2011). Patients randomized to the 1-year trastuzumab and observation
arms were included in the present analysis. Central assessment of hormone receptor status was considered. Histological BC subtype was assessed locally.

Results: Of the 1703 women randomized to one-year of trastuzumab and 1698 to observation, 5.5% (n=187) and 94.5% (n=3213) were diagnosed as HER2+ ILC and IDC, respectively. Central hormone receptor status was available in 88.3% (n = 2838) of IDC and 86.1% (n=161) of ILC. ER and/or PR positivity was more common in IDC than ILC (63.4% [102/161] vs. 46.3% [1314/2838]; p<0.001). Allred scores for ER are shown in the table below. The DFS hazard ratios comparing one year of trastuzumab versus observation were 0.63 (95% CI 0.34-1.14) for ILC and 0.77 (95% CI 0.67-0.89) for IDC. There was no evidence of an interaction between histological subtype and trastuzumab benefit (interaction [subtype lobular and subtype ductal and not lobular] p=0.49).

Conclusion: HER2+ ILC accounts for 5.5% of patients included in a large population of over 3,000 HER2+ BC. While only a limited number of patients with ILC was enrolled, this analysis suggests an increased ER positivity in ILC compared to IDC. There was no suggestion that patients with HER2+ ILC derived a different magnitude of benefit from adjuvant trastuzumab when compared to the HER2+ IDC cohort. The lack of central pathology review for BC subtype assessment is a caveat of our study. Future research in the field of ILC and particularly in the HER2+ subset should be encouraged.

P2-18-02
Cardiac Outcomes of Patients on Adjuvant Weekly Paclitaxel (T) and Trastuzumab (H) for Node Negative, HER2 Positive Breast Cancer (BCA).

Dang C, Tolaney S, Najita J, Gelman R, Yardley D, Marcom K, Albain K, Rugo H, Miller K, Ellis M, Shapira I, Wolff A, Carey L, Vahdat L, Burdette-Radous S, Budd T, Krop I, Burstein H, Hudis C, Winer E. Memorial Sloan-Kettering Cancer Center; Dana-Farber Cancer Institute; Tennessee Oncology and Sarah Cannon Research Institute; Duke University; Loyola University Medical Center; University of California-San Francisco Comprehensive Cancer Center; Indiana University; Washington University; North Shore-Long Island Jewish Medical Center; Johns Hopkins University; University of North Carolina; Weill Cornell Medical College; University of Vermont; Cleveland Clinic Taussig Cancer Institute Case

Background: Twenty-five percent of node-negative HER2-positive BCA have a higher risk of recurrence than those with node-negative HER2-negative disease. Several randomized trials have shown the benefit of chemotherapy (most with an anthracycline) and trastuzumab (H) for pts with node-negative and high-risk node-negative BCA. However, the benefit of chemotherapy and H needs to be further explored in the node-negative group. Due to the 2-4% risk of symptomatic congestive heart failure (CHF) with an anthracycline-based treatment (Rx) followed by H, we set out to conduct a study of a taxane-based Rx with H in a node-negative population.

Design: This is a single arm, multicenter, phase II study of paclitaxel (T) (80 mg/m²) and trastuzumab (H) x 12 weekly (w) (4 mg/kg load \(-2 mg/kg\) \(\rightarrow\) H x 52 w (2 mg/kg weekly or 6 mg/kg q 3 w). Pts with HER2-positive BCA (IHC 3+ or FISH amplified at \(\geq 2.0\)) with negative nodes (micrometastasis later allowed) and with a tumor size \(\leq 3\) cm were enrolled. The primary endpoint is disease-free survival. Secondary endpoints include the incidence of G 3/4 left ventricular systolic dysfunction or congestive heart failure (CHF). Pts had serial left ventricular ejection fraction (LVEF) monitored at baseline (BSLN), and at month (mo) 3, mo 6, and mo 12 w/ a multi-gated acquisition scan or echocardiogram. H was held for significant asymmetrical (Asx) LVEF \(\downarrow\) (10-15% \(\downarrow\) from BSLN and < lower limit of normal or \(\geq 16%\) \(\downarrow\) from BSLN), and H was stopped for CHF.

Results: From 10-9-2007 to 9-3-2010, 406 pts were enrolled. The median (med) age was 55 years (range 23-84 years); 118/406 (29%) had hypertension and 30/406 (7%) had diabetes. As of 6-1-2011, 307 are reported as off Rx of which 261 have completed protocol therapy; 99 remain on therapy. To date, 100%, 94%, 84%, and 83% of pts had LVEF monitoring at BSLN, mo 3, mo 6, and mo 12. The med LVEF at BSLN was 65% (range 50%-81%), at mo 3 was 64% (range 45%-81%), at mo 6 was 64% (range 45%-81%), and at mo 12 was 65% (range 37%-90%). Two pts had CHF; 1 pt had CHF at mo 11 (LVEF was 55% at BSLN and 37% w/ CHF event) and 1 pt had CHF at mo 6 (LVEF was 66% at BSLN and 49% w/ CHF event). To date, 13 pts had H held for significant Asx LVEF \(\downarrow\); details on those who had appropriate LVEF recovery and had H restarted will be provided. All patients will have completed 12 mo of Rx by October 2011, and an accurate report of the incidence of CHF will be available.

Conclusion: This represents the cardiac report of pts receiving TH as adjuvant Rx for node-negative (micrometastasis allowed) HER2 positive BCA. Both the CHF events and number of pts w/ H hold due to significant Asx LVEF \(\downarrow\) appear low. Overall, the serial med LVEFs remain stable throughout the 12 mo of Rx. Final data on all 406 pts will be available in December 2011.

P2-18-03
Systemic Adjuvant Treatment of T1a and T1b N0M0 HER2+ Breast Carcinomas; an AERIO/UNICANCER Study.

Peron J, Vano Y, Frenel J-S, Wassermann J, Albigez L, Rodrigues MJ, Coutte PH, Centre Léon Bérard, Lyon, France; Centre Antoine Lacassagne, Nice; Institut de Cancérologie de l'Ouest, Centre René Gauducheau, Nantes; Institut Curie, Centre René Huguenin, Saint-Cloud; Institut Gustave Roussy, Villejuif; Institut Curie, Paris

Background: Trials have shown benefit of adjuvant trastuzumab (TZM) for node-negative (N-) or T1c+ HER2-positive breast carcinomas. Methods: Retrospective series in 6 french cancer centers from 2000 to 2010 of T1abN0M0 HER2 positive breast carcinomas. Multifocal tumors were excluded.

Results: Two hundred five N- cases were retrieved. Median size was 8 mm (range, 2 to 10 mm), 51 were T1a (25%), 152 tumors were T1b; 120 tumors (59 %) exhibited significant hormonal receptors (HR) expression. All patients had surgery, 65 % (n= 133) had a local irradiation. Ninety percent of HR+ patients (108/120) received hormonal therapy: 77 received aromatase inhibitors (AI) upfront or sequential; 23 received tamoxifen (TAM) alone 13 received LHRH agonists alone or in combination with TAM or AI. Forty-nine percent (n=101) had chemotherapy (CT) (Anthracycline alone for 41 cases, taxane alone for 31 cases, sequential A/T for 28 cases and concurrent for 1 case), associated with TZM in 90 cases. TZM was administered without chemotherapy in 3 cases. Decision of adjuvant CT and/or
TZM was associated with (all p<0.05) HR-negative status, Elston-Ellis grade 2/3 and high mitotic index (MI) while patients with HR+/low MI tumors were rarely treated (p=0.01). With a 41 months median follow-up, there was a statistically significant difference in invasive recurrences between TZM treated patients and others (log-rank test p=0.04). Twelve of the 112 patients treated without TZM (11%) had a recurrent invasive disease including 6 metastatic cases and 3 fatal events. There was one invasive recurrence in TZM group. There were as much recurrences in T1a as in T1b tumors. Three of the 12 recurrences (25%) in the group without TZM occurred in T1a cases.

Conclusion: TZM was associated with (all p<0.05) HR-negative status, Elston-Ellis grade 2/3 and high mitotic index (MI) while patients with HR+/low MI tumors were rarely treated (p=0.01). With a 41 months median follow-up, there was a statistically significant difference in invasive recurrences between TZM treated patients and others (log-rank test p=0.04). Twelve of the 112 patients treated without TZM (11%) had a recurrent invasive disease including 6 metastatic cases and 3 fatal events. There was one invasive recurrence in TZM group. There were as much recurrences in T1a as in T1b tumors. Three of the 12 recurrences (25%) in the group without TZM occurred in T1a cases.

P2-18-04
Pilot Evaluation of Bevacizumab (Bev) in Combination with Docetaxel (T) and Cyclophosphamide (C) as Adjuvant Treatment (AdjRx) for Patients (pts) with Early Stage (ES) Breast Cancer (BrCa).

Background: The combination of Bev + chemotherapy (CRx) has been shown to produce superior response rates and progression free survival compared to CRx alone, providing a rationale for the study of Bev with AdjCRx for pts with ESBrCa. As Bev can cause hypertension (HTN) and may increase the risk of cardiac failure, there is a rationale for studying a standard non-anthracycline (Anth) AdjCRx with Bev, e.g. TC (docetaxel-cyclophosphamide). We performed a pilot phase II study to evaluate the feasibility and toxicity of TC+Bev in pts with ESBrCa in preparation for participation in a random assignment trial. We have previously reported preliminary toxicity data. Methods: Eligibility criteria included: ESBrCa which was HER-2 normal, node+ or, N- and primary tumour (T) >2 cm and receptor negative, or T>3 cm, normal left ventricle ejection fraction (LVEF), no active/uncontrolled cardiovascular disease, normal organ and marrow function. Treatment consisted of four 3-weekly cycles of docetaxel 75 mg/m2 together with cyclophosphamide 600 mg/m2. Patients commenced Bev 15 mg/kg i.v. on day 1, and then every 3 weeks to a total of 18 cycles of treatments. Pts were monitored clinically, with echocardiograms and with serial estimations of BNP and troponin.

Results: A total of 106 female pts were accrued in 9 ICORG sites between 11/2008 and 7/2010. Ages ranged from 25-75 (median 52). On 20/06/2011, 105 pts have completed study Rx, 1 will finish 7/2011. A total of 36 serious adverse events (SAEs) have been reported so far, 33 involving hospital admission, 3 serious for other reasons. In 25 (24%) pts study Rx was discontinued due to: HTN-9, intestinal perforation-2, consent withdrawl-7, infection-2, proteinuria-1, anaphylaxis-1, cancer relapse-1, arthralgia-1, anal fistula-1. The two perforations occurred at cycles 1 and 16 of Bev respectively. Neither pt with perforation had history of prior abdominal surgery. The median number of cycles achieved by the discontinued pts was 9. HTN of any grade occurred in 49 out of 103 (48%) pts who had no HTN at baseline (BL) and 42 of them required Rx. Among pts who experienced HTN on study Rx and completed Bev, 34 (81%) were still on anti-hypertensive 4 weeks after last infusion of Bev. Forty-one (39%) pts had LVEF drop >10% from BL during study Rx. In 8 (7.5%) pts LVEF declined below 50%, 6 are documented to have recovered to normal, 2 had no further LVEF measurements (1 declined, 1 unknown reason). No episodes of CCF were reported. Troponin and BNP levels were normal in all 57 pts with serial measurements. Forty-four pts required treatment for neutropenia-related infection or for abscess/fistula. Conclusions: In this study Bev overall toxicity in ESBrCa pts was similar to that reported for pts with MBC, and Bev discontinuation due to toxicity was relatively frequent. Although no pt developed CCF 7.5% of decline in LVEF<50% was observed. Intestinal perforation can occur in ESBrCa pts in absence of prior intestinal surgery and in the post-CRx phase of Bev. Pts receiving Bev with non-Anth AdjCRx require careful monitoring for toxicity.

P2-18-05
Cardiotoxicity Risks of Adjuvant Trastuzumab in Asian Breast Cancer Patients.
Shih V, Chan A, Sim MH, Teo C, Chen W, Wong ZW. National Cancer Centre, Singapore; National University of Singapore, Singapore

Background: Adjuvant trastuzumab (T)-based chemotherapy reduces relapse and improves overall survival in early breast cancer. However, T-associated cardiotoxicity potentially limits its use. Our study aims to report the incidence, severity and reversibility of cardiotoxicity amongst Asian breast cancer patients.

Methods: This is a retrospective review of patients who have received adjuvant T from June 2005 to March 2011 at our centre. CT was defined as a drop in left ventricular ejection fraction (LVEF) to less than 50% and / or reduction of ≥ 10% of baseline. Cardiovascular (CVS) risk factors were defined as having at least one of the following factors: family or previous history of CAD, hypertension, diabetes mellitus, hyperlipidemia and smoking. One-way repeated measures ANOVA was used to evaluate the mean LVEF change and Chi-square test to evaluate the association of demographics and CT.

Results: A total of 314 female patients were reviewed. CT was reported in 124 (39.5%), of whom 96 had asymptomatic decline in LVEF and 28 were symptomatic. T was withheld (n=53) due to asymptomatic decline in LVEF (n=40), symptomatic heart failure (n=3) and both (n=10). Forty-three patients with resolution of CHF (n=11) or LVEF recovery (n=32) were rechallenged. Cardiotoxicity recurred in 14 - asymptomatic decline in LVEF (n=10), recurrent CHF (n=1) and both (n=3). Overall, there were no cardiac-related deaths. Factors that predicted for CT included low normal pre-trastuzumab LVEF (<60%) (p=0.018). Three-monthly LVEF showed statistically significant decline against baseline (p=0.003). As expected, the decline in LVEF demonstrated significant interaction with CT groups and non CT group (p<0.001).
Conclusions: A higher incidence of CT (39.5%) was observed among Asian breast cancer patients compared to previously reported in Caucasians (24%). Although 77.4% of patients presented with asymptomatic decline in LVEF, approximately one-third of patients experienced recurrent CT upon rechallenge.

P2-18-06
Conventional Trastuzumab Is an Antagonist of Natural Killer Cells: Making the Case for Fucose-Depleted Trastuzumab.

Listinsky JJ, Siegel GP, Listinsky CM. University of Alabama at Birmingham, Birmingham, AL; Case Western Reserve University, Cleveland, OH

The discovery of the HER2 receptor and later the development of trastuzumab (an anti-HER2 antibody) were major advances leading toward the treatment of a significant proportion of human breast cancers. Trastuzumab (Herceptin®) is a humanized monoclonal antibody. Trastuzumab's FAB portion binds to the HER2 extracellular domain, interrupting HER2 signaling. The FC components of the antibody. Trastuzumab's Fc portion binds to the FC receptors located on effector cells. The superior ADCC effect offers several potential advantages over conventional trastuzumab. Such advantages in clinical use, we postulate, include (1) treatment of patients with trastuzumab-resistant tumors, (2) treatment of patients with equivocal or low expression of HER2, and (3) decreased cost of treatment.

P2-19-01
Impact of Zoledronic Acid on Fractures, Bone Mineral Density and Bone Remodeling in the AZURE Trial (BIG 01-04).

Coleman R, Woodward E, Turner L, Marshall H, Collins M, Dodwell D, Davies C, Bell R, Cameron D, Brown J. University of Sheffield, Sheffield, United Kingdom; University of Leeds, Leeds, United Kingdom; Andrew Love Cancer Centre, Geelong, Victoria, Australia; Western General Hospital, Edinburgh, United Kingdom

Background: The AZURE trial was designed to determine whether the addition of zoledronic acid (ZOL) to standard adjuvant therapy improves disease free survival (DFS) in patients (pts) with stage II/III breast cancer. Although in a recent analysis after 752 events and a median follow-up of 59 months no difference in overall DFS was seen between ZOL and control pts, significant benefits were seen in women >5years post menopause. Here, we report the impact of ZOL on fractures in the main study, and on bone mineral density (BMD) and bone remodeling evaluated within a sub-study.

Materials and methods: 3360 pts were randomized to receive (neo) adjuvant chemotherapy (CT) and/or endocrine therapy with (n=1681) or without (n=1678) up to 19 doses of ZOL 4mg over 5 years. Pts with osteoporosis and those using bisphosphonates, either at baseline or in the previous year, were excluded from study entry. BMD was assessed in 228 patients within a sub-study; 40 of these also underwent quantitative bone scanning (QBS), a novel imaging technique that yields values for \(^{99m}\)Tc-MDP/HMDP whole skeleton plasma clearance (\(K_{wss}\)) as a surrogate for the rate of bone remodeling and enables assessment of specific regions of interest within the skeleton.

Results: Fractures occurred in 152 (4.5%) pts; 60 (3.6%) ZOL pts compared with 92 (5.5%) control (CTRL) pts (difference -0.9%; 95%CI -1.6%, -0.2%). For pts with a DFS event, the majority of fractures in the ZOL group and 68 (61.8%) in the CTRL group (difference -0.4%; 95%CI -10.2%, -3.7%). For pts with a DFS event, the majority of fractures occurred after a skeletal recurrence; 87.5% (7 of 8) ZOL pts and 68 (61.8%) in the CTRL group (difference -1.9%; 95%CI -3.3%, -0.5%). The difference in fracture incidence appeared early and persisted throughout the follow-up period. Fifty-six (86.2%) of the fractures in the ZOL group and 68 (61.8%) in the CTRL group occurred in the absence of, or prior to a DFS event. The fracture rates before disease recurrence were similar at 3.0% (51 pts) in the ZOL group and 3.4% (57 pts) in the CTRL group (difference -0.4%; 95%CI -1.6%, 0.8%). In contrast, 2.1% (8 ZOL pts) and 9.1% (34 CTRL pts) experienced a fracture after a DFS event (difference -6.9%; 95%CI -10.2%, -3.7%). For pts with a DFS event, the majority of fractures occurred after a skeletal recurrence: 87.5% (7 of 8) ZOL and 88.2% (30 of 34) CTRL pts. BMD Z-scores at completion of protocol treatment were higher in patients treated with ZOL. \(K_{wss}\) was lower in ZOL patients (26.5 vs 29.8 ml min\(^{-1}\) using \(^{99m}\)Tc-MDP and 34.3 vs 39.3 ml min\(^{-1}\) with \(^{99m}\)Tc-HMDP). Expressed as a percentage of whole skeleton clearance, regional values in the mandible were similar 1.15% (ZOL) vs. 1.22% (CTRL).

Conclusions: Adjuvant ZOL given in the schedule studied in AZURE reduced the fracture rate in patients who developed recurrence of
breast cancer. BMD was higher and the rate of bone remodeling less in patients treated with ZOL. Further follow-up will determine the duration and clinical relevance of these effects on bone health.

**P2-19-02**  
**Multidisciplinary Treatment of Pregnancy-Associated Breast Cancer.**  
Meisel JL, Economy KE, Zabicki-Calivillo K, Gelber S, Kereakoglow S, Winer EP, Partridge AH, Mayer EL. Brigham and Women’s Hospital, Boston, MA; Dana-Farber Cancer Institute, Boston, MA  

**Background**  
Breast cancer complicates pregnancy in a significant minority of younger breast cancer (BC) patients (pts). Application of standard treatment algorithms is limited by the lack of randomized data to support safety and efficacy. A multidisciplinary approach attempts to maximize treatment efficacy for a pt while minimizing fetal toxicity. We sought to describe contemporary multidisciplinary BC treatment in an academic setting and explore early maternal and fetal outcomes.  

**Methods**  
A search of the Dana-Farber/Harvard Cancer Center clinical database was performed to find BC pts self-identified as pregnant at presentation with >2 visits at our institution. Information available within the database along with complementary chart review provided sociodemographic, disease, staging, pregnancy and treatment information as well as short-term maternal and fetal outcomes.  

**Results**  
55 pts diagnosed between 1996-2011 were identified. The median age at diagnosis was 34 years. 25.5% were stage I, 49.1% stage II, 20% stage III, and 5.4% stage IV. 63.6% had hormone receptor positive disease, 36.3% HER2 positive, and 18.1% triple negative. 71% underwent testing for germline BRCA 1/2 mutations, with 9% of all pts testing positive. 29% were diagnosed in the first trimester (T1), 29% in T2, and 42% in T3. 89% underwent ultrasound imaging for staging, 49% X-ray imaging, 16.3% MRI, and 0% CT. 67% underwent surgery during pregnancy: 43.2% mastectomy, 48.6% lumpectomy, and 8.1% lumpectomy with subsequent mastectomy during pregnancy. 18.9% underwent surgery in T1, 45.9% in T2, and 37.8% in T3. 27.2% underwent sentinel lymph node biopsy. 51% received chemotherapy (C) during pregnancy: of those, 100% received anthracycline/cyclophosphamide (2-4 cycles), 11% paclitaxel, and 0% trastuzumab. 28.5% received C on a dose-dense schedule, with 25% supported by growth factors (14.2% filgrastim, 10.8% pegfilgrastim). 28.5% received neoadjuvant C. C was initiated during T1 for 0%, T2 for 64.3%, and T3 for 35.7%. Two pts terminated pregnancy in T1, one spontaneously miscarried at 12 weeks (wks), and two are currently in the third trimester of pregnancy; therefore, a total of 50 pts had delivered at the time of this analysis. The median time of delivery was 36 wks. 50% delivered prior to 37 wks and were considered preterm; of those, 76% were inductions or Caesarian sections planned to facilitate cancer therapy. Only 12% delivered prior to 34 wks. For the 25 infants for whom Pappar scores were available, 76% had scores of ≥ 8 at delivery, and 100% had scores of ≥ 8 at 5 minutes. For the 25 infants for whom birth weights were available, the median birth weight was 6lbs 1oz. Only 4 were less than 5lbs at the time of delivery. A total of 4 fetal abnormalities were noted: cleft palate (2), club foot (1), and ventricular septal defect (1).  

**Conclusions**  
Within a multidisciplinary academic center, treatment of pregnancy-associated BC using contemporary treatment algorithms, including taxane chemotherapy, growth factor support, and sentinel lymph node biopsy, has been pursued without significant adverse effect on fetal outcomes when compared to other published series. A considerable number of preterm deliveries have been observed. Further data collection is ongoing for confirmation of initial observations.

**P2-19-03**  
**Influence of Zoledronic Acid on BMD in Premenopausal Women with Breast Cancer and Neoadjuvant or Adjuvant Chemotherapy and/or Endocrine Treatment – The ProBone Studies.**  
Hadiji P, Kaouka A, Bauer T, Kaldner M, Albert U, Birkholz K, Baier M, Math M, Ziller M. Philipps-University of Marburg, Marburg, Germany; Novartis Pharma GmbH, Nuernberg, Germany  

**Background**  
Based on baseline bone mineral density (BMD), adjuvant chemotherapy or endocrine therapy for early breast cancer patients can lead to substantially increased fracture risk. A significant decrease of BMD >10% after 2 years of chemotherapy (CT) and/or endocrine therapy (ET) has been reported. In recent studies, zoledronic acid (ZOL) produced an increase in BMD in premenopausal and postmenopausal patients with breast cancer (ABCGS-12, Z-FAST, ZO-FAST, etc). In addition, a significant increase in disease-free survival (DFS) with ZOL vs no ZOL was observed in most of these studies.  

**Methods**  
The aim of 2 single-center, placebo-controlled, randomized studies—Probone I and Probone II—was to investigate the effect of adjuvant treatment with ZOL on BMD in premenopausal women with early breast cancer treated with CT and/or ET. Patients with hormone-receptor–negative (HR-) breast cancer (Probone I) were treated with (neo)adjuvant CT; patients with hormone-receptor–positive (HR+) breast cancer (Probone II) were treated with ET alone or in combination with (neo)adjuvant CT. Randomized patients received ZOL 4 mg or placebo IV every 3 months for 24 months. The primary objective was the change in BMD at the lumbar spine between baseline and month 24 (measured by dual-energy X-ray absorptiometry [DXA]). Secondary objectives included DFS; BMD at total hip, femur, and os calcis; quantitative ultrasonometry (QUS) at os calcis and phalanges; markers of bone turnover (C-telopeptide of type I collagen [CTX] and N-terminal propeptide of type I procollagen [P1NP]); endocrine hormones (follicle-stimulating hormone [FSH], estradiol, testosterone, sex hormone-binding globulin [SHBG], parathyroid hormone [PTH], vitamin D, anti-Müllarian hormone [AMH], inhibin A/B, etc); pathologic fractures; and safety and tolerability.  

**Results**  
70 HR+ and 11 HR- breast cancer patients have been enrolled into the studies. The last patient will have been treated for 24 months by the end of June 2011.  

**Conclusions**  
The effects of ZOL on lumbar spine BMD at 24 months and secondary endpoints will be presented at the meeting.

**P2-19-04**  
**Changes in Adjuvant Treatment of Early Breast Cancer in Italy between 2000 and 2008. The NEMESI Study Versus the NORA Study.**  
Mustacchi G, Cazzaniga ME, Pronzato P, Clavarezza M, Del Mastro L, Venturini M, Amadori D, Bidoli P, Boni C, Caruso M, RicCARDI F, DonD I. Università, Trieste, Italy; Ospedale San Gerardo, Monza, Italy; IRCCS Istituto Nazionale Ricerche sul Cancro, Genova, Italy; Ospedale Sacro Cuore Don Calabria, Negrar (VR), Italy; I.R.S.T., Meldola (Forlì), Italy; Azienda Ospedaliera S Maria Nuova, Reggio Emilia, Italy; Centro Oncologico Catanesi, HumanaItis, Catania, Italy; Ospedale Cardarelli, Napoli, Italy; Sanofi Aventis, Milano, Italy  

**Background**  
In the early 2000s, we identified treatment patterns of early breast cancer (EBC) in Italy (NORA study). To ascertain whether...
attitudes have changed, we conducted a similar study in 2008. Patients and methods: In this retrospective study (NEMESI), we recorded the clinical, tumour and treatment characteristics of 1.894 EBC patients in 63 Italian oncological centres in 2008, and compared the results with those of NORA, on 3.515 patients in 70 same/similar Italian institutions, in 2000-2003. Tumor stage, surgery and endocrine-responsiveness are not comparable because of different recruitment protocols, patients characteristics and adjuvant treatment strategies are perfectly comparable as a reliable picture of adjuvant strategies in Italy.

Results: There was no difference in age class distribution, menopausal status, ECOG performance status, tumor grade, ki67 and estrogen receptors content. HER2 status was simila but determined in 98% of cases in NEMESI vs 46.2% in NORA. The overall use of endocrine treatment (HT) increased from 80.3% in NORA to 83.5% in NEMESI (p = 0.005); the overall use of chemotherapy (CHT) decreased from 68.4% to 57.8% (p = 0.00001). HT alone increased from 31.0% to 42.2% (P = 0.00001) and CHT alone decreased from 18.8% to 16.2% (p = 0.017). The use of both treatments decreased from 49.2% to 41.6% (p = 0.00001). Trastuzumab was never given in NORA and in 15% of cases in NEMESI (85% of all HER2 positive cases).

The choice for HT was tamoxifen for 5 years in 32.5% of cases in NEMESI and 86.6% in NORA (p = 0.00001), and aromatase inhibitors for 5 years in 55.2% vs 13.3% of cases, respectively (P = 0.000001). The “switch” from tamoxifen 2-3 years to aromatase inhibitors 2-3 years was planned in 10.1% of cases in NEMESI and actually done in 12.9% of cases in NORA (p = 0.001). The overall use of LHRH analogues was significantly higher in NEMESI vs NORA (26.7% vs 3.0%, p = 0.00001). CMF-like regimens decreased from 37.0% in NORA to 9.1% (p = 0.000001). Anthracycline-containing regimens decreased from 52.1% in NORA to 48.8% in NEMESI, p = 0.0001). CMF-like regimens decreased from 37.0% in NORA to 9.1% (p = 0.000001). Anthracycline-containing regimens decreased from 52.1% in NORA to 48.8% in NEMESI (p = 0.00001). The use of taxanes alone regimens remained low (3.5% vs 3.7%, ns). The overall use of anthracyclines and taxanes increased from 53.0% to 87.5% and from 4.3% to 42.1%, respectively (both p = 0.00001).

Conclusions: EBC treatment has changed significantly in 6 years. Adjuvant strategies are significantly different, with a great increase of aromatase inhibitors and LHRH analogues associated with tamoxifen; anthra-taxane combinations have also significantly increased. Financial Support by Sanofi Aventis Italy

P3-01-01
Geminin Overexpression Prevents the Completion of Topoisomerase IIα Chromosome Decatenation Leading to Aneuploidy in Human Mammary Epithelial Cells.
ElShamy WM, Gardner L, Malik R, Shimizu Y, Mullins N. University of Mississippi Medical Center, Jackson, MS

Topoisomerase IIα (TopoIIα) cleaves DNA in a reversible manner, making it a valuable target for agents such as etoposide that trap the enzyme in a covalent bond with the DNA end it cleaves and prevents DNA re-ligation and triggers cell death in cancer cells. However, development of resistance to these agents limits their therapeutic use. In this study, we examined therapeutic targeting of geminin for improving the therapeutic potential of TopoIIα agents. Human mammary epithelial (HME) and breast cancer cell lines were used. Geminin, TopoIIα, Cdc7 silencing was done using specific siRNAs. Transit or stable inducible overexpression of these proteins and CKIe were also used, as well as several pharmacological inhibitors that target TopoIIα, Cdc7, or CKIe. We manipulated HME cells expressing H2B-GFP, in order to detect chromosome bridges. Immunoprecipitation and direct western blot were used to detect interactions between these proteins and their total expression, respectively, whereas interactions on chromosomal arms were detected using the TARDIS assay. TopoIIα phosphorylation by Cdc7 or CKIe was done using in vitro kinase assay. The TopoGen decatenation kit was used to measure TopoIIα decatenation activity. Finally, comet assay and metaphase chromosome spread were used to detect chromosome breakages and changes in chromosome condensation or numbers, respectively.

We found that geminin and TopoIIα interact in G2/M/early G1 cells on chromosomes, that geminin recruits TopoIIα to chromosomal decatenation sites or vice versa, and that geminin silencing in HME cells triggers the formation of chromosome bridges through suppressing TopoIIα access to chromosomal arms. CKIe kinase phosphorylates and positively regulates TopoIIα chromosome localization and function. CKIe kinase overexpression or Cdc7 kinase silencing (also phosphorylates TopoIIα in vitro), restored DNA decatenation and chromosome segregation in geminin-silenced cells before triggering cell death. In vivo, at normal concentration, geminin recruits the desumoylating enzymes SENP1 and SENP2 to desumoylate chromosomal bound TopoIIα and promote its release from chromosomes following completion of DNA decatenation. In cells overexpressing geminin, premature departure of TopoIIα from chromosomes is thought to be due to the fact that geminin recruits more of these desumoylating enzymes, or recruits them earlier, to chromosomal bound TopoIIα. This triggers premature release of TopoIIα from chromosomes, which we propose induces aneuploidy in HME cells, since chromosome breakages generated through were not sensed and/or repaired and the cell cycle was not arrested. TopoIIα recruitment and its chromosome decatenation function require normal level of geminin. Geminin silencing induces a cytokinetic checkpoint in which Cdc7 phosphorylates TopoIIα and inhibits its chromosomal recruitment and decatenation function. Geminin overexpression prematurely desumoylates TopoIIα, triggering its premature departure from chromosomes and leading to chromosomal abnormalities and the formation of aneuploid, drug resistant cancer cells. We propose that therapeutic targeting of geminin is essential for improving the therapeutic potential of TopoIIα agents.

Bhaskaran SS, Kesavaram N, Nickisch KJ, VandeBerg JL, Nair HB. Texas Biomedical Research Institute, San Antonio, TX; Evestra, Inc., San Antonio, TX

Progesterone receptor (PR) is a ligand activated transcription factor which plays a crucial role in female reproduction. PR antagonists have been shown to repress estrogen dependent proliferation in the uterus and mammary gland. Even though PR antagonists are potent therapeutic candidates for breast cancer, partial agonism towards glucocorticoid receptor (GR) and androgen receptor (AR) lead to undesirable side effects. Evestra’s rational design and development approach in the synthesis of EC304 was aimed at minimizing these side effects as well as to deliver more potent and selective antiprogestins. We used select screen® (Invitrogen) to determine relative binding affinity of EC304 with AR, GR and PR. The binding affinity of EC304 showed strong antagonism towards PR with mild or negligible agonism with AR or GR. PR transactivation was inhibited by EC304 with IC50 of 0.04nM in the presence of progesterone (5nM).
EC304 showed superior cytotoxicity over known antiprogestins ZK230211, ORG33628, CDB2914, CDB4124 and RU486 in T47D cells. IC50 of EC304 was found to be 0.5nM in a 6-day cytotoxicity assay (MTT) in T47D cells stimulated with 1nM estrogen (E2). In a 21-day in vitro tumorigenicity assay, EC304 inhibited 80 and 100% of colony formation of T47D cells in the presence of E2 at 1 and 10 nM respectively. Further studies revealed that EC304 induced apoptosis and G1-phase arrest in cell cycle progression when co-incubated with E2 for 24 h. Treatment with EC304 down regulated PR target genes and up regulated cell cycle dependent kinase (CDK) inhibitor P21 in vitro. Ongoing studies address whether EC304 is specifically acting on PR-A or PR-B isoform at gene expression, protein levels and PR isoform specific knockdowns in T47D and other metastatic breast cancer cells. Considered together, these data indicate that EC304 might be a safer but efficacious novel antiprogestin for hormone sensitive postmenopausal breast cancer patients.

**P3-01-03**
The Hominoid-Specific Gene SHON Is Oncogenic in Human Mammary Carcinoma.
Jung Y, Shastri BG, Kong X-J, Zhu T, Perry JK, Lobie PE, Liu D-X. Liggins Institute, Auckland, AKL, New Zealand; Hefei National Laboratory for Physical Sciences, Hefei, Anhui, China; Cancer Science Institute of Singapore, Singapore, Singapore

Breast cancer is still the most common malignancy and the leading cause of cancer deaths in both developed and under developed countries. Molecular targeted therapy, in particular monoclonal antibody-based treatment, has emerged as a promising approach to treat this disease because of its high specificity and reduced toxicity. As a consequence, identification of novel molecular therapeutic targets is of crucial importance. In an effort to discover new targets for monoclonal antibody-based targeted therapy, we have identified a novel and secreted hominoid-specific molecule, SHON (secreted hominoid-specific oncogene), in the human mammary carcinoma cell line, MCF-7. Like other hominoid-specific genes, SHON has no known orthologs outside of the primate lineage. It is highly expressed in all cancer cell lines tested so far including breast, lung, liver, stomach, colon and prostate cancer as determined at the mRNA level by RT-PCR and at the protein level by western blotting. Forced expression of SHON in MCF-7 cells significantly increased cell proliferation and survival as demonstrated by 5-bromo-2'-deoxyuridine (BrdU) incorporation and Annexin V-propidium iodide apoptosis assays, respectively. Forced expression of SHON also promoted MCF-7 cell anchorage independent growth in soft agar and enhanced cell migration and invasion. Moreover, forced expression of SHON in MCF-7 cells increased tumour volume in a xenograft model of human breast cancer in immunodeficient mice. Furthermore, depletion of endogenous SHON expression using small interfering RNAs, or functional inhibition using an inhibitory rabbit anti-SHON polyclonal antibody, decreased MCF-7 cell proliferation and survival, and reduced MCF-7 oncogenicity and invasiveness. Therefore, SHON is a novel oncogene for mammary carcinoma cells which may be useful as a therapeutic target for the treatment of breast cancer.

**P3-01-04**
Differential Impact of Gefitinib and PLX4720 on Proliferation of MCF10A and Isogenic Lines as Measured with a Metastasis Expression Score.

Background: We previously reported that a published “Metastasis Score” (MS) could be used to evaluate the effects of a PI3K inhibitor (GDC-0941) on mutated human isogenic breast cancer cell lines. MS, based on the expression of 14 genes, has been shown to predict distant metastasis in ER(+), node (-), breast cancer. We were interested to determine the impact of gefitinib (EGFR inhibitor) and PLX-4720 (selective inhibitor of BRAF V600E) on MS to assess the applicability of this score to a broader class of targeted agents. In addition, given the cross-talk between metabolism and proliferation, we also profiled gene expression in glycolysis, fatty acid metabolism and oxidative phosphorylation.

Methods: Parental MCF10A (WT for all genes) and isogenic lines of MCF10A harboring PI3K (H1047R), p53 null or KRAS(G12V) mutations were cultured overnight in DMEM:F12 media under identical conditions. Cells were then treated with gefitinib, PLX4720, or DMSO (vehicle control) and further incubated for 24hr. Expression analysis was performed by RT-PCR.

Results: The MS of the PI3K (H1047R) and p53 null lines was higher than the parental line and lower for the KRAS (G12V) line. Treatment of parental, PI3K and KRAS cell lines with gefitinib resulted in dose-dependent decreases in MS, as reported for GDC-0941, with a higher dose required to inhibit growth of PI3K (H1047R) cells. Treatment of p53 null cells with gefitinib, however, had only a modest effect on MS. In contrast to gefitinib, MS increased with PLX-4720 treatment in all 4 lines; the greatest increase was observed in KRAS (G12V) cells. The expression of metabolic genes differed significantly depending on the oncogenic mutation harbored by the cell line. ACTA2, ACLY, RPLA, KHK, GLS2 were most highly expressed in p53 null but lowest in KRAS (G12V) cells. The enhanced proliferation of a BRAF WT cell line treated with gefitinib or PLX-4720 supports the findings that sensitivity to gefitinib requires active p53 in order to induce apoptosis through a p53-dependent pathway. Increases in MS were observed in all 4 cell lines treated with gefitinib or PLX-4720, with the largest increase observed in KRAS (G12V) cells. The expression of metabolic genes differed significantly depending on the oncogenic mutation harbored by the cell line. ACTA2, ACLY, RPLA, KHK, GLS2 were most highly expressed in p53 null but lowest in KRAS (G12V) cells. The enhanced proliferation of a BRAF WT cell line treated with gefitinib supports the impact of this EGFR inhibitor on cell proliferation. The modest effect on MS in p53 null cells supports the findings that sensitivity to gefitinib requires active p53 in order to induce apoptosis through a p53-dependent pathway. Increases in MS were observed in all 4 cell lines treated with PLX-4720, with the largest increase observed in KRAS (G12V). The enhanced proliferation of a BRAF WT cell line with a KRAS mutation is consistent with the Ras-dependent nature of this pathway. The metabolic genes showed diverse expression patterns that differed with different oncogenic mutations and likely reflect the multiple mechanisms controlling metabolism in cancer. An improved understanding of the expression of metabolic genes relative to proliferation in cell lines with various oncogenic mutations may provide additional insights into the dysregulation of these cellular processes and the possible role of anti-metabolite intervention.
Wnt Signaling: A New Target for Treatment and Prevention of Endocrine Resistant Breast Cancer?
Micallef RA, Smith C, Barrow D, Nicholson RI, Gee JMW, Barratt-Lee PJ, Hiscox SE. Cardiff University, Cardiff, Wales, United Kingdom; Velindre NHS Trust, Cardiff, Wales, United Kingdom

Background: Wnt signaling is altered in nearly half of all breast cancers. Both up regulation of Wnt pathway activators and down regulation of pathway inhibitors have been identified in breast cancer. Previously we have reported that activity of β-catenin is altered in acquired tamoxifen-resistant (TamR) breast cancer cells compared to endocrine–sensitive parental MCF7 cells, with an increase in β-catenin-mediated gene transcription. Data is lacking on the role of Wnt signaling in acquired endocrine resistance in breast cancer. Endocrine relapse predicts a poor clinical outcome and remains an important target for future drug development. In this study we investigated the role of Wnt signaling in acquired tamoxifen resistance and its contribution to the associated aggressive phenotype in vitro.

Materials/ Methods: We performed exploratory Affymetrix HGU-133A gene microarray analysis of key Wnt pathway components in log-phase TamR vs. MCF7 cell lines, as well as comparing MCF7 cells +/- 10 day tamoxifen exposure. This was paralleled by western blot (WB) analysis. Effects of Wnt signaling inhibition on growth and cell migration were explored using two commercially available inhibitors: IWP2 (inhibits Wnt production, pLRP6) and PNU74654 (interferes with β-catenin-Tcf/Lef binding). MTT cell proliferation assays (6 days) and cell migration assays (24hrs) were carried out. Results: Microarray analysis of key Wnt pathway components revealed up regulation of wnts 3, 4 and 6; up regulation of Wnt pathway activators LRP5 and LRP6; down regulation of pathway inhibitors (DKK1, DKK4); and down regulation of Axin1 (destruction complex component). Changes are >1.5-fold. WB analysis confirmed up regulation of total β-catenin and LRP6 in TamR versus MCF7 cells as well as activity of LRP6. In accordance with this, inhibition of Wnt signaling using IWP2 10uM or PNU74654 10uM, whilst having no effect on MCF7 cell proliferation, significantly suppressed the growth of TamR cells (p<0.001). Inhibition of Wnt signaling in TamR cells also suppressed cell migration (p<0.001). Gene microarray data for MCF7 cells treated with tamoxifen for 10 days showed up regulation of LRP6 and wnt4 and down regulation of LRP5, wnt6, Axin1 and DKK4 compared to control.

Discussion: These observations suggest that deregulated Wnt signaling may play a role in acquired tamoxifen resistance in breast cancer where it may act to promote growth and the development of a more aggressive phenotype. Its interaction with other pathways is important in the prevention of resistance with co-treatment strategies. Wnt1 can rescue MCF7 cells from growth suppression caused by 4-hydroxytamoxifen. Given the early changes in the Wnt pathway in MCF7 cells treated with tamoxifen, further exploration in the context of earlier Wnt targeting alongside anthornabone treatment is required. Monitoring of Wnt signaling within clinical samples from patients who have relapsed after hormone treatment is urgently warranted given that the Wnt inhibitors showed promise in controlling this state in vitro.

NF-κB Inhibition Promotes Radiosensitivity of Breast Cancer Cells in Three-Dimensional Culture through Abating β1-Integrin Expression.
Ahmed KM, Zhang H, Park CC. Ernest Orlando Lawrence Berkeley National Laboratory, Berkeley, CA

Therapy-associated tumor resistance, giving rise to recurrence and mortality, is a critical issue in cancer therapy. The molecular mechanisms causing tumor resilience to the therapeutic radiation remain elusive. Nuclear factor-KB (NF-KB), a stress-sensitive heterodimeric transcription factor in the regulation of the stress-responsive genes, has been shown to initiate prosurvival signaling pathways. The cooperative function of NF-KB with other key stress elements in radiosensitivity remains to be elucidated. We have previously reported that induction of α5β1-integrin is associated with the enhanced cell survival of breast cancer cells after exposure to high dose IR (ionizing radiation). Because a typical NF-KB binding site was located in human β1-integrin promoter region, β1-integrin-mediated resistance to radiation may be regulated by NF-KB. The aim of the present study was to reveal a connection between NF-KB and β1-integrin pathways in radioprotection of malignant T4-2 mammary epithelial cells in 3D IrECM (three-dimensional laminin-rich extracellular matrix). We show that the elevated NF-KB activity was correlated with enhanced clonogenic survival, and increased NF-KB heterodimer p50/p65 levels were associated with an increase in total and phosphorylated (Thr 788/789) β1-integrins. Inhibition of NF-KB activation significantly reduced clonogenic survival with the inhibition of β1-integrin. These results indicate that NF-KB-mediated induction of β1-integrin is associated with an increased radiation resistance. Treatment of T4-2 colonies, formed at day 4, with NF-KB activation inhibitor in 3D IrECM before exposure to IR (4-Gy X-ray) resulted in a reduction of the size of colonies. The surviving colonies were associated with a decrease in proliferation and increase in apoptosis, indicating a decrease of resistance to IR. Together, these results provide the first evidence that NF-KB-mediated β1-integrin expression is responsible for tumor radiosensitivity. The NF-KB/β1-integrin pathway may serve as an efficient drug target to re-sensitize radiosensitive tumor cells.

Solano AR, Orlando UD, Garona J, Ripoli GV, Duarte AB, Maloberti PM, Avagnina MA, Alonzo DF, Gomez DE, Podesta EJ. School of Medicine University of Buenos Aires, Buenos Aires, Argentina; University of Quilmes, Quilmes, Buenos Aires, Argentina; Center of Medical Education and Clinical Investigation Norberto Quirno, Buenos Aires, Argentina

BACKGROUND: ciclooxygenase-2 (COX-2) has been suggested as a necessary component of the cellular and molecular mechanisms behind breast cancer cell motility and invasion. The potential therapeutic benefit of COX-2 inhibitors in a range of cancers is being seen as a great promise however, there have been recent concerns about potential cardiotoxicity. Thus, there is an urgency to develop new inhibitors exhibiting a better risk/benefit ratio. Acyl-CoA synthetase 4 (ACSL4), belongs to a five-member family of enzymes that esterifies mainly arachidonic acid into acyl-CoA. We have provided first-time evidence demonstrating that, ACSL4 is the key enzyme that regulates the induction of COX-2, the production of prostaglandin E2 (PGE2) and the proliferation and metastatic potential of breast cancer cells. Therefore, the aim of the study was...
the development of an in vivo model of human breast tumor xenografts for the study of the regulation of COX-2 expression and action.

RESULTS: stable transfection of MCF-7 cells with ACSL4 cDNA under the control of tetracycline (MCF-7 Tet-off-ACSL4) resulted in a significant increase in the expression of COX-2. The increment in COX-2 expression registered in MCF-7 Tet-off-ACSL4 cells is accompanied with an increase in the production of PGE₂, and the proliferation and metastatic potential of cancer cells. Next, we tested whether the injection of MCF-7 Tet-off/ACSL4 cells into nude mice resulted in tumor development.

The results of those experiments demonstrate that MCF-7 Tet-off/ACSL4 cells develop into murine mammary tumors whereas cells transfected with the MCF-7 Tet-off empty vector did not. Interestingly, treatment of nude mice with tetracycline resulted in tumor growth inhibition. The results show that the sole transfection of ACSL4 results in a phenotype change that endows the cells with the capacity to develop into tumors when injected into nude mice. Tumor volume (TV) at day 70 reached 468.4±189.3mm³. Treatment with tetracycline reduced TV to 189.3±65.9mm³ (p<0.05). The growth rate between days 45-70 was 12.30 mm³/day. Tumors were classified as Basal-like subtypes.

We have also observed an inhibition of proliferation and migration of MDA-MB-231 cell cultures when exposed to a combination of ACSL4 and COX-2 inhibitors. Interestingly, the compounds assayed markedly reduced cell proliferation and migration at concentrations that are less effective when used alone. These results point to an effect that has the advantage of exposing the cells to lower drug concentrations.

CONCLUSION: Based on our results, we hypothesize that ACSL4 and COX-2 could constitute potential therapeutic targets for the control of tumor growth. Our animal model of mammary tumors constitutes a proper platform for the study of those therapies.

In Vitro and In Vivo Antitumor Activity of the Aurora and Angiogenic Kinase Inhibitor ENMD-2076 in Triple-Negative Breast Cancer Models.

Diamond RJ, Eckhardt SG, Tan AC, Selby HM, Newton TP, Pitts TM, Bray MR, Fletcher GC, Tentler JJ. University of Colorado Cancer Center, Aurora, CO; EntreMed, Inc, Toronto, ON, Canada

Background: Triple-negative breast cancer (TNBC) is an aggressive biologic subtype which lacks effective targeted anti-cancer agents and is characterized by a high mitotic index and dependence on angiogenesis. ENMD-2076 is a novel orally bioavailable Aurora and angiogenic kinase inhibitor currently in clinical development with favorable pharmacokinetics and a manageable toxicity profile. The purpose of this study was to use TNBC cell line-based in vitro and in vivo models to demonstrate the antitumor activity of ENMD-2076 towards this breast cancer subtype compared to the luminal and HER2-amplified subtypes. Using significance of analysis of microarrays (SAM) analysis and GSEA, we identified Ran, a member of the mitotic spindle regulation pathway as upregulated in sensitive TNBC cell lines (p = 0.017). Interestingly, AURKA, the main target of ENMD-2076, is a core gene in this pathway.

Conclusions: ENMD-2076 exhibited robust anticancer activity towards preclinical models of TNBC, supporting future clinical investigations of this agent in TNBC with an emphasis on the continued development of biomarkers predictive of response in this breast cancer subset.

Oncogenic Activation of HSF1 Enables the Malignant Progression of Breast Carcinoma.

Mendillo ML, Santagata S, Kovea M, Fraenkel E, Ince TA, Whitesell L, Lindquist S. Whitehead Institute for Biomedical Research, Cambridge, MA; Brigham and Women’s Hospital, Boston, Boston, MA; Massachusetts Institute of Technology, Cambridge, MA; University of Miami Miller School of Medicine, Miami, FL; Howard Hughes Medical Institute, Cambridge, MA

HSF1 is best known for its role as the master transcriptional regulator of the evolutionarily conserved heat-shock response. In mice, Hsf1 knock-outs dramatically reduce susceptibility to malignant transformation and tumor formation, and markedly increased survival in cancers driven by both oncogenic and tumor suppressor mutations. Likewise, RNAi-mediated knockdown markedly reduces the growth and survival of human cell lines established from cancers driven by a diversity of genetic lesions. The transcriptional network that HSF1 coordinates during heat-shock is known, but is unknown in malignancy. We compare HSF1 function in isogenic breast cancer cells of high and low malignant potential. HSF1 orchestrates a far-reaching transcriptional program that is dependent on transformation and the degree of malignancy. The oncogenic HSF1 program differs markedly from the classical heat-shock response. It is enriched for genes involved in a myriad of cellular processes known to be important in malignancy, including transcription, translation, glucose metabolism and cellular adhesion. It includes only a particular subset of heat-shock protein genes, and many of these are regulated in a manner that differs from their regulation by heat-shock. We also find that HSF1 is overexpressed and activated in a large subset of all conventionally defined classes of breast cancer. Moreover, tumors with high expression of the oncogenic HSF1 transcriptional network
are strongly associated with poor outcome as monitored by metastasis and death. Our findings suggest that the oncopgenic HSF1 activation program is rooted in fundamental aspects of tumor biology and will prove a powerful new tool in the clinical management of patients with breast cancer and, likely, other malignancies as well.

**DMBA-Breast Cancer in Diet Induced Obesity (DIO) and Lean Mice Is Related to Leptin Signaling.**

Gillespie C, Penichet MG, Colbert LS, McGlothlen T, Guo S, Zhou W, Gonzalez-Perez RR. Morehouse School of Medicine, Atlanta, GA; Shenyang Medical College, Liaoning Pro, P.R., China

**Introduction:** Leptin, the major adipokine released by adipose tissue, is strongly related to obesity-related cancers. We have shown previously that inhibition of leptin signaling with pegylated leptin peptide receptor antagonist 2 (PEG-LPrA2) negatively impacted human xenograft and syngeneic mouse breast cancer growth as well as VEGF/VEGFR2 levels [1,2].

**Objective:** We hypothesize that leptin signaling is essential for 7,12-dimethylbenz[A]anthracene (DMBA)-mammary tumor (MT) particularly in obese mice.

**Methods:** The study investigated the potential of PEG-LPrA2 to prevent MT in lean and diet-induced-obesity (DIO)-C57BL/6J female mice treated with 1 mg/dose/weekly for 6 weeks of DMBa. Obesity was induced by feeding DIO-mice (95% obese mice after 5 weeks) with high fat diet (PDI-1; 45% Kcal from fat). Lean mice were fed a normal diet (PDI-1; 5% Kcal from fat). PEG-LPrA2 was administered intravenously. Lean and DIO-mice received either one or two PEG-LPrA2 dose/week (50 μl/0.1 mM) two weeks prior to DMBa to test its preventative potential through the end point (32 weeks). Control mice received saline injections. **Results:** Obesity was positively correlated to the development of DMBA-MT in mice. MTs were found in 17% of lean control and 69% of DIO-control mice. Notably, PEG-LPrA2 prevented the onset of DMBA-MT in lean (one and two doses: 0% tumor-bearing mice) and DIO-mice (one-dose, 29% and two-dose 0% MT). PEG-LPrA2 treatment did not alter body weight nor food intake in lean or DIO-mice. VEGF levels were significant higher (32 fold) in control DIO-mice. PEG-LPrA2 inhibition of leptin signaling decreased tumor levels of Notch ligands (Jagged-1 & DLL-4), receptors (Notch 1-4) and target genes (Survivin and Hey2) and reduced OB-R, IL-1Rt, VEGF/VEGFR2, bcl-2, HIF-1a and NFkB in 95% of lean and 69% of DIO-control mice. Notably, PEG-LPrA2 prevented the onset of DMBA-MT in lean (one and two doses: 0% tumor-bearing mice) and DIO-mice (one-dose, 29% and two-dose 0% MT). PEG-LPrA2 treatment did not alter body weight nor food intake in lean or DIO-mice. VEGF levels were significant higher (32 fold) in control DIO-mice. PEG-LPrA2 inhibition of leptin signaling decreased tumor levels of Notch ligands (Jagged-1 & DLL-4), receptors (Notch 1-4) and target genes (Survivin and Hey2) and reduced OB-R, IL-1Rt, VEGF/VEGFR2, bcl-2, HIF-1a and NFkB in 95% of lean and 69% of DIO-control mice.

**Conclusions:** Present data strongly suggest that leptin signaling is essential for DMBA-induced MT in the context of obesity. Overall, the effective chemoprevention of DMBA-MT by PEG-LPrA2 treatment in DIO and lean mice reinforces the potential use of leptin signaling inhibition for breast cancer prevention. These observations are most significant for obese populations showing higher levels of leptin and incidence of breast cancer. **Increased Gene Copy Number of c-KIT and VEGFR2 at 4q12 in Primary Breast Cancer Is Related to an Aggressive Phenotype and Impaired Prognosis.**

**Introduction:** Triple-negative breast cancer (TNBC) accounts for approximately 15% of all female breast cancer and is associated with aggressive clinical behaviour. No targeted treatments are available for TNBC. Drugs inhibiting tyrosine kinases, such as vascular endothelial growth factor receptor 2 (VEGFR2) and c-KIT, have however shown some promising results for patients with TNBC. The aim of the present study was to investigate whether gains and/or amplifications of VEGFR2 and c-KIT occur in TNBC. These genes may constitute novel candidate biomarkers for selecting TNBC patients for treatment with tyrosine kinase inhibitors.

**Material & Methods:** Fluorescence in situ hybridization (FISH) was used to quantify gene copy numbers of VEGFR2 and c-KIT in 83 primary human breast cancers, of which 31 were classified as TNBC. Gains were defined as > 4 copy numbers in more than 40% of the cancer cells, while amplification was defined as gene copy/CEP ratio > 2 in more than 10% of the cancer cells. A tumour was considered FISH positive for c-KIT and/or VEGFR2 if it displayed copy number gain and/or amplification. Immunohistochemical (IHC) staining was performed for assessment of c-KIT protein expression.

**Results:** Ten (32%) of the TNBCs were VEGFR2 FISH positive and nine (29%) were c-KIT FISH positive, whereas non-TNBCs were FISH positive for VEGFR2 and c-KIT in nine (18%) cases for both genes. No significant difference in frequency between TNBCs and non-TNBCs was found. There was a correlation between FISH positivity for VEGFR2 and c-KIT (c² test, P<0.001), and VEGFR2 and c-KIT FISH positivity correlated to ER/PgR negativity and high Nottingham histological grade (NHG). A significantly worse breast cancer specific survival (BCSS) was seen for FISH positive cases in the whole cohort as well as among untreated patients and non-TNBCs, but not among TNBC cases.

**Discussion:** The high correlation between VEGFR2 and c-KIT FISH positivity suggests that the genes are co-amplified. Increased copy number of both genes was related to aggressive disease and a worse prognosis, and thus has the potential of functioning as a novel predictive biomarker for selected targeted therapy particularly in the difficult-to-treat TNBC patient category.

**Prognostic Impact of RANK, RANKL and OPG Gene Expression in ER Positive Primary Breast Cancer.**

Ruckhaeberle E, Mueller V, Schmidt M, Saenger N, Hanke L, Gaetje R, Ahr A, Holtrich U, Karn T, Rody A, Kaufmann M. Department of Gynecological Oncology, Frankfurt, Germany; Department of Obstetrics and Gynecology, Hamburg, Germany; Department of Obstetrics and Gynecology, Mainz, Germany; Department of Obstetrics and Gynecology, Homburg/Saar, Germany

**Background:** The cell surface receptor RANK (receptor activator of NFκB), its ligand (RANKL) and the decoy receptor of RANKL osteoprotegerin (OPG) play an important functional role in bone physiology and in the survival of cancer cells. RANKL expression is positively correlated with cytotoxicity of breast cancer cells. We investigated whether expression of RANK, RANKL and OPG were associated with clinical breast cancer patient characteristics.

**Material & Methods:** We investigated human breast cancer samples obtained from four different patient populations: breast cancer patients with estrogen receptor positive (ER+) disease, patients with breast cancer with triple negative phenotype (TNBC) and patients with breast cancer who had received neoadjuvant chemotherapy (NAC) and patients who had received metastatic breast cancer (MBC). 116 ER+ and 58 TNBC breast cancer samples were collected. For the NAC and the MBC patients, the expression levels of RANK, RANKL, and OPG were measured.

**Results:** In the ER+ breast cancer samples, the expression of RANK and RANKL was associated with metastasis. More specifically, multivariate analysis showed that the expression of RANK and RANKL was significantly associated with the number of metastatic lymph nodes (P=0.001 and 0.002). The expression of RANK and RANKL was also associated with recurrence (P=0.003 and 0.001) and metastasis (P=0.001 and 0.001) in the ER+ breast cancer samples. Interestingly, the expression of RANK and RANKL was also associated with the HER2 status (P=0.002 and 0.001) and the number of metastatic lymph nodes (P=0.001 and 0.002) in the TNBC breast cancer samples. Multivariate analysis showed that the expression of RANK and RANKL was significantly associated with the number of metastatic lymph nodes (P=0.001 and 0.001) in the TNBC breast cancer samples. The expression of RANK and RANKL was also associated with recurrence (P=0.001 and 0.001) and metastasis (P=0.001 and 0.001) in the TNBC breast cancer samples. In addition, the expression of RANK and RANKL was also associated with the HER2 status (P=0.002 and 0.001) and the number of metastatic lymph nodes (P=0.001 and 0.001) in the ER+ breast cancer samples.

**Discussion:** Our findings suggest that the expression of RANK and RANKL is associated with clinical breast cancer patient characteristics. These results support the hypothesis that RANK and RANKL expression may be used as prognostic markers in breast cancer patients.
bone metastasis by regulating osteoclasts. Just recently it was shown that tumor-infiltrating lymphocytes can stimulate breast cancer metastases through RANK-RANKL signalling.

Material and methods:
We analyzed gene expression of RANK, RANKL and OPG in a combined Affymetrix dataset of 307 ER positive breast cancers from our institutions which were either untreated or treated with chemotherapy. Kaplan Meier analysis of disease free survival and Cox regression analysis was applied to examine the prognostic value of the different markers.

Results:
We observed no significant difference in survival when samples were analyzed according to either RANK or RANKL mRNA expression. In contrast when samples were stratified in quartiles of OPG expression a positive linear relationship of survival with the expression of OPG was observed. Moreover since OPG demonstrated a bimodal type of expression a cutoff value can be derived from the expression data. Using this cutoff value a hazard ration of 2.14 (95% CI 1.27-3.61; P=0.004) for low OPG expression was detected. OPG expression correlated with lower proportion of grade 3 tumors (15.7% vs 27%; P=0.022) and a higher proportion of PgR positive samples (86.2% vs 71.4%; P=0.002). No significant differences were observed for lymph node status, age, tumor size and HER2 status. In multivariate analysis only lymph node status remained significant while OPG, Ki67, age, grade, and PgR only displayed a trend towards significance.

Conclusion:
Expression of osteoprotegerin seems to correlate with good prognosis in ER positive breast cancer. These data are in line with in vitro studies demonstration that OPG inhibits RANKL induced migration of tumor cells.

P3-01-14
RANK and RANK Ligand (RANKL) Expression in Invasive Breast Carcinoma and Human Breast Cancer Cell Lines.

Purpose:
RANK and its ligand (RANKL), key factors for bone remodeling and metastasis, are crucial for the development of mouse mammary gland during pregnancy. RANKL functions as a major paracrine effector of the mitogenic action of progesterone in mouse mammary epithelium and has a role in ovarian hormone-dependent expansion and regenerative potential of mammary stem cells (MaSC). RANKL inhibition has been shown to reduce mammary tumor formation and pulmonary metastases in mouse models. Many published expression analyses of RANK and RANKL have been performed using immunohistochemistry (IHC) without documented validation of antibody specificity. This study assessed the expression of human RANK and RANKL in human invasive breast carcinoma (IBC) and human breast cancer cell lines using specific, monoclonal antibodies validated and optimized for IHC or flow cytometry.

Methods: RANK and RANKL expression was analyzed in a panel of human breast cancer cell lines representing luminal or basal breast subtypes using qPCR, flow cytometry and surface receptor quantitation. Antibodies against human RANK (N-1H8, N-2B10; Amgen) and human RANKL (M366, AMG161; Amgen) were used for flow cytometry, surface receptor quantitation or IHC staining. For human IBC, the intensity of IHC staining was scored on a semiquantitative scale (0=absent, 1=weak, 2=moderate, 3=intense). Incidence was scored as a positive IHC signal (any intensity). In vitro responses of cell lines to RANKL were also tested.

Results: The specificity of the antibodies was substantiated by concordant signals observed using multiple independent analyses, including IHC, flow cytometry and Western blots of positive and negative control cells and xenograft samples. Analysis of primary human IBC using IHC demonstrated that 25/114 (22%) IBC samples expressed RANK and 18/97 IBC (19%) expressed RANKL protein within the tumor epithelium. RANK protein was observed in mononucelar cells infiltrating the tumor in 87/114 (76%) and within normal mammary epithelium adjacent to tumors in 35/79 (44%) of samples. RANKL was observed in infiltrating mononucelar cells within

www.aacrjournals.org 339s  Cancer Res; 71(24 Suppl.) December 15, 2011
the tumor in 60/115 (52%) and within normal mammary epithelium adjacent to tumors in 15/68 (22%) of samples. Both mRNA and RANK surface protein were detected in multiple breast cancer cell lines, including basal and luminal subtypes. Functional RANK expression on cell lines was confirmed by the observation of RANKL-dependent increases in mRNAs (e.g. MMP-9, IL-6 or IL-8) or proteins in conditioned media (e.g. IL-6, IL-8), despite the relatively low surface expression of RANK observed (range = 1240-9120 sites/cell).

**Conclusion:** RANK and RANKL expression was observed in the epithelial carcinoma element in human IBC using IHC. RANK and RANKL expression was also observed in normal mammary epithelium and monocytic cells adjacent to breast tumors. Functional RANK expression was observed in human breast cancer cell lines, including both basal and luminal subtypes.

The Role of Src Homology Phosphotyrosyl Phosphatase-2 in Basal-Type/Triple-Negative Breast Cancer – Implications for Targeted Therapy.

Agazie YM, Matalka F, Hartman ZR. West Virginia University School of Medicine, Morgantown, WV; West Virginia University School of Medicine, Morgantown, WV

Background: Of all breast cancer subtypes, the basal-type/triple-negative breast cancer (BTBC) has the worst clinical outcome. The major reasons are the highly invasive nature of the disease and the limited treatment options available to patients. As opposed to the HER2-positive and the hormone-positive breast cancers, targeted therapy against BTBC is unavailable. These premises underscore the need for discovering and characterizing drug targets in BTBC.

In this study, we have focused on the Src homology phosphotyrosyl phosphatase 2 (SHP2) which seems to play pivotal roles in BTBC. The major reason for focusing on SHP2 is that it is an essential downstream effector of mitogenic and cell survival signaling downstream of receptor tyrosine kinases such as EGFR (HER1) and IGF-1R, and the cytoplasmic tyrosine kinase Src, which are known to be elevated in BTBC.

Materials and Methods: The state of SHP2 and EGFR expression in BTBC tumors was determined by immunohistochemistry. The functional significance of SHP2 in BTBC cells was investigated by ablating its expression with specific siRNA and then assessing impact on mitogenic and cell survival signaling using immunoblotting with phospho-specific antibodies, effect on transformation using 3D cultures such as growth in soft agar and matrigel, consequence on cell motility and invasiveness using flow-cytometry-tagged matrigel. Furthermore, the impact of SHP2 inhibition on tumorigenesis was tested by intramammary transplantation in vivo and monitoring and analyzing tumor growth and metastasis.

Results: We have shown that the SHP2 protein is elevated in BTBC tumors. More importantly, the elevated expression of SHP2 is highly correlated with overexpression of the EGFR (HER1), suggesting their potential synergistic role to promote BTBC. Inhibition of SHP2 in BTBC cells reversed transformation and suppressed proliferation, indicating their dependency on the function of SHP2. Moreover, inhibition of SHP2 abolished EGF-induced mitogenic and cell survival signaling, which is in agreement with its role in cell proliferation and transformation. More dramatic was that the invasive phenotype of BTBC cells in 3D matrigel was completely blocked by inhibition of SHP2, suggesting that the invasive property of these cells is dependent on SHP2. Even more dramatic was that the tumorigenic and metastatic potential of BTBC cells was abolished by SHP2 inhibition.

Discussion: The current study demonstrates that SHP2 plays a pivotal role in promoting BTBC. Given that SHP2 is a tyrosine phosphatase with positive signaling role, its promotion of BTBC must occurs through promotion of tyrosine kinase signaling. Together, our results provide the first glimpse on the potential of SHP2 as a drug target in BTBC.

**P3-01-16**

Expression of Basal Markers in Correlation with PTEN and BRCA 1 in Triple Negative Breast Carcinomas (TN) Treated with Chemotherapy Versus PARP Inhibitors.

Chivukula M, Carter G, Puthalla S, Magee Women’s Hospital of Pittsburgh, Pittsburgh, PA; Magee Women’s Hospital of UPMC, Pittsburgh, PA

The link between the BRCA1 tumour-suppressor gene and hereditary breast and ovarian cancer is established. The morphologic and immunohistochemical features of basal like phenotype carcinomas have shown to be correlated with the BRCA 1 expression. PTEN (phosphatase and Tensin Homolog) is a novel tumour suppressor gene located on chromosome 10. PTEN mutations are believed to exert their effects through the putative PI3K-AKT-mTOR signaling pathway. Lack of PTEN expression, suggests that PARP inhibitors may be therapeutically useful for a subset of invasive breast cancers. The data on PTEN status in breast carcinomas is emerging. The aim of our study is to assess the immunohistochemical expression of basal markers, PTEN and BRCA 1 in a subset of triple negative breast carcinomas with known BRCA status. Results: Results are shown in Table 1.

TN: triple negative; Chemo: patients who received chemotherapy; (**): Study ongoing with new patients; (+): Positive; (-): Negative

Conclusions: 1. Initial results from our study indicate high expression of PTEN is seen in TN breast carcinomas. 2. There appears to be decreased BRCA 1 protein expression in TN patients who tested positive for BRCA mutations. 3. Given the loss of PTEN in a subset of TN Chemo group, PARP inhibitors may be suggested to be therapeutically useful and needs to be evaluated further. 4. The lack of CK 5 basal keratin in some patients needs to be addressed further. The study is on going with addition of new cases. The updated data and preliminary data with patient responses on PARP inhibitor will be presented.

**P3-02-01**

A Novel Bispecific, Hexavalent, Antibody (HexAb) Inhibits Anchorage-Independent Growth and Reduces Invasiveness of Triple-Negative Breast Cancer Cell Lines In Vitro.

Background: Combination therapy using two different monoclonal antibodies to achieve improved efficacy without increased toxicity
is being pursued in various preclinical and clinical studies but, in principle, could be accomplished with a single bspecific antibody (bsAb). We note the elevated expression of the type-I insulin-like growth factor receptor (IGF-1R) and the trophoblast cell-surface marker (Trop-2) in diverse epithelial tumors, including breast cancers, and the increasing evidence of their correlation with poor survival. Therefore, we chose to explore the potential of 1R-(E1)-(E1), the bspecific HexAb constructed from hR1 (humanized anti-IGF-1R) and hRS7 (humanized anti-Trop-2) for treating breast cancers. Methods: 1R-(E1)-(E1) was generated by the Dock-and-Lock (DNL) method to comprise a full IgG of hR1 linked to two stabilized dimers of hRS7 Fab, and evaluated in three HER2-negative breast cancer cell lines: the non-evasive MCF-7, the moderately invasive MDA-MB-468, and the highly invasive MDA-MB-231. The in vitro characterizations of 1R-(E1)-(E1) included flow cytometry to determine cell binding, soft agar assay to evaluate the effect on anchorage-independent growth, and BD matrigel chambers to assess invasion properties. Statistical differences (P values) between two populations were determined by Student's t-test. Results: All three cell lines were found to express both IGF-1R and Trop-2, with MCF-7 and MDA-MB-468 notably higher in IGF-1R and Trop-2, respectively. As expected, 1R-(E1)-(E1) bound to all three cell lines. At 50 μg/ml, 1R-(E1)-(E1) reduced the invasion of MDA-MB-468 to less than 10% of the untreated control, whereas under the same conditions, MDA-MB-231 appeared to be resistant, while the parental antibodies showed no effects. The ability of 1R-(E1)-(E1) to inhibit anchorage-independent growth was demonstrated at 200 nM in MDA-MB-231, with a statistically significant difference (P=0.041) when compared with samples treated with parental antibodies at the same concentrations. Cells treated with 1R-(E1)-(E1) produced few and much smaller colonies, the largest size of which was less than 1/10 of the untreated cells. The parental hR1 alone, but not hRS7, had some effect on inhibiting the growth of MDA-MB-231 in soft agar, presumably resulting from the down-regulation of IGF-1R. Conclusions: These promising results warrant further evaluation of 1R-(E1)-(E1) in other breast cancer cell lines, as well as the exploration of new bspecific HexAbs that comprise different antibodies capable of targeting other solid cancers.

P3-02-02
Novel Ranpirnase-Based ImmunoRNases Display Potent Cytotoxicity in Diverse Human Breast Cancer Cell Lines.

Ranpirnase (Rap) is an amphibian ribonuclease originally isolated from the oocytes of Rana pipiens. Rap shows anti-tumor activity in diverse cancers and its potency can be enhanced by chemically linking or recombinantly fusing Rap to a tumor-targeting antibody, as demonstrated for CD22- or CD74-expressing hematological malignancies, as well as a variety of Trop-2-expressing cell lines derived from breast, cervical, lung, pancreatic, and prostate cancers. The Dock-and-Lock (DNL) platform enables the design and generation of targetable therapeutics that are multivalent, multispecific, and multifunctional. Here, we report the successful application of the DNL method to generate a novel class of Rap-based immunomRNases, each of which features a pair of dimeric Rap molecules covalently tethered to a select monoclonal antibody at the carboxyl termini of the heavy chains. Two such constructs, designated E1-Rap and 22-Rap, were developed with hRS7 (humanized anti-Trop-2) and epratuzumab (humanized anti-CD22), respectively, purified to near homogeneity, and evaluated in a panel of human breast cancer lines, including the basal-like, triple-negative subtype (MDA-MB-468, MDA-MB-231, BT20, HCC1806, and HCC1395), the luminal B, HER2-negative subtype (MCF-7), and the HER2-positive subtype (SKBR3), all except HCC1395 expressing high to moderate levels of Trop-2, and none expressing CD22. As demonstrated by flow cytometry, E1-Rap and hRS7 bound equivalently to MDA-MB-468, indicating the affinity of E1-Rap for Trop-2 is not compromised. Surprisingly, 22-Rap, but not epratuzumab, also bound substantially to MDA-MB-468, albeit to a lesser extent than E1-Rap. We thus postulate that the four highly basic Rap molecules in the DNL conjugate may confer a spatial configuration to largely enhance their interaction with negatively-charged cell surface proteins, such as heparan sulfate proteoglycans. Whereas the individual DNL component (IgG or Rap) alone or in combination showed negligible in vitro cytotoxicity in all seven breast cancer cell lines examined, E1-Rap exhibited EC50 values of 1 nM or less in MDA-MB-468 (0.03 nM), MCF-7 (0.1 nM), BT20 (0.18 nM), HCC1806 (0.19 nM), and SKBR3 (1.29 nM). In comparison, the potency of 22-Rap was at least 10-fold lower than E1-Rap in MDA-MB-468, BT20 and HCC1806, with an EC50 of ~2 nM. Neither E1-Rap nor 22-Rap was very effective in inhibiting the proliferation of the more aggressive MDA-MB-231, with an EC50 above 50 nM. In the Trop-2-negative HCC1395, the dose-response curves obtained for E1-Rap and 22-Rap were nearly identical (EC50~100 nM), as they should be if the cytotoxicity was mediated mainly through the Rap component. The results of Immunofluorescence microscopy showed E1-Rap was effectively internalized and localized in the cytosol. Thus, these ImmunoRNases are potentially new cancer therapeutics for breast and other solid tumors.

Toyama T, Kondo N, Endo Y, Sugiuira H, Yoshimoto N, Iwasa M, Takahashi S, Iwase H, Fujii Y, Yamashita H. Nagoya City University Graduate School of Medical Sciences, Nagoya, Aichi, Japan; Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan

Background: microRNAs (miRNAs) have emerged as a new class of non-coding genes involved in regulating cell proliferation, differentiation, and viability. Recent studies have identified miR-210 among a set of hypoxia-regulated miRNAs and demonstrated a direct regulatory role of hypoxia-inducible factor-1 alpha (HIF-1α) in its transcription. High expression of miR-210 has been reported to be a poor prognostic factor in several types of cancers including breast. Materials and Methods: TaqMan MicroRNA assays for miR-210 expression were performed in 219 breast cancers (58 triple-negative TNBCs), and 161 ER-positive and HER2-negative. Correlations between miR-210 expression and clinicopathological factors were analyzed. The effects of several variables on survival were tested by Cox proportional hazards regression analysis. Results: miR-210 expression in TNBCs was significantly higher than in ER-positive and HER2-negative breast cancers (p<0.001). Patients whose TNBCs had low miR-210 expression experienced significantly better disease-free and overall survival compared with high miR-210 expressors (p=0.02 and p=0.05, respectively). Notably, among 40 node-negative TNBCs, 5-year disease-free survival was approximately 60% in patients whose tumors had high or intermediate miR-210 expression (n=26), while no patients with low miR-210 expression (n=14) suffered recurrent disease. Cox univariate and
multivariate analyses demonstrated that low expression of miR-210 was an independent good prognostic factor in TNBCs. miR-210 expression in breast cancer: Cox proportional hazards regression analysis in breast cancer patients: Cox proportional hazards regression analysis

Discussion: Although prognosis of patients with TNBCs is poor, those whose tumors expressed low levels of miR-210 had a more favorable prognosis. Thus, the degree of miR-210 expression might be a clinically useful prognostic factor for decision-making regarding treatment in the adjuvant setting, especially in node-negative TNBC patients.

P3-03-02
Higher Expression Levels of Circulating miR-21, miR-19a and miR-10b Are Associated with High Risk Features in Breast Cancer.

Anfossi S, Giordano A, Cohen EN, Gao H, Cristofanilli M, Valero V, Alvarez RH, Hortobagyi GN, Woodward W, Ueno NT, Lee B-N, Reuben JM. The University of Texas MD Anderson Cancer Center, Houston, TX; Fox Chase Cancer Center, Philadelphia, PA

Background
MicroRNAs (miRs) have oncogenic and tumor-suppressor functions. MiR-21, miR-19a and miR-10b are overexpressed in breast cancer and regulate tumor cell migration, invasion and angiogenesis. We assessed the levels of miR-21, -19a, and -10b in sera of breast cancer patients and their association with the stage, histological type, hormonal receptor (HR) status and HER2 amplification in the primary tumor. Since circulating tumor cells (CTC) detected by CellSearch® are an independent and strong predictor of overall survival in metastatic breast cancer (MBC), we assessed the relationship between circulating miRs and CTCs.

Methods
The study consisted of 30 healthy donors (HD) and 95 breast cancer (BC) patients. Patients’ sera were collected before starting a new line of treatment. Total RNA was isolated, reverse transcribed to cDNA and then subjected to qRT-PCR for the detection of miR-21, -19a, -10b and -192 using the TaqMan MicroRNA Assay (Applied Biosystems, Foster City, CA). MiR-192 was used to normalize the expression levels of the other miRs. Fold-changes in expression of miRs were calculated using the 2^(-ΔΔCt) method, where DCt = mean CT_{mir-target} - mean CT_{mir-192}. CTCs were enumerated using CellSearch™ (Veridex LLC, Warren, NJ). Mann-Whitney U test was used to determine differences in serum miR expression levels between patients and HD.

Results
Of the 95 BC patients, 39 were non-MBC and 56 MBC. Patients grouped according to the receptor expression by immunohistochemical staining consisted of 27 HR+HER2-; 30 HR+HER2+; 20 HR-HER2-, and 18 HR-HER2-triple negative BC (TNBC). MiR-21 and miR-19a were higher in non-MBC patients than in HD (p=0.001; p=0.001, respectively). MiR-21, miR-19a and miR-10b levels were higher in metastatic patients than in HD (p<0.001; p<0.001; p=0.038, respectively). MBC patients had a higher median level of miR-21 than that of non-MBC patients (p=0.02). Patients with (HR+HER2+, HR-HER2-, TNBC) had significantly higher median levels of both miR-21 (p=0.018; p=0.009; p=0.045) and miR-10b (p=0.011; p=0.014; p=0.03) compared with HR-HER2 BC. HER2+ patients had higher median levels of both miR-21 and miR-10b than those of HER2- BC (p=0.033; p=0.01) and HD (p<0.001; p<0.009). Further, median miR-19a expression was higher in IBC patients than in non-IBC patients (p=0.025). Finally, patients with <5 CTCs had a higher median expression level of miR-10b than that of patients with ≥5 CTCs (p=0.042).

Discussion
High expression levels of miR-21, miR-19a and miR-10b in sera are observed in breast cancer patients, especially with advanced disease. HER2+ BC patients had higher serum levels of miR-21 and miR-10b than HER2-. IBC patients had a higher serum level of miR-19a than non-IBC patients. Moreover, patients with <5 CTCs had high serum levels of miR-10b that can be induced by Twist1 during the epithelial-mesenchymal transition (EMT) and, in part, explain the inability of CellSearch® to detect CTCs undergoing EMT.

P3-03-03
Congruence between Patterns of microRNA Expression and Histologic Grading of Invasive Breast Carcinomas.

Ellsworth DL, Croft DT, Field LA, Deyarmin B, Kane J, Ellsworth RE, Hooke JA, Shriver CD. Windber Research Institute, Windber, PA; Henry M Jackson Foundation, Rockville, MD; Walter Reed Army Medical Center, Washington, DC

Background: Histologic grading may be used as an indicator of prognosis in breast cancer; patients with low-grade carcinomas have ~85% ten-year survival compared to just 45% survival in patients with high-grade disease. Although useful for risk stratification, assigning nuclear grade is subjective, and a large proportion of carcinomas are classified as intermediate-grade with uncertain prognosis, thus limiting clinical utility. MicroRNAs (miRNAs) regulate gene expression and serve an important role in breast cancer development. In this study we examined miRNA expression profiles in low-grade and high-grade breast carcinomas to determine if miRNA expression is associated with pathological classifications of tumor grade.

Methods: Breast tumors were obtained from 69 patients enrolled in the Clinical Breast Care Project. Samples were partitioned into low-grade (n=30) or high-grade (n=39) categories using the Nottingham Histologic Score. Following laser microdissection of frozen tissue sections, miRNA was isolated from pure populations of breast tumor cells and hybridized to Affymetrix GeneChip® miRNA arrays containing over 800 human miRNA probes. Expression profiles were analyzed with Partek Genomics Suite using the miRNA Expression Module.

Results: We identified 30 unique miRNAs that showed differential expression at a False Discovery Rate (FDR) p<0.05 between low-grade and high-grade breast carcinomas. Gene targets for these miRNAs function primarily in metabolism and cell communication. Expression of hsa-mir-18a and hsa-mir-572 was significantly different between histologic grades at an FDR p<1x10^-5 and hierarchical clustering based on these miRNAs correctly classified 97% (29/30) of low-grade and 90% (35/39) of high-grade tumors. MiR-18a has been shown to inhibit ER signaling and promote cellular differentiation, while the role of miR-572 in breast carcinogenesis is not well known.

Conclusions: Dysregulation of miRNAs may accompany changes in cellular morphology typically used in histologic classification of breast carcinomas. Patterns of miRNA expression may improve reproducibility and clinical utility of tumor grading and may prove useful for prediction of recurrence and survival for patients with intermediate-grade carcinomas.
P3-03-04
Targeted Modulation of HER Receptor Signaling in Breast Cancer Using miR-21.
Aubele M, Rudyga N, Braselmann H, Atkinson MJ, Auer G, Anastasov N. Helmholtz Zentrum München, German Research Center for Environmental Health, Neuherberg, Germany; Karolinska Institute and Hospital, Stockholm, Sweden

Introduction: MicroRNAs (miRNAs) are multifunctional nucleic acids that regulate the stability and translational efficiency of targeted messenger RNAs. Endogenously altered miRNA levels have been linked in breast cancer to acquired chemo resistance and changed radiosensitivity. Thus the modification of miRNA expression represents an attractive therapeutic strategy. We now show that the targeted inhibition of miR-21 can modify expression of the HER2 receptor in breast cancer.

Materials and Methods: Using TaqMan-based technology the expression of five selected miRNAs (miR-7b, miR-10a, miR-17-5p, miR-125a, and miR-21) was investigated in formalin-fixed, paraffin-embedded breast carcinoma tissues expressing different levels of HER2 (n=60). Possible regulation of HER2 was explored in cell lines using lentivirus to stably downregulate or upregulate HER2 and miR-21 expressions. The effects were analyzed using qRT-PCR, Western blots, proliferation and migration assays.

Results: In tumor tissues we identified overexpression of miR-10a and miR-21, and underexpression of miR-17-5p and miR-125a in most of the tumor tissue samples. Significant associations (p≤0.05) were found between HER receptor expression and the expression of miR-17-5p and miR-125a, and miR-21 showed correlation with expression of ESR1 and PR. Furthermore, analysis of miR-21 downregulation in breast cancer cell lines showed inhibition of cellular proliferation and HER2 protein synthesis. Additionally, downregulation of HER2 expression decreased miR-21 expression and showed moderate change in cellular proliferation activity.

Conclusions: Based on these results we conclude that there is tight interplay between HER2 and miR-21 expression in breast cancer cells. Because miRNAs modulate gene expression we suggest that modulation of miR-21 has the potential to impact tumor therapy by interference with specific signaling pathways.

P3-03-05
Identification of miRNAs and Their Associated Target Genes Involved in Endocrine Resistance in Breast Cancer.
Healy NA, Creighton CJ, Fu X, Tsimelzon A, Hilsenbeck SG, Miller N, Kerin MJ, Osborne CK, Schiff R. Baylor College of Medicine, Houston, TX; National University of Ireland, Galway, Ireland

Background: Despite the widespread use of the selective estrogen receptor modulator tamoxifen or strategies of estrogen deprivation in the treatment of estrogen receptor-positive breast cancer, tumor resistance to endocrine therapy remains a serious clinical problem. MiRNAs are a class of endogenous, single stranded RNA molecules that play a pivotal role in the regulation of gene expression. Altered expression levels of these molecules have been implicated in a number of malignancies, including breast cancer. The aim of this study was to identify those miRNAs that may be associated with endocrine resistance and to further investigate their role in development of this resistance.

Methods: MCF7L breast cancer cells were cultured in regular parental medium (Par) or in phenol-red free, 10% charcoal-stripped FBS medium treated by estrogen deprivation (ED, >6months), tamoxifen (Tam, 10⁻⁸M, >6months), or estrogen (E2, 10⁻⁸M, >1month). Cells treated by long-term Tam or ED developed resistance (TamR or EDR) and resumed cell growth, which was confirmed by growth curve assay. Parallel short-term treatment (10 days) with estrogen deprivation or tamoxifen to represent the endocrine-sensitive phase, and short-term E2 treated cells as a control was also performed. A whole-transcriptome miRNA microarray was performed by High Throughput Genomics (Tucson, AZ), using cell lysates from Par, short-term/endocrine sensitive, E2 treated cells, TamR and EDR. The expression levels of several miRNAs were validated by real-time quantitative PCR (Q-PCR). MiRNAs dysregulated in TamR cells were integrated with predicted gene targets showing anti-correlated expression patterns across human breast tumors in The Cancer Genome Atlas (TCGA) datasets.

Results: The miRNA microarray identified 23 miRNAs that are upregulated in TamR cells (>1.7 fold change, p<0.005) compared to parental cells grown in the presence of E2, and 37 miRNAs that were downregulated (>50%, p<0.005). In addition, 6 miRNAs were observed to be upregulated in EDR and 3 downregulated in EDR compared with controls. Validation of four of these upregulated miRNAs within the TamR group, miR221, miR-222, miR-301b and miR-181c, was performed using Q-PCR. Previously identified genes associated with TamR were scanned for potential binding sites of these deregulated miRNAs using miRanda and TargetScan and many potential miRNA targeted genes are downregulated in TamR. Both miR-221 and miR-181c are predicted to target estrogen receptor gene (ESR1), and downregulation of this target gene was confirmed at the mRNA level by Q-PCR. A strong negative correlation was identified between ESR1 and both miR-181c and miR-221 expression levels in breast tumor samples, according to TCGA data. Work is ongoing to identify the role of miR-181c and other miRNAs in tamoxifen resistance, using a loss-of-function approach. Parallel miRNA profiling of multiple endocrine models is underway to identify commonly deregulated miRNAs associated with endocrine resistance.

Conclusions: This study has identified those miRNAs associated with endocrine resistance in breast cancer. These miRNAs may provide potential predictive markers of resistance to endocrine therapy and modulation of these may lead to increased therapeutic sensitivity.
hGH expression in human breast cancer have demonstrated that hGH expression is positively correlated with lymph node metastasis, tumour stage, HER-2 status and proliferative index. In mammary carcinoma cells autocrine hGH promotes cell proliferation, survival, migration/invasion and epithelial-to-mesenchymal transition as well as tumour formation in a xenograft model. In the current study we demonstrate that autocrine hGH regulates miRNA biogenesis in breast cancer cells.

Methods: Forced expression of hGH was established in the mammary carcinoma cell lines MCF-7 and T47D by stable transfection. miRNA expression was determined using miRNA microarray, quantitative real-time PCR (qPCR) arrays and qPCR assays. The expression levels of genes and proteins involved in miRNA biogenesis were assessed using real-time qPCR assays and Western blotting.

Results: More than 90% of miRNAs assayed were downregulated in hGH-transfected MCF-7 and T47D cells, compared to control transfected cells, as demonstrated by miRNA microarray and qPCR array. Changes in miRNA expression determined by microarray and qPCR array were verified using miRNA-specific qPCR assays. In MCF-7 cells, autocrine hGH did not significantly affect the mRNA expression levels of miRNA machinery components Drosha, DGC8R, PACT, TARBP, EXP-5, Dicer and AGO2 when compared to control transfected cells. Whereas in T47D cells autocrine hGH increased mRNA expression of TARBP, PACT and EXP-5 by 2.0, 2.3 and 1.8 fold respectively, compared to control transfected cells. Western blot analysis demonstrated that, autocrine hGH decreased protein levels of Dicer in MCF-7 cells, whereas Drosha and AGO2 were unchanged compared to control transfected cells. In T47D cells autocrine hGH decreased protein levels of Dicer, Drosha and AGO2 when compared to control transfected cells.

Conclusion: Our findings demonstrate that autocrine hGH stimulates global downregulation of miRNA expression in breast cancer cells. This may be one mechanism whereby autocrine hGH promotes tumour progression. Our results also indicate that autocrine hGH-mediated global downregulation of miRNA expression may occur through regulation of proteins involved in the miRNA biogenesis.

P3-03-07
A Novel Approach Integrating microRNA and mRNA Signatures of HMAPK Signaling Is Highly Predictive of ER- Status and Outcome in Breast Cancer – Role of HMAPK microRNAs in Repression of ER and p27.
Miller P., Clarke J, Koru-Sengul T, Brinkman J, El-Ashry D. University of Miami, Miami, FL

Deregulation of the MAPK signaling pathway in breast cancer is known to facilitate the down-regulation of the estrogen receptor and to contribute to the aggressive nature of ER negative and triple negative breast cancers. We have identified a microRNA signature indicative of hyperactive MAPK (HMAPK) signaling, which complements a previously established hyperactive MAPK gene expression signature. We have shown that hMAPK signaling also alters the regulatory activity of many microRNAs, including particular microRNAs with established roles in the biology of breast cancer, miR-221/222 and miR-22. Expression correlation with both the hMAPK microRNA signature and HMAPK mRNA signature is significantly associated with ER-negative status, increased tumor grade, high proliferation rate, and, importantly, poor disease specific survival among breast cancer patients, regardless of ER status. The hMAPK microRNA signature contains 127 microRNAs, 47 up-regulated and 70 down-regulated. Of note, hMAPK up-regulated microRNAs include miR-221/222 and 22, both of which have been demonstrated to target ER while miR-221/222 targets the cell cycle regulatory protein p27. Down-regulated microRNAs include miR-375, which positively regulates ER expression by down-regulating expression of an ER repressor. miR-221/222 and miR-22 exhibit both enhanced expression and enhanced regulatory activity in the context of HMAPK signaling, indicating an important role for these microRNAs in the biology of HMAPK signaling in breast cancer. In addition to these microRNAs, an unbiased approach of determining MAPK regulated microRNAs targeting the 3' UTRs of both ER and p27 will identify novel microRNAs involved in the MAPK regulated repression of ER and p27. These data not only suggest a regulatory role for microRNAs whose expression and biological activity are altered under conditions of hyperactivation of MAPK signaling in establishing and maintaining ER negativity and tumor aggression, but also indicate that hMAPK signaling may represent a novel aggressive tumor biology that is indicative of poor disease outcome in breast cancer.

P3-03-08
microRNAs in Mammary Stem-Like Cells and Triple-Negative Breast Cancer; Conserved Functions and Treatment Potential.
Williams C., Aydigu E., Katchy A., Lin C-Y., Haldosen L-A., Helguero L. University of Houston, Houston, TX; Karolinska Institute, Stockholm, Sweden; University of Aveiro, Aveiro, Portugal

Background: Mammary stem and progenitor cells are thought to be precursors of different subclasses of breast cancer. Triple-negative breast cancer exhibit similarities to stem or progenitor-like cells. microRNAs (miRNAs) play pivotal roles in both stem cell biology and oncogenesis. Given their potential as therapeutic targets, little is known, however, regarding miRNAs expression and functions in normal and breast cancer cells. Our objective was to identify which miRNAs are involved in mammary stem cell maintenance and differentiation and study their potential roles in triple-negative breast cancer. We investigated their expression during induced differentiation of mammary stem-like cells, correlated their expression to that of triple-negative breast cancer cells and studied the functions of the most regulated and conserved candidates.

Material and Methods: Using large-scale profiling and extensive qPCR confirmation we defined miRNAs regulated during stem-like cell differentiation. We investigated their expression in different breast cancer cell lines, and performed functional studies using miRNA mimics and inhibitors in normal stem-like cells and triple-negative breast cancer cells.

Results: Twenty-one miRNAs were strongly regulated in repeated rounds of mammary cell differentiation. The majority, including the miR-200 family and known tumor suppressor miRNAs, was upregulated during differentiation. Only 4 miRNAs, including the oncomiR, miR-17, were upregulated in the stem cell-like stage. Pathway analysis indicated complex interactions between regulated miRNA clusters and major pathways regulated during this transition, including stem cell maintenance, proliferation and differentiation. The cell model used exhibited gene expression profiles resembling basal-like poor prognosis breast cancer. Moreover, we present data of miRNAs that target the genes and networks responsible for this correlation. miRNAs detected in this study can also differentiate between human non-cancer and breast cancer cell lines, and a subclass of miRNAs, was specifically downregulated in a basal-like breast cancer cell line. The functions of five miRNAs (miR-200a, -200b, -146b, -148a and -206) were further investigated.

Discussion: Our findings suggest that the identified miRNAs have significant roles in biological pathways and networks associated with mammary stem/progenitor cell maintenance and triple-negative breast cancer.
African breast cancer is biologically distinct and shows remarkable
differences in histological type, grade, hormone receptors & HER2
status when compared with breast cancer in white women. The early
age at presentation, predominance of high grade and triple negative,
but not necessarily basal phenotype, may explain the poor prognosis
and requires tailoring treatment strategies to target this unique profile.

**P3-04-02**

**Bevacizumab Treatment Alters Intrinsic Subtypes in a VEGF-
Reinforced Xenograft Model of ER-Positive Breast Cancer.**

Gökmen-Polar Y, Toroni RA, Goswami C, Sanders KL, Sirimalle
U, Mehta R, Li L, Ivan M, Badve S, Sledge GW. Indiana University
School of Medicine, Indianapolis, IN

Background: Anti-vascular endothelial growth factor (anti-VEGF)
therapy improves disease-free but not overall survival in metastatic
breast cancer. To seek further insight on resistance to anti-VEGF
antibody bevacizumab (BEV) at the molecular level, we developed
cancer xenograft models allowing comparison of tumor
response at different time-points. Here we report the gene expression
and miRNA analyses of response and non-response to BEV in these
models.

Methods: MCF-7 cells transfected with control vector (ML20) or
VEGF (MV165) were implanted into the mammary fat pads of
athymic mice. Tumors from short-term treatment with BEV (3
weeks; Responders to BEV, R) or long-term treatment (8 weeks;
Non-Responders, NR) or with vehicle control group (V) were subjected
to whole-genome gene expression analysis (Human WG-6v2 Expression
Beadchips, Illumina) and miRNA profiling (TaqMan ArrayHuman
MicroRNA A+B Cards Set v3.0, Applied Biosystems). Validation of
the chosen genes was performed using quantitative real-time RT-PCR
(qRT-PCR) and Immunohistochemistry (IHC).

Results: Short-term treatment to BEV (3 weeks; 5 mg/kg, i.p./twice
weekly) inhibited primary tumor growth significantly in MV165
xenografts compared with vehicle control, whereas BEV treatment
did not affect the tumor growth in the ML20 model. MV165 xenografts
progressed after 8 weeks of BEV treatment. Gene set enrichment
analysis (GSEA) revealed that luminal A-related gene sets were
enriched in MV165-R compared to MV165-NR group including
DESMEDT (ESR1), SMID_Breast_Cancer_Luminal_A_up, and
MASSARWEH_Tamoxifen_Resistance_Down. Myoepithelial-
specific gene sets were upregulated in both the R and NR groups
compared with the vehicle group. qRT-PCR analysis showed that
estrogen receptor alpha (ESR1) representative for luminal A
decreased significantly in the MV165-NR group (P=0.001) compared to vehicle.
In contrast, Cytokeratin 5 (KRT5) levels increased significantly in both
R (P=0.02) and NR (P=0.03) groups. In addition, KRT14 was
upregulated in R (P=0.04) and in NR (P=0.14) group in comparison
with the vehicle group, suggesting the upregulation of myoepithelial
phenotype specific to BEV treated MV165 model, but not ML20
model. Similar results were obtained by IHC. Consistent with mRNA
changes, ESR1 regulated miRNA such as miR-107 (P=0.007) and
miRNA important in tamoxifen resistance such as mir-451 (P=0.0003)
were also altered in MV165-NR group compared to vehicle.
Conclusion: These results suggest that treatment with BEV may alter
the intrinsic subtypes in the presence of VEGF expression. These data
may help to explain the variable results to anti-VEGF therapy based
on the duration of BEV treatment.

**Molecular Characterization of African Breast Cancer; Results
from a Large Tissue Microarray Study.**

Shaaban A, Hatfield A, Omowoni Esan GO, Komolafe AO, Daranola
A, Pathak D, D’Cruz N, Alizadeh Y, Lewis P, Titiloye NA. St James’s
Institute of Oncology, Leeds, United Kingdom; Obafemi Awolowo
Teaching Hospital Complex, Ile-Ife, Nigeria; Swansea School of
Medicine, Swansea, United Kingdom; College of Medicine University
of Lagos/ Lagos University Teaching Hospital, Lagos, Nigeria

**Introduction**

Breast cancer in African women has been understudied for decades.
Evidence derived mainly from studies on African-American women,
supports that tumours of black women are biologically different and
more aggressive than those occurring in the white population. Of the
4 main taxonomic groups of breast cancer, basal tumours are more
represented in those women. In the present state of knowledge, very
little is known about the biology and molecular profile of breast cancer
in Africa. The aim of this study was to test the hypothesis that the
molecular profile of African breast cancer is distinct from its Western
counterpart. This was achieved by collecting a large cohort of breast
carcinomas from an indigenous African population for phenotypical
characterization and testing for expression of potential predictive
and prognostic markers.

**Methods**

Breast tumours were collected via collaboration with five centres
in Nigeria (the most populous country in Africa) and assembled
into tissue microarrays (TMAs). All tumours were reviewed by a
specialist breast pathologist following the Royal College of
Pathologists (RCPath) guidelines to confirm diagnosis, type, grade
and nodal status. Patients age, tumour size and clinical data, where
available, were collected from the original pathology reports and
case notes. Representative tumour areas were selected and marked
for TMA construction. TMA sections were stained for a range of
markers including hormone receptors (ERα, ERβ, PR, AR), cyclin
D, HER2, Ki67, bcI2, basal (CK5/6, CK14) and luminal cytokeratins
(CK18, 19).

**Results**

A total of 830 tumours were assembled into TMAs. The mean age
diagnosis was 47.69yrs with 58% of patients presenting under the
age of 50. Only 8.5% of tumours were of grade 1. Most tumours
(87%) were of ductal no special type, followed by lobular and
metaplastic carcinomas. The majority of the tumours were ERα, PR
and HER2 negative (77%, 80% and 81% respectively). The triple
negative tumours were the predominant phenotype (55.6%). Luminal
A type tumours comprised 24.3% followed by the HER2 positive
(87%) were of ductal no special type, followed by lobular and
metaplastic carcinomas. The majority of the tumours were ERα, PR
and HER2 negative (77%, 80% and 81% respectively). The triple
differences in histological type, grade, hormone receptors & HER2
negative tumours were the predominant phenotype (55.6%). Luminal
A type tumours comprised 24.3% followed by the HER2 positive
(87%) were of ductal no special type, followed by lobular and
metaplastic carcinomas. The majority of the tumours were ERα, PR
and HER2 negative (77%, 80% and 81% respectively). The triple
differences in histological type, grade, hormone receptors & HER2
status when compared with breast cancer in white women. The early
age at presentation, predominance of high grade and triple negative,
but not necessarily basal phenotype, may explain the poor prognosis
and requires tailoring treatment strategies to target this unique profile.

markers including hormone receptors (ERα, ERβ, PR, AR), cyclin
D, HER2, Ki67, bcI2, basal (CK5/6, CK14) and luminal cytokeratins
(CK18, 19).

**Results**

A total of 830 tumours were assembled into TMAs. The mean age
diagnosis was 47.69yrs with 58% of patients presenting under the
age of 50. Only 8.5% of tumours were of grade 1. Most tumours
(87%) were of ductal no special type, followed by lobular and
metaplastic carcinomas. The majority of the tumours were ERα, PR
and HER2 negative (77%, 80% and 81% respectively). The triple
differences in histological type, grade, hormone receptors & HER2
negative tumours were the predominant phenotype (55.6%). Luminal
A type tumours comprised 24.3% followed by the HER2 positive
(13.9%) and luminal B tumours (6.2%). The differences of all those
parameters were statistically highly significant (p<0.001). Most
tumours expressed ERβ including 75% of those that were ERα/PR
negative. A large proportion of the tumours (22%) were of the basal
phenotype of which two thirds were also triple negative. Over half
of the triple negative tumours were also node positive.

Hierarchal cluster analysis showed the basal tumours dendrogram
to comprise two groups; one showing clustering of ERα/PR/HER2 and
the second showing clustering of ERβ with CK5 and CK14.

**Conclusion**

To our knowledge, this is largest and most comprehensive study of
African breast cancer to date. Our data confirms the hypothesis that
African breast cancer is biologically distinct and shows remarkable
cancer and support their further evaluation as potential prognostic
markers and therapeutic targets in the treatment of breast cancer.
Identification of Hormone-Responsive Genes as Biomarkers for Menstrual Cycle Phases and Menopausal Status.

Wang J, Lee O, Heinz R, Ivanic D, Scholten D, Chatterton RT, Khan SA. Northwestern University, Chicago, IL; Northwestern University

Background: The definition and validation of biomarkers in archived breast tissue samples for prognostic research is limited by the fact that the exact menstrual cycle phases and menopausal status at the time of tissue sampling is often unknown or not accurate by patient survey. Biomarkers that vary with menstrual cycle phases in premenopausal women would be difficult to standardize. There are also significant differences in gene expression in pre- and post-menopausal women. Therefore, menstrual cycle fluctuation and menopausal status need to be considered for all candidate biomarkers as part of the validation process. The aim of this study is to identify genes responsive to different hormones to accurately define menstrual cycle phases and menopausal status.

Methods: We studied gene expression profiles of 18 random fine-needle aspirate (rFNA) samples from unaffected contralateral breast (8 pre-menopausal, mean age 44.5; 10 post-menopausal, mean age 58.8) and investigated the correlation between gene expression and serum hormone levels of estradiol (E2), progesterone (P4) and follicle stimulating hormone (FSH). Genes that were highly correlated with the serum levels of each hormone (Pearson correlation coefficient r > 0.60) were considered as specific hormone-responsive genes (P < 0.0085). The combined gene profiles of hormone-responsive genes were used to dissect samples in different menstrual cycle phases and menopausal status. Selected genes related to mammary gland development and hormone regulation based on gene function and gene network analysis were validated using qRT-PCR in 18 original rFNA samples and in 28 independent samples.

Results: From 35,964 genes and 12,838 undesignated transcripts, we identified genes/transcripts highly correlated with E2 (1091 genes), P4 (127 genes) or FSH (58 genes). The most significantly correlated genes in each group were selected to define four panels of genes: Panel A-21 genes stimulated by E2 (r > 0.78); Panel B-22 genes stimulated by P4 (r > 0.75); Panel C-7 genes stimulated by FSH (r > 0.65); and Panel D-10 genes suppressed by FSH (r < -0.65). Hierarchical clustering analysis using the combination of gene panels dissected the samples into four clusters based on three phases of menstrual cycles and post-menopausal status. Specifically, high panel C and low panel D expression segregated post- from pre-menopausal samples. Low expression of panel A and B genes dissected early follicular phase from late follicular and luteal phases, while higher expression of panel B genes discriminated luteal phase from late follicular samples.

Conclusion: Our results indicate that the menstrual cycle phases and menopausal status determined by age, patient survey and serum hormone concentrations are reflected in the expression of specific gene sets in the normal breast. The combination of hormone-responsive gene panels would allow the classification of breast samples regarding to the menstrual phases and menopausal status at the time of sampling. It would also facilitate the selection and validation of breast cancer biomarkers that are independent of menstrual cycle fluctuation and menopausal variation for clinical use.

Patterns of Distant Metastasis According to the Molecular Subtypes of Breast Cancer; Results of 529 Breast Cancer Patients.

Hwang MJ, Seo YJ, Lee JH, Son GT, Choi JE, Bae YK, Kang SH, Lee SJ. Yeungnam University College of Medicine, Daegu, Republic of Korea

Background: Distant metastasis from breast cancer arises from various sites. But few studies concerning factors that can predict metastasis patterns in breast cancer has been reported. In this study, we analyzed the effect of breast cancer molecular subtypes on distant metastasis patterns and tried to determine factors that predict metastasis sites.

Patients and methods: From January 1995 to January 2004 at Yeungnam university hospital, patients diagnosed with the primary invasive breast cancer and received treatments were included in this study. Patients with bilateral breast cancer or distant metastasis at diagnosis were excluded. After analyzing estrogen receptor (ER), progesterone receptor (PR), human epidermal growth factor 2 (HER2), epidermal growth factor (EGFR) and cytokertin (CK) 5/6 status, we classified patients into 5 categories, luminal A, luminal B, HER2-enriched, basal-like, and normal (triple negative nonbasal) breast cancers. Distant metastatic patterns of each category were analyzed.

Results: 529 patients were eligible for tissue microarray analysis and median follow-up period was 7.7 years. In this period, total 82 patients (15.5%) had locoregional relapse or distant metastasis and distant metastasis were identified in 54 patients (10.2%). Each distant metastatic rate was 10.5% (33/313) in luminal A, 8.7% (4/46) in luminal B, 10.2% (6/59) in HER2-enriched, 7.9% (7/89) in basal-like, and 18.2% (4/22) in normal subtype. Most frequent site of distant metastasis in all patients was bone and such result was consistent with Luminal A subtype. Liver metastasis was most frequent in Luminal B subtype, lung metastasis in HER2 enriched and normal subtype and brain metastasis in basal-like subtype.

Conclusions: There was a definite association between breast cancer molecular subtype and distant metastatic pattern. If more patients and prolonged follow up periods are analyzed, we would be able to determine the best follow up intervals, methods and treatment directions concerning subtypes of breast cancer.

Expression Profiles of RANK and RANKL mRNA and Protein in the Mammary Gland of Female Cynomolgus Monkeys after Long-Term Treatment with Different Menopausal Hormone Therapies.

Branstetter D, Wood CE, Rohrbach K, Borgerink H, Dougall WC. Amgen Inc., Seattle, CA; Wake Forest School of Medicine, Winston-Salem, NC

Background: RANK and its ligand (RANKL), key factors for bone remodeling and metastasis, are crucial for the development of the mouse mammary gland during pregnancy. OPG also binds RANKL and inhibits RANKL action. Treatment of mice with progesterone increases RANKL expression in mammary epithelium. RANKL functions as a major paracrine effector of both progesterone-dependent...
mitogenic action in mammary tissue, and also in ovarian hormone-dependent expansion and regenerative potential of mammary stem cells. RANKL inhibition in vivo reduces progesterin-induced mammary preneoplasias and adenocarcinomas. In postmenopausal women, the addition of a progesterin to estrogen therapy has been associated with significant increases in mammary proliferation, breast density, and breast cancer risk and recurrence. The goal of this study was to characterize the expression of RANK, RANKL, and OPG in the mammary gland following estrogen + progesterin therapy in comparison with estrogen-alone therapy or placebo in a postmenopausal primate model.

Methods: Ovariectomized female cynomolgus monkeys (Macaca fascicularis) were randomized into 3 treatment groups: placebo, oral conjugated equine estrogens at 0.625 mg/d (CEE) and CEE with medroxyprogesterone acetate (MPA) at 2.5 mg/d (CEE+MPA). Treatments were administered in the diet for 2 years. RANK, RANKL, and OPG mRNA were measured in mammary gland samples (n = 28 to 31/group) using quantitative real-time reverse transcriptase polymerase chain reaction (qPCR). Antibodies against human RANK (N-2B10 and N-188; Amgen) and human RANKL (M366; Amgen) were used for immunohistochemistry (IHC) of formalin-fixed tissues (n = 20 to 23/group) along with an isotype control. The intensity of IHC staining was scored on a semi-quantitative scale (0 = absent, 1 = weak, 2 = moderate, 3 = intense). Incidence was scored as a positive IHC signal (any intensity).

Results: Analysis of mRNA revealed that treatment with CEE+MPA resulted in a significantly greater ratio of RANKL to OPG compared to treatment with placebo (P < 0.01) or CEE (P < 0.05). IHC demonstrated RANK protein was predominately localized to basal cells of ducts and acinar cells, while RANKL protein was localized to luminal cells. RANK protein was detected in mammary glands of animals in all groups: placebo (74%), CEE (55%), and CEE+MPA (53%). RANKL protein was expressed in the animals treated with CEE+MPA (74%) and CEE (15%), but not in placebo-treated animals. Quantitative expression of specific mRNA markers for epithelial proliferation (MKI67) and density (KRT19) was highest for CEE+MPA, intermediate for CEE, and lowest for placebo.

Discussion: Key components of the RANKL/RANK pathway are expressed in the normal postmenopausal primate mammary gland, modulated by long-term estrogen+progesterin exposure at clinically relevant doses, and associated with changes in estrogen+progesterin-driven proliferation of mammary tissue.

P3-04-06
Comparison of MammaPrint, BluePrint, and TargetPrint with Clinical Parameters in Patients with Breast Cancer: Findings from a Prospective United States Cohort.
Nguyen B, Sinha R, Kerlin D, Barone J, Garcia A, Yao K, Rivera E, Stork-Sloots L, Deck K. Long Beach Memorial Health Care, Long Beach, CA; Rockwood Clinic, Spokane, WA; John Muir, Walnut Creek, CA; Comprehensive Breast Care of San Diego and Sharp Memorial Hospital, San Diego, CA; University of Southern California, Los Angeles, CA; North Shore University Health System, Chicago, IL; The Methodist Hospital/Weill Cornell University, Houston, TX; Agenda Inc, Irvine, CA; Saddleback Memorial Medical Center; Laguna Hills, CA

Background: MammaPrint (MP) is a powerful predictor of disease outcome in early stage breast cancer. In addition, TargetPrint (TP), a quality approved microarray-based test that measures the mRNA expression level of ER, PR and HER2 and an 80 gene expression Molecular Subtyping profile BluePrint (BP) were developed. In the present study, MP, BP and TP were measured in a prospective U.S. breast cancer patient cohort.

Methods: MP results were evaluated in fresh tumor samples from 141 breast cancer patients (T1-4N0-2; median age 62 [35-97 yr]) collected by core needle biopsy or from a surgical specimen between July 2008 and February 2011. We compared treatment advice as recommended by NCCN guidelines and classification according to MP. In addition, we compared IHC/FISH ER, PR and HER2 assessments with TP. The MP and BP results were used to subtype the patients into molecular subgroups.

Results: For the group of patients (n=69) for which NCCN recommends the use of a multi-gene signature for determining chemotherapy treatment recommendations, 50 patients were classified as High Risk and 19 as Low Risk by MP. Comparison of TP with IHC/FISH indicated a concordance of 98% for ER, 91% for PR, and 94% for HER2. For a subgroup of 63 patients combined MP and BP results were available: 22 patients were Luminal-type/MP Low Risk, 31 patients were Luminal-type/MP High risk, 1 patient was Her2-type/MP Low Risk, 2 patients were Her2-type/MP High Risk and 7 patients were Basal-type/MP High Risk.

Conclusion: The multi-gene signature MammaPrint, as well as BluePrint and TargetPrint provides additional information for treatment guidance. By combining MammaPrint with the BluePrint molecular subtyping profile, specific groups of patients can be recognized that are at high risk of recurrence and that would possibly benefit from specific treatment. This study shows that TargetPrint provides high quality second opinion for local IHC/FISH assessment.

P3-04-07
Physiological Concentrations of Genistein and 17β-Estradiol Inhibit MDA-MB-231 Breast Cancer Cell Proliferation by Increasing Bax/Bcl2 Ratio and Decreasing pERK1/2 Expression.
Rajah TT, Peine KJ, Du N, Serret CA. DePaul University, Chicago, IL

Background: Our previous results were the first to show that physiological concentrations (1 µM) of genistein, a soy component, in the presence of 17β-estradiol (1 nM) inhibited the cell proliferation of MDA-MB-231 (Estrogen receptor (ER) β positive) breast cancer cells. These results are relevant in premenopausal women with breast cancer of the ERα-negative and ERβ-positive type, especially given the increasing trends of soy intake among the US population in the past decade. The aim of the present study was to identify the mechanism by which genistein plus 17β-estradiol inhibits the cell proliferation of ERα-negative and ERβ-positive breast cancer cells. Our hypothesis is that the balance of signaling actions by genistein plus 17β-estradiol from different signaling pathways is likely to lead to the cell’s choice to either proliferate or enter the apoptotic pathway. For this purpose, the effect of low and high concentrations of genistein (1 µM and 100 µM) in the presence or absence of 17β-estradiol (1 nM) was studied on the expression of cell signaling proteins involved in cell proliferation, survival and apoptosis (pERK1/2, pAkt, Bax and Bel2) and correlated to cell proliferation and apoptosis in MDA-MB-231 (ERβ positive and ERα negative) breast cancer cells.

Methods: Cell proliferation was determined by the MTT assay, apoptosis determined microscopically by the use of acridine orange and ethidium bromide dyes and the expression of cell signaling proteins by western blotting.
Results: Our results show that 1µM genistein plus 17β-estradiol significantly increased apoptosis (p<0.05) as compared to the control (12.47% vs 5.87% respectively). Increased expression of Bax/Bcl2 (2.5 fold) along with a decreased expression of phosphorylated ERK1/2 (2 fold) was observed in cells treated with 1µM genistein plus 17β-estradiol as compared to the control cells. Phosphorylated Akt did not show any differences in the treatment condition as compared to the control. High concentrations of genistein (100 µM) in the presence or absence of 17β-estradiol also increased apoptosis; however these changes could not be correlated to the expression of Bax/Bcl2, or pERK1/2.

Conclusion: In conclusion, our results show that physiological concentrations of genistein in the presence of 17β-estradiol inhibit cell growth through apoptosis via increased Bax/Bcl2 and a concomitant decrease in pERK1/2 expression. Our results also suggest that different concentrations of genistein elicit cell responses through different signaling mechanisms. These results are especially relevant to the cohort of premenopausal women with breast cancer of the ERβ positive and ERα negative type.

P3-05-01

Background:
Breast cancer is currently classified in 3 groups based on estrogen receptor alpha (ER) and human epidermal growth factor receptor 2 (HER2/ERBB2) gene expression: one basal-like (ER-ERBB2-), one HER2-enriched (ERBB2+) and one luminal (ER+). Yet, in transcriptome-based classifications, ER-ERBB2+ group partially overlaps with more recently defined ER-AR+ (androgen receptor positive) group. This type was named molecular apocrine, in reference to the histopathologically characterized apocrine carcinomas (H-Apo), in which a marked activation of AR signaling was demonstrated with a distinct proteomic signature. H-Apo tumors correspond to 1% of invasive breast carcinomas and are clearly morphologically distinct from other AR+ tumors. However, no specific H-Apo transcriptome signature has been reported for this sub-group. In an effort to better characterize those tumors, we have performed a meta-analysis of genomic data, focusing on the ER-AR+ breast subset.

Samples and Methods:
Chips were from Affymetrix array generations HG-U133. 258 profiles were unpublished and 1145 were from published or in press data. Gene expression was carried out after GC-RMA normalization. Unsupervised hierarchical clustering and other statistical analysis were performed with R software.

Results:
160 of the 1403 investigated tumors were ER-AR+. An unsupervised hierarchical clustering clearly identified a small subgroup of 14 closely tumors expressing high transcripts levels of PIP, HPGD, ACSM1, AR, SDR5A1, HS3DB1. This profile was very similar to the proteomic signature previously described for the H-Apo tumors. In addition, the pathology report, although available only for 4 of those 14 tumors, described them as typical apocrine carcinomas. Taken together, these data suggested that this cluster was the H-Apo subgroup. Unexpectedly, when using the transcriptomic PAM50 classification, 13 were classified as Luminal and only 1 as HER2-enriched, although the 14 tumors were all ER-negative. CGH analysis with Agilent 244K chips was carried out with 25 ER-AR+ tumors, of which 5 were H-Apo carcinomas. Importantly, those 5 H-Apo tumors exhibited fewer DNA lesions than the other ER-AR+ apocrine tumors (17% copy number alterations in H-Apo group versus 41%, p=0.02). More CGH data are currently under investigations and will be discussed.

Discussion:
The histopathologically characterized apocrine carcinomas (H-Apo) display transcriptomic signs of active androgen metabolism and fewer DNA lesions than other molecular apocrine tumors. This could suggest that molecular apocrine and H-apocrine tumor derive from the same cell of origin, but that only H-Apo retains morphological apocrine features, possibly due to the presence of fewer genetic lesions. In any case, the prominent androgen signaling activation warrants functional assays of anti-androgen in these breast cancer subtypes.

P3-05-02
Subtype-Specific Co-Occurrence of Atypical Hyperplasia and In Situ Carcinoma with Invasive Breast Cancers.

Kovatch AJ, Kvecher L, Chen Y, Bekhash A, Hooke JA, Shriver CD, Mural RJ, Hu H. Windber Research Institute, Windber, PA; Walter Reed Army Medical Center, Washington, DC; MDR Global Systems LLC, Windber, PA

Background: Atypical ductal hyperplasia (ADH), lobular carcinoma in situ (LCIS), and ductal carcinoma in situ (DCIS) are considered risk factors for the development of invasive breast cancer (IBC). The co-occurrence of these lesions with IBC may provide insights into cancer initiation and development. IBC subtypes have distinct clinicopathological features. A clinically practical IHC-based subtyping classification has been developed based on the expression of ER, PR, HER2, and Ki67, defining Luminal A (LA), Luminal B (LB), HER2+, and Triple Negative (TN) subtypes. The Walter Reed Army Medical Center (WRAMC), through the Clinical Breast Care Project (CBCP), has enrolled over 500 IBC subjects with single pathologist review and central lab analysis. The co-occurrence of ADH, LCIS, and DCIS will be studied in relation to IBC subtypes.

Methods: Subjects were enrolled following IRB-approved protocols. IBC patients enrolled at WRAMC were selected and their clinical and pathology data were reviewed. ER and PR positivity is defined as ≥ 15%. For IBC subtypes, LA is ER+/HER2-/Ki67-; LB is either ER+/HER2-/Ki67+ or ER+/HER2+; HER2+ is ER-/PR-/HER2+; TN is ER-/PR-/HER2-. Statistical analysis was performed using SAS, and the Chi-Square test was used for categorical data analysis supplemented by the Fisher’s Exact test where appropriate. For age analysis, ANOVA was performed with Bonferroni adjustment for multi-pair t-test.

Results: A total of 459 IBC patients were identified and categorized into LA (41.6%), LB (27.7%), HER2+ (10.2%), and TN (20.5%). Many of the previously reported subtype-specific characteristics were confirmed. Age at diagnosis varied by subtype (p=0.0034) with LA being the oldest (Mean±SD=59.2±11.6 years) and TN the youngest (Mean±SD=52.2±12.6 years, p=0.0048). Ethnicity distribution of African American (AA) relative to Caucasian American patients varied significantly in subtypes with AA=18% in LA, 31% in LB, 32% in Her2+, and 42% in TN (p=0.0008). The grade, the AJCC stage and its components T and N were all significantly different among the subtypes (p ranges
from <0.0001 to 0.0020). The grades and stages were consistently lowest for LA, highest for HER2+ and TN. We further found that the co-occurrence of ADH, DCIS, and LCIS with IBC were subtype-specific with the following distributions: ADH—LA (25.1%), LB (18.9%), HER2+ (0%), and TN (6.4%) (p<0.0001, n=78); DCIS—LA (63.4%), LB (76.4%), HER2+ (80.9%), and TN (58.5%) (p=0.0039, n=311); LCIS—LA (36.7%), LB (19.7%), HER2+ (4.3%), and TN (6.4%) (p<0.0001, n=103).

**Discussion:** By including Ki67 in IHC-based IBC subtyping we confirmed many subtype-specific clinico-pathological characteristics in the CBCP WRAMC population. We further report subtype-specific co-occurrences of ADH, DCIS, and LCIS. These co-occurrence patterns may reveal distinct developmental mechanisms between the different subtypes of IBC.

**P3-05-03**

**Transcriptomic Validation of Molecular Classification of Invasive Ductal Carcinoma Based on Immunohistochemical Markers and Grade.**

Transcriptomic analyses identified four major groups among invasive ductal carcinomas, associated with different clinical outcomes. Their definitions in practice is still matter of debate. Our aims were 1) to validate definitions based on immunohistochemical markers and grade: luminal A= ER and or PR+ve, grade I HER2-ve, luminal B= ER+ve and /or PR+ve, HER2+ve or grade III, HER2 enriched carcinomas= HER2+ve and ER+ve, basal-like/triple negative carcinomas= grade III, ER-ve, PR-ve, HER2+ve and expression of at least one of the basal-like markers (CK5/6, CK14, EGFR); 2) to refine this immunohistochemical definition.

142 consecutive tumors were selected in our tumour bank (42 triple-negative and grade III; 31 HER2+ve and ER-ve; 35 luminal B ER or PR+ve and grade III (7 cases) or HER2+ve (28 cases); luminal A (34 ER+ve or PR+ve, grade I)). Transcriptomic analyses were performed using Affymetrix U133+2 arrays (good quality RNAs obtained for all frozen specimens). The molecular classes determined according to proposed definitions were compared to those obtained with unsupervised clustering analyses using data after GC-RMA normalisation (with the intrinsic gene list genes and with the highest variance genes). Marker patterns of expression (CK 8/18, 5/6, 14, EGFR, BCL2 and Ki67) were analysed within each molecular class.

Based on the phenotypical definition and grade, 10 and 9% of cases were misclassified respectively using unsupervised clustering either with the intrinsic gene list or the highest variance genes. The misclassified tumors were luminal B HER2+ve cases with low ER level of expression, or HER2+ve and ER-ve cases classified among the triple-negative group. 39 out of 42 (93%) triple negative expressed at least one of the basal markers. RP expression pattern differed between luminal A and B carcinomas. All luminal A showed at least > 15% of positive cells and 65% of them harboured > 50% of positive cells. In contrast, luminal B showed < 15% of positive cells in 70% of the cases. Bel2 was negative in 40% of the luminal B cases and positive (> 20% stained cells) in more than 90% of the luminal A cases. CK14 was positive (i.e. > 1% positive cell) in 65% of the triple negative cases, compared to CK5/6 positive in 58% of the cases. Ki67 was > 20% in 90% of the triple negative and in 55% of luminal B cases compared to less than 5% of the luminal A cases. 20 and 30% of HER2+ve ER-ve carcinomas expressed CK5/6 , CK14 and EGFR associated in more than 90% of the cases to CK8/18 positivity (> 20% positive cells).

Identification of molecular classes of breast carcinomas was accurately determined by immunohistochemistry and grade. Low level of RP expression and BCL2 negativity were part of the luminal B phenotype. CK14 was more sensitive in this population of triple negative carcinomas to identify basal-like carcinomas. Ki67 was highly expressed in the vast majority if not all breast triple negative carcinomas. HER2+ve ER-ve carcinomas can express basal markers but in contrast to basal-like carcinomas, associated in the large majority of the cases to CK8/18 expression. The accurate determination of molecular groups of breast carcinomas should be a key parameter for development of targeted therapies within each group.

**P3-05-04**

**Changes in Recurrence Risk of Breast Cancer Intrinsic Subtypes over Time.**

**Background:** Gene expression profiling and their immunohistochemistry-based surrogates have consistently revealed prognostically significant breast cancer (BC) subtypes: Luminal A (Lum A), Luminal B (Lum B), HER2, Basal-like (BL) and Triple negative phenotype-nonbasal (TNP-nb). In addition, there are clinical evidence that hazard of BC recurrence varies over time with two peaks of high risk at 18-24 and 60 months. This study compares the time-related patterns of recurrence within BC subtypes.

Methods: Tissue microarrays were constructed from 937 early BC patients diagnosed and treated at our Hospital from 1982 to 2005 with available archival paraffin tissue blocks. BC subtypes were defined using an immunopanel of estrogen receptor, progesterone receptor, HER2, epidermal growth factor receptor, cytokeratin 5/6 and Ki67 by prespecified published methods. Univariate and multivariate analysis (Cox regression) were performed on progression-free survival. Smoothed curves for hazard rates (HR) were estimated by a Kernel-like smoothing procedure. The statistical analysis was done by using the R software environment.

Results: Cases were classified as follows: Lum A 46.8%, Lum B 25.2%, HER2 11.3%, BL 11.3%, TNP-nb 5.4%. None of the patients were treated with adjuvant trastuzumab. With a median follow up of 80 months age, tumor size, nodal status and intrinsic subtypes were independent prognostic factors. HER2 and BL show high and early peak in HR curves and decreasing sharply to 36 and 48 months respectively. HR in Lum A, Lum B and TNP-nb exhibit a smoother and nearly steady curve.

Conclusions: BC subtypes have distinct outcome but also displays different pattern of recurrence over time. These data might imply that pathways underlying early and late recurrences could be different. This additional information would suggest the convenience of considering different timings and duration of adjuvant treatments depending of BC subtypes, and also in the design of surveillance recommendations.
P3-05-05
Cyclin D1 Gene Amplification Is Rarely Heterogeneous in Breast Cancer.

Background: Amplification of Cyclin D1 (CCND1) occurs in about 10 - 20% of breast cancers and has been suggested to predict resistance to anti-hormonal therapy. As the diagnostic accuracy of predictive biomarkers can be substantially limited by regional expression differences within tumors, heterogeneity of CCND1 amplification was assessed in this study. To assess heterogeneity, a novel tissue microarray based analysis platform was developed.

Material and Methods: To comprehensively assess the three-dimensional molecular composition of breast cancers, a “heterogeneity TMA” was constructed containing 8 different tissue cylinders from as many different cancer containing tumor blocks as possible (at least 4) from 147 primary breast cancers. Additional tissue samples were taken from 1-4 corresponding nodal metastases from 35 of these patients. Dual labeling fluorescence in situ hybridization (FISH) with probes for CCND1 and centromere 11 was applied.

Results: The analysis revealed amplification in 29 of 133 (21.8%) patients with interpretable FISH data. CCND1 amplification was more frequently seen in ductal (22 of 87; 25.29%) than in lobular type (5 of 32; 15.63%) (p=0.251). CCND1 amplification was also associated with high tumor grade with amplification rates of 1 of 18 (5.56%) in grade 1, 15 of 72 (20.83%) in grade 2 and 12 of 40 (30%) in grade 3 carcinoma (p=0.075). CCND1 amplification was more frequently seen in ER positive cases (27 of 110; 24.55%) than in ER negative cases (1 of 17; 5.88%) (p=0.052). No association could be found between CCND1 amplification and tumor stage (p=0.445) and CCND1 amplification and PR status (p=0.752). Heterogeneous amplification status was detected in 9 of 29 (31.00%) amplified tumors, i.e. in 6.8% of all informative cases. Heterogeneity was successfully validated on large sections in all 4 heterogeneous cases with high level amplification. In the remaining 5 “heterogeneous cases” discordant results were due to variable interpretation of borderline amplification results with CCND1/centromer 11 ratios between 1.7 and 2.3. There were no discrepancies seen between primary tumors and matched lymph node metastases.

Discussion: The high degree of homogeneity seen for CCND1 amplification suggests that this alteration represents an early event in tumor development/progression in a subset of breast cancers. CCND1 status determined in a small biopsy will be highly representative of the entire tumor and will thus be appropriate for predicting treatment outcome.

P3-05-06
Progression of Breast Cancer Molecular Subtypes through Different Clinical Stages.
Ciriñelos EM, Castaneda CA, Andrés E, Gomez HL, Castellano D, Mendiola C, Manso L, Ghamem I, Farfan C, Cortes-Funes H. Hospital Universitario 12 de Octubre, Madrid, Spain; Instituto Nacional de Enfermedades Neoplásicas, Lima, Peru

Purpose: Molecular classification of breast cancer (BC) through immunohistochemistry classifies patients globally in 4 subtypes with similar features and prognosis. The present study was designed to compare features of BC subtypes in early versus locally advanced clinical stages. A secondary objective was compare molecular subtypes of the primary vs recurrences.

Methods: The study included 1621 patients with non-metastatic invasive BC that were consecutively diagnosed at Hospital Universitario 12 de Octubre, Madrid, between 1997 and 2007. Luminal A was defined as ER+ and PR+, HER2-negative and Ki67 < 14%. Luminal B was defined as PR-negative, HER2-positive or Ki67≥14%. HER2 was defined as ER and PR-negative, and HER2-positive. Triple negative (TN) were tumors with ER, PR and HER2 -negativity. Clinicopathological characteristics and outcomes were retrospectively reviewed. Variables were compared with the X2 test, and survival curves were evaluated with Kaplan-Meier method.

Results: Most patients were diagnosed as T1 (48%) and T2 (39.7%) clinical stages, and classified as Luminal B (49%) and Luminal A (29%). GIII frequency increased from T1 to T3-4 in Luminal A (p=0.002), and Luminal B (p=0.051) subtypes, but not in HER2 (p=0.867) or TN (p=0.53).

Median ER tended to decrease from T1 to T3-4 in Luminal B (p=0.062). Median Ki67 of T1 and T3-4 were not different in HER2 (p=0.867) and TN (p=0.533) subtypes.

Molecular subtypes carry significant different prognosis (DFS and OS) in all T stages except for T1a cases. When T3-4 and T1 stages of the same molecular subtype were compared, a significant shorter DFS were found for more advanced stages in the Luminal A (p=0.0002), Luminal B (0.0001) and TN (0.0017), but not for HER2 (p=0.54) subtype. And, similar results were found for OS.

We compared molecular subtypes in the primary tumor and in the metastatic site in 83 cases (excluding contralateral recurrences) and found change of phenotype in 54% of the cases. Changes fromLuminal A to a more aggressive phenotype were more frequent than in the opposite situation (14 vs 2 cases).

Conclusion: Despite the molecular classification of early-stage BC that classifies patients in well-defined prognostic subgroups, tumors are continuously changing and tumor behavior becomes more aggressive through progression. Therefore, even tumors with favorable phenotype could lose their good prognosis in locally advanced stages. Obtention of tumor tissue at metastatic sites is also mandatory to a better selection of systemic therapies in relapsed patients.

P3-05-07
Genetic Heterogeneity of Amplification Status in Breast Invasive Carcinoma with 2+ HER2 Immunostaining: What Can We Learn?
Valent A, Delaloge S, Ferech M, Bernheim A, Mathieu M-C. Institut Gustave Roussy, Villejuif, France, Metropolitan

Background: The genetic heterogeneity of HER2 gene amplification (GA) in breast cancer has previously been described, but the clinical significance of this phenomenon remains unknown. We studied the genetic categories of a series of consecutive 2+ IHC cases over 5 years, with a focus on cases with HER2 GA detected in minor clone(s). We compared the HER2 status in primary tumors and positive axillary lymph nodes (ALN) when available to test the hypothesis that HER2 amplified cells are more aggressive and metastase quicker than non amplified cells.

Material and methods: From January 1st, 2006 to May 30, 2011, 4491 invasive breast carcinomas had HER2 immunohistochemical (IHC) and/or HER2 gene status evaluation on their tumor sample.
in Institut Gustave Roussy. The distribution according to their IHC was as follows: 0 in 2915 cases (65%), 1+ in 569 cases (12.6%), 2+ in 536 cases (11.8%) and 3+ in 471 cases (10.6%). All 2+ samples were checked by Fluorescence in situ hybridization (FISH). For each case we analysed 100 invasive cells in 10 microscopic fields. Heterogeneous amplification was defined as presence of 5-50% of amplified cells (ratio>2,2) within the tumors otherwise classified as not amplified or borderline (ratio for 100 cells: <2,2 according to the ASCO 2007 and CAP criteria). The IHC 2+ tumors show five main genetic categories.

**Results**: FISH with HER2/cen17 probes can classify IHC 2+ tumors into 5 genetic categories: normal gene status (two chromosomes (chr) 17 and two HER2 genes): 90 cases; chr 17 “polyomisy”/”17q gain: 145 cases; HER2 gain: 122 cases; HER2 amplification (major clone): 135 cases and chr 17 monosomy: 44 cases. We focused our interest to IHC 2+ cases where the major clone showed no HER2 amplification, but minority clone (cut off 5%) showed the HER2 amplification (ratio >2,2 or >HER2 copies per cell). We found 48 such cases (10% of 2+ cases). These cases had been reported as not amplified (42/48) or borderline (6/48). To find out if the amplified cells are those which metastase, we checked 10 involved ALN: they all showed the similar genetic heterogeneity as a primary tumor with a global ratio <2,2. Other cases with involved ALN are in ongoing study by FISH.

**Conclusions**: The genetic heterogeneity of IHC 2+ tumors is a common event and five different genetic categories can be detected. A part of the HER2 negative cases contained one or several HER2 amplified clones. Preliminary results show a similar genetic heterogeneity of metastatic population. Our results on the small series of cases do not confirm the hypothesis that the only amplified clones metastase, but all clones (amplified and not amplified) has a metastatic capacity. A multi-center collaboration is needed to collect the high number of cases with heterogeneous amplification to:
1) Find out a proportion of such patients in HER2 IHC 2+ group (10% in our study).
2) Study a status of the gene in relapse cases.

**P3-05-08**

**Hormone Receptor Heterogeneity in Ductal Intraepithelial Neoplasia (Ductal Carcinoma In Situ) of the Breast.**

Sowden M, Flynn C, Bossuyt V, Lannin D, Chagpar AB. Yale University School of Medicine, New Haven, CT

**Background**

Ductal Intraepithelial Neoplasia [DIN] often shows heterogeneity of both morphology and nuclear grade within the same patient. It is unknown whether this implies heterogeneity with respect to hormone receptor status that may affect treatment. We sought to determine the rate of heterogeneity in terms of nuclear grade and receptor status in DIN patients.

**Methods**

A hospital tumor registry was queried for patients diagnosed with DIN between 1980 and 2010. Of the 746 patients identified, 579 (77.6%) had a concomitant invasive tumor. Of the remaining 167 patients, 70 were diagnosed prior to 2007 (when ASCO-CAP guidelines for hormone receptor measurements were released), 2 were found to have lobular intraepithelial neoplasia rather than DIN, and in 11 cases, pathology slides were not available for review. Of the 84 remaining patients with DIN, 17 (20.2%) had DIN 1 alone, 19 (22.6%) had DIN 2 alone, and 7 (8.3%) had DIN 3 alone. 41 (48.8%) of the patients had more than one grade of DIN. These patients formed the cohort of interest. Slides were reviewed by a single pathologist who evaluated ER and PR positivity within the different grades of DIN in each patient, classifying tumors staining 1% or greater as positive. Statistical analyses were performed using SPSS.

**Results**

The median patient age was 53 years old. Of the 41 patients with multiple grades of DIN, 32 (78.0%) had DIN 1 and 2, 6 (14.6%) had DIN 2 and 3, and 3 (7.3%) had DIN 1, 2, and 3 within the same tumor. 93.8%, 94.7% and 88.9% of DIN 1, 2 and 3 lesions respectively were ER-positive. A difference in hormone receptor status between different grades of DIN within the same tumor was noted in 12 (29.3%) of patients; of these 3 (10.3%) varied in ER status and 10 (34.5%) varied in PR status. Of the 2 patients with ER-negative DIN 1, both had ER-positive higher grade DIN within the same tumor. Of the 2 patients with ER-positive DIN 2, one had ER-positive DIN 1 while the other had ER-negative DIN 3. Therefore, of the total 41 patients, 40 (97.6%) had at least one component of DIN that was ER-positive, and evaluating more than one grade of DIN for ER allowed 75% of patients with at least one ER-negative component to be offered hormonal therapy.

**Conclusions**

Nearly 50% of patients with DIN will have more than one nuclear grade in the same tumor. These different nuclear grades vary in hormone receptor status in approximately 30% of patients. The majority of patients (97.6%) have at least one component of their DIN that is ER-positive. For those who have at least one component that is ER-negative, up to 75% may be offered hormonal therapy by considering other grades of DIN in treatment decision-making.

**Comparison of Clinical Features and Patterns of Recurrence in Triple Negative Breast Cancers in Relation to Other Breast Cancers.**

Tosello de Oliveira C, Barbosa EM, Costa de Andrade J, Lyra EC, Felzener MC, Krutman Zweibil D, Grosso SHG, Sampaio Goes de Oliveira R, Sampaio Góes JC. Instituto Brasileiro de Controle do Cancer, Sao Paulo, Brazil

**Background**: Breast cancer is an heterogeneous disease that have several and different biological characteristics and clinical behaviours. Of these, triple negative breast cancer represents 10-17%.This kind of tumor is characterized by estrogen, progesterone and HER2 receptor negativity and they are very aggressive, associated with poor prognosis, younger patients, high incidence of metastases and shorter relapse free survival. Triple negative breast tumours are more likely to experience local recurrence and distant relapse than other breast tumours, and require a more aggressive intervention.

**PURPOSE**: To compare the incidence of metastases, clinical features and outcome among patients with triple negative breast cancer and women with other types of breast cancer.

**METHODS**: This is a retrospective cohort analysis from 3893 patients with invasive breast cancer, diagnosed between January 2000 and April 2011 and attended at Brazilian Institute of Cancer Control (IBCC) in Sao Paulo, Brazil. Five hundred of these tumors were triple negative. We made a correlation of clinical variables such as age, tumor stage (TNM) and analysis of last follow-ups, such as metastases, disease free survival, death for tumor, death for other reasons, lost of follow-up, hygiene and diet regime (RHD) and local recurrence.

**Results**: The median follow-up for the cohort was 4.29 years. The mean age at diagnosis in triple negative group was 54.8 and for the others group was 57.1 years. Subgroup analysis of tumor grade showed that the triple negative breast tumors were diagnosed...
later (Stage II and III; p<0.0001). There was no difference in the appearance of the two types of tumors, when considering diagnose age. The incidence of metastases, death for tumor and free survival in triple negative tumors, respectively; 25.6%, 13.8% and 57.2% (p<0.0001) demonstrates the aggressiveness of this kind of tumor.

P3-05-10
Standardized Quantitative Methods for Investigating the Intratumor Heterogeneity of HER2 in FFPE Breast Cancer Specimens Utilizing the Vectra System, inForm and AQUA Technology.

Hoyt CC, Gustavsson MD, Davis WL, Lane KA, Scott CG, Graves, Jr LL, Caliper Life Sciences, Hopkinton, MA; HistoRx, Branford, CT

Background: While intratumoral heterogeneity of HER2 gene expression is well documented, the HER2 intratumor protein expression heterogeneity and its clinical relevance is largely unknown but generally believed to be worth of investigation to ascertain its impact on HER2 targeted treatment outcome. Methods for investigating intratumor protein expression heterogeneity must preserve tissue architecture yet provide quantitative protein measurement. Immunohistochemistry (IHC) generally lacks standardization and quantitative capabilities and furthermore, current scoring methods do not account for, or report, heterogeneity. Robust and automated methods for characterizing and quantification of heterogeneity are needed. Material and Methods: Whole tissue samples stained for HER2 protein expression by fluorescent quantitative IHC methods were analyzed by digital imaging microscopy (VeCTra system with inForm software, Caliper, Hopkinton MA) providing automated pattern-recognition-based selection of area of interest and field of view sampling strategies. Quantitative image analysis (AQUA technology, HistoRx, Branford, CT) for quantitative measurement of HER2 protein expression as well as objective, quantitative determination of heterogeneity were performed. Requirements for percent tumor sampling at high-power to capture heterogeneity were assessed, to support optimization of slide scanning. Results: Heatmap representation of HER2 expression levels, and a statistical heterogeneity score developed based on the Simpson’s biodiversity index (Simpson 1949) demonstrate visually as well as quantitatively HER2 heterogeneity in breast cancer tissues. Heterogeneity as a function of % area needed for accurate determination of whole section score along with confidence intervals as a function of percentage tumor analyzed inform appropriate sampling strategies. Conclusion: This study demonstrates the suitability of standardized quantitative methods for measuring heterogeneity and the feasibility of its use in investigations exploring the clinical relevance of HER2 intratumor heterogeneity with respect to both measurement strategies as well as treatment outcome. Through characterization of heterogeneous HER2 expression in tumors and optimized measurement strategies, it should be possible to design optimized treatment strategy aimed at treating the whole tumor as a function of objective quantitative assessment of HER2 expression.

P3-06-01
Next Generation RNA Sequencing Reveals Changes in Gene Expression and Alternative Splicing upon Brief Exposure to Therapy in Early Breast Cancer.

Varadan V, Kamalakaran S, Janevski A, Banerjee N, Lezon-Geyda K, Bossuty V, Flowers D, Sikov W, Abu-Khalaf M, Rizack T, Dimitrova N, Harris LN. Philips Research North America, Briarcliff Manor, NY; Yale University School of Medicine, New Haven, CT; Brown University School of Medicine, Providence, RI

Background:
The use of next generation RNA sequencing (RNA-seq) allows for the characterization of the transcriptome at levels of detail unachievable by array-based technologies. RNA-seq analysis can quantify expression of novel transcripts and alternatively spliced isoforms in addition to known genes. Alternative splicing allows for flexibility in production of protein isoforms and is frequently dysregulated in cancer. As splice variants may play a role in response to therapy (Solier, et al, Cancer Res., 2010), we studied differential gene and isoform expression in breast cancers after one dose of treatment, prior to a course of preoperative therapy.

Methods:
We sequenced transcriptomes of core biopsy samples from 8 breast cancer patients enrolled in a preoperative clinical trial using trastuzumab (HER2 positive) or bevacizumab (HER2 negative) with chemotherapy. Tumor core biopsies were taken before and after 10 days of either biologic or nab-paclitaxel treatment and stored in OCT compound. Total RNA was extracted, amplified and libraries were constructed for the 16 samples using TrueSeq (Illumina). Paired-end sequencing was performed on the Illumina GAII platform with read length of 74bp. Sequence data was mapped using TopHat and transcript abundance in FPKM units (Fragments per kilo-base of mRNA per million reads) estimated for a total of 22,160 unique genes and 34,449 unique transcripts from RefSeq. Differential expression of transcripts between baseline and 10-day samples was estimated using t-statistics with read-counts modeled as a Poisson distribution. Differentially expressed transcripts were selected at a significance level of 0.05 after multiple testing correction.

Results:
Each sample had on average 46 million paired-end reads, of which on average 70% were mappable to the human reference genome (UCSC, hg19). A median of 138 (range 68-948) transcripts were analyzed for differential expression upon brief exposure to chemotherapy. GO analysis showed enrichment of cell adhesion, apoptosis, differentiation and cell proliferation pathways. Interestingly, the isoforms of several known cancer genes such as TP53 were seen in all treatment types. Certain isoforms were only seen to change upon brief exposure to chemotherapy such as BCL2 whereas TNF ligand and PCDH isoforms showed significant change only with biologic agents.
Conclusions:
These results suggest that recurrent changes in both canonical genes and splice variants occur over the course of treatment in early breast cancer. This underscores the value of RNA-seq to provide novel information that may be clinically useful. Brief exposure to monotherapy prior to combination treatment may provide important mechanistic insights and produce predictive biomarkers. Biologic treatments may produce unique changes that can only be discovered with novel next generation sequencing techniques.

P3-06-02
Identification of Redundant, Tumor Subtype Specific Fusion Transcripts in Primary Breast Tumors.

Background: The role of fusion genes and associated fusion transcripts has long been recognized in hematopoietic malignancies. Until quite recently it has been difficult to detect such events on a genomic scale in solid tumors. Consequently, little is known about the potential role of fusion genes, transcripts, and proteins as driver mutations, biomarkers, or therapeutic targets in breast cancer.

Methods: We have developed a novel analytical pipeline, Snowshoes-FTD, for detection of fusion transcripts in breast cancer cell lines and tumor samples (Asmann, et al. NAR 2011; May 27 ePub ahead of print). Preliminary analyses have been carried out with a panel of 8 each ER+, HER2+, and triple negative (TN) primary breast tumors, 8 primary human mammary epithelial cell (HMEC) lines from biopsy samples, plus 16 normal tissues from the Illumina Body Map dataset.

Results: We have identified 120 redundant, tumor-specific fusion transcripts, expressed in two or more tumors and in no non-transformed samples. Sixteen of these represent intrachromosomal fusions and 104 arise from fusion of transcripts that map to two different chromosomes. Every breast tumor expressed one or more fusion transcripts. Twenty-nine fusion transcripts appeared to be tumor subtype specific. Among these, we have identified 2 HER2+, 10 ER+, and 17 triple negative specific redundant transcripts. In general, HER2+ tumors expressed fewer fusion transcripts (range 4 to 28/tumor) compared to TN (range 11 to 44/tumor). Chromosomal distribution patterns were also markedly different among the tumor subtypes. For example, ER+ tumors expressed a preponderance of redundant fusion transcripts that involve chr1 and 2, whereas TN tumors had no fusion transcripts that map to either chromosome. Conversely, the predominant locus for TN fusion transcripts was chr19, which contains only one HER2+ fusion and no ER+ fusion transcripts.

Conclusions: Primary breast tumors express many chimaeric transcripts, which we presume to arise primarily from genomic rearrangements. The majority of these transcripts are redundant, and a subset are tumor subtype specific. These transcripts may mark regions of chromosomal instability. HER2+ tumors, in general, appear to evidence less chromosomal instability, as inferred from fusion transcripts; although some HER2+ tumors appear to be quite unstable. TN tumors contain many more redundant fusion transcripts, implying increased genomic instability, particularly in chr19. We conclude that these fusion transcripts represent a class of heretofore unrecognized biomarkers that may be used for sub-classification of breast tumors. Some of these transcripts appear to encode proteins that may function as tumor-subtype-specific driver mutations and may have potential as therapeutic targets in breast cancer.

P3-06-03
Hypodiploidy, 1pter Loss and Inactive X Chromosome Retention Are Associated with BRCA1 Somatic or Germline Inactivation in Basal-Like Breast Carcinomas: Proposal for a New BRCA1ness Genomic Signature.
Manié E, Popova T, Vincent-Salomon A, Dubois T, Delattre O, Sastre-Garau X, Stoppa-Lyonnet D, Stern M-H. Institut Curie, Paris, France; INSERM, Paris, France; Université Paris-Descartes, Paris, France

Basal-Like Carcinomas (BLCs) are high grade ductal carcinomas identified by large scale transcriptomic analyses among carcinomas with triple-negative phenotype (ER- PR- HER2-). A particular relationship between this phenotype and the BRCA1 breast cancer susceptibility gene has been described based on several observations including high genomic similarities of sporadic and BRCA1 BLCs. BRCA1 mutated patients have been shown to strongly benefit from treatments using PARP inhibitors. However, significant benefit of this treatment was not demonstrated in sporadic triple-negative breast cancers in association to standard chemotherapy in phase III clinical trials, which emphasizes the necessity for a better selection of DNA repair deficient tumors. The goal of this study was to determine whether BRCA1 inactivation leads to particular genomic alterations that could be used to identify BRCA1 deficient sporadic BLCs.

Genomic profiling was performed using SNP-arrays (Affymetrix and Illumina) and high quality profiles were obtained for 60 BLCs with more than 35% of tumor cells. The series contained 28 BRCA1 BLCs and 32 sporadic BLCs consisting in 10 sporadic BLCs with BRCA1 somatic inactivation by promoter methylation (BRCA1-like BLCs) and 22 sporadic tumors without BRCA1 methylation (nonBRCA1 BLCs). Genomic data was mined with GAP methodology (Popova et al, Genome Biol 2009), which allows absolute copy-number evaluation with DNA content calculation and clarification of Loss Of Heterozygosity (LOH) status.

Genomic patterns of BLCs were characterized by frequent and highly recurrent allelic losses. Comparison between BRCA1, BRCA1-like and nonBRCA1 BLCs confirmed their overall similarity, and identified few significant differences enhanced when BRCA1 and BRCA1-like BLCs were considered as one group. Firstly, hypodiploidy characterized BLCs with BRCA1 germline and/or somatic inactivation. Secondly, the 1p region was found more often lost in BRCA1 and BRCA1-like BLCs than in nonBRCA1 BLCs. Thirdly, retention of inactive X chromosome was a characteristic of BLCs with BRCA1 germline and/or somatic inactivation. Finally, a BRCA1ness score based on the above described difference is proposed.

In conclusion, despite a strong similarity of genomic patterns in BLCs, BRCA1 inactivation leads to few key genomic aberrations which constitute a new BRCA1 molecular signature namely hypodiploidy, 1p loss and inactive X chromosome retention. This signature needs to be further evaluated in terms of response to PARP inhibitors in order to evaluate its capacity to identify patients that will benefit from this treatment.

P3-06-04
Sno/miRNA Expression Via Next Generation Sequencing: Variation in Patients before and after Treatment.
Banerjee N, Kamalakaran S, Vayadan V, Janevski A, Lezon-Geyda K, Bossuyt V, Flowers D, Sikov W, Abu-Khalaf M, Rizack T, Harris L, Dimitrova N. Philips Research North America, Briarcliff Manor, NY; Yale University School of Medicine, New Haven, CT; Brown University School of Medicine, Providence, RI

Background: Aberrant expression of small RNA molecules has been shown in breast cancer. It is yet unclear if variation exists in...
small RNA molecule expression in response to treatment. Since next generation sequencing offers more globally sensitive detection of sno and miRNAs, we performed an RNA-seq study to explore patients pre- and post-brief exposure to treatment.

Methods: We sequenced transcriptomes of frozen biopsy samples from 8 breast cancer patients enrolled in a clinical trial for neoadjuvant therapy using trastuzumab (HER2 positive) or bevacizumab (HER2 negative) with chemotherapy. Tumor core biopsies were taken before and after 10 days of either biologic or nab-paclitaxel treatment and stored in OCT compound. Total RNA was extracted and libraries were constructed for the 16 samples using TruSeq (Illumina). We performed 74bp paired-end sequencing with the Illumina GAI1 platform. Sequences were aligned to the sno/miRNA track (containing 928 miRNAs and 413 snoRNAs) in UCSC and read counts were determined using Bowtie. We performed differential miRNA and snoRNA expression analysis pair-wise in all pre- and post-therapy samples. Given that miRNA deregulation relies on their protein-coding gene targets, we analyzed the predicted targets of the significantly varying miRNAs for functional enrichment.

Results: Each sample had on average 46 million paired-end reads, of which on average 70% were mapped to the human genome. Overall, we detected 138 miRNAs in at least one sample, with each sample expressing 33 miRNAs on average. We detected a total of 11 miRNAs (7%) that showed significant differential expression with treatment. Interestingly, 6 of these miRNAs varied in all patients. The predicted targets of these miRNAs were enriched in DNA-dependent transcription, gene expression, cell proliferation and cell communication. Similarly, we detected 202 snoRNAs in at least one sample, with each sample expressing 87 snoRNAs on average. Of these, we found 21 snoRNAs (10%) to vary significantly upon treatment and 6 of these snoRNAs showed expression changes in all patients.

Conclusions: These results suggest that variation in sno/miRNA expression may play a role in response to treatment. The consistent variation of sno/miRNAs in response to treatment suggests shared small RNA-mediated mechanisms. If validated, these results suggest that next generation sequencing technologies will allow lead to improved methods of stratifying, subclassifying and managing breast cancer.

Comparison of Oncotype DX® Recurrence Scores between Surgical and Core Biopsy Specimens in Breast Cancer Patients.
Stull TS, Goodwin MC, Anderson JM, Baehner FL, Sing AP, Yoshizawa CN, Barrio AV, Frazier TG. The Bryn Mawr Hospital, Bryn Mawr, PA; Genomic Health, Inc, Redwood City, CA

Introduction: The Oncotype DX® 21 gene assay is usually performed on surgical resection specimens (SRx) for patients (pts) with early stage, estrogen receptor positive (ER+) breast cancer to predict the risk of recurrence and likelihood of benefit from adjuvant chemotherapy (CT) and hormonal therapy (HT). Using the Recurrence Score (RS) to aid in making a decision to administer preoperative CT requires assaying the core biopsy specimen (CBx). The objective of this study is to compare the RS obtained from paired CBx and SRx specimens. Methods: 25 pts with invasive breast cancer diagnosed by CBx with a subsequent Oncotype DX® 21 gene assay performed on the SRx were identified. Fixed, paraffin embedded tissue from these paired CBx were sent to Genomic Health. The H&E slide from the paired SRx sample sent for the RS was used to compare the histology with the paired CBx. The RS from the CBx and SRx pairs were examined descriptively with scatterplots and Pearson correlation coefficients.

Results: Median age of diagnosis was 64 (range 39-78). Sufficient RNA was obtained from all but 1 of the CBx. H&E from CBx and SRx were histologically dissimilar for 3 of 24 pairs with RT-PCR data. The Pearson correlation for RS between CBx and SRx was 0.83 (95% CI 0.64, 0.92) for all 24 pairs. The distribution of RS groups from CBX was 19 low (RS<18), 3 intermediate (RS 18-30), 2 high (RS≥31). The RS group from SRx was unchanged for 22 (92%) pts. Two pts switched RS groups, CBx RS 5 to SRx RS 18 and CBx RS 8 to SRx RS 24; only the latter is clinically meaningful because the former straddles the low-intermediate cutoff. Correlations between CBx and SRx for individual single gene scores were 0.84 (95% CI 0.65, 0.93) for ER, 0.83 (95% CI 0.64, 0.92) for PR, and 0.82 (95% CI 0.61, 0.92) for HER2. Similar results were obtained excluding the 3 histologically dissimilar pairs.

Conclusion: The RS’s obtained from CBx’s were consistently similar to the RS’s obtained from the paired SRx. Using an RS obtained from a CBx in pts with ER+ disease to make a decision regarding neoadjuvant CT or HT is clinically acceptable, thus, giving physicians an additional tool to improve pt care and outcomes.

P3-06-06
Comparison of Gene Expression Profiles of Lymph Node Positive and Lymph Node Negative ER Positive Breast Tumors in Pre- and Postmenopausal Women.
Rapuri PB, Xing L, Brilhart G, Deyarmin B, Kvecher L, Hu H, Hooke JA, Shriver CD, Mural RJ. Windber Research Institute, Windber, PA; Walter Reed Medical Center, Washington, DC

Background: Breast cancer is the most common female cancer in US and is the second leading cause of cancer related death in women. Metastases are the primary cause of cancer morbidity and mortality. Axillary lymph node (LN) status has long been used as a prognostic factor for breast cancer. The molecular mechanisms that control LN metastasis remains poorly understood. To better understand the various genes and regulatory pathways that drive breast cancer LN metastasis, we compared the gene expression profiles between breast tumors that have metastasized to the LNs and those which have not in pre- and postmenopausal women.

Material and Methods: Tumor cells were isolated from the primary tumors (ER+) of postmenopausal node positive (PMNN; N=20), postmenopausal node negative (PMNN; N=19), premenopausal node positive (PRPN; N=18) and premenopausal node negative (PRPN; N=16) women using laser capture microdissection. RNA isolation was performed using the RNAqueous®-micro kit (Ambion, Austin, TX). Total RNA was converted to Biotin-labelled aRNA using two rounds of amplification with MessageAmp II aRNA amplification kit (Applied Biosystems, Foster City, CA). The aRNA concentration was determined by Nanodrop 1000 and the quality was assessed with a Bioanalyzer. The aRNA was fragmented and hybridized to Human Genome U133 Plus 2.0 GeneChip (Affymetrix, Santa Clara, CA). Microarray raw data were analyzed using a variety of R programming packages for probe density processing, background correction, normalization, quality control/quality assessment, and calculation of gene expression value, etc. To identify differentially expressed genes, Wilcoxon rank sum test with FDR (false discovery rate) control was performed for pair-wise comparison between different groups. Functional analyses were performed on the identified statistically significant differentially expressed genes to search for the functional categories and pathways in which they are involved and further understand their potential roles in breast cancer metastatic process. Results: Multivariate data mining (hierarchical clustering analysis and principal component analysis, etc) revealed that in postmenopausal...
women, the node positive and node negative women are well separated while this was not the case in premenopausal women. Further analysis of the PMNN and PMNP groups to identify differentially expressed genes (with at least a 1.5 fold difference) at FDR =0.1 showed that 232 genes were upregulated and 470 genes were downregulated in PMNP vs PMNN groups. Gene function analysis revealed that genes down regulated in the PMNP group compared to PMNN are related to extracellular matrix, cell adhesion, EGF-like pathway, cytoketoson etc, while the over-expressed genes are related to cell cycle and cell division, chromosome condensation, etc.

**Discussion:** The ability to differentiate lymph node positive cases from lymph node negative cases in ER+ breast cancer based on transcriptional profiling may have an impact on the clinical management of ER+ breast cancer cases. Having transcriptional profiles that identify ER+ tumors likely to have poor outcomes would suggest more aggressive treatment for such patients.

Integrated Genomic and Pathway Analysis Reveals Key Pathways across Breast Subtypes.

Benz S, Sanborn JZ, Vaske C. Five3 Genomics, LLC, Santa Cruz, CA

Cancer is a disease of genomic perturbations that lead to dysregulation of multiple pathways within the cellular system. While common pathways are believed to be shared within specific cancer types, the mechanisms behind why particular patients respond differently to treatment is not well understood. Genomics studies such as The Cancer Genome Atlas (TCGA) and Stand Up To Cancer (SU2C) attempt to address this issue by collecting large-scale whole-genome measurements of mRNA expression, DNA copy number, and epigenetic features. Common analysis of these measurements integrates data across multiple samples to distinguish signal from noise. However, serious challenges remain in identifying genomic features and pathways significant for prognosis and clinical treatment classifications.

We have created the Five3 Analysis Pipeline to streamline discovery of individual samples’ mutations, small indels, copy number alterations, genome rearrangements, expression changes, and resulting pathway activities. This pipeline is capable of processing and integrating data from both next generation sequencing and microarray platforms in the analysis of single or multiple tumor samples. Our sequence analysis corrects for both tumor sample impurity and germline variation to accurately identify somatic mutations present in the tumor. Our pathway analysis incorporates gene copy number, mutations, expression, and promoter methylation on a superimposed pathway constructed from several curated pathway databases in a sample-specific manner.

By applying this pipeline to the TCGA breast cancer datasets, we recapitulate established breast subtypes at a pathway-dependent level. For example, basal tumors appear enriched for proliferation pathways compared to luminal samples within this cohort. Expanding the pathway analysis to include TCGA lung cancer samples, we find similar subnetworks activated between basal and squamous lung and between luminal and lung adenocarcinomas. This hints at similar genomic mechanisms for these subtypes independent of tissue of origin. Finally, by analyzing genomic alterations across all breast cancers we see mutational clusters in PIK3CA that correspond with publicly-available hotspots [1]. As suggested by previous reports [2], we find that samples with mutations clustered in exon 10 exhibit differential pathway activities relative to those samples with mutations clustered in exon 21, independent of subtype and TP53 mutation status. These results show the power of this integrated genomic platform in elucidating pathway signatures and the need to consider cross cancer analyses to identify shared tumorigenic mechanisms that may suggest common therapeutic targets.

**P3-06-08**

The South Sweden Cancerome Analysis Network - Breast (SCAN-B) Initiative is a multidisciplinary network of clinical providers of breast cancer (BC) treatment and pre-clinical scientists whose multiyear purpose is to 1) prospectively collect and analyze the “omes” of a very large, consecutive, and population-based sample of BCs for translational research; 2) utilize this genomic data to develop new clinically-relevant biomarker assays; and 3) to build the infrastructure for future real-time clinical implementation of resultant biomarkers for individualized treatment. Patient enrollment began in the Fall of 2010 at the seven BC surgical units of the South Sweden Healthcare Region, where approximately 1500 new breast cancer diagnoses are treated yearly following the guidelines of the South Sweden Breast Cancer Group. Currently, tumor and blood samples are being collected at the rate of 80-100 patients per month, which represents approximately 75% of the catchment population. SCAN-B will initially focus on tumor transcriptome analysis using mRNA-sequencing on Illumina HiSeq 2000 instruments, and in the future multimodal data generated from other genomic platforms will also be integrated. Here we present initial experiences from this multidisciplinary collaboration including descriptions of the clinical routines, specimen handling, laboratory processing, mRNA-seq data quality control, short- and long-term projects and future directions. We believe large initiatives like SCAN-B could significantly reduce the time to discovery, validation, and clinical implementation of more powerful diagnostic, prognostic, and treatment-predictive tests for breast cancer.

Are the Findings of ASOCOG Z0011 Applicable to District General Hospital Breast Unit – And How Should They Change Our Practice? Olsen SB, Amr B, Omar A, Smith J, Thomson S, Monib S, Lai LM. West Hertfordshire NHS Trust, St Albans, Hertfordshire, United Kingdom

Background: There has been considerable debate on the management of the axilla in breast cancer patients with lymph node metastasis found on sentinel lymph node biopsy (SLNB) following publication of the ACOSOG Z0011 study. This study conclude that axillary lymph node dissection (ALND) does not add any benefit to overall and disease free survival in some patients with positive SLNB. However it is not know if the patient characteristics of this study are transferable to other settings. A previous UK study has suggested that only a minority of patients from an academic specialist centre fit the ASOCOG Z0011 criteria and that the patient populations may not be
comparable. The aim of our study was to assess the applicability of the Z0011 study to our patient population of a large District General Hospital in the UK and to what extent it should influence our practice. Methods: The Z0011 eligibility criteria for inclusion in analysis were applied to all patients undergoing SLNB for invasive cancer at West Hertfordshire Breast Unit from 2007-2011. These were: no neo-adjuvant chemotherapy, clinical T1 and T2 tumours, breast conserving surgery followed by whole breast radiotherapy and 1-3 positive nodes on SLNB. Patent characteristics and results were compared using fisher’s exact test.

Results: In our unit a total of 434 patients underwent SNLB of whom 64(14.7%) met the inclusion criteria of Z0011. Our patient population was comparable to that of Z0011 with regards to lymphovascular invasion, proportion of patients with micro-metastases and those with additional lymph nodes found on completion ALND. Our patients had significantly more T2 tumours. The only other statistically significant difference was in the proportion of estrogen receptor (ER) and progesterone receptor (PR) positivity.

</table>

Conclusion: Only a small proportion (14%) of patients undergoing SNLB in our patient population fit the criteria for Z0011. This was a higher proportion than in the previous UK study of this type. Similar to this study we found the proportion of patients with T2 tumours were greater in our patient population compared to Z0011. This is most likely a reflection of this unit not being a screening centre and brings into question the international generalisability of Z0011. However the only other significant difference in our patients was a lower risk profile in terms of hormone receptor positivity with more ER/PR positive and fewer ER/PR negative patients. The implications of Z0011, will in our practice, not make a significant difference to the rate of ALND. We are however considering changing our patient management based on the result of Z0011 and this current study of our population, to offer no further axillary surgery to patients over 50 with T1 and ER/PR positive tumours who otherwise fit the Z0011 protocol.

P3-07-02
Prediction of Non-Sentinel Lymph Node Status in Breast Cancer Patients with a Micrometastatic Sentinel Lymph Node Determined by the One Step Nucleic Acid Amplification (OSNA) Assay.
Di Filippo F, Casini B, Gallo E, Terrenato I, Botti C, Motolese M, Pescarmona E, Maranondo F, Bugliosi S. Regina Elena National Cancer Institute, Rome, Italy; Regina Elena National Cancer Institute, Italy

Background: Axillary lymph node dissection (ALND) may not be necessary in women with breast cancer (BC) who have micrometastasis in a sentinel lymph node (SLN), owing to the low risk of non-SLN (NSLN) involvement. In our Institute we validated and adopted the new molecular diagnostic tool OSNA (One Step Nucleic Acid Amplification) based on the quantitative measurement of Cytokeratin 19 (CK19) mRNA. The aims of our work in a subgroup of women with micrometastatic SLN, were: 1) to correlate the copy numbers of CK19 mRNA with the risk of additional positive NSLNs; 2) to assess the relationships between the molecular subtype classification based on the immunohistochemistry phenotypic patterns and the probability of a positive ALND; 3) to verify whether a combination of the new above mentioned parameters is able to identify a subgroup of patients with a micrometastatic SLN and a negligible risk of positive NSLNs in whom ALND may be avoided.

Material and Methods: The intraoperative clinical study was conducted on 901 fresh SLNs from 709 consecutive patients with clinically node negative BC. The SLN lysates were analyzed by OSNA assay. If the CK19 mRNA copy number/mL lysate was less than 250 copies/mL, the result was regarded as negative (-); copy numbers between 250 and 5000/mL were regarded as micrometastasis (+), and copy numbers greater than 5000/mL as macrometastasis (++). We analyzed only patients with a micrometastatic SLN. Complementary ALND was performed concurrently in case of OSNA assay positivity and the probability of having a positive lymph node axillary dissection was calculated by the unconditional logistic regression model. This series of BC patients were divided into four main subtypes taking in account the BC classification as defined by a combination of estrogen, progesteron receptors and HER2 status evaluated by immunohistochemistry (IHC) and confirmed by FISH in case of IHC-HER2 2+

Results: OSNA positivity for micrometastasis was reported in 91/709 cases (12.8%). The number of patients with positive ALND was 20 (22%). The statistical analyses showed that the metastatic involvement of NSLNs is associated with SLNs with a high copy numbers (>2000) of CK19 mRNA together with luminal B subtype. Otherwise none of the luminal A patients with a positive SLN but presenting a copy number <1000, had a positive NSLNs.

Conclusions: We showed that biologically-driven analyses may be able to build new models with higher performance in terms of breast cancer axillary status prediction after positive SLN biopsy for micrometastasis. The copy numbers of CK19 mRNA and the molecular subtypes are more advantageous than traditional parameters because they are not pathologist-dependent and therefore they are more reliable and reproducible.

P3-07-03
One-Step Nucleic Acid Amplification (OSNA) for the Diagnosis of Sentinel Lymph Nodes of Breast Cancer – Results of the China Multicenter Study CBCSG-001c
Wang YS, Ouyang T, Wu J, Liu YH, Cao XC. Shandong Cancer Hospital & Institute, Jinan, Shandong, China; Beijing University Cancer Hospital, Beijing, China; Fudan University Cancer Hospital, Shanghai, China; Guangdong General Hospital, Guangzhou, Guangdong, China; Tianjin Midical University Cancer Hospital, Tianjin, China

Background: With the adoption of sentinel lymph node (SLN) biopsy as the standard of care, there is an increasing need for the rapid and accurate intra-operative diagnosis of SLNs. CBCSG-001c was a prospective multicenter trial to validate the One-step nucleic acid amplification (OSNA) assay in China. The primary endpoint was the concordance rates of intraoperative OSNA assay with the in-depth permanent histological analyses based both on cases and SLNs.

Methods: From Feb. to Dec. 2010, 1188 SLNs from 552 breast cancer patients were enrolled in the CBCSG-001c study at 5 centers. SLNs were cut into alternating ~2mm sections. One half of the sections were sampled for H&E, with 4 sections at different intervals. The other half was fully tested with the OSNA assay. Predetermined cutoffs were calibrated so only metastases >0.2 mm were detected.

Results: The concordance rate was 89.1% (95% CI, 86.3-91.5%), sensitivity 87.7% (95% CI, 81.0-92.7%), and specificity 89.6% (95% CI, 86.3-92.4%) based on 552 cases, and the concordance...
rate was 91.4% (95% CI, 89.7-92.9%), sensitivity 83.7% (95% CI, 77.7-88.6%), and specificity 92.9% (95% CI, 91.1-94.4%) based on the 1188 SLNs. This quantitative molecular assessment allows the distinction of the size of the metastasis, and the PPV of OSNA [-+] for macrometastases was 83.2% (95% CI, 75.0- 89.1%). Discordant results were thought to be partly due to the fact that different tissue sections were used for OSNA assay and histology, and SLNs with ITCs were not considered as histological positive nodes. After discordant case investigation, the sensitivity of OSNA assay was significantly higher than that of intraoperative frozen section and touch imprint cytology.

Discussion: As the largest OSNA study to date, our results, together with that of Japan, Germany, and France study, proved the OSNA assay based on CK19 mRNA expression to be a reliable and standardized tool for the intraoperative detection of SLN metastases of breast cancer patients as compared to in-depth permanent histology. The high sensitivity of OSNA assay means reducing the risk of second operation for ALND, medical care costs and patients anxiety.

P3-07-04
Does Omission of Axillary Dissection after a Positive Sentinel Node Biopsy Influence Indication to Adjuvant Chemotherapy in Operable Breast Cancer Patients?

Introduction: Based on the recently published ACSOG Z0011 study (JAMA 2011;305:569), axillary dissection (AD) may be avoided in breast cancer (BC) patients with a clinically negative axilla and a positive sentinel lymph node (SLN) biopsy receiving breast conserving surgery (BCS). Because the number of positive axillary lymph nodes (ALN) is a widely accepted prognostic marker, we evaluated the potential impact of omission of AD on indication to adjuvant chemotherapy (ACT).

Patients and methods: Among 1497 patients operated at our Institution over 10 years, we identified 321 patients fulfilling the inclusion criteria of the ACSOG Z0011 study (BCS plus SLNB, cT1-2, cN0 breast cancer and 1 to 2 positive SLN). All patients underwent AD. Each case, which was anonymized, was reviewed by our breast team in two rounds. In the first round, patient age, histopathology, linfovascular invasion, tumor grade, hormone receptor, HER2, and ki67 status and number of positive SN nodes (micro and/or macrometastatic) were available. In the second round, the information on ALN was added. At each round, the panel chose between three indications: 1) Recommend ACT; 2) Discuss ACT; 3) No ACT.

Results: SN was micrometastatic in 145 (45%) and macrometastatic in 176 patients (55%). ALD revealed non-SNs metastases in 96 patients (30%). Forty-four of these patients had >3 positive ALN (range 4-24).

Indications at round 1 and 2 are summarized below.

<table>
<thead>
<tr>
<th></th>
<th>Round 1</th>
<th>Round 2</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Recommend ACT</td>
<td>Discuss ACT</td>
</tr>

<td>Round 1</td>
<td>Discuss ACT</td>
<td>26 (41)</td>
</tr>
<tr>
<td>No ACT</td>
<td>9 (11)</td>
<td>9 (11)</td>
</tr>
<tr>
<td>Totals round 2</td>
<td>177</td>
<td>40</td>
</tr>
</tbody>
</table>

As a result of the disclosure of the total number of involved ALN, a change in the indication occurred in 51 patients (16%). The most frequent change was a recommendation to ACT (35 patients, 69% of the changes). Among these patients, 9 changed from No-ACT to recommend ACT. All except one change in the indication to ACT occurred in patients with immunohistochemically defined Luminal A and Luminal B/HER2 negative tumors and were mostly towards ACT.

Conclusions: Omission of AD in patients with a positive SLN receiving BCS would have altered the indication to ACT in 16% of the patients at our Institution. Changes occurred almost exclusively in patients with hormone receptor positive/HER2-negative tumors. The implications of omission of AD must be taken into account before its widespread acceptance, including the possibility of a biologically tailored surgical approach.

P3-07-05
Nomogram Incorporating SLN Metastasis Size Provides the Most Accurate Prediction of Non-SLN Involvement in Breast Cancer Patients.
Gainer SM, Mittendorf EA, Hunt KK, Bassett RL, Yi M, Meric-Bernstam F, Ross MI, Babiera GV, Kuerer HM, Candle AS, Hwang RF, UT-M.D. Anderson Cancer Center, Houston, TX

Introduction: The finding of metastatic disease in the axillary nodes remains an important factor that guides adjuvant therapy decisions in breast cancer. The value of completion axillary lymph node dissection (ALND) may not be the same in all patients and determining the risk of non-SLN involvement can be a guide in surgical decision making. We recently developed a nomogram that incorporates the maximum SLN metastasis size to predict non-SLN axillary involvement (Mittendorf et al., Ann Surgery 2011, in press). The purpose of this study was to compare the accuracy of this nomogram to another widely used nomogram that does not include SLN metastasis size.

Methods: We queried a prospective breast cancer database for patients with clinically negative nodes undergoing sentinel node biopsy who did not receive neoadjuvant therapy. We identified 431 patients with invasive breast cancer treated from 1996 to 2007 who had a positive SLN and underwent completion ALND. We evaluated clinicopathologic data including histology, multifocality, nuclear grade, pathologic tumor size, number of SLNs recovered, number of positive SLNs, maximum SLN metastasis size, presence of extranodal extension, hormone receptor status, and presence of lymphovascular invasion. Data were entered into our nomogram and the nomogram that does not include SLN metastasis size. The accuracy of the 2 nomograms in predicting non-SLN axillary metastasis was compared in all patients and in subgroups of patients based on burden of disease in the SLN.

Results: For the entire cohort of 431 women with positive SLNs, our SLN size nomogram was more accurate in the detection of non-SLN disease (area under the receiver operating characteristic curve [AUC] 78.3% vs. 72.4%, p<0.01). Whether or not SLNs were subjected to frozen section did not influence the relative accuracies of the 2 nomograms. When patients were analyzed by burden of disease in the SLNs, our SLN size nomogram was more accurate in predicting non-SLN disease in patients with macrometastases in the SLN (AUC 77.3% vs. 70.3%, p=0.008). There was no significant difference in the accuracy of the 2 nomograms for patients with isolated tumor cells or micrometastases in the SLNs.

Conclusions: Our nomogram incorporating SLN metastasis size with other clinicopathologic factors is the most accurate predictor of the risk of non-SLN metastasis in patients with a positive SLN. The SLN size nomogram is highly accurate in women with macrometastases, who may benefit the most from completion ALND. Using a nomogram with SLN metastasis size can provide the most accurate information for patient counseling and surgical decision making.
P3-07-06
Prognostic Utility of Upfront Nodal Staging Prior to Neoadjuvant Chemotherapy: The UAB Experience.
Purpose: Controversy exists regarding the prognostic utility of upfront lymph node staging in patients receiving neoadjuvant chemotherapy. This retrospective study explores whether upfront versus outback nodal staging influenced locoregional control and survival endpoints.
Methods: Between 1999 and 2005 one hundred and fifteen patients treated with neoadjuvant chemotherapy at UAB were identified. Patient, tumor, and treatment variables were recorded. Timing of nodal assessment was based on either surgeon preference or stipulated upfront per several clinical protocols. Survival was measured using the Kaplan Meier statistics. Univariate and multivariate analyses of covariates associated with local-regional control (LRC), progression-free (PFS) and overall survival (OS) were performed. Results: Mean age was 49 years and mean follow-up was 5.8 years. Stage distribution was as follows: 40 IIA, 34 IIB, 26 IIIA, 10 IIIB, and 5 IIIC. Definitive surgery included breast conservation in 49 patients, total mastectomy in 21 and modified radical mastectomy in 44. Seventy-two patients had upfront nodal sampling before neoadjuvant therapy, 36 by fine needle assessment and the remainder by sentinel node biopsy. Forty-three patients had their nodal assessment following neoadjuvant chemotherapy. Of those with upfront nodal staging: forty-nine patients had a positive nodal result and 23 had negative findings. In those that were sampled at the time of definitive surgery: 21 had positive results, 21 had a negative result, and 1 patient did not have any nodes in the specimen. One hundred five patients had post-operative radiation therapy. Overall there was no difference in LRC, PFS or OS outcomes between patients that had an upfront nodal staging procedure and those that had their nodes sampled at the time of definitive surgery. Patients achieving pCR had a non-significant trend towards improved overall survival (p=0.12). Final pathologic T, N and group stage were statistically significant in determining the progression free, p=0.003, 0.011, 0.005 and overall survival, p=0.02, 0.037, and 0.009. Lymphovascular space invasion was associated with progression free survival on univariate analysis, p=0.0179, but not multivariate analysis. Other covariates including age, biologic subtype, grade, type of chemotherapy, use of radiation therapy, radiation volume, time to complete radiation therapy, and use of hormonal therapy did not affect outcomes. Discussion: Upfront as compared with outback lymph node staging did not influence locoregional control or survival endpoints. Final pathologic stage and not initial clinical stage remains the most important prognostic factor associated with survival.

P3-07-07
Effect of Sentinel Lymph Node Biopsy without Axillary Lymph Node Dissection on Overall Survival in Patients with T1 or T2 Node-Positive Breast Cancer: A Report from the Korean Breast Cancer Society.
Park HS, Chae BJ, Song BJ, Jung SS, KBCS Investigators. The Catholic University of Korea College of Medicine, Seoul, Korea; Korean Breast Cancer Society
Introduction: Sentinel lymph node biopsy (SLNB) is accepted as an alternative method to axillary lymph node dissection for staging axillary lymph node status in clinically node-negative breast cancer. Current practical guidelines recommend that axillary lymph node dissection (ALND) should be performed in cases with sentinel node metastasis, and most of node-positive patients should receive adjuvant systemic therapy to reduce locoregional/distant recurrence and to improve overall survival irrespective of the number of lymph node metastasis. However, patients with ALND are more likely to develop lymphedema than those with SLNB alone, and appropriate systemic chemotherapy or hormone therapy significantly reduce locoregional and distant recurrence in early breast cancer patients. For this reason, the previous prospective study, American College of Surgeon Oncology Group Z0011 trial, was conducted and it suggested that there is no difference in overall survival between node-positive patients who received breast conserving treatment with SLNB alone and those with ALND after SLNB. This study is aimed to evaluate the difference of survival between node-positive patients who underwent SLNB alone and those who received ALND after SLNB using the Korean Breast Cancer Society registry.
Methods: In 87671 patients with breast cancer in the registry, we enrolled 2581 patients who meet the eligible criteria in the study. All enrolled patients had T1 or T2 breast cancer, and received mastectomy or breast conserving treatment followed by documented adjuvant systemic therapy between Jan. 2001 and Apr. 2011. Log-rank test and Cox-proportional hazard model were used to access the difference of overall survival according to the axillary procedure.
Results: There were 197 patients with SLNB alone and 2384 patients with ALND after SLNB, respectively. Smaller tumor size, lower number of nodal metastasis, and higher proportion of breast conserving surgery were shown in patients with SLNB alone than in those with ALND after SLNB. There was no significant difference in overall survival between 2 groups in the log-rank test. ALND after SLNB showed no significant improvement on overall survival in Cox-proportional hazard model adjusted by tumor size, number of nodal metastasis, and operation type (P=0.78, HR=0.73, 95% CI=0.80-6.62). Conclusion: The current study suggests that ALND after SLNB in cases with sentinel lymph node metastasis may not influence on the improvement of overall survival and supports the results of Z0011 trial. Further validation studies are necessary to expand the understanding of the role of performing SLNB alone in patients with node-positive breast cancer.

P3-07-08
Accurate Staging of Axillary Lymph Nodes from Breast Cancer Patients Using a Novel Molecular Method.
Okato T, Iwase T, Kimura K, Yamashita K, Horii R, Akiyama F. Cancer Institute Hospital of Japanese Foundation for Cancer Research, Koto-ku, Tokyo, Japan
Background: In breast cancer, the number of axillary lymph node metastases is the powerful prognostic factor. However, it is obvious that conventional histopathological examinations are non-standardized...
and limited in their ability to detect metastases accurately due to the partial evaluation of a node. This may lead to underestimation of nodal staging. The one-step nucleic acid amplification (OSNA) assay was developed to overcome this limitation of the histopathological examination. This assay can assess the whole lymph node and yields semi-quantitative results for the detection of clinically relevant nodal metastases by detection and amplification of cytokeratin 19 mRNA. This assay can classify the nodes into 4 categories, (+), (++), (+I), (+), and negative. (+++) and (+I) are theoretically regarded as macrometastasis and (+) as micrometastasis according to the American Joint Committee on Cancer (AJCC) staging system. We have shown the OSNA whole node assay detects more sentinel node (SN) metastases, particularly micrometastases than 2-mm-section frozen-section histology. Thus, we had hypothesized that the OSNA assay for non-sentinel nodes (nonSNs) in addition to SNs enables the classification of accurate nodal staging for breast cancer patients. In the present retrospective cohort study, we compared the performance of the OSNA assay with that of routine permanent histology for the detection of nonSN metastases among patients with positive SN biopsy who have undergone axillary dissection.

Patients and methods: Subjects comprised of consecutive 183 patients with clinically and ultrasonographically node-negative pT1-2 breast cancer who had undergone axillary dissection after positive SN biopsy with the OSNA assay between April 2009 and September 2010. Of these, for nonSN evaluation, 64 had single-section permanent histology while 119 patients underwent the OSNA whole node assay. We compared 1) detection rates of nonSN metastasis, including macro- and micrometastases and 2) upstaging rates from SN stage after the nonSN assessment according to the 7th AJCC staging system between both cohorts. We performed the two-population z test.

Results:
1) NonSNs were found to be positive for metastasis more frequently in the OSNA cohort than in the histology cohort (histology 13/64, 20.3%, 95% CI 11.7-32.6% vs. OSNA 66/119, 55.5%, 95% CI 46.1-64.5%; P<0.001). We found no significant difference in the frequency of macrometastasis in nonSNs (12/64, 18.8%, 95% CI 10.5-30.8% vs. 30/119, 25.2%, 95% CI 17.9-34.2%; P=0.42). However, we found significant difference in the frequency of micrometastasis in nonSNs (1/64, 1.6%, 95% CI; 0.1-9.5% vs. 36/119, 30.3%, 95% CI; 22.3-39.5%; P=0.001).

2) Total upstaging rates were similar in both cohorts (histology 9/64, 14.1%, 95% CI 7.0-25.5% vs. OSNA 20/119, 16.8%, 95% CI 10.8-25.0%; P=0.79).

Conclusion: The OSNA whole node assay detects a far greater proportion of nonSN metastases than single-section histology in patients with positive SN biopsy. However, in terms of the AJCC staging system, upstaging rates from the SN stage were similar in both cohorts. Follow-up of the OSNA cohort is required to clarify the prognostic implications of this technique; this may lead to the establishment of a new breast cancer staging.

P3-07-09

Background: The Memorial Sloan Kettering Cancer Center-Breast Cancer Nomogram (MSKCC-BCN) predicts additional nodal metastasis in patients with positive sentinel lymph node (SLN). This statistical tool does not include HER2 status. It has been shown that the interaction covariate between estrogen receptor (ER) and HER2 status was a determinant of SLN positivity. The purpose of our study was to determine if the accuracy of MSKCC BCN could be enhanced with new variables.

Patients and methods: Our dataset consisted of 2769 consecutive patients treated for operable breast cancer with SLN biopsies between 2006 and 2009. We selected all the patients (n = 588) with a positive SLN who underwent a completion axillary lymph node dissection (ALND). The MSKCC-BCN was used to calculate the theoretical risk of additional nodal metastasis for all patients. The evaluation of the MSKCC-BCN was performed with calibration test (Cox method) and performance test (Bleeker). Multivariate analysis used a logistic regression model. The input was based on the variables found significant in the univariate analysis. Interaction covariate between ER and HER2 status was included in the model. Our model was then analyzed in terms of discrimination (area under the curve) and of calibration (Hosmer-Lemeshow test).

Results: Calibration test showed significant differences between the probability of additional nodal disease predicted by the MSKCC-BCN and the probability observed in our population for the following subgroups of patients: histological grade 3 (p = 0.007), lymphovascular invasion (p = 0.03), multifocality (p = 0.04), positive ER (p = 0.002), micrometastasis in the SLN (p = 0.003), isolated tumor cells in the SLN (p = 0.02 and positive HER2 (p = 0.01). Performance test showed significant differences for the following variables: histological grade (p = 0.02), size of the SLN metastasis (p = 0.04) and HER2 status (p = 0.01). This shows that the MSKCC-BCN is not well calibrated and cannot be used for our population. A multivariate model to determine the probability of additional nodal metastasis was defined with the following variables: pathologic size of the sentinel node metastasis, interaction covariate between the ER and HER2 status, number of positive SLN and number of SLN removed [Table 1].

This multivariate model resulted in a nomogram tested on the training population. It was discriminating with an area under the curve of 0.76 [0.720-0.808] and well calibrated (Hosmer-Lemeshow test p = 0.51).

Conclusions: We showed that HER2 status and pathologic size of the SLN metastasis are determinant to predict additional nodal metastasis after a positive SLN. These two variables were included in a new nomogram that could help in the decision-making concerning further axillary treatment in these patients. Our model has to be validated prospectively in external series to confirm its accuracy.

P3-07-10
Sentinel Lymph Node Navigation Surgery Using Combination of Indocyanine Green Fluorescence and Blue Dye for Breast Cancer Patients.

Takahashi M, Hayashida T, Jinno H, Kitagawa Y. Keio University School of Medicine, Tokyo, Shinjuku, Japan

Background: Sentinel lymph node (SLN) biopsy is now widely accepted for staging the axilla in breast cancer patients. Several methods are presently used to detect SLNs. Combined use of blue dye and radiocolloid has been previously described as a superior method for detecting SLNs in breast cancer patients, but radiocolloid is not...
generally available in Japan. SLN detection guided by indocyanine green (ICG) fluorescence could emerge as a new and effective method for SLN biopsy. The aim of this study was to evaluate SLN biopsy using combination of ICG fluorescence and blue dye methods for breast cancer patients.

Material and Methods: We enrolled 75 patients with clinically node-negative breast cancer. An isosulfan blue dye solution (5ml) was injected subcutaneously just above the tumor and in the periareolar area after the induction of anesthesia. The injection site was massaged for five minutes and ICG (2ml) was then injected subcutaneously just above the tumor and in the periareolar area before starting the surgical procedure. Subcutaneous lymphatic channels draining from the areola to the axilla were visualized with a fluorescence imaging system (Photodynamic Eye: PDE, Hamamatsu Photonics Corporation, Japan) under fluorescence within several minutes. SLNs were dissected under direct visualization supported by fluorescence and dye navigation and diagnosed by intraoperative frozen section with hematoxylin and eosin staining. Any patient with a positive SLN underwent immediate axillary lymph node dissection (ALND). Results: SLNs were detected in all 75 patients. The fluorescence imaging identified 2.6 SLNs in 74 (98.7%) of 75 patients. The blue dye identified 1.6 SLNs in 68 (90.1%) of 75 patients. Twelve of the 75 (16.0%) patients had metastatic SLNs and ALND was immediately performed. No metastasis revealed in any non-SLN in eight of these 12 patients. Metastatic SLNs were detected by the ICG fluorescence and not by blue dye in four of these 12 patients.

Discussion: The combination of ICG fluorescence and blue dye method had two advantages; it could reveal lymph flow on the surface before we determined the skin incision line; and it had a high SLN detection rate. In hospitals where radioisotopes are unavailable, a combination of the two methods would be advantageous.

A median of 1.95 SLNs were assessed by FS and a median of 2.06 SLNs by OSNA (p=0.15). Intraoperative histopathological assessment detected 67 SLNs metastasis by FS and 107 SLNs metastasis by OSNA assay (p=0.07). There were no differences in rates of macrometastasis (54 by FS and 74 by OSNA) and micrometastasis (13 by FS and 33 by OSNA) (p=0.09). When compared the OSNA assay with permanent section, 92 SLNs had metastasis by permanent section (63 macrometastasis and 29 micrometastasis) with no statistically significant differences (p=0.5).

SLNs metastasis were found in 71 patients (31.1%) by permanent section and in 83 (33.2%) by OSNA assay (p=0.69).

Axillary lymph node dissection (ALND) for metastatic SLN was performed in 148 patients, 79 (31.6%) in OSNA group and 69 (30.2%) in the permanent section group (p=0.68). All patients diagnosed by OSNA had a complete ALND during the initial surgical procedure. On the other hand, ALND was performed in 51 patients (73.9%) in the permanent section in the initial surgery, and ALND was performed in a second surgical procedure in 18 patients (26%), due to false negative results of the FS (p<0.001).

CONCLUSIONS:
The OSNA assay can detect SLN metastasis as accurately as conventional pathology, with no increased detection of positive SLNs. Given the definitive pathology of the SLN intraoperatively, the use of OSNA can reduce the need for a second surgery in 26% of patients with breast cancer and a positive SLN.

Diepstraten SC, Sever AR, Buckens CF, Veldhuis WB, van den Bosch MA, Mali WP, Verkooijen HM. University Medical Center Utrecht, Netherlands; Maidstone Hospital, United Kingdom

Purpose: Women affected with invasive breast cancer generally undergo sentinel node biopsy (SNB) of the axilla, which is followed by axillary dissection if lymph node metastases are found. This systematic review and meta-analysis aims to evaluate the utility of...
preoperative axillary ultrasound-guided needle biopsy in terms of staging the axilla and preventing futile SNB.

Methods: We systematically searched Pubmed, Embase and Cochrane through March 14, 2011, for studies addressing preoperative assessment of axillary lymph node (ALN) status by axillary ultrasound and biopsy. Eligible studies had to report on biopsy indication and method, and true and false positive and negative outcomes. A pooled estimate was calculated for prevalence of futile SNB (defined as the proportion of patients needing secondary ALN dissection after a negative axillary ultrasound and biopsy) and sensitivity (defined as the proportion of patients with ALN involvement detected by axillary ultrasound and biopsy).

Results: Twenty-three studies were included which reported on a total of 6205 procedures. The pooled prevalence of futile SNB was 25% (95% CI = 23% to 27%) and the pooled sensitivity was 51% (95% CI = 43% to 59%). There was substantial heterogeneity across studies for both futile SNB prevalence (I² = 60.5) and sensitivity (I² = 93.3), which could not be explained by between-study differences in biopsy technique, inclusion criteria, biopsy indication or study design. Sensitivity was increased in studies with a high prevalence of axillary lymph node metastases.

Conclusion: Preoperative axillary ultrasound guided biopsy is a useful step in the process of axillary staging as around fifty percent of breast cancer patients with axillary involvement can be identified pre-operatively and are spared a two step surgical intervention. Still, one in four women with a US biopsy ‘proven’ negative axilla have ALN involvement on SNB and need to undergo completion axillary dissection. New techniques may be able to reduce the prevalence of futile SNB.

Chen K, Jia W, Zeng Y, Fan M, Su F, Li S. Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, Guangdong, China

Background: Several models for predicting the risk of nonsentinel lymph node (NSLN) metastasis in breast cancer patients with positive sentinel lymph nodes (SLNs) have been developed. Independent validation of these models in different populations is necessary before clinical application. This study aimed to validate and compare these models in Chinese patients.

Patients and Methods: A total of 159 breast cancer patients with positive SLNs treated at our institution were included. Chi-squared tests, RP-ROC, CART and multivariate logistic regression were used to analyze the risk factors for NSLN involvement in our population. ROC curves, calibration plots and false-negative (FN) rates were evaluated for 11 reported models. The threshold of each model for classifying patients into the low-risk group was adjusted to render the FN rate close to 10%.

Results: In total, 81 (50.9%) patients had at least one NSLN involvement. Univariate and multivariate analyses revealed that the number of negative SLNs (P=0.01, HR=0.63) and the metastasis size of the positive SLNs (P=0.01, HR=1.15) independently predicted the NSLN status in our population. The Cambridge and Mou models outperformed the others, both with AUCs of 0.73. The other models performed as follows: the Mayo, Tenon, MDA, MSKCC, Ljubljana, SNUH and Louisville models had AUCs of 0.68, 0.66, 0.66, 0.64, 0.62, 0.61 and 0.60, respectively. The Stanford and Saidi models did not present any discriminative capabilities, with AUCs of 0.54 and 0.50, respectively. The Cambridge, MSKCC and Mayo models were well calibrated. The Ljubljana model did not calibrate well.

With adjusted thresholds, the Mayo model outperformed the others by classifying the highest proportion of patients (20%) into the low-risk group. The Cambridge, Mou and MDA models defined 17.0%, 14.5% and 15.1% of patients as low-risk, respectively.

Sensory Disturbance of the Ipsilateral Upper Arm after Breast Cancer Surgery with Sentinel Node Biopsy Alone Compared with Axillary Dissection – A Prospective Study.

Okusumi S, Kiyoto S, Takahashi M, Haru F, Takabatake D, Takashima S, Aogi K, Shimozuma K. NHO Shikoku Cancer Center, Matsuyama, Ehime, Japan; Ritsumeikan University, Kusatsu, Shiga, Japan

Background: Axillary surgery for breast cancer causes several postoperative complications including edema of the ipsilateral arm and sensory disturbance of the ipsilateral upper arm. Although sentinel node biopsy has been considered as a standard procedure for node-negative patients, some complications bother patients even after it. Although data regarding the quality of life of patients and/or subjective and objective assessment of arm morbidity after axillary surgery have been reported, to our knowledge, quite a few data have been reported on actual examination of sensory disturbance of the ipsilateral upper arm after sentinel node biopsy alone. We report comparative data regarding the objective and subjective degrees of postoperative sensory disturbance of the ipsilateral upper arm examined prospectively between sentinel node biopsy alone and axillary dissection.

Patients and Methods: A total of 118 patients, who received breast cancer surgery with sentinel node biopsy alone (51 patients)(SN group) or axillary dissection (67 patients)(AD group) at NHO Shikoku Cancer Center, were prospectively evaluated sensory disturbance regarding the following: (a) dysesthesia, (b) paresthesia, (c) degree of disturbed tactile sensation, (d) degree of disturbed pain sensation, (e) ratio of disturbed area of tactile sensation (defined as A/B) length of disturbed area (B) total length of upper arm, and (f) ratio of disturbed area of pain sensation (defined as A/B). Patients were either asked
about the above or examined for them at one month, 6 months and 1 year, respectively, after surgery. At surgery it was recorded whether or not the intercostobrachial nerve(s) were totally preserved in patients who underwent axillary dissection. Unpaired t-test, Mann-Whitney U-test and Wilcoxon signed rank test were used to test statistical significance.

Results: The mean ages at surgery were 54.7 and 53.7 years in the SN and AD groups, respectively (P = 0.66). The mean number of biopsied lymph nodes in the SN group was 2.4 (range: 1-5). In 22 patients of the AD group the intercostobrachial nerves were totally preserved. There was no difference in dysesthesia, paresthesia, and the level of disturbed pain sensation between the two groups throughout one year after surgery. However, the patients in the SN group showed milder disturbed tactile sensation at one and 6 months than those in the AD group (P = 0.04 and 0.03, respectively). Both the ratios of disturbed area of tactile and pain sensation were statistically significantly lower in the SN group than in the AD group throughout one year (P = 0.03 ~ <0.0001). The mean ratios of disturbed area of those sensations were stable in the SN group over the year (0.03-0.05 for both tactile and pain sensations, P > 0.12 for any comparison). On the other hand, the mean ratios in the AD group became lower from 0.23 to 0.17 for tactile sensation and from 0.20 to 0.13 in pain sensation (P = 0.02, and 0.05 for tactile and pain sensations, respectively).

Conclusion: Sensory disturbance of the ipsilateral upper arm after sentinel node biopsy alone was much milder than after axillary dissection throughout the study period.

P3-07-15
Sequential Peri-Areolar and Peri-Tumoural SPECT/CT Lymphoscintigraphy Has Identified High Rates of Discordance in Both Axillary and Internal Mammary Sentinel Lymph Node Mapping.
Nouthis F, Spillane A, Gehski V, Snook K, Gillet D, Cooper R, Allwright S, Uren R, Sydney University, Sydney, New South Wales, Australia; Mater Hospital, Crows Nest, New South Wales, Australia

Introduction:
The release of the MA20 intergroup trial results has confirmed the importance of locoregional radiation on local and distant disease control and survival. Sentinel lymph node (SLN) evaluation is the gold standard for regional lymph node evaluation and radiation oncologists continue to utilize the nodal staging to plan adjuvant locoregional therapy. Despite over a decade of experience in SLN evaluation there persists a common belief that the lymphatic drainage of the whole breast is to anteroposterior axillary lymph nodes. Several different lymphoscintigraphy injection techniques are in use with claims that they all identify the same axillary sentinel nodes. However this is not based on a high level of evidence. The evolution of SPECT/CT has led to the accurate anatomic identification of SLN, hence the different lymphoscintigraphy techniques can now be directly compared.

Method:
38 patients underwent double sequential lymphoscintigraphy (periareolar followed by peri-tumoural) separated by 1-7 days. Patients were referred by 4 surgeons to 3 separate lymphoscintigraphy centres with standardisation of tracer substance (99mTc-antimony sulfide colloid), lymphoscintigraphy and SPECT/CT evaluation techniques. The degree of discordance in sentinel node evaluation was defined as:

• Type 1 - One study demonstrates SLN(s) in a nodal basin [axilla or internal mammary chain (IMC)] and the other study demonstrates none.
• Type 2 - Both studies identified SLN(s) in a nodal basin however the SLN(s) are all different.

• Type 3 - Both studies identified SLNs in a nodal basin, however some SLN(s) are identical and others not.

Notably 21 patients (55%) had either axilla or IMC lymphoscintigraphy discordance. Two patients had both axilla and IMC lymphoscintigraphy discordance.

The majority of discordance was identified in the IMC. In the discordant IMC lymphoscintigraphies neither study demonstrated IMC SLN. There were no studies that identified identical IMC nodes in both PA and PT lymphoscintigraphy. Discordant axillary drainage was more evident in patients with lateral sector tumours compared to IM discordance with medial sector tumours.

Conclusions:
Accurate lymphoscintigraphy is the road map to assist a surgeon identify lymph node metastases. In turn accurate staging will determine appropriate adjuvant therapy decisions particularly regional node irradiation. This study demonstrates a high degree of discordance between PA and PT lymphoscintigraphy techniques in 55% of patients. Inadequate lymphoscintigraphy can result in unrealized false negative results, which could impact patient outcomes and clinical trial results.

Seo YJ, Hwang MJ, Lee JH, Son GT, Choi JE, Bae YK, Kang SH, Lee SJ, Yeungnam University College of Medicine, Daegu, Republic of Korea

Background:
Lymphedema affects over 20% of breast cancer patients undergoing axillary dissection. Axillary reverse mapping (ARM) technique to identify and preserve arm node during sentinel lymph node biopsy (SLNB) or axillary lymph node dissection (ALND) was developed to prevent lymphedema. The purpose of this study was to investigate the location and the metastatic rate of the arm node, and finally to evaluate the short term incidence of lymphedema after arm node preserving surgery.

Patients and Methods:
From January 2009 to October 2010, 97 breast cancer patients who underwent ARM were enrolled. 2.5ml blue dye was injected in ipsilateral upper inner arm. After at least 20 minutes after injection, SLNB or ALND was performed in the usual manner and blue stained arm nodes and/or lymphatics were identified. We checked arm circumference at baseline and average of 8.8 months after operation in ALND cases and 13.7 months in SLNB cases. Patients were divided into two groups, arm node preserved group (70 patients in ALND, 10 patients in SLNB) and unopened group (13 patients in ALND, 4 patients in SLNB). The difference of arm circumference between preoperative and postoperative was checked in these groups.

Results:
The mean number of identified blue stained arm nodes was 1.4±0.6. The arm nodes were found in the inferolateral side of axillary and thoracodorsal vessels in 57 patients (58.76%), the inferomedial side in 37 patients (38.14%), the superolateral side in 2 patients (2.06%), and the superomedial side in 1 patient (1.04%). In the majority of patients (92%), arm nodes were located between the lower level of the axillary vein and just below the second intercostal brachial nerve.
In arm node unpreserved group, 2 patients had metastasis in their arm node. The one had a common pathway between the arm node and the sentinel lymph node. Another did not have a common pathway, but had extranodal extension with N3 metastasis. Among ALND patients, in arm node preserved group, the difference of arm circumference between preoperative and postoperative in ipsilateral and contralateral arm was 0.27cm and 0.07cm, respectively, whereas 0.47cm and -0.03cm in unpreserved group, and one lymphedema was found after 6 months. No difference was found between arm node preserved and unpreserved group among SLNB patients (0.21cm and 0.39cm in in preserved group, 0.2cm and 0.02cm in unpreserved group).

**Conclusion:** Arm node preserving was possible in all breast cancer patients with identifiable arm node, during ALND or SLNB, except for those with high surgical N stage, and lymphedema did not develop in patient with arm node preserving surgery. Metastasis was not found in arm node preserving group in current results, but need to be observed in the ongoing progress.

**Optimal Number of Sentinel Lymph Nodes That Could Avoid Completion of Axillary Lymph Node Dissection in Operable Breast Cancer.**

Salmon RJ, de Ricke Y, Falcon MC. Institut Curie, Paris, France

**Background:** Axillary lymph node dissection (ALND) has been the standard of care for breast cancer patients with sentinel lymph node (SLN) metastasis. It is now under discussion since the publications of ACOZOG Z0011 and NSABP-32. The 1-3% rate of axillary recurrence is very low in these studies, whereas the rate of additional nodal metastasis after the completion of ALND varies from 15% to 35%. The purpose of this study was to determine the optimal number of nodes to be removed in order to obtain an axilla free of disease after initial surgery.

**Patients and methods:** 4928 consecutive patients treated for breast cancer ≤ 2 cm with primary breast surgery with SNB between 2000 and 2009 were reviewed from the Institut Curie breast cancer prospective database. 1165 patients with a positive SLN (macrometastasis, micrometastasis and isolated tumor cells) underwent ALND. The proportion of patients with positive ALND was analysed according to the total number of sentinel lymph nodes biopsied. Results were compared with Chi-square test for qualitative variables and with Kruskal-Wallis for quantitative variables.

**Results:** Among the 1165 patients, 308 (26.4%) had a positive ALND. Among them, 81.1% of patients had a macrometastasis in the SLN versus 45.6% in the 857 patients with negative ALND (p < 0.0001); 10.8% had a micrometastasis versus 31.4% (p < 0.001) and 8.1% of patients had isolated tumor cells in the SLN versus 23% (p < 0.001). The proportion of patients with positive ALND decreased with the number of sentinel nodes removed (Figure 1), independently of the number of positive SLN. Among the 1165 patients, the rate of patients with 5 nodes removed or more and with residual disease in the axilla was < 1% (n=11). Those patients could have avoided completion ALND, representing 3.6% of the total positive ALND that would have been neglected.

**Conclusions:** We showed that patients with positive SLN have a very low risk (<1%) of residual disease in the axilla when 5 nodes or more have been removed. This number which is a major component of nomograms, could be used as a threshold to avoid completion ALND.

**Long-Term Outcome of Internal Mammary Lymph Node Detected by Lymphoscintigraphy in Early Breast Cancer.**

**Purpose:** The purpose of this study is to determine the long-term significance of internal mammary lymph node (IMLN) detected by lymphoscintigraphy.

**Background:** IMLN metastasis is an important prognostic indicator in breast cancer. However, the necessity of internal mammary sentinel lymph node (IMSLN) biopsy for accurate staging, for choosing adjuvant treatment, and as a prognostic indicator, has remained controversial.

**Methods:** From January 2001 until December 2006, 525 female breast cancer patients underwent radical surgery after preoperative lymphatic scintigraphy. We retrospectively analyzed the follow-up results, recurrences and deaths of all patients.

**Results:** There was no significant difference in clinicopathologic characteristics between the axilla and the IMLN group. The median follow-up period was 118.8 (range, 7-122) months in the axilla group and 107.7 (range, 14-108) months in the IMLN group. During the median follow-up period, the breast cancer-related death rate in the axilla group was 3.6%, which was not significantly different from that of the IMLN group (1.3%) (P = 0.484). The five-year survival rates (5YRS) did not differ between the two groups (P = 0.306). The overall recurrence rate and the locoregional (LR) recurrence rate also did not differ between the two groups (P = 0.835 and P = 0.582, respectively). The recurrence rate of IMLN (both ipsilateral and contralateral) metastasis was very low, accounting for only 0.5% in the axilla group and 1.3% in the IMLN group (P = 0.416).**Conclusion:** The long-term follow up results showed that there was no significant difference in both overall outcome and regional recurrence between the two groups. Therefore, the necessity of identification of nodal basins outside the axilla or the necessity of IMLN sentinel biopsy should be reconsidered.

**P3-07-20**

**An Independent Assessment of Seven Nomograms for Predicting the Probability of Additional Axillary Nodal Metastasis after Positive Sentinel Lymph Node Biopsy in a Cohort of British Breast Cancer Population.**

Nadeem RM, Gudur LD, Saidan ZA. Lancashire Teaching Hospitals NHS Foundation Trust, Chorley, United Kingdom

**Background:** Axillary lymph node dissection (ALND) is currently the recommended procedure in patients with positive sentinel lymph node (SLN) biopsy. A significant proportion of patients with positive SLNs will not have any additional metastasis in non-sentinel lymph nodes (NSLNs). Nomograms could identify a subgroup of patients with low risk of further disease in whom completion ALND can be avoided. The aim of this study is to assess the accuracy of currently available seven nomograms in a cohort of British breast cancer population.
Methods: 138 patients with positive SLNs who underwent completion ALND between October 2006-April 2011 were identified. Multiple pathological variables including the histological size of the SLNs metastasis were analysed. Data was then used to calculate the probability of further metastasis in non-SLNs according to the seven nomograms that are currently in use: MSKCC, Cambridge, Turkish, Stanford, MDACC, Tenon and MOU models. The area under the receiver-operator characteristic (ROC) curve (AUC), 95% confidence intervals, false negative and positive rate were calculated for each nomogram. Subgroup analysis includes pathological tumour size (≤ 2 cm and >2 cm) and macro- or micrometastasis in SLNs. AUC value ≥ 0.80 has an excellent discriminatory power.

Results: 56 of 138 patients (41%) had additional metastasis in non-SLNs.

AUC values with 95% confidence intervals and false negative rate are shown in table 1.

Subgroup analysis also shows persistently better AUC value for MOU nomogram. None of the models were able to achieve an AUC value > 0.80 in a cohort of British breast cancer patients.

Discriminative power.

Conclusions: 46/138(33.3%) had tumour size ≤ 2 cm and 18/46(39%) had additional NSLNs metastasis. AUC values were calculated for each nomogram. Subgroup analysis includes the following variables: tumour size (≤ 2 cm and >2 cm) and macro- or micrometastasis in SLNs.

Discussion:

Conclusion:

Methods: A total of 497 patients with clinically node negative T1-T3 breast cancer underwent SLN biopsy from 2005 to 2009. Patients were divided in two groups depending on the timing of SLN biopsy. Patients were classified according to ER/PR/Her2 status as (ER/PR/HER2 + (TP), ER/PR/HER2 – (TN), ER/PR + HER2 - and ER/PR -HER2 +). For SLN metastasis the following variables were tested in univariable and multivariable models: age, tumor grade, tumor type, and the combined hormone receptors and Her2.

Results: The SLN was positive in the surgery first group in 127 of 429 patients (29.6%) while in 27 patients (34.7%) in the neoadjuvant group (p = 0.08). Forty patients (8.1%) were classified as TP, 25 (5.1%) as ER/PR – HER2 +, 364 (73.2%) as ER/PR+ HER2 – and 68 (13.6%) as TN. Triple positive BC patients were more likely to have axillary SLN metastasis compared to other molecular subtypes (p < 0.006). Multivariate logistic regression revealed age (≤ 50 years) and TP tumors to be independent predictors of SLN metastasis. Odds ratio (OR) for TP vs other molecular subtypes was 3.646 (IC 95% 1.566-8.488). OR for age ≤ 50 years was 2.353 (IC 95% 1.554-3.559).

Discussion:

Conclusion: Her2 overexpression favours SLN metastasis in ER/PR positive tumors over other ER/PR status. Even with increased SLN metastasis, TP breast cancer patients do better than TN and ER/PR-HER2 positive patients. Molecular subtype classification may hold more potential value in the decision-making process in patients with BC than the currently staging system.

P3-07-22

Combined Approach for Staging the Axilla in Breast Cancer Patients with Clinically Negative Nodes Versus Sentinel Node Biopsy Alone.

Patel RK, Krol VY, Cibull ML, McGrath PC, Fjällskog M-L, Pirruccello EA, Szabunio AL, Samayoa LM. University of Kentucky, Lexington, KY; Uppsala University, Uppsala, Sweden; VAMC Lexington, KY

Background: Prognostic information and local control for managing the majority of clinically node negative (cN0) breast cancer patients may be achieved by sentinel node biopsy (SNB) alone and/or limited axillary dissections (LAD). Currently, 20-30% of clinically node-negative (cN-) patients have unnecessary surgery. This study compares the results from staging the axilla using SNB alone versus using the combined approach shown below.

Methods: Clinically node-negative (cN-) patients (n=176) were subclassified according to their primary tumor histology, axillary ultrasound (US) data, and US-guided fine needle aspiration (US-FNA) results, as follows: Low Risk (LR) for axillary metastasis (n=62); High Risk (HR) with normal axillary US (n=17); HR with US suggestive minimal N1a disease (n=23); HR with US suggesting N1a disease (n=52); HR with US suggesting N2-3 disease (n=22). All patients with (+) SNB or (+) US-FNA had Axillary Lymph Node Dissections (ALND). The number of (+) Sentinel Nodes (SN), Non Sentinel Nodes (NSN) and (+) LNs after a (+) US-FNA from each patient category was correlated with corresponding preoperative data. HR patients were defined as having grade II tumors > 1.5 cm and grade III tumors > 1.0 cm. US abnormalities in the axilla were interpreted as follows: minimal N1a disease equivalent to cortical defects <5 mm in 1-3 LN; N1a disease, cortical defects >5 mm in 1-3 LN and N2-3 disease, complete nodal replacement in ≥ 1 LN. LAD refers to level I dissections (1-5 LN).

Results: Three subgroups of patients were identified: Group A, patients not requiring ALND (128/176 = 72%); Group B, patients...
requiring ALND bypassing SNB (22/176 = 13%) and Group C, patients requiring LAD (26/176 = 15%). Preoperatively these 3 groups were categorized as follows: Group A included patients at LR for axillary metastasis, HR patients with normal axillary US, HR patients with axillary US suggesting minimal N1a disease and HR patients with axillary US suggesting N1a disease with (-) US-FNA; Group B included HR patients with axillary US suggesting N2-3 disease and (+) US-FNA; Group C included HR patients with axillary US suggesting N1a disease and (+) US-FNA. The post ALND characteristics for these 3 groups are summarized as follows: all Group A patients had N1a disease represented by ≤ 2 (+) LN, 94% (17/18) were SN (+) only, 85% (15/18) with 1 (+) LN and 15% with 2 (+) LN; in Group B, 20 patients had N2-3 disease and 2 patients had N1a disease, all Group B patients had > 2 (+) LN; in group C, 20 patients had N1a disease and 2 patients had N2 disease, and 77% had single (+) node disease.

Conclusion: By following this approach a more patient oriented method for staging the axilla can be implemented as follows: 1. SNB alone for LR patients and for HR patients with axillary US findings suggesting no axillary disease, minimal N1a disease and/or N1a disease with (-) US-FNA; 2. ALND for HR patients with axillary findings suggesting N2-3 disease and a (+) US-FNA; 3. LAD for HR patients with US findings suggesting N1a disease and (+) US-FNA. This approach would result in a 38% (48/176) reduction in the number of SNB and a 30% (22/66) reduction in the number of ALND. This translates in to $200,000 (30 - 40%) in procedure-associated savings.

P3-07-23
Intraoperative Molecular Analysis of Sentinel Lymph Nodes in Breast Cancer Using One Step Nucleic Acid Amplification (OSNA).
Chaudhry A, Massey E, Jenkins M, Calder C, Winters ZE, Rayter Z. Bristol Royal Infirmary, Bristol

Introduction: The OSNA method for the intra-operative analysis of sentinel lymph nodes (SLNs) in breast cancer has been introduced in 3 UK centres since 2007. The methodology uses a polymerase chain reaction to quantitate CK19, a cytokeratin specific to breast duct epithelial cells. OSNA provides “real-time” results on SLNs analysed as negative (-) or positive with either micro (+) or macrometastases (+). Methods: This is a single-centre prospective pilot study of all patients undergoing breast cancer surgery including sentinel node biopsy from February 2010 to May 2011. SLN identification was performed using a dual localization technique with peri-areolar Patente V blue dye and Te99 radio-active isotope. SLNs were cut into 4 slices labeled as A, B, C and D, respectively after the removal of all perinodal fat. In all SLNs, slices A and C were processed in OSNA and slices B and D underwent histological assessment by H&E staining. Slices A and C were prepared for OSNA analysis with the required reagent (Lynorhag), followed by centrifugation and homogenization. Micro-pipetted samples were processed against control specimens, to produce normalized and quantitative curve results. The primary outcome measure was to correlate the results of OSNA with histopathology for each SLN. A negative SLN resulted in no further axillary surgery compared to a level II dissection following the presence of micrometastases and a level II dissection following the detection of macrometastases. The total duration of OSNA for all SLNs was recorded in relation to delays in the completion of the intended breast surgery in each patient.

Results: 251 SLNs were analysed in 112 patients (mean age of 55 years). Comparisons between OSNA and histopathology were made in 116 nodes (34 SLNs analysed by OSNA only). SLN positivity was evident in 30 nodes (26%) comprising either macrometastases (n=13) or micrometastases (n=17). The OSNA sensitivity and specificity of was 93% and 89%, respectively. Accounting for a tissue allocation bias in the presence of micrometastases only, the specificity rose to 94% if these cases were excluded in the analysis. There was no correlation between SLN positivity and tumour grade, size or receptor status. The time to OSNA results were analysed in 75 patients undergoing 45 wide local excisions (WLE), of which 18 were wire localized; 23 mastectomies and 22 SLNB alone. The mean time for OSNA was 40.5, 51.8, 54 and 61.5 minutes for 1,2,3, and 4 sentinel lymph nodes respectively. Operation time was prolonged by a median of 20 minutes (range -48 to +65 minutes) WLEs were delayed by the greatest time

Exclusions: Nodes that were not available for histological comparison i) nodes weighing <0.05g (n=34) were processed whole. ii) Departmental agreement from mid March 2011 to process nodes whole via OSNA (n=51); 6 had micro or macrometastases.

Conclusion: OSNA prevented staged axillary surgery in 24 (21%) of patients. A median time of 20 minutes for the OSNA procedure is comparable with acceptable operating times. Current experience supports the use of OSNA for each individual whole SLN analysis. The pilot data has resulted in a prescribed change in policy to analyse the whole SLN using this technique.

P3-07-24
Accuracy and Cost Effectiveness of Frozen Section Examination of the Sentinel Lymph Node (SLN) in Ductal Carcinoma In Situ (DCIS) of Breast.
Ballehaninna UK, Santoro E, Schaefer SS, Blackwood MM, Chamberlain RS. Saint Barnabas Medical Center, Livingston, NJ; Maimonides Medical Center, Brooklyn, NY; Saint George’s University School of Medicine, West Indies, Grenada; University of Medicine and Dentistry of New Jersey, Newark, NJ

Background: SLN biopsy (SLNB) can avoid reoperation for axillary staging in DCIS patients upstaged to invasive breast cancer (IBC) following resection. Intraoperative frozen section (IFS) examination of the SLN is a widely accepted tool for IBC patients in order to select candidates for axillary lymph node dissection (ALND), and avoid reoperation. Until now, utility of IFS in DCIS patients has not been addressed.

Methods: Data from DCIS patients undergoing resection with SLNB (2000-11) was analyzed to determine the utility and cost of IFS exam and its impact on axillary management. A binomial regression analysis was performed to assess factors predictive of IFS positivity and SLN metastases (SLNM).

Results: 401 patients (core biopsy, N=276, or excisional biopsy, N=125) underwent partial (N=84) or total mastectomy (N=317) with SLNB. 77 patients (19.2%) were upstaged to IBC. SLNM was identified in 24 patients (5.9%). Immunohistochemistry (IHC) positive individual tumor cells (ITCs) was the most common pattern of SLNM (N=12, 50%) and macrometastases in 3 patients (12.5%). 365s
Conclusions: Most common patterns of SLNM in DCIS (ITCs/SLNmi) were identified only on routine pathologic assessment. Utility of IFS examination in DCIS patients is limited by poor sensitivity, high FNR and increased costs. Higher axillary nodal metastases are applicable to IFS positive patients (N=5). 11 of 24 patients with SLNN mand not change after biopsy and PST. The recently published Z11 trial of observation vs. axillary dissection for patients with a positive sentinel lymph node showed amazingly low axillary recurrence rates in both groups, and has the potential to dramatically alter practice. However questions remain about whether the Z11 population is representative of the larger population of breast cancer patients.

Methods

An institutional database was queried to identify all patients who underwent sentinel node biopsy at our breast center from 2004 to 2010. These cases were retrospectively reviewed to determine the percentage of patients who would have met the Z11 eligibility requirements, and the demographics and outcomes for this subset were compared to those for Z11.

Results

Out of 1215 patients undergoing sentinel node biopsy, 282 (23%) had at least one positive sentinel node. However when patients were eliminated who had T3 or T4 tumors, more than 2 positive sentinel nodes, neo-adjuvant chemotherapy, or who underwent mastectomy, only 88 remained who would have been eligible for Z11 (31% of those with a positive sentinel node). These patients are compared to the Z11 patients in the following table.

Comparison of Z11 trial and our database for T1 - T2 patients with 1 or 2 positive SN's and no neo-adjuvant chemotherapy.

* for axillary dissection group in Z11

Our lumpectomy patients were generally quite similar to those of Z11 except ours had a lower percentage of micrometastases and a higher percentage of 4 or more positive nodes. As with most other published prediction models, the chance of having 4 or more positive nodes

P3-07-25

Sentinel Lymph Node Mapping in Breast Cancer after Primary Chemotherapy.

Bonardi S, Andreis D, Allevi G, Agugnini S, Milani M, Generali D, Bersiga A, Brizi MP, Dogliotti L, Berruti A, Bottini A. Azienda Ospedaliera Istituti Ospitalieri, Cremona, Italy; Azienda Ospedaliera Universitaria San Luigi di Orbassano, Università di Torino, Orbassano, Torino, Italy

Background: The high false negativity rate and the possibility of interference of primary systemic treatment (PST) and biopsy on the lymphatic drainage in the breast and axilla are the disadvantages of sentinel lymph node biopsy (SLNB) after PST. The primary aim of our study was to evaluate success rate for identification and isolation of sentinel lymph node (SLN) in patients treated with PST. Secondary aims were to verify if chemotheraphy and biopsy can really alter the lymphatic drainage, and to identify biological and clinical factors that can influence the accuracy of this technique.

Methods: Between June 2000 and April 2007, 176 consecutive operable or locally advanced breast cancer patients (T1-4N0-1M0) treated with antracyclin-based PST were enrolled in this single Institution study. Before performing a surgical biopsy and starting the treatment a lymphatic mapping was performed and the skin projection of the SLN location was then marked with permanent ink, with the aim to verify if the SLN marked did not change after biopsy and PST.

Results: The SLN was removed in 164 patients, with an identification rate of 93.2% (95% confidence interval (CI) = 89.4-96.9%). Fifty patients (30.5%) had metastatic involvement at SNB, and in 21 (42.0%) of them the SLN was the only positive node. Nine patients (5.5%) had a false negative SLN. The false-negative rate was 15.3% (95% CI = 7.1-32.9%). The SNB revealed a sensitivity of 84.7% (95% CI = 73.0-96.4%), an accuracy of 94.5% (95% CI = 90.1-99.0%) and a negative predictive value of 92.1% (95% CI = 85.8-98.4%). In 163 patients (99.4%) the SLN marked at baseline was the same removed at the end of treatment, while only in 1 case (0.6%) a different SLN was identified by the lymphatic mapping performed with radioactive colloid. According to clinical and tumor characteristics the rate of identification and removal of SNB was higher in patients aged <50 (95.6%) vs >50 (91.6%), with clinical node negative (95.1%) vs positive (88.6%) and with lower grade G2 (98.0%) vs G3 (91.2%). False negative rate of SNB was higher in patients aged >50 (17.9%) vs <50 (10.0%) and with clinical node negative (17.1%) vs positive (12.5%). Lymph node involvement was significantly associated with baseline ER positivity (p=0.0059 Chi-square test).

Conclusion: The identification rate, sensitivity and accuracy do not differ from other studies of SNB after PST. The false-negative rate is still high and we are performing analysis to identify biological and clinical features that can influence the accuracy of this technique. To our knowledge this is the first study with an in vivo demonstration that chemotherapy and biopsy do not alter the lymphatic drainage of the breast. We are performing exploratory analyses to evaluate the influence of false-negative rate of SNB on overall survival (OS) and progression free survival (PFS).
in our patients was directly proportional to tumor size and number of positive sentinel nodes, and inversely proportional to number of negative sentinel nodes.

Conclusions
A relatively small percentage of node positive patients at our institution actually met the eligibility requirements for Z11, but this subset was similar in most respects to the Z11 population. We have developed an algorithm that can be prospectively tested that will allow the majority of these patients to forego axillary dissection but that will exclude patients most likely to have 4 or more positive nodes.

P3-07-27
ROCK II Expression Can Be a Potential Marker of Non-Sentinel Lymph Node Metastasis in Breast Cancer Patients with Sentinel Lymph Node Involvement.

Shigematsu H, Taguchi K, Shiotsu S, Kawaguchi H, Nishiyama K, Ohno S, Okada M. Hiroshima University Hospital, Hiroshima, Japan; National Kyushu Cancer Center, Fukuoka, Japan

(Background) It becomes controversy whether axillary lymph node dissection is mandatory performed for breast cancer patients with positive sentinel lymph nodes (SNs), given that more than half of patients with a positive sentinel lymph biopsy have no metastasis in non-sentinel lymph nodes (non-SNs). Rho-associated kinase (ROCK) is essential part in tumor invasion and metastasis, and its activation is reported to be potential marker of lymph node metastasis.

(Purpose) The purpose of this study was to evaluate the expression of ROCK II as predictive factor of non-SNs metastasis in breast cancer patients with positive SNs.

(Patients and Method) ROCK II protein expression was determined using immunohistochemical analysis on formalin-fixed and paraffin-embedded primary tumor samples composed of 119 SN-positive patients who underwent axillary lymph node dissection in National Kyushu Cancer Center. ROCK II expression was defined positive when there was strong intensity of cytoplasm staining.

(Results) ROCK II expression tended to be strong in invasive area, but weak in intraductal component. Of the 119 patients, 35 (29%) were determined to be positive for ROCK II expression. Patients with ROCK II positive tumor had significantly higher probability of non-SNs metastasis compared with patients with ROCK II negative tumor (20/35, 57% for positive; 28/84, 33% for negative, p=0.02). In multivariate analysis, positive ROCK II expression was significantly associated with non-SNs metastasis even after accounting for other predictive factors including tumor size, lymphovascular invasion, number of SNs metastasis and extra-capsule invasion (positive vs. negative, HR 2.6, p=0.04).

(Conclusion) These findings suggest that ROCK II expression can be a predictive factor for non-SNs involvement in breast cancer patients with SNs metastasis.

P3-07-28
One Step Nucleic Acid Amplification (OSNA) for Intraoperative Molecular Detection of Lymph Node Metastases and Micro-Metastases in Breast Cancer.

Babar MM, Madani R, Jackson P, Irvine T, Layer G, Kissin M. Royal Surrey County Hospital, Guildford, SU, United Kingdom; University of Surrey, Guildford, SU, United Kingdom

Introduction: Ideally, intraoperative sentinel lymph node analysis in breast cancer should be automated, concordant with histopathology and practically applicable. One step nucleic acid amplification (OSNA), a highly sensitive intraoperative assay of cytotheratin 19 mRNA, is used for the detection of sentinel lymph node (SLN) macro- and micro-metastases in breast cancer. Guildford adopted the intraoperative OSNA “live” in December 2008 after undertaking a multicentre evaluation of its accuracy and high concordance with histopathology and here we present our two year data since its introduction.

Methods: Data was collected prospectively from 2008-10. All patients eligible for sentinel node biopsy were offered OSNA and operations were performed by five consultant breast surgeons. On detection of micro-metastases (+) and positive but inhibited metastases (i+), a level 1 axillary nodal clearance (ANC) and for a macro-metastasis (++), a level 3 ANC was performed.

Results: 471 patients had 999 SLN analysed, median age being 61. All except one were females. 72% (n=340) had wide local excision, 26% (n=120) underwent mastectomy and 2% (8) SNB alone. Mean tumour size was 18.3 mms. 80% (n=371) of the cases were IDC and 55% (n=256) had grade II tumour. 34% (n=161) had grade II tumour. 34% (n=161/471) had positive SLN who underwent axillary surgery at the same operation. This technique eliminates the need for a second operation in sentinel lymph node
positive patients and avoids the anxious wait for results in all, streamlining the patient’s cancer journey. OSNA upstages patients with micro-metastases and long term studies are needed to determine the clinical relevance of molecular micro-metastatic disease.

**P3-07-29**

*Validating the Lymph Node Ratio as a Prognostic Indicator among South East Asian Breast Cancer Patients.*

Saxena N, Hartman M, Bhoo Pathy N, Aziz R, Siew EL, Lee SC, Yip CH, Verkooijen HM. National University of Singapore, Singapore, Singapore; Faculty of Medicine, University of Malaya, Kuala Lumpur, Malaysia; University Medical Center Utrecht, Utrecht, Netherlands; National University Cancer Institute, National University Health Systems, Singapore, Singapore

Background: Several studies in Caucasian settings have suggested that the lymph node ratio (LNR, i.e. the ratio of the number of positive nodes to the total number of nodes excised) is a superior prognostic indicator for breast cancer as compared to the absolute number of nodes involved (pN stage). This study validates the prognostic performance of LNR in the South East Asian setting.

Methods: All patients diagnosed with non-metastatic invasive breast cancer at the National University Hospital (Singapore) or University of Malaya Medical Center (Kuala Lumpur) between 1990 and 2007 and with information on axillary nodes removed and involved were included for analysis (n = 1589). Multivariate Cox regression analysis was performed to evaluate the prognostic value of the LNR [low (<0.2), intermediate (0.2 to 0.65) and high risk (>0.65 to 1)] and pN staging [pN1, pN2 and pN3] for all cause mortality. Patients staged pN0/LNR 0 were excluded from analysis.

Results: According to the LNR classification, 758 patients were categorized as low risk, 574 as intermediate risk and 257 as high risk LNR. For classic pN staging, 879 were pN1, 447 pN2 and 263 pN3. Women in the intermediate risk category (0.2 to 0.65) had a 1.5 fold increased risk of death [Adjusted hazard ratio (HRadj) of 1.5 (95%CI, 1.2 to 1.9)], and women with high risk (>0.65 to 1) LNR had a 3.2 fold increased risk of death [HRadj of 3.2 (95%CI, 2.6 to 4.1)] as compared to the low risk women (>0 and <0.2). Similarly, women with pN2 disease had a 1.9 fold increased risk of death [HRadj of 1.9 (95%CI, 1.5 to 2.4)], and women with pN3 disease had 3.1 fold increased risk of death [HRadj 3.1 (95%CI, 2.5 to 3.9)] compared to pN1 patients.

Conclusion: Among South East Asian breast cancer patients, both the Lymph Node Ratio and the pN Staging system seem to be equally good at predicting all cause mortality.

**P3-07-30**

*Applying the Findings of the Z11 Trial to a UK Practice.*

Chalmers CR, Mallon EA, Stallard S, Doughty JC, Wilson CR. Western Infirmary, Glasgow, Scotland, United Kingdom

Introduction: The finding of a positive sentinel node is currently managed by further Level III axillary lymph node clearance (ALNC). The rationale behind this approach is that of local disease control, but there is little evidence that axillary lymph node clearance results in a reduction in axillary recurrence or in mortality. ALNC is however associated with increased morbidity (lymphoedema, nerve damage, reduced shoulder function) and significantly prolongs hospital stay. The Z11 trial suggests that ALNC following positive sentinel node biopsy does not result in lower axillary recurrence rates compared to the group in whom clearance was not undertaken and has obvious implications for evidence-based practice. The Z11 trial has strict inclusion criteria (T1/T2 tumour, breast conservation surgery) with all patients receiving adjuvant whole breast radiotherapy and systemic chemotherapy or endocrine therapy. For patients who do not meet the patient population of Z11, such as women undergoing mastectomy, the Sloane-Kettering predictive normogram provides an estimate of risk for residual axillary disease after positive sentinel node biopsy and the estimate of this risk may inform the clinical decision to clear the axilla based on individual cancer characteristics.

Methods: Our population comprises both symptomatic and screening patients, with an axillary positivity rate of approximately a third. This study was undertaken to assess the impact that Z11 would have on our practice. We prospectively maintained records were searched for ALNC patients treated between 2003 and 2011. We assessed the number of node-positive patients conforming to Z11 criteria and the number who demonstrated residual axillary positivity at clearance after a positive sentinel node. The axillary recurrence rate for this group after ALNC was recorded. We calculated the number of clearances that could have been avoided, and extrapolated the reduction in morbidity in lymphoedema and nerve damage using the audited incidence of these complications in our institution. We calculated the financial cost saving in terms of theatre usage and hospital stay. In addition, we assessed whether the Memorial Sloane Kettering predictive normogram is useful in the prediction of residual axillary disease for the group of patients excluded from the Z11 cohort.

Results: 1601 patients underwent axillary staging. 65% of our patients with node-positive disease were identified pre-operatively with ultrasound and biopsy and proceeded directly to ALNC. Our overall axillary recurrence rate was low (<1% at 5 years). 26% of our patients would not meet the criteria for Z11, predominantly due to the requirement for mastectomy. Of those that met the Z11 criteria, 60% had no further axillary disease at clearance and a further 25% demonstrated low volume (1-3 positive nodes) residual disease only. The Memorial Sloane Kettering normogram can be used in estimating risk of residual axillary disease in patients undergoing mastectomy.

Discussion: Using these criteria nearly 25% of axillary clearances in our population of breast cancer patients could be avoided with obvious cost savings both in terms of morbidity and finance, considerations that are important in planning our service for the future.

**P3-07-31**

*Intra-Operative Assessment of Sentinel Lymph Nodes in Breast Cancer with Touch Imprint Cytology (TIC) in 460 Consecutive Patients.*

Iqbal M, Shetty G, Randhawa S, Sandhu F, Chachlani N, Simon J, Harries S, Jones L, Clarke D. Warwick Hospital, Warwick, West Midlands, United Kingdom

Background: Sentinel node biopsy (SNB) accurately predicts the axillary lymph node status in patients with breast cancer. The sentinel lymph node (SLN) is evaluated by routine histology, requiring 3-5 days for the results and a second operation if the SLN is positive. However a second operation can be avoided if a reliable intra-operative assessment of the SLN was available. The techniques used for intra-operative assessment of the SLN include frozen section, touch imprint cytology (TIC) and more recently molecular biology assays. The aim of this study was to evaluate the accuracy of TIC in the assessment of the SLN.

Methods: A prospective study to include 460 patients with breast cancer who underwent SNB and had the sentinel node assessed intra-operatively with TIC. The SLN was bisected and a touch imprint was made on to a slide. The imprint was stained with
Giemsa stain. Permanent sections were evaluated with H&E and immunohistochemical staining. The TIC results were compared with the final histology of the SLN.

**Results:** 766 SLN’s were harvested from 460 patients (Mean - 1.66). Of the 460 patients, TIC was falsely negative in 50 (24%) patients. No patients had false positive results. Negative predictive value was 87%. The accuracy rate was 89%. 94 patients were positive on histology. TIC was positive in 44 patients and negative in 50. In the sensitivity, specificity and positive predictive value of TIC was 47%, 100% and 100% respectively. By acting on the results of TIC, 44 patients (47%) had an axillary clearance at the primary operation and were thus spared a second operation.

**Conclusion:** TIC in our cohort of 460 patients and 766 sentinel lymph nodes had an accuracy rate of 89% and specificity of 100%. Our study compares favourably with published literature, confirming that TIC is a simple, quick, reliable and reproducible technique that can be used for intra operative assessment of the SLN. A sensitivity of 47% means that about half of the SLN positive patients were spared a second operation. We had hoped that with more experience, our sensitivity would improve but since this has not been the case we are now moving towards molecular biology assays (OSNA) to assess the sensitivity would improve but since this has not been the case we are now moving towards molecular biology assays (OSNA) to assess. TIC is a simple, quick, reliable and reproducible technique that can be used for intra operative assessment of the SLN. The Role of Axillary Ultrasound in the Detection of Metastases from Primary Breast Cancers.

Yamashita M, Little E, Fraley J, Hovanessian-Larsen L, Sener SF. Keck School of Medicine, University of Southern California, Los Angeles, CA

**Background:** The value of ultrasound (US) in the preoperative evaluation of axillary nodes has yet to be completely clarified. Preliminary experience with this technique in our institution was examined.

**Methods:** Patients with a radiographic or palpable abnormality of the breast had simultaneous breast and axillary US. The exams were performed by dedicated breast radiologists using a 12 MHz linear array transducer (HDI 5000: Philips Ultrasound). Results were reviewed for all patients with invasive cancers who were cN0 and had definitive surgical procedures between June 2006 and May 2008. Criteria for abnormal lymph nodes were loss of reniform shape, focal or diffuse cortical thickening, or eccentric/replaced fatty hilum. US-guided biopsies were done using a 16g spring-loaded core biopsy device (16g MD TECH SuperCore). Patients with positive axillary node biopsies bypassed sentinel lymph node biopsy (SLNB) and had axillary dissection, whereas those with sonographically normal nodes or benign/non-diagnostic biopsy results had SLNB at the time of definitive surgery.

**Results:** Of 128 patients diagnosed with invasive cancer, 23 (18%) had abnormal axillary US at the time of initial diagnosis. Biopsies were performed in 18 of the 23, of which 12 (67%) were malignant and 6 (33%) were benign. Ultrasounds were negative in 105 (82%) patients. SLNB was done in 110 patients: 103 with negative US; 4 patients with abnormal US but negative axillary biopsies; 2 patients with abnormal US but no core biopsies; and 1 patient with a positive US biopsy. SLNB was negative in 91 (83%) patients and positive in 19 (17%). The node-positive status was N1a in 14 patients and N1mic in 5. Axillary dissection was done in 32 (25%) of 128 patients, comprised of 11 patients with US-guided positive biopsies, 12 with positive sentinel nodes, 2 with US-guided negative biopsies, 2 with negative ultrasounds, 3 with unbiopsied abnormal ultrasounds, and 2 with a false-negative SLNB. For determining axillary metastases with US, sensitivity was 16/31 (52%), specificity was 90/97 (93%), positive predictive value was 16/23 (69%), and negative predictive value was 90/105 (86%).

**Conclusions:** US examination was a valuable method of evaluating the axilla in newly diagnosed breast cancers. Of 32 patients having an axillary dissection, abnormal US eliminated the need for SLNB in 17 (53%). Patients with US-guided positive nodes were submitted to axillary dissection without SLNB. Therefore, we were unable to determine how often US identified an abnormal non-sentinel node, thus upstaging the axilla relative to SLNB alone. This question should be the topic of further clinical study.

Are Single Node Metastases More Common in Patients with Breast Cancer in the Sentinel Node Era?

Shetty G, Randhawa S, Mohammed I, Harries S, Jones L, Clarke D. Warwick Hospital, Warwick, Westmidlands, United Kingdom

**Background:** The axillary recurrence rate after axillary lymph node dissection has been reported as approximately 3%. Since the introduction of sentinel node biopsy (SNB), it has become apparent that, there is a significant decrease in axillary recurrence, ranging from 0.26% to 0.9% in published literature. One of the concerns that arises from this data is that, the sentinel node may have been missed when routine axillary node clearance were being performed. The aim of this study was to compare the results of a cohort of patients who had an axillary staging procedure prior to the introduction of SNB (axillary clearance) with patients after the introduction of SNB in relation to the number who had only one positive node in the axilla.

**Methods:** From June 2003 to November 2010 data was collected on demographics, histopathology and procedure performed. All patients with invasive breast cancer prior to April 2005 had an axillary node clearance (ANC) with either wide local excision or mastectomy. Since April 2005 all patients with invasive breast cancer had a SNB and patients with a positive sentinel node (SN) underwent ANC. Patients with a negative SNB had no further axillary surgery.

**Results:** 702 patients had axillary node surgery between June 2003 and November 2010. 251 patients had axillary node clearance (pre SN period) and 451 had SNB (SN period). Average age was 57 years. 509 patients (156 in pre SN period and 353 in post SN period) had no nodal metastases. Amongst the 193 node positive patients, 100 had single node involvement. In the pre SN period 33 (34.7%) patients had single node involvement, compared to 67 (68.3%) in SN period. The histopathological type of cancer did not vary significantly between the one node positive, multiple node positive and node negative groups.

**Conclusion:** Our study confirms a significant rise in patients with a single node positive in the sentinel node period. This could be due to the SNL being “missed” during surgery when an axillary node clearance was performed, which would explain the reported higher axillary recurrence rates in the pre sentinel node period compared to the sentinel node period. Another possibility is that the SN is undergoing more detailed histopathological assessment as there are fewer number of lymph nodes to be examined.
P3-07-34
Occult Metastasis in Sentinel Node: Should This Affect the Clinical Decision Making? A Systematic Review and Meta-Analysis.

Background: The role of occult metastases (micrometastasis or isolated tumor cells [ITC]) in sentinel lymph nodes (SLN) remains a field of debate and speculation. The purpose of this systematic review and meta-analysis was to investigate the prognostic relevance of occult metastases in SLN.

Methods: We searched PubMed, without year or language restriction through June 2011, for studies on patients with invasive breast cancer with micrometastasis or ITC in the SLN and presented Hazard Ratios (HR) on Overall Survival (OS) / Disease-Free Survival (DFS) or enough data for HR-calculation. We used fixed- or random-effects meta-analyses, as appropriate, to calculate pooled estimates of HR.

Results: Fifteen studies were considered eligible. Of those, 3 studies were excluded due to the lack of data for HR-calculation. Both the presence of ITC (5 studies; 1264 patients with ITC) and micrometastasis (10 studies; 1093 patients with micrometastasis) were associated with worse DFS (pooled HR 1.29, 95% Confidence Interval [CI]: 1.09-1.52, P-value = 0.002 for ITC, pooled HR 1.45, 95% CI: 1.28-1.64, P-value < 0.001 for micrometastasis). No significant differences were observed regarding OS neither for the presence of ITC (5 studies; 877 patients with ITC; pooled HR 1.20, 95% CI 0.98-1.46) nor for micrometastasis (8 studies; 1094 patients with micrometastasis; pooled HR 1.36, 95% CI: 0.98-1.88).

Conclusion: Based on the current evidence, it seems that the presence of occult metastasis in SLN is of prognostic significance in regard to DFS. However, the clinical significance of this difference is questioned since it cannot be translated into differences in OS. In anticipation of randomized trials aimed at evaluating the optimal management of each category of tumor burden within SLN, current evidence suggest a limited clinical significance of occult metastases in SLN.

P3-07-35
Tanaka S, Sato N, Fujioka H, Takahashi Y, Kimura K, Iwamoto M. Osaka Medical College, Takatsuki, Osaka, Japan

Purpose: Axillary lymph node dissection (ALND) is recommended for breast cancer patients with sentinel lymph node (SLN) metastasis, but further nodal disease is not always present. Several models exist for predicting non-sentinel lymph node (non-SLN) metastasis in SLN metastasis. This study evaluated and compared the predictive values of the Memorial Sloan-Kettering Cancer Center (MSKCC) nomogram and the Stanford nomogram, which were conveniently available online, and clarified their usefulness for the micrometastasis or isolated tumor cell (ITC) subgroup.

Methods: Data from 89 patients with positive SLN biopsy who underwent ALND were used, including 59 patients with micrometastasis and 30 with micrometastasis/ITC. The predicted probability of non-SLN metastasis was calculated using a computerized model from the websites for each nomogram. Results were compared using area under the curve (AUC) of the receiver operating characteristics curve for each model. False-negative and false-positive rates were also calculated.

Results: AUC for the entire population was 0.701 with the MSKCC nomogram and 0.756 with the Stanford nomogram. AUCs of micrometastasis and micrometastasis/ITC were 0.680 and 0.469 with the MSKCC nomogram and 0.676 and 0.574 with the Stanford nomogram, respectively.

Although false-negative cases were not identified, false-positive rates were high in both subgroups with these nomograms.

Conclusions: This independent comparison found no significant difference between the two nomograms. In our results, these nomograms could not reliably predict positive non-SLN in cases with SLN micrometastasis/ITC. Further validation in other patient populations is needed.

P3-07-36

Background: The Memorial Sloan-Kettering Cancer Center (MSKCC) developed a nomogram to predict the presence of sentinel lymph node (SLN) metastasis in breast cancer patients. In our study, The MSKCC nomogram performance for prediction of SLN metastases was assessed in Chinese breast cancer population. A new model (Shanghai Cancer Center Nomogram, SCC nomogram ) was developed with clinically relevant variables and possible advantages.

Methods: Data were collected from 771 patients with successful SLN biopsy who were treated during March 2005 to June 2010. Touch imprint cytology (TIC) and serial section with H&E staining were performed routinely on each sentinel node. 580 SLN biopsy procedures from March 2005 to November 2009 were used as training group to validate the MSKCC nomogram and assessed with multivariable logistic regression to predict the presence of SLN metastasis in breast cancer. The predictive accuracy of MSKCC nomogram was assessed by calculating the area under the receiver-operating characteristic (ROC) curve (AUC). The SCC nomogram was created from the logistic regression model. The new model was subsequently applied to 191 sequential SLN biopsies from January 2010 to June 2010 as the validation group.

Results: It was shown that age, tumor size, tumor type, histological grade, lymphovascular invasion and neural invasion was correlated with the probability of SLN metastasis by univariate analysis (P<0.05). By multivariate analysis, tumor size, histological grade and
lymphovascular invasion were identified as independent predictors of SLN metastasis. The SCC nomogram was then developed with four variables associated with SLN metastasis: age, tumor size, histological grade and lymphovascular invasion. The new model was accurate and discriminating, with AUC of 0.773 when applied to the validation group, as compared to the MSKCC nomogram with AUC of 0.754 in the modeling group. The trend of actual probability in various decile groups was comparable to the predicted probability. For predicted probability cut-off points of 7% and 15%, the false-negative rates of SCC nomogram were 0% and 8.1%.

Conclusion: As far as we know, this is the first study designed to evaluate the MSKCC nomogram and develop a new nomogram in Chinese early breast cancer population. Compared to the MSKCC nomogram, the SCC nomogram was developed with similar AUC but less variables and lower false-negative rates for low-probability subgroups. It could provide a more acceptable clinical accessory in the preoperative discussion with patients, especially in the very low risk of patients. For those patients, the SCC nomogram could be used to safely avoid a SLN procedure, thereby reducing postoperative morbidity, whereas the rate could be as high as 7% in the literature. Although the SCC nomogram that predicts metastasis of breast cancer in the sentinel lymph node performed well in Chinese breast cancer population, it is imperfect. The SCC nomogram was developed and validated in the single instite. The SCC model should be validated in different patient groups before it is demonstrated to be reproducible and would be applied widely.

Hegg R, Mattar A, Gebrim LH, Emenerciano K, Pinotti M, Perdicaris M, van Eyll B, Franke F, Pinczowski H, Freitas Jr R, Jendiroba D, Borges G, Queiroz G, Nascimento YV, Gampel O, Matias C, Buel V, Strepassos E, Delgado G, Perola Byington Hospital, Sao Paulo, SP, Brazil; Liga Norte Riograndense; EGIMAJAP; Instituto Santista de Oncologia; Servidor Publico do Estado de Sao Paulo; Nucleo de Oncologia da Bahia; Universidade Federal do Para; Hospital Sao Rafael; Hospital Santa Lucinda

Background: Breast cancer is the most common type of cancer among Brazilian women with almost 50,000 new cases per year. There are few data regarding the clinical presentation, treatment and specially outcome of this population. Brazilian health system is composed by Public institutions (Pu), Private centers (Pr) and some institutions that assist both Public and Private patients (PuPr).

Material and Methods: We collected data from 17 cancer centers distributed throughout Brazil among Pu; Pr and PuPr centers. We’ve analyzed data from 1-clinical characteristics, 2-pathologic characteristics and 3-type of treatment received among 2435 patients from May 2008 to May 2009.

Results: Mean age at diagnosis was 53 years, with about 30% below age 50. Most of the cases were Invasive Ductal Cancer (83%). Stage 0 was seen in 3.2%, Stage I in 21.8%, Stage II in 46.6%, Stage III in 24.6% and Stage IV in 3.9%. Clinical Stage III + IV was seen in 18.5% of the Pu institutions, only 3.7% of the Pr ones and about 6.2% among those PuPr. Hormone receptors were positive in 55%. Her-2 was overexpressed in 27.3% of the patients, and triple negative were seen in 11.6%. Most of the patients were submitted to surgery (92.9%). In Pu institutions only 36% of the patients were submitted to Breast Conserving Surgery (BCS) and in the Pr institutions 49.4% of the patients were submitted to BCS and in the PuPr 47%. Breast reconstruction was made in 15.8% and did not differ between Pu and Pr institutions. Sentinel node biopsy was done in 30.6% of the patients (26.8% of the patients from the Pr institutions and 26.8% of the Pu ones and 33% among PuPr). Neoadjuvant treatment was done in 21.5% of the patients (Pu=27.2%; Pr=13.9% and PuPr 13.2%). Most of this neoadjuvant treatment was chemotherapy (93.8%) and only 4.3% was hormone therapy (HT). 30% of the patients received AC, 41% A+taxane and 18.9% FAC/FEC. Besides we have almost 30% of Her-2 overexpressed only 1.1% of the patients received trastuzumab in the neoadjuvant setting. Tamoxifen was used in 48.3% when neoadjuvant HT was done, and aromatase inhibitor (AI) was used in 34.5%. Most of the patients received any kind of adjuvant treatment (89.2%). Chemotherapy was done in 76.6% and hormone therapy in 69.8%. When chemotherapy was used the preference regimen was FAC/FEC (27.3%), followed by CMF (17.5%) and AC (11.9%). Trastuzumab was used in only 5.8% of the patients (Pu=6.8%, Pr=18.3% and PuPr 3% among all patients that received chemotherapy). In the adjuvant setting, Tamoxifen (TAM) was prescribed in 69.8% of the cases (Pu=87.6%, Pr=79.6% and PuPr 78.8%), AI in 8.2% (Pu=5.9%, Pr=9.3% and PuPr 13.8%), and sequential TAM/AI in 6.6% (Pu=61%, Pr=8.3% and PuPr 6.4%). About 17% of the patients had metastasis.

Conclusions: There are important differences between the public and private institutions in Brazil, the patients from the Pu institutions were five times more likely to be diagnosed in stage III or IV, they usually receive neoadjuvant treatment, and when surgery was done, most of them were treated with radical procedures. Besides the overexpression of Her-2 (30%) a minority of the patients received treatment with trastuzumab even for the Private centers (high cost for a developing country).

P3-07-38 Selective Omission of Blue Dye in Patients Undergoing Sentinel Lymph Node Biopsy for Breast Cancer.

Waters JL, Iqbal M, Jones L, Harries S, Clarke D, Warwick Hospital, South West Warwickshire Foundation Trust, Warwick, West Midlands, United Kingdom

Background: Combined blue dye and radioisotope colloid injection with scintigraphy is standard practice for mapping and biopsy of sentinel lymph node in breast cancer within the UK. Whilst this combination aids sentinel node detection rate, blue dye has a number of possible adverse effects including anaphylaxis (reported as 1-3% of patients), semi-permanent skin tattooing and staining of bodily fluids which may cause distress for the unwary patient. It can also cause obscuration of the operating field, making identification and dissection of planes more difficult.

Methods: Patients undergoing sentinel lymph node biopsy (SLNB) using either a combination of blue dye and radioactive colloid, or radioactive colloid alone during a 14 month period were compared for identification rate, node harvest number and final positive rate. A total of 122 axillary sentinel node biopsies in 121 patients were identified. All patients scheduled for sentinel lymph node biopsy had intradermal injection of radiocolloid and lymphoscintigram pre-operatively and were checked for radioactive intensity with gamma probe on the table before draping for surgery. Patients with good signal proceeded to surgery without blue dye. Those with more than 3 nodes (n=9), radioisotope skin contamination (n=2), absent signal on scintigraphy (n=7) and/or with weak pre-operative radioactive
signal (n=22) were given 2 millilitres of patent V dye subdermally in the periareolar region. Sentinel node biopsy then proceeded in the standard fashion. Data was also collected from the year prior to be used as a control group, where the combination of blue dye and radioisotope was used for all patients (n=90), and compared with the group receiving radioisotope alone.

**Results:** The rate of identification for single agent and dual agent was 100% and 97.5% respectively, with no significant difference in mean node harvest using radioisotope alone (1.80) as compared to combined technique (1.87 p= 0.88, 95%CI 0.39 to 0.34). There was no significant difference in the number of patients with positive nodes on final histology when using single agent (13 (14%)) when compared to the dual agent technique (10 (25%) p=0.21). There was also no difference in the rate or number of node harvest in the group who underwent the single agent technique when compared to the control group (100% identification, mean harvest 1.84, p=0.77, 95% CI 0.36 to 0.27), with no difference in node positivity (16 (17%) p=0.68). No intra operative adverse reaction was reported in any of the groups.

**Discussion:** This study has shown no significant difference in the localisation rate when selectively omitting blue dye in suitable patients compared to the combined technique. This may be due to significant operator experience or change in the method of radioisotope injection since initial studies were performed. In this study, 86 out of 126 SLNB proceeded without blue dye, meaning not only a reduction in the number of patients with minor adverse effects, but also a potential reduction in severe adverse reaction of 68% or 2 patients per year within this breast unit.

**P3-07-39**

**Where To Look for Sentinel Lymph Node in Breast Cancer.**

Düran A. Klinikum Bayreuth GmbH, Bayreuth, Bayern, Germany

**Hypothesis:**
The sentinel Lymph node (SLN) is not only the first extra mammary point of metastatic spread, it also undergoes reactive changes. Sonographically this is evident through an increased width of the hypo-echoic cortex of the lymph node. We examined, if it is possible to localize SLN on sono-morphological features, if it is sonographic detection comparable with the radio nuclide tracer method and if false negative rate (FNR) of SLNB can be reduced by ultrasound.

**Method:**
From 1/2001 to 5/2003, 117 patients with breast cancer where prospectively examined for SLN localization using sonography in addition to radio nuclide -Tc99m- and/or patent blue-methods. The lymph node identified as the SLN in ultrasound was marked using a hook-wire. The sonographic parameters used to identify the SLN were: The node with the widest hypo echoic cortex, located in the caudal axilla and the closest to the glandular tissue and with the greatest diameter.

**Results:**
In all 117 patients, in the region of the caudal axilla, an enlarged, reactive, either tumor free or metastatic SLN could be verified. The location of the SLN was in all cases on the lateral-caudal thoracic wall and consistent with the lymph node group at the lateral border of the pectoralis major. The sonographic detection rate of the SLN was 86%. 70.6% of the sentinel lymph nodes where affected by metastatic spread. In those patients with a pT1a-c-tumor the rate of SLN metastatic spread was 20%. The false negative rate (FNR) for SLN localization with Te99mBlau was 10.6 %. Experience has shown that the FNR increases with increasing degree of metastatic spread to the SLN. With the addition of sonography of the axilla the FNR could be decreased to 3.5%.

**Sonographic SLN detection rate: 86% (n=101/117)**

**False-negative-rate (Blue/Tc) 10.7% (n=6sln-/56N+)**

**False-negative-rate (Blue/Tc + Sonography) 3.5% (n=2sln-/56N+)**

**Conclusions:**
The false-negative-rate of detection of suspected lymph nodes can be reduced using sonographic localization of the SLN. Sonography of the axilla should therefore be an integral part of and standard in the sentinel node-biopsy of breast cancer patients.

**P3-07-40**

**Impact of the Sentinel Lymph Node Procedure on the Detection of Positive Lymph Nodes in Breast Cancer.**

**Introduction:**
The objective of the sentinel lymph node (SLN) procedure in breast cancer is to perform an accurate axillary staging and provide good local control, while sparing the patients the morbidity of an axillary lymph node dissection (ALND). Since its routine clinical use, questions have been raised concerning the upstaging of a subgroup of node-negative patients and an increase in the overall percentage of node-positive patients.

The goal of our study was to investigate the impact of the SLN procedure on the detection of positive lymph nodes.

**Patients and methods:**
We included 1119 consecutive breast cancer patients from one center (2007-2009) who underwent primary surgery for a breast cancer smaller than 5 cm diameter without clinical involvement of axillary lymph nodes. 31 patients had a bilateral breast cancer.

**Results:**
We compared the SLN biopsy group (n=90) with the ALND group (n=828). In univariable analysis, the rate of node-positive patients was not significantly different in the two groups (16% versus 17%, p=0.68). The difference in the rate or number of node harvest in the group who underwent SLN biopsy as compared to ALND was not significant (p=0.77). The false-negative rate (FNR) of SLNB can be reduced by sonography.

**Conclusion:**
For comparable tumors, the chance of detecting positive lymph nodes is not lower when applying SLN procedure compared to ALND. The results even point in the direction of a higher detection rate with SLN.
However, care should be taken in making this conclusion given a non-significant result.

**Lymphovascular Invasion Best Correlates with Presence of Nodal Metastasis in Sentinel Lymph Node Biopsy.**

Ahsar MS, Adelekan MO, Patel E, Cotterill S. North Manchester General Hospital, Manchester, United Kingdom; University of Manchester, Manchester, United Kingdom

Background. Sentinel lymph node biopsy (SLNB) biopsy is routinely practised for axillary staging with 25-30% having positive SLN. Tumour size is the most important parameter taken into consideration in decision making in node negative patients with a size cut off for 4-5cm dependent on different units. Lymphovascular invasion (LVI) and Ki-67 a cell-cycle antigen are known important prognostic markers along with the tumour grade, oestrogen receptor and herceptin receptor status.

Aim. To examine whether lymphovascular invasion, Ki-67 or any other factors can be used as a predictor for axillary lymph node involvement and hence prognosis.

METHODS. A prospective study of 264 patients with invasive breast cancer undergoing SLN biopsy between January 2009 and December 2010. Histopathology reports were reviewed regarding LVI, Ki-67, grade, oestrogen, Progesterone and Herceptin receptor and SLN status. Stats direct was used to analyse data. Logistic regression was used and p-value calculated.

RESULTS. LVI (p value=0.0001) and size(p value=0.0273) were the two most significant factors associated with node positivity. Grade of tumour had a p-value of 0.0825 and Ki67 had a p-value of 0.5217 which were not significant.

**DISCUSSION.** LVI is the factor which best correlates with presence of metastasis in sentinel lymph node. If this information is available at the time of decision making, it should be strongly considered and pathologists should be encouraged to provide the information. In the absence of LVI, size still remains the best predictor of sentinel lymph node metastasis pre-operatively although consideration of other factors, such as the grade is definitely relevant.

**P3-07-43**

**The Impact of Timing in Sentinel Lymph Node Biopsy in Primary Breast Cancer.**

Gäth U, Schmid SM, Myrrick ME, Obermann EC, Viehl CT, Rochlitz C, Forrer F. University Hospital Basel, Basel, Switzerland

Background. There is minimal data concerning the impact of timing on the radiolabeled colloid marked sentinel lymph node (SLN) procedure. Some surgeons believe that the operation should be performed as the first case in the morning because a delay could theoretically lead to a variation in number of lymph nodes removed; there could be a) an artificially higher number due to diffusion of the radiolabeled colloid, or b) a lower number due to decay of the radiolabeled colloid. We examine the correlation between the number of SLN removed and the time of day when the SLN procedure was performed.

METHODS: Between January 2003 and December 2009, 391 SLN procedures were performed in histologically confirmed invasive breast
carcinomas at the University Women’s Hospital Basel, Switzerland. In line with the procedure defined by the “Swiss Multicenter Sentinel Lymph Node Study in Breast Cancer Patients”, each patient underwent standard labeling, removal and pathological diagnosis of the SLN. In all cases, lymphatic mapping was performed with 99mTc-labeled nanocolloid the day before the operation between 2.00 and 3.00 p.m. In addition, 2-4 ml of patent blue V was injected 5-10 minutes prior to incision. The radiolabeled colloid marked SLN were intraoperatively identified by the use of a handheld gamma probe. All samples were sent for immediate assessment to the local Institute of Pathology. The number of lymph nodes was determined and frozen sections were performed.

The timing of the SLN removal can be pinpointed unequivocally in all cases, since the pathology report records the arrival of the tissue samples for frozen section to the exact minute. In order to analyze the correlation between the timing of surgery on the operation day and the number of lymph nodes removed, we calculated the minutes from the beginning of the operating schedule in the morning (8.00 a.m.) until the arrival of the tissue samples in the frozen section laboratory (including subtraction of fifteen minutes handling and transport time). In order to calculate the association between the timing of the operation on the operation day and the number of the SLN removed, nonparametric spearman correlation (Spearman-Rho) was used; negative values of the coefficient rho indicate a descending trend.

Results: In 391 procedures, 928 SLN (median: 2; range: 1-11) were removed. Although blue dye was used in all cases, in the majority of cases (50.8%, n=471) the SLN were marked exclusively by radiolabeled colloid and only detected by the use of the handheld gamma probe. Only in 27 of the 928 SLN (2.9%), did the surgeon identify the lymph nodes through the blue coloration alone. The median time between start of the operation timetable and the SLN removal was 150 minutes (range: 25-420). There was a weak negative association between timing and the number of SLN removed (Rho=-0.070; p=0.168), i.e. there was a small, non-significant decrease in the number of SLN removed at a later time in the day.

Conclusion: After mapping SLN the previous day by using radiolabeled colloid method, the timing on the day of the operation has no relevant impact on the number of SLN removed.

P3-07-44
Noguchi M, Ohno Y, Nakano Y, Noguchi M, Kosaka T. Kanazawa Medical University, Kahoku, Ishikawa, Japan

Background: The axillary reverse mapping (ARM) procedure is based on the hypothesis that the lymphatic drainage from the upper arm is different from that of the breast. However, the oncologic safety of the procedure has not yet been determined.

Methods: The ARM nodes were identified using a fluorescence imaging system. Sentinel lymph node (SLN) biopsy was performed in patients with clinically uninvolved nodes. If the SLN was positive, ALND was performed with removal of ARM nodes. Otherwise, the identified ARM nodes were preserved unless they were the same as the SLN.

Results: The ARM node was identified in 30 of 91 patients who underwent SLN biopsy, and it was the same as the SLN in 23 patients. However, in 13 patients with a positive SLN who subsequently underwent ALND, ARM nodes were tumor-free when they were not the same as the positive SLN.

Conclusions: There are limits to the principle of non-overlap between breast and arm nodes. However, it may be feasible to spare ARM nodes during ALND in patients with clinically negative nodes.

P3-07-45
Role of SPECT-CT in Detecting Sentinel Lymph Nodes in Patients with Ipsilateral Breast Cancer Recurrence and Previous Axillary Lymph Node Dissection.
Cordoba O, Perez-Ceresuela F, Roca I, Mendoza C, Fortadellas T, Espinosa-Bravo M, Rodriguez J, Peg V, Rubio IT, Xercavins J. Hospital Universitari Vall d’Hebron, Barcelona, Spain; Universitat Autònoma de Barcelona, Barcelona, Spain

Background: Use of sentinel lymph node dissection in patients with ipsilateral breast cancer recurrence and a previous axillary lymph node dissection (ALND) is still controversial. Although previous reports have showed extra-axillary drainage in 40-60% of patients, the clinical significance of this drainage is unknown. SPECT-CT may help to localize aberrant sentinel nodes.

Material and Methods: Between 2008 and 2011, SLN were performed in 25 patients with ipsilateral breast cancer recurrence and previous ALND. The day before surgery 99Tc nanocolloid was injected retroareolar in the affected breast and injected intratumorally when the recurrence was after a mastectomy. Lymphoscintigraphy was obtained in all patients and a SPECT-CT was performed in all cases even when planar images showed no drainage. During surgery, the sentinel node was identified using a gamma probe. During the procedure the surgeon decided to remove the sentinel node if it was considered technically feasible. The project was IRB approved and all patients signed an informed consent.

Results: Records from the previous ALND showed 9 patients with positive axillary nodes with a mean of 19 (range 10-35) lymph nodes excised. Twenty four patients had undergone a lumpectomy and 1 patient a mastectomy. After the injection, the SPECT-CT showed at least one hot spot in 20 patients, with a mean of 1.8 hot spots (range 0-5). Hot spots on SPECT-CT were located as follows: in 10 patients axillary, 1 subclavicular, 7 internal mammary, 1 intramammary, 1 mediastinic and 7 patients had a contralateral axillary hot spot. In 4 patients we don’t found any hot spot on SPECT-CT. After excising 2 axillary nodes and 1 intrammary node in 3 patients, the pathologist didn’t identify any lymph node in the hot spot removed. This are considered as false positives (15%). In 4 patients although hot spots were identified, sentinel node dissection wasn’t performed because it was arguable the benefit for the patients taking into account the location and number of hot spots.

All this 4 patients are free of disease and any of them have developed recurrences. In 14 (56%) patients all the sentinel nodes were identified and removed. Three (3/14 = 21%) patients had positive sentinel nodes (1 in the ipsilateral axilla, 1 internal mammary and 1 in the contralateral axillary). One patient had 2 positive contralateral axillary sentinel nodes so an ALND was performed with no additional positive nodes. No surgical complications were observed.

Conclusions: In patients who had a previous ALND who develop a breast cancer recurrence, the SPTC-CT might show the exact location of aberrant hot spots but, some of the identified as hot spots may not
be lymph nodes. We must consider the exact location of the hot spot and the likelihood of false positives to avoid additional morbidity on the procedure.

**P3-07-46**

Accuracy of SPIO-Enhanced MR Imaging Alone for the Diagnosis of Sentinel Node Metastases in Patients with Breast Cancer.

Motomura K, Nakahara S, Ishitobi M, Komoike Y, Koyama H, Inaji H, Horinouchi T, Nakanishi K. Osaka Medical Center for Cancer and Cardiovascular Diseases, Osaka, Japan

**Background:** Superparamagnetic iron oxide (SPIO)-enhanced MR imaging has been reported to be promising for the detection of metastases in sentinel nodes localized by CT lymphography in patients with breast cancer (Motomura, Ann Surg Oncol 2011). The current SPIO technique involves imaging before and after contrast administration. This study evaluated the accuracy of SPIO-enhanced MR imaging alone without unenhanced imaging.

**Methods:** This study included 120 patients with breast cancer demonstrating clinically negative nodes. Sentinel nodes were identified by CT lymphography, and MR imaging of the axilla before and 18-24 hr after interstitial administration of SPIO was performed. A node was considered non-metastatic if it showed a homogenous low signal intensity and metastatic if there was an absence of low signal intensity either in the entire node or in a focal area on SPIO-enhanced MR imaging. The diagnostic accuracy of the SPIO-enhanced imaging alone was compared with that of combined unenhanced and SPIO-enhanced imaging.

**Results:** The mean number of sentinel nodes identified by CT lymphography was 1.2 (range 1-3). Pathologic evaluation demonstrated that 28 (23.3%) of 120 patients showed metastasis to at least one node. One false negative result was added when the evaluation was based solely on SPIO-enhanced MR imaging. Consequently, the sensitivity decreased from 84.0% to 80.0% and the accuracy decreased from 92.2% to 88.3%, respectively, in the SPIO-enhanced MR imaging alone. However, the differences in sensitivity and accuracy between SPIO-enhanced MR imaging alone and the combined unenhanced and SPIO-enhanced imaging were not significant (McNemar's test: p=1.0). The specificity of enhanced imaging alone and that of combined unenhanced and SPIO-enhanced imaging were both 90.5%.

**Conclusions:** A single MR imaging examination performed after SPIO administration can be used for accurate diagnosis of sentinel node metastases, and thus reduce the time and cost of imaging.

**P3-07-47**

Validated Nomogram To Predict Sentinel Lymph Node Positivity in Breast Cancer Patients.

Kaplan R, Qiu Q, Monni S, D’Alfonso T, Shin SJ. The New York-Presbyterian Hospital - Weill Cornell Medical College, New York, NY

Background: Sentinel lymph node (SLN) biopsy is commonly used to assess axillary lymph node status in breast cancer patients. Intraoperative (frozen section) evaluation of SLN may lead to immediate axillary dissection if the lymph node is found to be positive. In light of the recent outcomes of the Z00011 trial, the use of intraoperative evaluation for SLN should diminish since only select patients appear to benefit from axillary dissection. We have previously reported that tumor size and lymphovascular invasion (LVI) strongly predict SLN positivity in a cohort of 350 breast cancer patients [Modern Pathology (2011) 24, 30A]. From this test cohort, we developed a nomogram which could help identify patients more likely to have sentinel lymph node positivity. The aim of this study was to validate the efficacy of this nomogram by applying a new, non-overlapping cohort of breast cancer patients who had undergone sentinel lymph node sampling. Materials and Methods: 93 breast cancer patients aged 29-82 (mean:59) who underwent excision (54, 58%) or mastectomy (39, 42%) with a SLN biopsy were studied. Patients who had undergone neoadjuvant chemotherapy were excluded. Clinicopathologic parameters such as number of sentinel lymph nodes removed and/or positive, number of non-sentinel lymph nodes removed and/or positive, tumor size, histologic type/grade, presence of lymphovascular invasion, biomarker expression (ER,PR, HER-2/neu) and multifocality were recorded. Statistical analysis was performed to identify which variables correlated with SLN positivity in this validation cohort. In addition, the probability of SLN positivity for each case was determined by using the nomogram and this value was then compared to the patient’s true SLN status. Results: When analyzed separately, tumor size (p<0.03) and LVI (p<0.01) were variables that were significantly associated with SLN positivity in both the test and validation cohorts. Employment of the nomogram demonstrated that 60% of patients who were predicted to have a positive SLN with at least 0.5 probability were truly positive by histologic and immunohistochemical examination. Moreover, 89% of patients who were predicted to have a negative SLN with at least 0.8 probability were truly negative by histologic and immunohistochemical examination. Conclusions: We conclude that the utility of this nomogram prior to surgery can help predict SLN positivity. This can serve as a complimentary adjunctive tool to better select patients who will likely need intraoperative evaluation of their sentinel lymph node due to their higher risk of sentinel node positivity and thus, benefit from the option of immediate axillary dissection at that time.

Axillary Imaging with Dynamic MRI Following Subcutaneous Injection of Superparamagnetic Iron Oxide Nanoparticles.

Douek M, Johnson L, Parikh J, Charles-Eduards G, Hall-Craggs M. King’s College London, London, United Kingdom; Guy and St Thomas’ Hospitals, London, United Kingdom; University College Hospital, London, United Kingdom

Background: Surgical axillary staging with sentinel node biopsy in clinically node negative patients is standard of care in the management of breast cancer. However, sentinel node biopsy is associated with morbidity including a 5% risk of lymphoedema. Superparamagnetic iron oxide (SPIO) enhanced axillary MRI is a promising novel imaging modality that could be used to characterize sentinel nodes non-invasively. We evaluated subcutaneous SPIO enhanced axillary MRI for pre-operative axillary imaging.

Material and methods: Patients scheduled for sentinel node biopsy as part of surgical management of early breast cancer were invited to undergo pre-operative axillary MRI. All images were acquired on a 1.5T scanner using a surface coil. The initial 7 scans were acquired on a Siemens Avanto and the later scans on an Achieva MRI scanner (Philips, Best, Netherlands). Following a T2-weighted morphological scan, patients were injected with 2ml of SPIO (4ml in the final 3 patients) subcutaneously into the circumareolar margin in the upper outer quadrant of the affected breast. Post injection, a slightly T2*-weighted dynamic scan was performed (gradient echo, TE = 1.53ms, TR=2.9ms, flip angle 7 degrees, 3mm slice thickness). In addition to the dynamic scan, in 16 patients, a T2 mapping sequence was performed at 10minutes and 120 minutes post injection (turbo spin echo, 8 equi-spaced TE's from 10 to 80ms, TR=2136ms, 3mm slices with an in plane resolution of 1.4x1.4mm). Image analysis was...
undertaken using Osirix (v3.8, 64-bit). Two consultant radiologists experienced at reading breast and axillary MRI reported all scans. Results: A total of 23 patients underwent axillary MRI with subcutaneous SPIO. Of these 18 patients (78%), uptake of SPIO was seen in sentinel nodes and lymphatic tracts. At least 1 sentinel node was identified in 17 patients (74%). A total of 106 nodes were identified (4.6 ± 1.7 nodes per patient) and of these 40 demonstrated a significant drop in signal intensity following SPIO injection (1.7±1.3 nodes per patient). All 3 involved nodes were seen to contain a metastatic deposit on MRI.

Discussion: Axillary MRI with subcutaneous SPIO injection is a robust method for imaging sentinel nodes. The normal node count of the axillary basin is lower than expected on histology, suggesting that only the larger nodes and those that take up SPIO are visualized on MRI.

P3-08-01
Effects of an Integrated Yoga Program on Mood States, Distress, Quality of Life, Diurnal Cortisol Rhythms and Natural Killer Cell Counts in Metastatic Breast Cancer Survivors.
Gopinath SK, Rao RM, Sanjeevarao VH, Diwakar RB, Basavalingiaah AS, Patil S, Raghuram N, Rama Rao N, Usharani RM. HCG - BIO Super Speciality Centre, Bangalore, Karnataka, India; Swami Vivekananda Yoga Anusandhana Samsthana, Bangalore, Karnataka, India

Background and objectives: Metastatic breast cancer patients experience tremendous psychological distress due to treatment, disease and uncertainty of their survival. In this study we evaluated the effects of an integrated yoga program versus supportive counseling in advanced breast cancer survivors.

Methods: Ninety one Metastatic breast cancer survivors (group mean age 50.54 yrs ± 8.53 yrs) registered in hospital based cancer registry were recruited if they satisfied selection criteria and gave written consent for participation in the study. The study was approved by the institutional review board. Subjects were randomized to either receive yoga intervention (n=45) or supportive therapy (n=46) counseling as a standard of care for 3 months of intervention period. Subjects were assessed at baseline and after intervention for mood states using hospital anxiety and depression scale, sleep quality using Pittsburg Insomnia rating scale, quality of life using EORTC QoL C30 for breast and perceived stress using perceived stress scale. Saliva samples were collected between 0800hrs to 01000hrs for NK cell enumeration using flow cytometry. 35 subjects in yoga and 31 group compared to controls. There was significant decrease in 0600 hrs cortisol within the yoga group (p<0.001), role function (p=0.03) alone. There was a significant drop in signal intensity following SPIO injection (1.7±1.3 nodes per patient). All 3 involved nodes were seen to contain a metastatic deposit on MRI.

Results: There was a significant decrease in anxiety (p < 0.001), depression (p < 0.001), perceived stress (p = 0.01), fatigue severity (p < 0.001) and interference (p < 0.001) in yoga group compared to controls post intervention. There was a significant improvement in emotional function (p < 0.001), role function (p = 0.03) and cognitive function (p < 0.001) and global quality of life (p < 0.001) in yoga group compared to controls. There was significant decrease in 0600 hrs cortisol within the yoga group (p =0.03) alone. There was a significant increase in Natural killer cell percent in yoga group (p =0.03) compared to controls after intervention. Conclusion: The results suggest biobehavioral effects of yoga intervention could possibly improve quality of life, reduce psychological distress and modulate abnormal cortisol profiles and immune responses in metastatic breast cancer patients.

P3-08-02
Evaluating the Impact of Educational Material on Anastrozole Treatment Adherence – The Final Results of the ARTEMIS Study.
Nogaret J-M, Coibion M, Neven P, Soepenberg O, Graas M-P, Deschamp V, Vanlerberghe T, Jules Bordet Institute, Brussels, Belgium; CHC St-Vincent, Rocourt, Belgium; University Hospital Leuven, Leuven, Belgium; MariaZiekenhuis, Noord-Limburg, Belgium; CHC Saint-Joseph, Liège, Belgium; AstraZeneca Benelux, Brussels, Belgium

Rationale: Breast cancer (BC) is the most common cancer in European women. Compliance with the prescribed dosing regimen is essential for optimal effectiveness of cancer treatment. While adjuvant endocrine therapy reduces the risk of BC recurrence, only limited information is available regarding patient adherence to this type of treatment. Electronic monitoring of patients’ dosing histories has demonstrated the frequently irregular drug intake of patients. The ARTEMIS study (Arimidex Therapy compliance Electronic MonitorIng System, NCT00936442) evaluated the impact of educational material on the adherence to adjuvant treatment with anastrozole (Ax, Arimidex®).

Methods: This randomized (1:1), open-label, parallel-group study in 5 centers in Belgium had two treatment groups: GpA-Standard Treatment, GpB-Standard Treatment+Education. All patients received a 12 month follow-up of Ax treatment according to current clinical practice. Patients in GpB also received additional educational material on a regular basis (9 mailings). Eligible patients were postmenopausal women with hormone sensitive early BC prescribed Ax (<13 weeks duration). All patients received Ax (1mg orally/day) in a Medication Event Monitoring System (MEMS® AARDEX Ltd) that electronically records bottle openings. The 500 ml capacity contained medication for 6 months treatment to avoid additional clinical visits to resupply medication. The sample size was based on the primary objective: adherence to Ax (the daily proportion of patients taking Ax). Secondary variables included persistence with Ax (the estimated length of time during which the medication is taken), execution of the Ax regimen and reasons for treatment discontinuation.

Results: 107 patients (mean age 61.4±9.9 years) were enrolled: 54 in GpA, 53 in GpB. 16 patients (9 GpA, 7 GpB) discontinued prematurely based on the case report form with the MEMS system indicating that a further 4 patients (3 GpA, 1 GpB) discontinued. Overall, the adherence rate was high and decreased significantly over time (p=0.0061). There was no significant difference in adherence rate between the two groups (p=0.2358) with the daily average probability of correct intake 80.2±4.16% (GpA) and 86.7±4.94% (GpB). There was a trend for the persistence rate after 12 months to be better in GpB (84.7±5.0%) compared to GpA (77.8±5.7%; p=0.0782). An exploratory analysis showed a significant association between overall persistence and increasing postmenopausal age (Exp(coef)=0.942; p=0.038). The execution of the dosing regimen improved over time (p=0.0126) and was similar throughout the study for both groups (GpA: 96.5±3.1%, GpB: 94.0±3.1%; p=0.1674). Side effects (5 patients, 4.7%) were the most common reason for early discontinuation (GpA: 1 patient, GpB: 4 patients) but overall side effects were low.
Conclusion: Educational material by mail did not significantly affect patient adherence to anastrozole. Persistence with treatment was associated with the post-menopausal age of the women and showed a trend for improvement in those receiving educational material. Since anastrozole treatment normally lasts 5 years, a longer-term follow-up study may provide better insight into the usefulness of MEMS on treatment compliance.

P3-08-03
Exercise Increases Soluble Vascular Endothelial Growth Factor Receptor-1 (sFlt-1) in the Circulation of Adult Women.
Makey K, Patterson SG, Robinson J, Loftin M, Waddell DE, Miele L, Chinchar E, Huang M, Smith AD, Weber M, Gu J-W. University of Mississippi Medical Center, Jackson, MS; University of Mississippi, Oxford, MS

Background: Physical inactivity increases the risk of several different cancers, including breast cancer. Soluble fms-like tyrosine kinase-1 (sFlt-1) is an extra-cellular Ig-like domain of the VEGF receptor-1 that is released into the extracellular space and circulation where it inhibits the activities of VEGF. Over-expression of sFlt-1 has been shown to inhibit ovarian tumor growth in gene therapy experiments. The present study tests the hypothesis that exercise can increase sFlt-1 in the circulation of adult women.

Material and Methods: 63 African American and Caucasian adult woman volunteers aged 18-44 were enrolled into a prospective exercise study. All the participants walked on a treadmill for 30 minutes at a moderate intensity (40-60% heart rate reserve), and oxygen consumption (VO2) was quantified by utilizing a metabolic cart. Blood samples were collected before and immediately after exercise. The exercise test was conducted between the first and seventh day of the participant’s menstrual cycle. The plasma concentrations of sFlt-1, unbound VEGF, and endostatin were measured using ELISA kits from R and D Systems.

Results: Plasma levels of sFlt-1 were 67.8±3.7 pg/ml immediately after exercise (30 minutes), significantly higher than basal levels of 54.5±3.3 pg/ml before exercise (P=0.01; n=63). The % increase in sFlt-1 levels before and after exercise in adult women was 54%. There was no significant difference in the % increase of sFlt-1 levels between African American and Caucasian groups (P=0.5334). There was no significant difference in plasma levels of endostatin before (92.4±4.4 ng/ml) and immediately after (93.8±4.4 ng/ml; P=0.8216) exercise. The basal plasma levels of unbound VEGF (21.5±4.3 pg/ml) were similar to the plasma levels of VEGF (22.5±4.6 pg/ml; P=0.8652) immediately after exercise.

Discussion: We previously reported that plasma levels of sFlt-1 significantly increased 30 minutes after exercise in adult men, in which plasma levels of unbound-VEGF significantly decreased and plasma levels of endostatin significantly increased 2 hours after exercise. Until now, there has been no data on whether exercise increases plasma sFlt-1 levels in women. Our study is the first to show that exercise in adult women significantly increases plasma levels of sFlt-1. VEGF pathways have both autocrine and paracrine effects for promoting breast cancer progression. Previous studies have demonstrated that sFlt-1 inhibits the activities of VEGF and suppresses ovarian tumor growth in mice. Exercise-induced plasma levels of sFlt-1 could be an important clinical biomarker to explore the mechanisms of exercise training in reducing breast cancer progression. The sFlt-1 is produced in the microvascular and macrovascular endothelial cells that exist throughout the skeletal muscle tissues. It is therefore plausible that release of sFlt-1 from the skeletal muscles into the circulation might be due to exercise-dependent reductions in oxygen tension in the skeletal muscle. In future studies, we will determine whether sFlt-1 can be released directly from the exercised muscle.

P3-08-04
“How Important Is This for Me?” – The Role of Necessity Beliefs as Determinants of Breast Cancer Prevention Intentions among High-Risk Women.
Verma S, Paquet L, Stacey D, Davis I, Bedard M, Lowry S, Ianni L. The Ottawa Hospital Cancer Centre, Ottawa, ON, Canada; Carleton University, Ottawa, ON, Canada; University of Ottawa, Ottawa, ON, Canada

Background: Women at elevated risk for breast cancer (BC) face complex risk management decisions. Understanding the determinants of pre-counseling risk management intentions would be useful to clinicians in helping high-risk women make their decisions. Across several medical conditions, the Necessity-Concerns Framework (NCF) has emphasized the role of patient’ beliefs about interventions offered to them as central to decision-making. In the NCF, beliefs are conceptualized as perceived personal need for an intervention (necessity) and as concerns about its perceived negative effects. To date, the NCF has not been applied to investigate decision-making in the high-risk setting. Our objective was to use the NCF to describe the risk management beliefs of high-risk women prior to initial consultation.

The relative importance of BC fear, perceived susceptibility to BC and necessity-concerns beliefs in predicting prevention intentions was also examined. Methods: A survey was sent to patients prior to their first risk consultation. BC fear was assessed with Champion BC Fear Scale and perceived susceptibility was measured by asking women to rate their likelihood of developing BC (0 = definitely will not get it to 100 = definitely will get it). For each of screening, lifestyle modifications, pharmacoprevention (PP) and prophylactic surgery (PS), women rated (1 = strongly disagree to 5 = strongly agree) their need for the option (e.g., my health in the future will depend on this option, this option will protect me from becoming worse), and its negative consequences (e.g. I worry about the long-term effects of this option, this option will disrupt my life). Intentions were assessed by asking how strongly (1 = definitely not to 5 = Definitely Yes) they intended to adopt each option. The planned sample size is 100 women and recruitment is on-going. We report data from 44 women who have completed the questionnaire. Results: The majority intended to adopt screening (92%) and lifestyle (91%) compared to PP (23%) or PS (18%). Screening and lifestyle were associated with stronger intentions, higher perceived need, and lower concerns than PP and PS (all t-tests, p < 0.0001). Hierarchical regression analyses revealed that perceived need predicted intentions for each option (all ps < 0.005, except for screening, p < .1) whereas concern beliefs were only correlated with PP intentions (β = -0.398, p < .005). Fear of BC was related to PP intentions (β= -0.401, p < .005) and to intentions to remain smoke-free (β = -0.341, p < .05). Perceived susceptibility did not contribute to intentions. Conclusions: Our preliminary findings are promising and suggest that the NCF is useful for understanding decision-making in the high-risk setting. The findings emphasize the importance of necessity beliefs in BC risk management decisions. For the group as whole, across each risk management option, the strongest predictor of intentions was a women’s perception of her personal need for the option. Concerns about negative effects and BC fear played only a minor role and perceived susceptibility did not predict intentions. These observations stress the importance of making screening or prevention recommendations hand in hand with the individual beliefs and concerns.
P3-09-01
Change in Carbohydrate Intake and Breast Cancer Prognosis. Emond JA, Patterson RE, Pierce JP. UCSD Moores Cancer Center; La Jolla, CA; San Diego State University, San Diego, CA
Breast tumors over express insulin-like-growth-factor receptors (IGF-1R), and levels of expression may be inversely related to tumor grade. Dietary factors, particularly carbohydrate intake, may stimulate activation of IGF-1R and affect prognosis.
METHODS: Data are from N=2,651 women in the Women’s Healthy Eating and Living (WHEL) Dietary Intervention trial, a plant based intervention trial that did not have a carbohydrate goal. All women were diagnosed with breast cancer within the previous 4 years. Carbohydrate dietary intake data were extracted from multiple 24-hour dietary recalls at study entry and one year, and were compared by recurrence status. Time to recurrence was modeled on year-one change in carbohydrate intake adjusted for baseline intake, menopausal status, and disease, treatment, and study characteristics.
RESULTS: Baseline carbohydrate intake was 233 g/day. Women who recurred had a mean increase in carbohydrate intake over the first year, compared to those who did not recur (2.3 ±2.7 g/day; p=0.188). Change in starch intakes accounted for 48% of the change in carbohydrate intake (R-squared: 48%; p<0.001). Baseline starch intake did not differ by recurrence status (95.8 g/day; p=0.219). Mean year-one change in starch intake was -4.1 g/day among women who recurred vs -8.7 g/day among women who did not recur (p=0.015). Year-one change in starch intake was independent of the study intervention (p=0.326). In the adjusted model, a 5-g/day increase in starch related to a 3% increased risk of recurrence (HR=1.03; 95% CI 1.01 – 1.06; p=0.017). The increased risk was limited to women diagnosed with low grade tumors (Table 1).

DISCUSSION: Dietary modifications targeting starch intake warrant further investigation as a preventive measure against breast cancer recurrence.

P3-09-02
Intermittent Dietary Carbohydrate Restriction Enables Weight Loss and Reduces Breast Cancer Risk Biomarkers.
Harvie M, Wright C, Pegington M, Mitchell E, Evans DG, Jebb S, Clarke R, Goodacre R, Dunn W, Mattson M, Howell A. University Hospital of South Manchester, Manchester, United Kingdom; MRC Human Nutrition Research Group, Cambridge, United Kingdom; University of Manchester, Manchester, United Kingdom; National Institute of Aging, Baltimore
Background: Energy restriction is a potential strategy for breast cancer prevention but is difficult to achieve and maintain. We found that intermittent energy restriction (2 days strict dieting week) is comparable to the standard approach of moderate daily restriction for weight loss and marginally better for improving insulin sensitivity, but no easier to follow1. In this follow on study we wished to test whether 2 novel intermittent low carbohydrate/low energy diets were feasible and easier to follow than a standard daily energy restriction. Design: Randomised comparison of 3 dietary types over 4 months in 115 overweight or obese (mean body mass index 31.0 ±5.3 SD) kg/m² women at increased risk of breast cancer (lifetime risk > 1 in 6).
Diets:
1. A restricted low carbohydrate diet (RLCD): 650 kcal and <50g carbohydrate / day for 2 days per week
2. Ad lib low carbohydrate diet (ALCD): <50g / day for 2 days per week with other food types (e.g. protein) ad lib
3. A standard daily restricted Mediterranean diet (DRMD): ~1500kcal / day for 7 days per week

Methods: Weight, anthropometrics, blood markers for breast cancer; insulin resistance, oxidative stress markers, leptin, adiponectin, lipids, inflammatory markers IGF-1 were assessed at baseline, 1, 3 and 4 months.
Results: 88/114 completed the study (77%, drop outs 6 RLCD, 8 ALCD 12 DRMD). Last observation carried forward analyses show both intermittent low carbohydrate diets were superior to standard daily restriction for reducing weight and body fat: mean (95% confidence interval [CI]) change in body fat for RLCD was -4.3 (-5.6 to -3.0) kg, for ALCD -4.1 (-5.2 to -3.1) kg vs. -2.4 (-3.4 to -1.2) kg for DRMD (P value for difference between groups = 0.02). The intermittent groups had greater improvement in insulin resistance: mean (95% CI) change for RLCD was -22 (-35 to -11) %, ALCD -14 (-27 to -5%) % vs. -4 (-16 to 9) % for DRMD (P = 0.02). Other biomarkers are being assayed currently.
Conclusion: Greater weight loss, fewer drop outs and greater reductions in insulin resistance with the novel intermittent low carbohydrate diets indicate that these are alternative approaches for energy restriction for potentially reducing risk of breast cancer and other diseases.

Long-Chain Polynsaturated Fatty Acid Intake and Its Relationship to Long-Chain Polynsaturated Fatty Acids in Serum, Red Blood Cells and Breast Tissue.
Harvey KE, Li S, Carlson SE, Sullivan DK, Klemp JR, Kimler BF, Fabian CJ. University of Kansas Medical Center; Kansas City, KS
Background: Long chain omega-3 (n-3) polyunsaturated fatty acids (LCPUFA) have anti-inflammatory effects and are able to counteract the effects of the pro-inflammatory omega-6 (n-6) fatty acids such as arachidonic acid (AA) by substituting for the n-6 fatty acids in triglycerides (TG) and phospholipids (PL). Several pre-clinical, observational, and case control studies suggest that intake or tissue content of n-3 LCPUFA such as eicosapentaenoic acid (EPA), and docosahexaenoic acid (DHA), relative to intake or tissue content of long chain n-6 fatty acids such as AA may be associated with reduced risk of breast cancer. The goal of this study was to determine the relationships between dietary intake of fatty acids, tissue levels of fatty acids, and breast tissue biomarkers for risk of breast cancer.
Methods: Women (n=74) were recruited from a clinic in which women at increased risk for breast cancer had breast tissue acquired by random periareolar fine needle aspiration (RPFNA). Breast epithelial cells were assessed for cytomorphology and proliferation (Ki-67 immunochemistry). Fatty acid dietary intake was assessed with the National Cancer Institute Diet History Questionnaire. Plasma, erythrocyte, and breast specimens were processed for membrane PL and TG and analyzed for individual fatty acids by gas liquid chromatography.
Results: Total intake of n-3 PUFA was 1.1 ± 0.5 g/d, and the ratio of EPA+DHA:AA was 0.1:1.0 (n=66). Dietary n-3 LCPUFA correlated...
with n-3 LCPUFA in both plasma and erythrocyte PL (n=62). Breast epithelial cell number, Masood cytomorphology score, and percent Ki-67 positive cells were higher in RPFNFA specimens which exhibited cytologic atypia compared to those which did not (n=74; p=0.001, Mann-Whitney Test). Subjects with atypia consumed less dietary n-3 PUFAs (n=66, p=0.020), had lower plasma and erythrocyte PL and plasma TG EPA, DHA, total n-3, and EPA+DHA:AA (n=70; p=0.05). In breast tissue TG, the ratio of n-3:n-6 was also lower in subjects with atypia (n=40; p=0.025).

Conclusions: Overall, women in this high risk cohort consumed very low amounts of n-3 LCPUFAs. Dietary intake of n-3 LCPUFA was related to levels of n-3 LCPUFA in erythrocyte and plasma PL. Given the association of low levels of n-3 fatty acids with cytologic atypia (a known risk factor for breast cancer development), an intervention to increase n-3 fatty acids and n-3:n-6 ratios has merit and clinical trials in high risk women have been initiated.

P3-09-04
Comparative Preventive Efficacy of Aqueous Extracts from Lycium Barbarum Bark and Fruit on Estrogen Receptor Positive Human Mammary Carcinoma MCF-7 Cells.
Telang NT, Li G, Sepkovic DW, Bradlow LH, Wong GGY, Telang NT. Palindrome Liaisons, Montvale, NJ; American Institute for Chinese Medicine, New York, NY; Hackensack University Medical Center, Hackensack, NJ

Background: Chemotherapy, selective estrogen receptor modulators and aromatase inhibitors represent major treatment options for estrogen receptor positive (ER+) clinical breast cancer. These modalities frequently exhibit acquired resistance and adverse systemic toxicity. Natural herbs are increasingly being used in the integrative support of breast cancer patients undergoing conventional treatment modalities and for prevention purposes. We previously reported favorable findings for the fruit of Lycium barbarum (LB), known commonly as goji berry, in the prevention for ER+ breast cancer (Nutrition & Cancer 61:408-414, 2009). The present study compares the preventive efficacy of non-fractionated aqueous extracts from the bark of LB (LBB) and the fruit of LB (LBF) on a cell culture model for ER+ breast cancer.

Material and Methods: The ER+ human mammary carcinoma derived MCF-7 cells represented the model. Anchorage dependent growth, anchorage independent colony formation and cellular metabolism of 17β-estradiol (E2) represented the mechanistic bases for efficacy. Results: MCF-7 cells grown in serum depleted medium retained their responsiveness to E2, exhibiting E2 stimulated promotion of anchorage independent colony formation and cellular metabolism. LBB produced a 6.8 fold increase in 2-hydroxyestrone (2-OHE1), a 40% decrease in 16α-hydroxyestrone (16α-OHE1) and a 3.7 fold increase in estriol (E3) formation. The corresponding values for LBF were 3.9, 33 and 10.5. LBB treatment resulted in a 16.3 fold increase in estriol (E3) formation. The corresponding values for LBF were 3.9, 33 and 10.5. LBF treatment produced a 6.0 fold increase and a 2.9 fold increase, respectively, in these endocrine biomarkers. These data suggest that the preventive efficacy of LBB may predominantly be due to up-regulation of the anti-proliferative 2-OHE1 formation, while accelerated conversion of the pro-mitogenic 16α-OHE1 to the mitogenically inert E3 is the case with LBF.

Discussion: Growth inhibitory profiles of LBB and LBF may in part be due to their distinct chemical composition and their complementary actions on E2 metabolism. The superior sensitivity of LBB relative to LBF, together with its non-toxic nature, suggests the feasibility of its use in the prevention of human breast cancer. A prevention trial to assess its efficacy and to establish relevant dose schedule is warranted. This study validates a mechanism based approach to identify and prioritize efficacious herbal extracts for the prevention of ER+ breast cancer.

P3-09-05
Understanding the Role of Estrogen in Sex Differences in Adipocyte Biology for Cancer Prevention.
Stubbins RE, Holcomb VB, Hong J, Nunez NP. The University of Texas at Austin, Austin, TX

Background: Evidence shows that obesity increases the risk and mortality of many cancers, specifically breast cancer in post-menopausal women. Epidemiological studies demonstrate that males are at an increased risk for developing obesity, diabetes, and cancer compared to females, and after menopause, females mimic the males in their susceptibility to the above diseases. Furthermore, it has been established that obesity increases systemic and adipose tissue inflammation and oxidative stress, which is known to augment cancer progression. However, the role of estrogen in regulating these metabolic processes in adipose tissue is unclear; therefore, our objective is to determine the role of estrogen in adipose tissue morphology, inflammation and oxidative stress.

Methods: To determine the role of estrogen in gender differences in the susceptibility to obesity we used C57BL/6J mice (15/group): 1) males 2) nonovariectomized females 3) ovariecetomized females and 4) ovariecetomized females supplemented with estrogen, which were randomized to the following diets: 30% calorie-restricted, low-fat or high-fat diet. We measured weight gain, percent body fat, abdominal adipose tissue, and adipocyte size. Additionally, we assessed markers of adipose tissue inflammation, DNA damage, and oxidative stress.

Results: Male mice were more susceptible to obesity than female mice. Removal of the ovaries eliminated the protection to obesity and estrogen supplementation restored this protection in females. In the low-fat and high-fat diet groups, male and ovariecetomized female mice gained more abdominal adipose tissue due to increased adipocyte size compared to nonovariectomized female mice and ovariecetomized female mice supplemented with estrogen. In the mice consuming the high fat diet, the enlarged adipocytes observed in the male and ovariecetomized female mice were accompanied with crown-like structures surrounding necrotic adipocytes and F480 positive macrophages, suggesting macrophage infiltration. To determine if there were sex differences in oxidative stress, we stained adipose tissue with γH2AX. Results suggest that nonovariectomized female mice and ovariecetomized female mice supplemented with estrogen have less oxidative stress compared to males and ovariecetomized females. Additionally, our results show that nonovariectomized female mice and ovariecetomized female mice supplemented with estrogen have less oxidative stress compared to males and ovariecetomized females. In ovariecetomized females, estrogen supplementation has a protective effect against obesity, adipose tissue inflammation and oxidative stress.

Conclusion: Male mice are more susceptible to the obesogenic effects of high fat diets compared to nonovariectomized female mice. In ovariecetomized females, estrogen supplementation has a protective effect against obesity, adipose tissue inflammation and oxidative stress.
stress. Our future studies will determine the mechanisms by which estrogen protects female mice from adipose tissue inflammation and oxidative stress, whether it is a direct or indirect effect. Determining the role of estrogen on the above key metabolic processes related to obesity is necessary to develop effective strategies for cancer prevention specifically in post-menopausal females.

Changes of Serum Vitamin D According to the Breast Cancer Treatment.

**Kim HJ, Yi OY, Koh BS, Yu JH, Lee JW, Son BH, Ahn SH. Asan Medical Center, Seoul, Korea**

**Background**

Vitamin D deficiency is associated with increased breast cancer risk and decreased breast cancer survival. The purpose of this study was to determine the effect of breast cancer adjuvant treatment to the vitamin D status, as measured by the serum hydroxyvitamin D (25OHD) in breast cancer patients.

**Patients and Methods**

For 589 patients who was diagnosed as a non metastatic breast cancer in 2009 at the asan medical center, blood was prospectively analyzed in batches for serum 25 OHD level at basal and at 6 and 12month. We excluded the patients who took a vitamin D supplementation and got a neoadjuvant chemotherapy. Vitamin D sufficiency was defined as serum as 30ng/ml or greater, insufficiency as 20 to 29 ng/ml and insufficiency as less than 20ng/ml.

**Results**

At baseline, mean serum 25OHD was greater in summer (April to Oct) than Winter(Nov to May ) (28.2ng/ml vs 32.9ng/ml respectively, p=0.000). The patients who did not get a chemotherapy and anti-hormonal therapy as baseline, the patient with chemotherapy showed decreased serum 25OHD level than who without chemotherapy in 6 month but not in 12 month (p=0.003, vs p=0.156 respectively). The patients who had taken anti-hormonal therapy showed significant increasing serum 25OHD in 6 month and 12 months (p=0.000 both).

For the patients who got both chemotherapy and anti-hormonal therapy, the changes of serum 25OHD level is smaller than the patients who got a chemotherapy only.

For the patients who got a chemotherapy, 57% of patients were vitamin D sufficient at baseline, but 27% of patients in 6 month and 49% in 12 month (p=0.001).

**Conclusion**

Vitamin D status was worsen during chemotherapy but recovered after chemotherapy. Anti hormonal therapy make the serum vitamin D level increased. The translational research about the effect of chemotherapy and anti-hormonal therapy to the vitamin D status should be warranted.

**P3-10-01**

Alternative Dosing Regimens with the EGFR Inhibitors (Gefitinib and Lapatinib) in Mammary Cancer Models: Prevention and Therapeutic Efficacy.

**Lubet RA, Bode AM, Szabo E, Grubbs CJ. National Cancer Institute, Bethesda, MD; Hormel Institute, Austin, MN; University of Alabama at Birmingham, Birmingham, AL; Milwaukkee, WI**

The EGFR inhibitors are effective in treatment of lung and pancreatic cancers (erlotinib, gefitinib) and Neu overexpressing breast cancer (lapatinib) in humans; as well as preventing multiple cancers in animal models. However, the development of toxicities (Iressa, skin rashes; Lapatinib, diarrhea) limit their potential use in prevention; and perhaps even in an adjuvant setting. We examined whether alternative dosing regimens which might reduce toxicity would still achieve preventive and therapeutic efficacy. Female Sprague-Dawley rats were administered a single IV dose of methylnitrosourea (MNU) at 50 days of age. In a prevention study, MNU treated rats administered Gefitinib daily (10 mg/kg BW/day, 7x/week) or Gefitinib (70 mg/kg BW, 1x/week) beginning 5 days after MNU resulted in 94 and 75% reductions, respectively, in cancer multiplicity. Simultaneous measurements of tumor load (number of tumors x tumor weight) showed that both regimens resulted in greater than a 90% decrease. In the therapeutic study (initiating treatment when animals developed a small palpable cancer), both regimens were again highly effective. A prevention study was also performed with Lapatinib (75 mg/kg BW/day, 7x/week or 525 mg/kg BW, 1x/week). While the daily dose reduced cancer multiplicity 90%, the weekly dose caused a 70% reduction. Finally, we examined the effects of daily or weekly dosing with Iressa (100 mg/kg BW/day, 5x/week or 500 or 250 mg/kg BW, 1x/week) in an ER mouse model (using MMTV-Neu p53−/− mice). This study showed that while daily dosing with Iressa decreased tumor multiplicity roughly 80%, weekly dosing at either dose caused roughly a 50% decrease. These data show that even a significant alteration in the dosing of Gefitinib (EGFR 1) or Lapatinib (EGFR 2/1) still resulted in a large reduction in mammary cancers. The important clinical question will be whether this altered dosing will diminish the toxicities associated with these agents. We cannot determine this in animal models since, at the effective doses employed, the typical toxicities observed in humans are not observed. Supported by NC1 contract number HHSN261200433001C.

Gene Expression Changes in Methylnitrosourea (MNU)-Induced ER+ Mammary Cancers Following Short-Term Treatment of Rats with the Aromatase Inhibitor Vorozole.

**Lubet RA, Grubbs CJ, Bode A, You M, Lu Y. National Cancer Institute, Bethesda, MD; University of Alabama at Birmingham, Birmingham, AL; Hormel Institute, Austin, MN; Medical College of Wisconsin, Milwaukee, WI**

Aromatase inhibitors have proven to be highly effective in both therapy and prevention of ER+ breast cancer. Vorozole (R83842), a high affinity competitive inhibitor of aromatase (similar to letrozole and anastrozole) showed strong activity in early clinical trials against ER+ breast cancer. Furthermore, vorozole was highly effective in the prevention and therapy of ER+ cancers in the MNU-mammary cancer model (Lubet, et al., Carcinogenesis 19, 1345, 1998). In the present study, rats bearing mammary cancers induced by MNU were exposed to vorozole (1.25 mg/kg BW/day) for 5 days. Global gene expression analysis showed that 162 genes were down-regulated and 180 genes up-regulated in cancers treated with vorozole (p < 0.05 and fold change > 1.5). The genes modulated by vorozole were compared with two additional sets of data. First, thirty-two genes and a number of pathways exhibited significantly concordant changes with aromatase inhibitors both in the animal model and in at least three of four published human data sets. In particular, differentially expressed genes enriched in the cell cycle pathway that were related to chromosome condensation in prometaphase [including Aurora-A, Aurora-B, Bub1B, non-SMC condensin I complex, subunit H (BRN1), Condensin, CAP-G, CAP-G/G2, CAP-H/H2, CAP-D2/D3, CAP-E, TOP2, Cyclin A, Cyclin B, CDK1, Histone H1 and inner centromere protein (INCENP)] were downregulated after treatment with the aromatase inhibitor. These results appear to be in agreement with the strong anti-proliferative effects of aromatase inhibitors in both animal and clinical studies. A second comparison was with an
in vitro study in which estrogen was removed from MCF-7 cells in culture. Decreases in genes related to the E2F1 transcription factor were observed. In our study, 13 modulated genes exhibited E2F-1 binding sites in their promoter regions, and 7 genes contained both ER binding and E2F binding sites. We were able to confirm modulation of the cell cycle related and E2F-related genes in a large independent set of human samples treated with anastrozole. The results on RNA changes for Bub 1B, Cyclin A and CDK-1 were verified by employing IHC analysis. In summary, gene changes observed in the rat closely paralleled gene changes associated with aromatase treatment and estrogen withdrawal in humans.

P3-10-03
Bardoxolone (5MeCDDO) Inhibits Cancer Initiation but Promotes Progression in Rodent Models of Breast Cancer. What Does It Mean for the Antioxidant Response Element (ARE) as a Primary Prevention Target?
Luber RA, Townsend R, Vedell P, Steele VE, Grubbs CJ. National Cancer Institute, Bethesda, MD; Washington University School of Medicine, Saint Louis, MO; Medical College of Wisconsin, Milwaukee, WI; University of Alabama at Birmingham, Birmingham, AL

The preventive efficacies of the triterprenoid 5MeCDDO were examined in three preclinical models of breast cancer. We initially evaluated 5MeCDDO in an ER+ mammary model in which female Sprague-Dawley rats were administered MNU, i.v., at 50 days of age. 5MeCDDO (27 ppm) was administered in the diet beginning 5 days after MNU, and continuing for the duration of the study. Doses >50 ppm were toxic. 5MeCDDO failed to decrease tumor latency or multiplicity and, in fact, increased the size of the cancers which did develop. This concentration of 5MeCDDO greatly increased liver to body weight ratios. We also examined the preventive efficacy of 5MeCDDO (54 and 27 mg/kg diet) in a transgenic model (MMTV-Neu/p53KO) of ER mammary cancer. In this model, animals develop cancers which overexpress Neu and fail to have a mutation in the transmembrane domain of Neu. Similarly to results in the MNU model, 5 MeCDDO did not alter either tumor latency or multiplicity. The effect of 5MeCDDO was further evaluated in a third model in which ER+ tumors were induced by the procarcinogen dimethylbenzanthracene (DMBA). DMBA was administered by gavage to female Sprague-Dawley rats at 50 days of age. In this model (which examines the ability of an agent to alter the activation of the carcinogen) the preventive agent was administered beginning 7 days prior to DMBA and was continued until 7 days post DMBA. 5,6 Benzoflavone (500 ppm), a positive control, decreased tumor multiplicity >90%, while 5MeCDDO (27 or 2.7 ppm) decreased multiplicity 65 and 35%, respectively. The efficacy observed in this model is in agreement with the ability of the agent to stimulate the ARE, and to induce a variety of ARE related genes (e.g., GST Pi, quinone reductase, etc.). Thus, as expected, high induction of the ARE was associated with a decrease in DMBA-induced cancer initiation, but not a decrease in the progression stage of mammary cancer development in three cancer models. This latter finding brings into question whether merely measuring induction of the ARE (e.g., quinone reductase) is sufficient to imply the general preventive efficacy of a given agent or mixture. Supported by NCI contract number HHSN261200433001C.

P3-10-04
Halting Early Breast Cancer Progression with Omega-3 Ethyl Esters: Altering Tumor Microenvironment in 21T Series Cell Lines.
Chen CI, Rhodes ME, Fabian C, Hursting SD, deGraffenried LA. University of Texas at Austin, Austin, TX; University of Kansas Cancer Center, Kansas City, KS

Observable infiltration of immune cells in stages of early breast cancer progression mirrors two recently conceptualized factors of carcinogenesis: tumor microenvironment and tumor-promoting inflammation.

Clinical studies using immunohistochemical staining for CD45 in patient-derived breast tissue demonstrate the involvement of leukocytes in breast cancer development, but the lack of an appropriate in vitro model has hindered molecular studies thus far. However, the 21T series cell lines effectively mimic breast cancer progression. This cell line series was obtained from the same breast cancer patient and consists of three cell lines representing atypical hyperplasia (21PT), ductal carcinoma in situ (21NT) and invasive carcinoma (21MT-1). This unique cell line series is used in our molecular study of omega-3 ethyl esters as breast cancer preventive agents. Preliminary invasion assays have described varying degrees of monocyte recruitment according to stages of progression. 21PT cells when plated on the bottom chamber failed to mobilize monocytes as effectively as 21NT or 21MT-1 and the addition of omega-3 ethyl esters suppressed the baseline invasion capacity of monocytes by 30%. Epidemiologic studies suggest that omega-3 fatty acids can act as potent cancer preventive agents and are possibly more potent when used in an ethyl ester form. Based on this, we hypothesize that omega-3 ethyl esters may prohibit early breast cancer progression through inhibiting immune cell infiltration and disrupting the formation of a tumor-promoting inflammatory and oxidative microenvironment. Phenotypic studies aim to interrogate the effect of omega-3 ethyl esters on tumor microenvironment including chemokine secretion and MMP production whereas molecular experiments probe into the importance of the Wnt pathway as a key player in the transition from ADH to DCIS. This study will demonstrate how omega-3 ethyl esters may function as breast cancer preventive agents as well as provides a model of study to test the efficacy of cancer preventive agents in vitro.

P3-11-01
Effects of Exemestane Therapy on the Lipid Profile of Postmenopausal Women with an Elevated Risk of Developing Invasive Breast Cancer.
Gatti M, Venzon D, Zujewski J, Korde L, Isaacs C, Cohen P, Warren R, Gallagher A, Eng-Wong J. Georgetown University Hospital, Washington, DC; National Cancer Institute, National Institutes of Health, Bethesda, MD; University of Washington, Seattle, WA; Lombardi Comprehensive Cancer Center, Georgetown University Hospital, Washington, DC

Background: Aromatase inhibitors are effective for breast cancer prevention in postmenopausal women. In the recent MAP.3 study, exemestane significantly reduced invasive breast cancer in postmenopausal women with an elevated risk of developing breast cancer. At 35 months follow up there was no increase risk in cardiovascular events in this study; however, the effects of exemestane use on lipid profiles and cardiovascular health are still unclear.

Methods: We conducted a single-arm phase II trial of exemestane in women at increased risk for breast cancer and examined the impact of exemestane on lipid profiles. Postmenopausal women at high risk
for invasive breast cancer (e.g., Gail Model risk ≥ 1.7, a history of lobular neoplasia, atypical ductal hyperplasia, DCIS, or stage I/II breast cancer, or BRCA1/2 mutation) were given exemestane (25 mg orally daily) for 2 years. Fasting serum total cholesterol, HDL, LDL, triglycerides, and homocysteine were collected at baseline, 3, 12, and 24 months after initiation of exemestane therapy. Apolipoprotein A and B were collected at baseline, 3 and 12 months. Wilcoxon sign ranked test was used to analyze if changes from baseline values differed from zero. The Hochberg p-value adjustment was used to account for multiple hypothesis tests. Results: Of the 42 women enrolled in the study, 6 dropped out prior to completing 1 year and 1 dropped out prior to completing 2 years of exemestane therapy. Thirty-one women have completed 2 years of exemestane therapy and the remaining 4 are expected to complete 2 years of therapy by January 2012. On average, participants were 58.5 years old, mostly Caucasian (n = 37; 84.1%), and had a BMI of 29.2 kg/m2. A majority (n = 19) of participants were on lipid-lowering medications (14 were taking a statin) or taking fish oil supplements (n = 5) prior to starting on the trial and 1 was started on a statin approximately 10 months after starting the trial. There were no significant differences in mean lipid values for each of the 4 assessment points or in the mean change from baseline at 3, 12, and 24 months between patients who were taking lipid-lowering medications and those who were not. In unadjusted analyses, change in HDL from baseline was significantly different from zero and decreased from baseline at 3, 12 and 24 months (-8.0 mg/dL, -8.5 mg/dL, and -9.9 mg/dL; All p-values ≤ .001 before and after applying the Hochberg adjustment). Total cholesterol also significantly decreased from baseline at 3 months (-13.6 mg/dL, p = .002) but was no longer significant at 12 and 24 months (-9.6 mg/dL and -11.4 mg/dL, respectively; p-values = .07). The rest of the lipid panel did not significantly change during follow-up.

Discussion: In agreement with previous studies, we found that exemestane causes a significant decrease in HDL and total cholesterol, while leaving the rest of the lipid panel unchanged. Prior studies excluded patients on lipid-lowering medication; half of our participants were taking lipid-lowering medication. It is notable that both women off and on lipid-lowering medication had decreases in HDL. Additional studies are needed to elucidate long-term cardiovascular outcomes in this high risk but otherwise healthy population. 

P3-11-02 Changing Paradigms for Breast Cancer Chemoprevention? 
Chlebowski RT. Los Angeles Biomedical Research Institute @ Harbor-UCLA Medical Center, Torrance, CA

The SERMs tamoxifen and raloxifene are approved for breast cancer risk reduction but their acceptance in clinical practice has been poor largely related to rare but potentially life threatening side effects which requires identification of populations at higher breast cancer risk and careful risk benefit discussion (Visvanathan 2009). Recent findings from randomized placebo-controlled clinical trials suggest potential alternative approaches. In the MAP3 placebo-controlled trial including 4,650 postmenopausal women, exemestane decreased breast cancer incidence by 65% (P=0.002) (Goss 2011) with no significant difference between groups for fractures, CVD events, other cancers or treatment-related deaths. While the median Gail 5-yr risk score of participants was 2.3, eligibility factors included age alone (≥ 60 years) regardless of calculated breast cancer risk and accounted for 49% of entries. With extended follow-up from the Women’s Health Initiative (WHI) randomized, placebo-controlled trial evaluating estrogen alone in 10,739 postmenopausal women with prior hysterectomy, a statistically significant decrease in breast cancer incidence of 23% was seen with estrogen use (P=0.02) (LaCroix 2011). Younger postmenopausal women (age 50-59 years at entry) randomized to estrogen alone had lower risk of myocardial infarction (HR 0.54, 95% CI 0.34-0.86) and death (HR 0.73, 95% CI 0.53-1.00). These findings contrast to those in the WHI trial evaluating combined estrogen plus progestin in 16,608 postmenopausal women with an intact uterus where breast cancers were increased 25% (P=0.004) as was breast cancer mortality (increased by 96%, P=0.049) (Chlebowski 2010). The apparently paradoxical findings that in postmenopausal women estrogen addition, as conjugated equine estrogen, lowers breast cancer incidence and estrogen reduction, by aromatase inhibitor use, also lowers breast cancer incidence are consistent with preclinical studies indicating condition dependent change in estrogen influence on mammary cancers (Jordan 2011). Major eligibility for the WHI trials included anticipated 3-yr survival regardless of breast cancer or CVD risk. The findings from the MAP3 and WHI trials highlight the complex relationships between estrogen and breast cancer and suggest potential strategies for chronic disease risk reduction in select populations of postmenopausal women which may not require formal breast cancer risk assessment.

Lang JE, Miller JA, Nokes BT, LeBeau LG, Delbridge M, Chow H-HS. Arizona Cancer Center, University of Arizona, Tucson, AZ

Background: D-limonene (DL) is a highly lipophilic monoterpene found naturally in citrus that has been demonstrated in preclinical studies to have anticancer properties. Early phase clinical trials support the investigation of DL in the chemoprevention of breast cancer. We sought to evaluate whether DL and its presumed active metabolite perillic acid (PA) would distribute extensively to the breast tissue and reach an effective drug concentration. We hypothesized that the mechanism of DL is related to the induction of apoptosis in cancer cells.

Materials and Methods: We enrolled 40 patients with newly diagnosed Stage 0-2 breast cancer to take 2 grams daily of oral DL for 2-6 weeks prior to planned surgical intervention. Blood was drawn pre/post intervention to assess for toxicity and plasma concentration of DL and PA. Adverse effects related or possibly related to the study drug were noted. A small piece of breast tissue adjacent to the tumor mass was used to measure drug concentration for each patient. DL and PA levels in breast tissue were analyzed by gas chromatography and liquid chromatography, respectively, in tandem with mass spectrometry. Analysis of variance testing was used to determine if DL or PA preferentially concentrated in the breast tissue compared to plasma. We tested for a possible modulation of the biomarkers estrogen receptor (ER), progesterone receptor, HER2, Ki67 or grade pre/post treatment by comparing results from the core biopsy to the surgical pathology and applying pairwise Student’s T tests. The caspase 3 and the annexin V assays were performed by platting 10,000 cells
per well for the cell lines MCF7, MDA-231, BT474, and T47D and separately administering DL and PA acid in serial dilutions in their treatment concentration ranges in triplicate and read by microplate. Results: DL was found to preferentially concentrate in breast tissue versus plasma (tissue/plasma concentration ratio (TPCR) of 1297, p<0.001) while PA did not concentrate (TPCR of 1.4, p=0.9). 20 patients (50%) reported Grade 1 irritation, which was the most common adverse effect. A slight decrease in white count from a mean of 7.1 to 6.6 (p=0.03) and a slight increase in ALT from a mean of 22.5 to 26.9 (p=0.03) were noted. No other statistically significant changes in laboratory values related to serum complete blood count, renal, hepatic or other studies were noted. No change in tissue biomarkers were noted post-treatment. DL produced a dose dependent increase in the apoptotic markers cleaved caspase 3 and annexin V for the ER positive cell lines MCF7, BT474, and T47D; however, no such response was noted for the triple negative cell line MDA-231. A PA dose response trend was noted with the annexin V but not the caspase 3 assay for each cell line. Discussion: D-limonene preferentially concentrates in the breast tissue and is a candidate chemopreventive agent based on its favorable side effect profile. PA does not readily concentrate in the breast when administered as oral DL. Our correlative studies establish that DL induces apoptosis in ER positive breast cancer cell lines; no definite relationship between PA and apoptosis was found. Further clinical trials of DL are necessary to establish its potential role as a chemopreventive agent in breast cancer.

P3-11-04
A Randomized Phase II Biomarker Study of Atorvastatin in Premenopausal Women at Increased Risk for Breast Cancer.
Wood ME, Kingsley F, Ellerton JA, Atkins JN, Grabs SS, Mass HB, Garber JE. University of Vermont, Burlington, VT; Cancer Consultants, Las Vegas, NV; Southeastern Medical Center, Winston-Salem, NC; Medical Oncology Hematology Consultants, Newark, DE; University of North Carolina Lineberger Comprehensive Cancer Center, Chapel Hill, NC; Dana-Farber Cancer Institute, Boston, MA.

Statins have been shown in epidemiological and laboratory studies to have breast cancer risk reduction properties. We evaluated the effect of atorvastatin on mammographic density (MD) and other breast cancer biomarkers in a small randomized placebo controlled trial.

Methods: Premenopausal women at increased risk for breast cancer (due to family history, BRCA positivity, prior biopsy history or history of chemoradiotherapy for Hodgkins disease) enrolled after signing informed consent and received either 40 mg of atorvastatin or placebo daily for 1 year. Biomarker assessment was performed prior to initiation and prior to completion of study medication. MD was determined using both Breast Imaging Reporting and Data System (BI-RADS) and the Visual Analogue Scale (VAS).

Results: 63 women were enrolled between 7/05 – 8/10 in this multi-institutional trial. 44 have completed study medication and 3 remain on study. 25% have withdrawn; 17% of them for toxicity/side effects. Of those completing the study; mean age was 47 (range 35-50), 96% Caucasian, mean BMI 26.8. 66% had a strong family history (2% were BRCA+); 27.7% had ADH/LCIS. We present analysis of MD in the first 37 women completing study drug. The two treatment groups were well balance for age, BMI, risk factors and baseline density. Mean density by VAS was 31.6% at study entry and 32.4% at end of treatment. There was no different in change in density over time between atorvastatin and placebo using either BIRAD or VAS; controlling for BMI did not change results. Futility analysis demonstrates low probability of a significant difference between treatment groups and the study was closed.

Conclusions: In this multi-institutional randomized prospective clinical trial of premenopausal women at increased risk for breast cancer we have failed to demonstrate a significant effect of atorvastatin on mammographic density. There are several possible reasons for this relating to: the study population, method of density determination and/or biomarker analyzed. While the primary aim of this study (MD) was not met we have shown that biomarker studies can be done in a multi-institutional setting. Further biomarker evaluation may prove informative.

Funding: This study is sponsored by grants from Breast Cancer Research Foundation and Cancer and Leukemia Group B to M. Wood.

P3-11-05
An Efficient Resource To Accelerate Research into the Cause and Prevention of Breast Cancer: The Love/Avon Army of Women. 

Love SM, Dr. Susan Love Research Foundation, Santa Monica, CA

Background: It is well established that more research into the cause and prevention of breast cancer is needed. While many studies are done in cell lines and laboratory animals, translation of findings to women often falters due to perceived difficulty in recruiting women for research. The Dr. Susan Love Research Foundation received a grant from the Avon Foundation to form the Love/Avon Army of Women (AOW); an on-line recruitment resource launched in 2008, designed to partner one million women with the research community in an effort to accelerate breast cancer research.

Methods: Researchers submit a proposal to the AOW Scientific Advisory Committee. If a study is accepted, a mass e-mail describing the study procedures and inclusion/exclusion criteria is sent to the entire AOW database. Women sign up at www.armyofwomen.org to join and receive AOW e-mails about breast cancer research studies. Women self select based on interest and study criteria, and undergo a secondary on-line screening before contact information is passed on to the researcher for the enrollment process.

Results: Over 356,000 women have signed up, including survivors and healthy women, ranging from ages 18 to 100, representing all 50 US states and 49 countries. To date, the AOW has recruited for 48 studies, both regional and national, that vary from biomarker and/or circadian rhythm research to psycho-social and quality of life studies. With over 54,000 AOW members having participated in the research process, this method of recruitment has been found to be effective and efficient. The diversity of the AOW members has proved beneficial for many studies, such as those needing to enroll racial/ethnic minorities, women of varying sexual orientations, or young survivors. Nine studies were closed to enrollment within the first 48 hours after accruing all subjects while others were very quickly over-enrolled by 5-10%. A urine biomarker study in search of healthy women and breast cancer survivors closed within eight hours, after 2,076 women signed up, representing a 58% over-enrollment. This overwhelming response has led many researchers to seek additional funding to increase their statistical significance and accommodate all eligible subjects.

Conclusions: The AOW has proved to be a successful resource for scientists to accelerate accrual, expand the number and diversity of their subject population and to obtain exactly the type of specimens they need when they need it. This partnership between women and scientists has revolutionized research and accelerated efforts to eradicate breast cancer.
P3-11-06
A Pilot Study of RPFNA in Overweight and Obese Postmenopausal Women.
Korde LA, Grieco VS, Inamaya I, Kumai C, Mason C, Duggan CR, Wang C-Y, McTiernan A. University of Washington, Seattle, WA; Fred Hutchinson Cancer Research Center, Seattle, WA

Background: Random periareolar fine-needle aspiration (RPFNA) is a research-based procedure used to obtain breast epithelial cells and fluid. Data suggest that atypia in epithelial cells from RPFNA specimens is associated with an increased risk of breast cancer, and changes in the degree of atypia may be a viable biomarker for response to chemopreventive interventions.

Methods: We performed RPFNA on 37 overweight or obese (body mass index (BMI) ≥ 25.0 kg/m²) postmenopausal (50-75 y) women enrolled in a randomized clinical trial of Vitamin D vs placebo in combination with a lifestyle (diet + exercise)-based weight loss program. Eligibility criteria included serum vitamin D concentrations 10-32 ng/mL. The procedure was performed by two trained clinicians prior to randomization to assess baseline cell counts and degree of atypia. Two areas in the breast (10:00 and 2:00 positions) were infiltrated with lidocaine, and 8 to 10 aspirations of cellular material were performed using 1.5 inch, 21-gauge needles. The aspirated fluid was placed in 9 cc of Cytolyt Thinprep (Hologic Inc.) with 1 cc of 1% neutral buffered formalin and slides were prepared according to the University of Washington Department of Pathology non-gyn protocol. Results: Thirty-seven women were included in this analysis. The mean age and BMI of study participants was 59.3 years and 32.5 kg/m², respectively. The mean 5-year Gail risk score for study participants was 1.96%; 52% of women had a 5-year Gail risk ≥ 1.66%. Eight participants (21.6%) had >50 cells present on cytology examination. One additional participant had 10-50 cells, and one had <10 cells. No specimens showed cellular atypia. The remainder of study participants had only blood or fibroadipose tissue on cytology specimens. Women with epithelial cells present were younger (mean age 55.0 vs. 60.2 years, p=0.05). There were no significant differences in BMI or Gail risk score between those with and without epithelial cells. Conclusions: RPFNA in our sample of overweight/obese postmenopausal women did not yield epithelial cells in a majority of participants. Younger age was associated with a greater cell count. We are planning further studies to determine whether other markers in RPFNA specimens can be used to assess breast tissue changes in response to chemopreventive interventions.

P3-11-07
Mammary Gland Biopsy To Examine Surrogate Endpoint Biomarkers of Preventive Agent Efficacy.
Heckman-Stoddard B, Lubet RA, Bode AM, Grubbs CJ. National Cancer Institute, Bethesda, MD; University of Minnesota, Austin, MN; University of AL at Birmingham, Birmingham, AL

Phase II breast cancer prevention trials examine agent activity by sampling and imaging the breast through core needle biopsy or fine needle aspiration, or imaging (e.g., mammography). The biomarker endpoints in normal or at risk breast tissue employed with biopsies or fine needle aspirates (e.g., Ki67 or apoptosis) have often not been formally validated relative to a tumor endpoint. In this study, we have attempted to examine these endpoints in a preclinical model for which we have final tumor data. In the methylnitrosourea (MNU)-induced rat mammary cancer model, estrogen receptor positive cancers develop that are histologically similar to a large majority of human tumors. Here we present a protocol for correlating surrogate endpoint biomarkers and agent efficacy in the same animal. Biopsy samples are taken of the normal mammary gland after MNU treatment, and a week later the animals are started on the preventive agent. After 2 weeks, a second biopsy is taken and the animals are followed for tumor development. To test the protocol, we examined surrogate endpoints of tamoxifen efficacy at human equivalent dosages (5mg/d and 20mg/d). Both doses of tamoxifen prevented the development of tumors in the MNU-treated rats. The pre/post biopsy analysis revealed a statistically significant reduction in Ki-67 consistent with the clinical trial data. Additional biomarkers of apoptosis and the chromosome condensation pathway will be presented.

Postma EL, Verkooijen HM, van Esser SE, Hobbelen MG, van der Schelling GP, Koellemij R, Witkamp AJ, Contant CM, van Diet PJ, Borel Rinkes IH, van den Bosch MA, Mali WP, van Hillegersberg R. UMC Utrecht, Utrecht, Netherlands; St. Antonius ziekenhuis, Nieuwegein, Netherlands; Amphia Hospital, Breda, Netherlands; Maasstad Hospital, Rotterdam, Netherlands

Background
For the management of non-palpable breast cancer, accurate pre-operative localization is essential to achieve complete resection with acceptable cosmetic results. ROLL takes advantage of the intratumorally injected radiotracer, that is already used for the sentinel node procedure, to localize the primary tumor during surgery. In a multicenter randomized controlled trial, we determined if ROLL is superior to the standard of care (i.e. wire guided localization, WGL) for preoperative tumor localization.

Methods
Women (>18 yrs.) with histologically proven non-palpable breast cancer and eligible for breast conserving treatment (BCT) with sentinel node procedure were randomized to ROLL or WGL. Patients allocated to ROLL received an intra-tumoral dose of 120 Mbq Technetium99 nanocolloid. Guided by a gamma detection probe, the surgeon excised the primary tumor and the sentinel node(s). In the WGL group, patients received a similar intra-tumoral or periaureolar dose of technetium in order to allow sentinel node biopsy. Ultrasound or mammography guided insertion of a hooked wire provided surgical guidance for excision of the primary tumor. Primary outcome measure was the proportion of complete tumor excisions (i.e. with negative margins). Furthermore, the proportion of patients requiring re-excision was assessed. Data were analyzed according to intention to treat analysis.

Results
Three hundred and fourteen patients with 316 invasive breast cancers were enrolled. There were no significant differences in proportion of complete tumor removal with free margins and re-excision rate; complete tumor removal with negative margins was seen in 87.7% of patients in the ROLL group versus 85.5% (p=0.97) of patients in the WGL group. Re-excision was required in 11.7% of patients in the ROLL group versus 9.2% (p=0.47) in the WGL group. Incorrect pre-operative localization (i.e. failure to identify the correct localization of the lesion) occurred in 5 (3%) patients in the ROLL group versus 0 patients in the WGL group (p=0.029). Differences in the volume of the excised specimen, duration of the procedure, success rate of the sentinel node procedure, surgeons’ preferences and patients’ pain perception are currently being analyzed.

Conclusion
With this multicenter randomized controlled comparison, the first of its kind in patients with histologically proven breast cancer, we show that ROLL is not superior to WGL in terms of complete tumor excision and re-excision rates. Furthermore incorrect lesion localization occurred more frequently when applying ROLL. Data on long term (6 months) cosmetic results and quality of life (6 weeks, 3 months, 6 months) are awaited.

*Intra-Operative Margin Assessment of Diffuse Disease with MarginProbe™ as an Adjunct to Standard of Care, Results from a Randomized Prospective Multi Center Study.*

Booibol SK, Cocilovo C, Tafra L. Beth Israel Medical Center, New York, NY; Inova, Alexandria, VA; Anne Arundel Health System, Annapolis, MD

**Background**

The ability to obtain negative margins with a single surgical procedure remains a challenge, particularly in patients with diffuse disease such as DCIS and lobular pathology. A novel device (MarginProbe, Dune Medical Devices, Inc.) is intended to provide surgeons with real time, intraoperative detection of cancerous tissues at the margins of excised specimens. A study was performed to determine if there was a device-associated improvement in complete surgical resection (CSR) and therefore a decrease in the rate of patients requiring re-excision with these disease types. The current analysis stratified the data based on tumor type with a special focus on DCIS patients, patient with a DCIS component, and lobular patients.

**Methods**

All 596 patients underwent breast conservation, with image-guided localization, and were randomized in a prospective, international, multicenter (n=21) study. Randomization occurred in the operating room, following standard lumpectomy procedure, including palpation followed by additional cavity resections as indicated. In the device arm, MarginProbe was used on each specimen margin and device positive readings required additional resections of the cavity. Pathologists were blinded to study arm. Re-excision criteria were not dictated by the protocol.

A primary endpoint of this study was CSR, defined as the correct intraoperative identification and resection (if not skin or fascia) of all positive margins on the main lumpectomy specimen. Positive lumpectomy specimens were defined as those having at least one margin having cancer ≤1mm from the surface. Successful CSR results in reduced positive margin rate after lumpectomy.

**Results**

Results are presented in Table 1. The improvement in CSR was significant for all diagnosis types. The decrease in candidates for re-excision due to failed CSR was significant for all DCIS and mixed tumor types.

**Conclusions**

Use of the device resulted in significant improvement in CSR and therefore a significant decrease in the need for reexcisions. Further studies should be conducted to evaluate the use of the device for additional patient cohorts, such as patients receiving neoadjuvant treatment and patients who have undergone prior breast surgery.

*A Prognostic Index of Ipsilateral Breast Tumor Recurrence in Patients Treated with Breast-Conserving Surgery after Preoperative Chemotherapy: Validation of M.D. Anderson Prognostic Index.*

Ohno S, Ohsumi S, Inaji H, Akiyama F, Akashi-Tanaka S, Sato N, Takahashi K, Oura S. National Kyusu Cancer Center, Fukuoka, Japan; National Shikoku Cancer Center, Matsuyama, Ehime, Japan; Osaka Medical Center for Cancer and Cardiovascular Disease, Osaka, Japan; The Cancer Institute of the Japanese Foundation for Cancer Research, Tokyo, Tokyo, Japan; National Cancer Center Hospital, Tokyo, Tokyo, Japan; Niigata Cancer Center Hospital, Niigata, Japan; Shizuoka Cancer Center, Santo-gun, Shizuoka, Japan; Wakayama Medical University, Wakayama, Japan

**Background**

Preoperative chemotherapy (PCT) is widely used to increase the possibility of breast-conserving treatment (BCT). However, the appropriate indication for BCT after PCT is controversial, because the rates of ipsilateral breast tumor recurrence (IBTR) may be higher than those reported for BCT when surgery is used first. We performed a multicenter retrospective study to evaluate factors that were associated with IBTR in patients with BCT after PCT, and validated M. D. Anderson Prognostic Index (MDAPI) (Cancer 2005;103:689-95) using our data set.

Patients and Methods: From eight Japanese hospitals, data were extracted on a total of 381 patients with invasive breast cancer (BC) who were treated with ≥2 cycles of PCT followed by breast-conserving surgery and irradiation. The rates of IBTR were evaluated by MDAPI including clinical N2 or N3 disease, pathologic residual tumor >2 cm, multifocal pattern of residual disease, and lymphovascular space invasion in the specimen. Kaplan-Meier method was used to estimate cumulative recurrence rates. Log-rank test and Cox’s proportional hazard model were used for statistical analyses.

Results: Median age at diagnosis of the primary tumor was 48 years; median size of the primary tumor at diagnosis was 4.0 cm. One hundred and forty-six patients received postoperative chemotherapy and 211 received postoperative endocrine therapy. At a median follow-up period of 50 months, 18 of 381 patients developed IBTR, which resulted in 5-year IBTR-free rate of 94.1%. Univariate analyses revealed that estrogen receptor (ER) status both before and after PCT (positive vs. negative), pathological nodal status after PCT (≥4 vs. 0-3 positive nodes), and pathologically residual invasive tumor (≥1.8 vs. ≤1.7 cm) were significantly associated with IBTR (all P < 0.05). Pathological margin status did not affect IBTR rate (P=0.88).

Multivariate analysis revealed that significant independent predictors of IBTR included ER status after PCT (Hazard Ratio [HR], 0.10; P<0.01), size of residual invasive tumor (HR, 5.29; P=0.05), and pathological nodal status after PCT (HR, 3.59; P=0.02). The rates of IBTR of patients with MDAPI 0-3 were 1.3%, 2.9%, 16.0%, and 3.6%, respectively. Based on the data of our multivariate analysis, ER status after PCT (ER positive:0 and ER negative: 1 was added to MDAPI. Total scores of the prognostic index including MDAPI and ER status after PCT ranged between 0 and 5. The rates of IBTR correlated well with this prognostic index. The 5-year IBTR-free survival rates were 0% for 23 patients in score 0, 3.4% for 89 in score 1, 3.9% for 51 in score 2, 21.2% for 33 in score 3, and 16.7% for 6 in score 4 (P<0.01).

Conclusion: Our prognostic index (MDAPI plus ER status) would be useful for clinical decision making according to surgical procedures after PCT. BCT is an appropriate treatment option for patients with the low prognostic index (0 to 2). The high risk population with the high prognostic index (3 to 5) may benefit from mastectomy.
P3-12-04
Involved Anterior Margins after Breast Conserving Surgery: Is Re-Excision Required?
Mullen R, Macaskill EJ, Khalil A, Elseedawy E, Brown DC, Lee AC, Purdie C, Jordan L, Thompson AM. Ninewells Hospital, Dundee, United Kingdom; Perth Royal Infirmary, Perth, United Kingdom
Background: Complete tumour excision in breast conserving surgery (BCS) is critical for successful treatment; involved circumferential resection margins are associated with increased disease recurrence. However, the importance of an involved anterior margin is less clear. The purpose of this study was to audit an aggressive approach to involved anterior margins and hence assess whether anterior margin re-excision yields clinical benefit.

Material and Methods: A retrospective case note and pathology review was performed for all patients who underwent BCS between 2006 and 2010 through a single cancer centre. An involved margin was defined as <1mm clearance of invasive or in situ breast cancer. Results: 1667 patients underwent BCS for invasive and/or in-situ disease, of whom 114 (6.8%) underwent re-excursion, most commonly for mixed invasive and in-situ pathology. The annual re-excision rate rose significantly (p=0.001), with no change in whole tumour diameter, specimen weight or specimen volume. A total of 170 involved margins were identified: most commonly the anterior margin (59 margins, 30.6%) followed by the posterior (39 22.9%) or inferior (31, 18.3%) margin. Patients with anterior margin involvement were more likely to have grade 3 invasive disease (p=0.0323) but less likely to have residual disease found at re-excision (2/49 vs. 32/101 margins, p=0.0033); there were no differences when in-situ characteristics were compared.

Conclusions: Re-excision of involved anterior margins rarely excises residual disease and may be unnecessary. Multidisciplinary teams should consider whether further therapy for an involved anterior margin is required on a patient by patient basis.

P3-12-05
Breast Cancer Recurrence: 2nd Conservative Treatment Versus Mastectomy.
Michel V, Houvenaeghel G, Bannier M, Tallet A, Minsat M, Lambaudie E, Salem N, Buttarelli M, Resbeut M. Paoli Calmettes Cancer Institute, Marseille, France

Objectives: Mastectomy (Mt) is considered standard treatment for isolated local recurrence (LR) of breast carcinoma. The aim of our study was to evaluate a second conservative treatment (defined as lumpectomy followed by interstitial brachytherapy (LpIB)) and to determine if it compares favorably with the current standard treatment.

Materials and methods: Between January 1981 and December 2009, 348 patients were treated to the Paoli Calmettes Institute (IPC) for an isolated LR: 232 (66.7 %) underwent Mt, 62 (17.8 %) received a second radio-surgical conservative treatment (LpIB) and 54 (15.5 %) a 2nd single surgical treatment (Lp).

We classified each population according to the well known prognosis factors. Then, populations Mt and LpIB were matched taking into account these criteria to compare the overall survival (OS), metastasis free survival (MFS) and 2nd local recurrence free survival according to the treatment delivered.

Results: On 348 reviewed patients, with a median follow-up of 73.3 months, 65 patients died (42/232 Mt, 8/62 TecCur, 15/54 Tec) and 100 presented metastasis (64/232 Mt, 15/62 TecCur, 21/54 Tec). There was no difference in MFS for the 2 groups, LpIB and Mt (80 % at 5 years) and the OS was non significantly better in the group LpIB compared to the group Mt (90 % and 82 % at 5 years respectively, p=0.28), whereas in the LpIB group 17 % and 30 % presented a relapse at 5 years and 10 years respectively. They subsequently underwent a salvage mastectomy.

Worse results were obtained with lumpectomy alone (OS = 72 % and MFS = 68 % at 5 years) compared with 2 other option treatments.

Conclusion: A second conservative treatment for breast cancer recurrence, i.e. lumpectomy and interstitial brachytherapy, is possible for selected patients, without any negative impact on overall survival, nor metastasis free survival.

Keywords: Local recurrence, interstitial brachytherapy, lumpectomy, conservative treatment, mastectomy, overall survival, metastasis free survival, breast carcinoma.

P3-13-01
Boost Radiation Therapy Not of Value in Reducing IBTR of Invasive or Noninvasive Breast Cancers for Patients with DCIS:
Results from the NSABP B-24 Trial.
Julian TB, Vicini FA, Costantino JP, Arthur DW, Kidwell KM, Land SR, Mamounas EP, Wolmark N. National Surgical Adjuvant Breast & Bowel Project, Pittsburgh, PA; Allegheny General Hospital, Pittsburgh, PA; Beaumont Health System, Royal Oak, MI; Virginia Commonwealth University, Richmond, VA; Graduate School of Public Health, University of Pittsburgh, Pittsburgh, PA; Aultman Health Foundation, Canton, OH

Background: Whole breast irradiation therapy following lumpectomy for invasive breast cancer (IBC) or noninvasive breast cancer (DCIS) significantly reduces the risk of local recurrence. Boost radiation therapy to the tumor bed has been proven to additionally lower the risk of recurrence for IBC. The benefit of boost therapy in patients with DCIS is less certain. We carried out a review of the NSABP B-24 trial to assess the benefit of boost therapy.

Methods: After lumpectomy and radiation therapy, 1804 women with DCIS were randomly assigned to placebo (902) or tamoxifen (902). Whole breast irradiation therapy (50 Gy) was mandatory. Boost radiation therapy was optional, and boost status was known for 1,569 patients. Of these, 1392 patients (86.9%) were identified as having all data sufficient for multivariate analysis. Of these, 613 received boost therapy ranging from 1 Gy to 20 Gy, with 81.5% receiving 10 Gy. Mean time of follow-up was 161 months.

Results: Patients who received boost radiation therapy were more likely to be younger (p<0.04), have positive margins (p=0.007), and be more likely to have comedo necrosis (p=0.03). Multivariate analysis identified only treatment (tamoxifen vs placebo) (HR=0.74, 95% CI=0.57-0.98, p=0.034), age (≥ 50 vs < 50) (HR=0.47, 95% CI=0.36-0.61, p<0.0001), and margin status (positive vs negative) (HR=1.79, 95% CI=1.31-2.43, p<0.001) as significant predictors for ipsilateral breast tumor recurrence (IBTR). Boost had no significant effect on IBTR (HR=0.87, 95% CI=0.66-1.15, p=0.33). The lack of boost effect applied to both invasive (HR=0.86, 95% CI=0.58-1.27, p=0.44) and noninvasive IBTR (HR=0.89, 95% CI=0.60-1.33, p=0.56). No interaction was seen between boost and treatment, age, margin status, or comedo necrosis.

Conclusion: In NSABP B-24, the addition of boost radiation therapy was not found to be of value in reducing IBTR of invasive or noninvasive breast cancers for patients with DCIS.

Supported by PHS grants NCI-U10-CA-69651, NCI-U10-CA-12027, and NCI P30-CA-14599 from the US NCI and AstraZeneca.
P3-13-02
The Impact of Lymph Node Status on Clinical Outcomes Following Accelerated Partial Breast Irradiation.
Shah C, Wilkinson JB, Wallace M, Vicini F. William Beaumont Hospital, Royal Oak, MI

Background: Limited data exists on outcomes following accelerated partial breast irradiation in node-positive breast cancer patients. The purpose of this analysis was to compare clinical outcomes following accelerated partial breast irradiation (APBI) between node-negative and node-positive early stage breast cancer patients and to identify if nodal positivity leads to increased rates of local or axillary failure. Materials and Methods: 510 patients with early stage breast cancer received accelerated partial breast irradiation (APBI) as part of their breast conservation therapy between April 1993 and November, 2010. Of these, 39 were lymph node positive with 10 patients having N1mi disease (median size of mets= 0.82 mm) and 29 patients having N1 disease (61.5% had one node positive [median size of mets= 2.5 mm], 30.8% had 2 nodes positive [median size of mets= 8.0 mm], and 7.7% had 3 nodes positive [median size of mets= 20 mm]). Patient, clinical, and pathologic factors were analyzed and compared for the node-negative and node-positive cohorts including age, tumor size, receptor status, margin status, adjuvant hormonal therapy, adjuvant chemotherapy, and length of follow-up. Clinical outcomes were analyzed including local recurrence (LR), regional recurrence (RR), axillary recurrence (AR), regional-nodal recurrence (RR), distant metastases (DM), disease-free survival (DFS), cause-specific survival (CSS), and overall survival (OS).

Results: Node-positive patients were younger (p=0.04), had larger tumors (p<0.001), and were more likely to receive chemotherapy (p<0.001). Median follow up was 5.3 years for node-negative patients and 5.9 years for node-positive patients (p=0.06). At 5 years, no differences were seen in the 5-year actuarial rates of LR (2.2% v. 2.6%, p=0.86), AR (0% v. 0%, p=0.69), DFS (90.0% v. 88.0%, p=0.79), CSS (98.0% v. 90.0%, p=0.06), or OS (91.0 v. 84.0%, p=0.65) while higher rates of RR (0% v. 6.1%, p=0.001) and DM (2.2% v. 8.9%, p=0.005) were noted in node-positive patients. A total of 10 LRs occurred in the node-negative patients and 1 LR in the node-positive patients at a median of 2.6 and 1.5 years respectively. Both RR that developed in node-positive patients were within the supraclavicular fossa at a median of 2.8 years. Univariate analysis of LR was performed and age (p=0.31), tumor size (p=0.48), ER status (p=0.13), PR status (p=0.34), T-stage (p=0.48), chemotherapy (p=0.41), APBI technique (p=0.80), and nodal status (p=0.86) were not associated with LR while there was a trend for the association of LR with close/positive margins (p=0.07), and failure to receive adjuvant hormonal therapy (p=0.06). No variables were associated with any type of AR.

Discussion: No difference was seen in the rates of local recurrence or axillary failure between node-negative and node-positive following APBI with 5-years of follow-up. Increased rates of regional failure were noted with APBI in node-positive patients due to supraclavicular failures; however, traditional whole breast irradiation techniques would not have covered these failures.

P3-13-03
Long-Term Symptoms after Radiotherapy of Supraclavicular Lymph Nodes in Breast Cancer Patients.
Lundstedt D, Gustafsson M, Steineck G, Alsadius D, Sundberg A, Wilderäng U, Holmberg E, Johansson K-A, Karlsson P. Institute of Clinical Sciences, Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden; Institute of Clinical Sciences, Gothenburg, Sweden; Karolinska Institute, Stockholm, Sweden

Background and Purpose: Irradiation of the supraclavicular lymph nodes has historically been shown to increase the risk of brachial plexopathy with neurological problems in the upper limb. The purpose of this study was to compare long-term symptoms after modern radiotherapy (based on 3D dose planning) in breast cancer patients with or without irradiation of the supraclavicular lymph nodes.

Material and Methods: We collected information from 814 recurrence free women consecutively treated with adjuvant radiotherapy for breast cancer at the Sahlgrenska University Hospital in Gothenburg, Sweden, 1999 to 2004. The women had breast conserving surgery or mastectomy with axillary dissection or sentinel node biopsy. The breast area was irradiated to 50 Gy in 2.0 Gy fractions. Women with more than three lymph node metastases had regional radiotherapy to the supraclavicular lymph nodes delivered in 2.0 Gy fractions up to 50 Gy. Systemic treatments were given according to regional guidelines. In this study the women were classified into three groups depending on if they had axillary dissection and regional radiotherapy. The first group had both axillary dissection and regional radiotherapy, the second group had axillary dissection without regional radiotherapy, and the third group had sentinel node biopsy (i.e. no axillary dissection) without regional radiotherapy. Three to eight years after radiotherapy, the women received a questionnaire asking about paresthesia, pain and strength in the upper limb.

Results:
Among women with axillary dissection and regional radiotherapy 38/192 (19.8%) reported paresthesia in the hand compared to 68/505 (13.5%) among women with axillary dissection without regional radiotherapy; relative risk (RR) 1.47; 95% confidence interval (95% CI) 1.02 – 2.11, and compared to 9/112 (8.0%) among women with sentinel node biopsy without regional radiotherapy; RR 2.46 (95% CI 1.24-4.90). Type of breast surgery, number of examined axillary lymph nodes, and chemotherapy had no impact on the occurrence of paresthesia. Age was an effect modifier among the women with axillary dissection and regional radiotherapy; up to 49 years of age 26.8% reported paresthesia (RR 2.45; 95% CI 1.05-5.73), between 50 and 59 years of age 19.7% reported paresthesia (RR 1.81; 95% CI 1.24-4.90), and above 59 years of age 10.9% reported paresthesia (RR 1.81; 95% CI 1.02 – 3.09). Long-Term Symptoms after Radiotherapy of Supraclavicular Lymph Nodes in Breast Cancer Patients.

Type of breast surgery, number of examined axillary lymph nodes, and chemotherapy had no impact on the occurrence of paresthesia. Age was an effect modifier among the women with axillary dissection and regional radiotherapy; up to 49 years of age 26.8% reported paresthesia (RR 2.45; 95% CI 1.05-5.73), between 50 and 59 years of age 19.7% reported paresthesia (RR 1.81; 95% CI 1.24-4.90), and above 59 years of age 10.9% reported paresthesia (RR 1.81; 95% CI 1.02 – 3.09).

Type of breast surgery, number of examined axillary lymph nodes, and chemotherapy had no impact on the occurrence of paresthesia. Baschnagel A, Shah C, Wilkinson JB, Dekhne N, Margolis J, Arthur DW, Vicini F. William Beaumont Hospital, Royal Oak, MI; VCU Massey Cancer Center, Richmond, VA

Purpose: To examine the rate of breast reconstruction failure and cosmetic outcomes following post-mastectomy radiation therapy (PMRT) with temporary tissue expander or implant in place.

Methods and Materials: Ninety-four patients with 95 primary breast malignancies underwent mastectomy and immediate tissue expander reconstruction followed by PMRT. Ninety tissue expanders and five implants were irradiated. All patients received a dose of 5,400 cGy given in 180 cGy fractions. Twenty-one patients (22%) received tangents alone and seventy-four patients (78%) were treated with tangents and a supraclavicular field via a mono-isocentric technique. Bolus was used in 91 patients (96%). Eighty-eight patients (93%) received chemotherapy and 78 patients (82%) received endocrine therapy.

Results: With a median follow up of 22.4 months, nineteen patients (20%) developed a reconstruction failure. Ten patients lost their tissue expanders with a median time to reconstruction failure of 7 months (range 3-9 months) while ten patients lost their permanent implant with a median time to loss of 19 months (range 9-31 months) following PMRT. The one and two-year actuarial rate of reconstruction failure was 11.2% and 24.9%, respectively. The most common cause of failure was infection (37%), followed by skin break down (21%), extrusion of expander or implant (16%), fibrosis/eschar (11%), trauma (11%) and pain (5%). Out of the 19 failures, eight patients were salvaged with an autologous flap reconstruction. Univariate analysis was performed to examine the association between age, chemotherapy, hormonal therapy, smoking status, hypertension, diabetes, menopause status, weight and the use of a third supraclavicular RT field on reconstruction failure. However no risk factors were found to be associated with reconstruction failure. In patients who did not have reconstruction failure, good/excellent cosmesis was observed in 79% of patients and fair/poor cosmesis was observed in 21% of patients.

Conclusions: In our series of women with a high risk of recurrence, PMRT with a tissue expander in place followed by a prosthetic implant provides good cosmesis in the majority of women with an acceptable risk of expander or implant loss.

P3-13-05
Analysis of Heart Dose-Volume Parameters and Cardiac Events among Node Positive Breast Cancer (NPBC) Patients Treated with Three-Dimensional Conformal Radiation Therapy (3D-CRT).

Background: For NPBC patients the use of regional nodal irradiation (RNI) to the supraclavicular, axillary, internal mammary lymph nodes (IMN) in addition to the chest wall and/or breast can maximize locoregional control and improve overall survival. However, comprehensive RNI for breast cancers located on the left side has been linked to late cardiac morbidity, potentially lessening the therapeutic benefit of treatment. The optimal radiation dose-volume constraints for the heart in this setting are not fully understood. We examined NPBC patients treated with RNI using 3D-CT based radiation therapy (RT) to evaluate cardiac dose and incidence of cardiac events.

Methods: Between 2000 and 2007, 150 NPBC patients were treated with RNI following lumpectomy or mastectomy using 3D-CRT. In all cases, treatment target and normal tissue volumes were delineated on treatment CT scans. The heart contour included the ventricles and the left atrium. The dose-volume histogram of the cardiac doses delivered and the incidence of cardiac events is reported.

Results: Median follow-up of surviving patients is 7 (1-10.6) years. Median patient age is 50 (27-91). 52.35% are premenopausal, 75.7% estrogen receptor positive, 66.3% progesterone receptor positive and 15.92% HER-2 positive. Mean positive lymph nodes is 5 (1-29). Extracapsular extension is present in 47.31%. Mean microscopic tumor size is 3.73 (0.1-21) cm. The IMN receive > 40 Gy in 65.5%. 94% had chemotherapy, and in 82.3% it was anthracycline-based. At the time of RT, 12.2% smoked, 9.5% had diabetes, 32.4% with hypertension, and 4.7% with a history of coronary artery disease. There was 1 (0.7%) right sided patient with cardiac events and 4 (2.7%) left sided experiencing cardiac events (p = 0.121, Fisher’s Exact test). A total of 10 cardiac diagnoses were experienced among the 5 patients: coronary artery disease with myocardial infarction (3), congestive heart failure (2), cardiomyopathy (2), and arrhythmia (3). The median time interval to onset of the events is 2.5 years (0-4.3 years).

The cardiac doses among 150 patients are as follows: mean V25 is 5.7, (0.0 - 20.0%), V25 is < 9 % in 74.4% of patients, mean V45 is 1.8% (0-13.3%), V45 is < 5.5% in 91.8%. The mean maximum point dose is 42.8 Gy, and the mean heart dose is 5.6 Gy (0.2-25.3 Gy). The mean V25 and V45 in those 5 patients with a cardiac event is 6.7% (0.9-11.9%) and 3.7% (0-6.6%), respectively; in the 145 remaining patients, 5.7% (0-20.0%) and 1.7% (0-13.3%), respectively. The mean heart dose in those with an event is 5.2 Gy (2.4-7.3 Gy) versus 5.6 Gy (0.2-25.3 Gy) in the remaining patients.

Conclusions: The cardiac event rate among these NPBC patients treated with RNI and anthracycline-based chemotherapy is low. However, those patients with cardiac events have a higher mean V45. No other dose-volume relationships are discernible. Additional analysis using 3DCRT volumes are important to validate these findings and better define the dose-volume parameters for cardiac toxicity.

P3-13-06
Cardiovascular Magnetic Resonance Imaging and Radiation-Induced Heart Disease Following Radiotherapy for Breast Cancer.

Background
Radiotherapy (RT) forms a vital component of treatment for breast cancer, contributing to the increasing number of survivors worldwide. It is known from historical cohorts that breast RT increased the risk of developing heart disease 10 years or more following treatment. It is less certain whether the lower cardiac radiation doses received during modern RT still increase cardiac risk. Cardiovascular Magnetic Resonance (CMR) imaging has the potential to provide early surrogate markers of radiation-induced heart disease that may help predict which women will be at increased risk in the future.
Methods
This is a prospective longitudinal imaging study to evaluate CMR findings in a cohort of women receiving adjuvant RT for early breast cancer at the Oxford Cancer Centre. The patients undergo CMR imaging (with gadolinium enhancement and adenosine stress), Doppler echocardiography, blood testing (including BNP and troponin), ECG and clinical examination prior to RT, within 72 hours of completing RT, and at 3 months, 6 months and 5 years following RT. The results of these investigations will be related to cardiac radiation exposure estimated using 3D-dosimetric data obtained by analysis of CT-based RT planning.

Recruitment and Provisional Results
As of May 2011, 30 women have been recruited. The women had a mean age of 57.1 years (range = 42.0 to 63.9). All women had left-sided cancer and none received adjuvant cytotoxic chemotherapy. The mean whole heart dose was 1.47 Gray (range = 0.65 to 4.20), the mean left ventricle dose was 2.03 (range = 0.88 to 6.99) and the mean left coronary artery dose was 7.55 Gray (range = 1.50 to 24.59). Preliminary analysis of the first 10 participants showed that all had a normal left ventricular ejection fraction at baseline (mean 76%, range 60-82%) and immediately following RT (mean reduction 3%, p=0.18). None had myocardial oedema as detected by T2-STIR imaging or fibrosis and scarring as demonstrated by late gadolinium enhancement (LGE).

Conclusion and Future Plans
Preliminary results suggest that the relatively low heart doses received by the women undergoing modern CT-planned left breast RT at the Oxford Cancer Centre do not result in any cardiovascular abnormality detectable by CMR imaging. Further and updated results will be available for the San Antonio Breast Cancer Symposium. Recruitment will continue until at least 20 women have completed baseline scans and follow-up scans up to 6 months. At this stage a full analysis will be performed including a wider range of CMR endpoints including:
- Overall LV systolic function (EF and volumes)
- Regional wall motion analysis
- T2-weighted imaging (oedema)
- T1 and T2 mapping (quantitative T1 and T2 relaxation times)
- Tagged myocardial strain analysis
- Stress perfusion defects (endothelial/microcapillary damage)
- Late gadolinium (LGE) imaging (fibrosis/scarring)

Depending on the results of this analysis, recruitment may be expanded to include women with either lower cardiac risk (e.g. with right-sided breast cancer) or higher cardiac risk (e.g. receiving anthracycline chemotherapy).

P3-13-07
The TARGIT-A Trial Update Confirms No Increase in Local Recurrence.
Vaidya JS, Baum M, Wenz F, Bulsara M, Tobias J, Alvarado M, Saunders C, Williams N, Joseph D, On Behalf of the TARGIT Trialists Group. University College London, London, United Kingdom; University of Heidelberg, Mannheim, United Kingdom; University of Notre Dame, Fremantle, United Kingdom; University College Hospital and Whittington Hospital, London, United Kingdom; School of Surgery, University of Western Australia, London (All), United Kingdom; University of San Francisco, London (All), United Kingdom; Sir Charles Gairdner Hospital, London (All), United Kingdom

Introduction
In June 2010, we published the results of the TARGIT-A trial (1) that compared “one-size fits” all radiotherapy (whole breast radiotherapy-E/BRT group) with risk -adjusted radiotherapy (TARGIT- group: single dose TARGeted Intraoperative radion Therapy with additional whole breast radiotherapy if adverse prognostic factors were found). These results showed that the risk of local recurrence in the TARGIT group was non-inferior to that of the EBRT group (the difference between the two arms was 0.25% at 4 years). We now report the results analyzed after further follow up of the total trial cohort without unblinding.

Method
As often repeated, unplanned analysis comparing two groups in a randomized trial can result in an increased alpha-spent as well as carry the risk of a false positive result, we have remained blinded to the further recurrences in the trial according to allocated treatment, since the original publication in the Lancet. Instead we proposed and performed a blinded analysis of the local recurrence rate for the whole cohort. We plotted the Kaplan Meier plots and compared the estimated 4-year recurrences.

Results
Amongst the 2232 patients randomized, there were 13 recurrences at the time of Lancet publication and since then, we have had 8 additional recurrences. The number of patients who have completed at least 4 years of follow up has increased from 420 to 717. We found that the 4-year Kaplan Meier estimate of local recurrence was 1.08% (95% CI 0.59 -1.96) at the time of the Lancet publication and it is 1.09% (95% CI 0.65 - 1.85) now.

Conclusion
We found that the overall 4-year recurrence rates of the TARGIT-A trial have remained stable with a longer follow up and therefore; it is statistically implausible, that one particular arm has a significantly higher local recurrence.

Survival Analysis and Recurrence Patterns in Locally Advanced Breast Cancer Following Neoadjuvant Chemotherapy and Preoperative Concurrent Chemo Radiotherapy.
Shaw RJ, Lara F, Robles CD, Vilari D. Instituto Nacional de Cancerologia, Mexico City, Mexico

Introduction: Although not widely used, preoperative concurrent chemo radiotherapy (CCRT) following poor response to neo adjuvant chemotherapy (CT) has been recently associated with an improved prognosis in patients with locally advanced breast cancer (LABC) and high recurrence risk, showing acceptable toxicity profiles, acceptable post surgical complication rates and increases in both clinical and pathologic response rates and local control rates. The objective of this study was to assess disease free survival (DFS), overall survival (OS) and patterns of recurrence in a cohort of patients with LABC treated with pre operative CCRT following poor response to neo adjuvant CT.

Methods: This longitudinal study included a total of 287 patients with LABC treated with pre operative CCRT following poor response to neo adjuvant CT between February 2000 and December 2002. Demographic, clinical/pathologic, therapeutic and follow up data were collected from patient charts to determine DFS, OS and recurrence patterns.

Results: Stages IIB, IIIA and IIIB accounted for 22.3, 37.6 and 40% of the population, respectively. Clinical response rates compared to pathologic response rates following anthracycline based CT and CCRT were minimal or stable in 16% vs 62.4%, partial in 53 vs 76.3% and complete in 30 vs 23.3%. No significant treatment related toxicities were identified. Post surgical complications included flap ischemia in 16%, partial flap necrosis in 18%, both ischemia and partial flap necrosis in 13.2% and partial wound dehiscence in 7.7%. With an average follow up of 64.1±37.2 months, (0-126.3 months), 36.9% of the population relapsed and 55.1% remained disease free. With regard to recurrence patterns, 22.6% presented loco regional relapse, 67.7% recurred at a distant site and 9.8% showed presented both. Median OS was 64.2 months (0-126 months). Five and ten year survival probability was shown to be 75% and 60%, respectively.

Conclusions: Despite improvements in local control rates and overall outcomes with current therapeutic regimens combining chemotherapy, surgery, and radiotherapy, 30 to 40% of patients with locally advanced breast cancer develop post treatment loco regional recurrence and 5 year overall survival remains low (50%). Multimodal treatment integrating pre operative CCRT is therefore a valid alternative in the LABC setting, showing promising results in regard to OS, DFS and recurrence rates. Prospective clinical studies to evaluate its use are warranted.

P3-13-09
Impact of Estrogen Receptor Negativity on Clinical Outcomes Following Accelerated Partial Breast Irradiation.
Wilkinson JB, Baschneagel A, Shah C; Amin M, Nadeau L, Mitchell CK, Wallace MP, Chen PY, Grills IS, Martinez AA, Vicini FA. Beaumont Cancer Institute, Oakland University William Beaumont School of Medicine, Royal Oak, MI

Purpose: To determine the impact of estrogen receptor (ER) negativity on clinical outcomes for patients treated with Accelerated Partial Breast Irradiation (APBI).

Materials/Methods(s): We evaluated 506 consecutive patients treated with interstitial brachytherapy (n=199), balloon-based brachytherapy (n=203), and 3D-CRT (n=104). ER negative (ERN) status was assigned using the traditional definition of an ER nuclear IHC stain < 10%, which corresponds to an Allred/NSABP staining score of < 10%, which corresponds to an Allred/NSABP staining score of <

2.63 patients (12.5%) were ER negative and 443 (87.5%) were ER positive (ERP). Patient demographics and clinical outcomes (IBTR, RNF, DM, DFS, CSS, OS) were analyzed for each group.

Results: The two groups had similar patient characteristics. Tumor sizes were slightly larger for the ERP group at 11.9mm vs. 10.7mm, although this was not statistically significant (p=0.14). No differences were seen in median age (63 vs. 64 years, p=0.36), rate of HER-2/neu overexpression (83% vs. 91%, p=0.11), or lymph node positivity (6% vs. 9%, p=0.55) between the ERP vs. ERP groups, respectively. There were an equal distribution of invasive ductal carcinoma (ERP n=55, 87%; ERP n=387, 87%) and DCIS (ERN n=8, 13%; ERP n=56, 13%) patients within each group. The use of chemotherapy (55% vs. 15%, p<0.001) and nuclear grade (71% vs. 12%, p<0.001) were higher in the ERP vs. ERP cohort. With a mean follow up of 6.1 years, the 5-year actuarial rates of ipsilateral breast tumor recurrence (IBTR), regional nodal failure (RNF), and distant metastasis (DM) for the entire cohort were 1.8%, 0.6%, and 3.2%. Although this was not statistically significant, ERP patients appear to have an increased rate of local failure than patients with ERP histology (4.0% vs. 1.5%, p=0.13). Rates of RNF and DM were, however, significantly higher for the ERP group (RNF: 4.9% ERP vs. 0% ERP, p<0.001; DM: 12.1% ERP vs. 2.0% ERP, p<0.001). Although there was no difference in overall survival at six years (86% vs. 90%, p=0.67), we observed a shorter disease-free survival (86.4% vs. 96.5%, p=0.01) and cause-specific survival (90% vs. 98%, p=0.01) for the ERP vs. ERP groups.

Conclusion: The ER negative phenotype of early-stage breast cancer may have a decreased rate of locoregional control. We observed a higher rate of DM with reduced disease-free and cause-specific survival in ERP negative cases, emphasizing the importance of systemic therapy and careful, long-term follow up for these patients. Prospective study of this histologic subtype with a larger cohort of patients is needed to substantiate these findings.

P3-13-10
Does Lapatinib Increase Pulmonary Toxicity When Concurrently Used with Radiation Therapy? An Experimental Study with Wistar-Albino Rats.

Purpose: Lapatinib (L) is an oral receptor tyrosine kinase inhibitor which has shown activity in the treatment of metastatic breast cancer. Adjuvant usage of L is being investigated in clinical phase III trials. There is no data regarding the side effects of combination of RT and L which has shown activity in the treatment of metastatic breast cancer. Adjuvant usage of L is being investigated in clinical phase III trials. There is no data regarding the side effects of combination of RT and L which may be a problem when L is used in the adjuvant setting. Lung is the most radiosensitive organ to observe late effects of RT. We evaluated if concurrent administration of L has any impact for the development of radiation induced pulmonary fibrosis in rats (RIPF).

Material Methods: 40 female Wistar-albino rats (WAR) were divided into 4 experimental groups (G). G1 (control) did not receive any treatment. G2 (RT) received RT to whole thoracic region. G3 (L) received L without RT. G4 (L+RT) received L with RT. A total dose of 30 Gy in 10 fractions was given to both lungs with an anterior field at 2 cm depth. L equivalent to 1500 mg/day, 60 kg adult dose, were calculated according to the mean weight of rats, orally administrated with a feeding tube twice daily including the week-ends until WAR were sacrificed. WAR were anesthetized and sacrificed 16 weeks after RT which was shown to be a sufficient period for the development of RIPF in rats. Paraffin sections (5 µm thick) of lungs were stained with hematoxylin-eosin and Masson’s trichrome. A comparative analysis was performed among 4 groups by scoring the pulmonary injury...
between 0 and 3 according to the infiltration of inflammatory cells into the alveolar spaces, alveolar wall thickening and architectural deformation across the entire lung section. Normality distribution were tested, then one-way ANOVA followed by post hoc Holm-Sidak testing were used.

Results: In G2 inflammatory cell infiltration, fibrosis with damage to lung structure and formation of small fibrous masses were observed. Alveolar septa was significantly thicker than G1 (p<0.05), which revealed totally normal pulmoner structure. G3 showed minimal alveolar septal thickening and infiltration of inflammatory cells into the alveolar spaces which was not significantly different than G1. Histopathological findings in G4 were similar to those in G2 and statistically different when compared with the G1 and G3 (p<0.05).

Conclusion: Study shows that addition of L to RT does not increase RIPF in rats.

P3-13-11
Horowitz DP, Ng J, Burri RJ. Columbia University Medical Center-
New York Presbyterian Hospital, New York, NY

Background: The role of post-mastectomy radiation therapy (PMRT) for breast cancer patients with intermediate-risk (1-3 positive nodes) disease remains controversial. This Surveillance, Epidemiology, and End Results (SEER) study investigated the impact of PMRT in the intermediate-risk breast cancer patient population on cause-specific survival (CSS) and overall survival (OS). The study also investigated the impact of estrogen receptor (ER) status, which has been reported in the SEER database since 2004, on the impact of PMRT in this patient population on CSS and OS.

Methods: The SEER database was used to identify all breast cancer patients who were treated between 2004-2007, who had undergone mastectomy, and who had T1-2 tumors and 1-3 pathologically positive lymph nodes. The status of radiation therapy, ethnicity, tumor grade, TNM stage, year of diagnosis, number of LNs sampled, number of LNs positive, and estrogen/progesterone receptor status was recorded. Patients missing pathologic or treatment-related information were excluded. Statistical analysis for CSS and OS was performed using the Kaplan-Meier method and analyzed using the log-rank test. Multivariable analysis was performed using the Cox proportional hazards regression model. Statistical analyses were performed using PASW, version 18.

Results: 10,517 patients were identified, with a median follow-up of 21.8 months (range 0-47 months). 2339 patients (22.2%) received PMRT. Younger patients, increasing tumor size, increasing tumor grade, and ER negative tumors were more likely to receive PMRT. PMRT was associated with improved OS, 92.8% (95% CI 91.2-94.4%) versus 88.7% (95% CI 87.3-89.7%), p < 0.001. However, there was no overall CSS benefit to PMRT, p = 0.197. In the subgroup with ER positive tumors, PMRT was associated with both improved OS, 95.5% (95% CI 93.9-97.1%) versus 91.0% (95% CI 90.0-92.0%), p < 0.001, and improved CSS, 97.6% (95% CI 96.6-98.8%) versus 96.1% (95% CI 95.3-96.9%), p = 0.009. Multivariable analysis showed that PMRT was significantly associated with improved survival (HR 0.744, p = 0.011); increasing age, tumor grade, ER negative tumors, increasing tumor stage, and increasing positive nodal ratio were associated with increased risk of death.

Conclusion: Patients with intermediate risk breast cancer who received PMRT have improved OS compared to those who did not receive PMRT. For patients with ER positive tumors, PMRT also appears to be associated with improved CSS. Greater consideration for post-mastectomy radiation therapy use may be warranted for this patient population.

Electrons for Intraoperative Breast Radiotherapy in Selected Patients: Long-Term Results of the Montpellier Phase II Trial.
Lemanski C, Dubois JB, Gutowski M, Gourgou S, Ailleres N, Azria D. CRLC Val d'Aurelle, Montpellier, France

Background and purpose: Postoperative whole breast external radiotherapy remains the current standard of care for patients with early operable breast cancer. In the elderly, the low crude numbers of recurrence and the frequency of comorbidities urged teams to investigate the feasibility and the results of intraoperative radiotherapy (IORT) delivered in one fraction during the surgical procedure.

Material and methods: 94 patients (> 65 years old) accepted to be included in this phase II trial according to clinical and histopathology criteria and signed the informed consent. Among them, 42 presented all the inclusion criteria, namely pT0-1 pN0, non lobular invasive unifocal carcinoma, margin ≥ 2 mm (assessed during the surgical procedure) and estrogen receptors positivity. All patients were operated upon in a dedicated IORT facility (linear accelerator) located centrally among six operated rooms. After tumor removal, the surgical bed was approximated by sutures to bring the tissue within the radiation target volume. The tumor beds were completely encompassed by 4 to 6 cm circular fields using flattened applicators at a 110 cm distance. One fraction of 21 Gy was prescribed and specified at the 90% isodose using electron with energies ranging from 6 to 10 MeV. In vivo dosimetry was performed for all patients using real-time in vivo semiconductor detectors (PTW) fixed by the surgeon within the surgical bed. A 5 year adjuvant hormonotherapy was prescribed according to the recommendations.

Primary end-point was the quality index [QI] - ratio between the prescribed dose and the in vivo measured dose-. Secondary endpoints corresponded to quality of life, local recurrences, cosmetic results, specific and overall survival.

Results: Median follow-up is now 54 months [range 12-62]. Median age was 72 years [66-80] and median tumor diameter was 10 mm [3-19 mm]. 36 tumors were grade 1 or 2 and 100% of the tumors expresses estrogen receptors. All patients received the total prescribed dose. No external postoperative radiotherapy was delivered. Intraoperative dosimetry demonstrated a good accordance between the delivered and the prescribed doses for 97% of the 37 evaluable patients. No acute grade 2 or greater toxicities were observed. Scores for quality of life were collected for all patients and showed no modification between pre and posttreatment evaluations. Late cosmetic result was good to excellent. All patients are still alive and the 4 year-disease-free-survival is currently 97%. Two patients recurred: (i) one infracentimetric superficial recurrence in the border of the surgical bed and close to the skin (at 18 months) (ii) a second primary tumor in another quadrant (at 6 months). These two patients underwent salvage mastectomy and are free of disease at the time of analysis.
Conclusion: For a very selected population, these results confirm that partial breast IORT with electrons may be considered as an interesting alternative to the standard 6-weeks radiotherapy, offering therefore a safe one-step procedure treatment.

P3-14-01
Panitumumab in Combination with FEC 100 (5-Fluorouracile, Epirubicin, Cyclophosphamide) Followed by Docetaxel (T) in Patients with Operable, Triple Negative Breast Cancer (TNBC): Final Results of a Multicentre Neoadjuvant Pilot Phase II Study.
Nabholz J-M, Weher B, Gligorov J, Mouret-Reynier M-A, Tredan O, Vanlemmens L, Petit T, Mayer F, Van Praagh-Doreau I, Dubray-Longereras P, Nyl B, Ferriere J-P, Jouannaud C, Devaute H, Tubiana-Mathieu N, Abrial C, Kwiatkowski F, Planchat E, Chalabi N, Penault-Llorca F, Chollet P, Jean Perrin Comprehensive Cancer Centre, Clermont-Ferrand, France, Metropolitan; Alexis Vautrin Comprehensive Cancer Centre, Vandoeuvre les Nancy, France, Metropolitan; Tenon University Hospital, Paris, France, Metropolitan; Leon Berard Comprehensive Cancer Centre, Lyon, France, Metropolitan; Oscar Lambret Comprehensive Cancer Centre, Lille, France, Metropolitan; Paul Strauss Comprehensive Cancer Centre, Strasbourg, France, Metropolitan; Georges François Leclerc Comprehensive Cancer Centre, Dijon, France, Metropolitan; Jean Godinot Comprehensive Cancer Institute, Reims, France, Metropolitan; Limoges University Hospital, Limoges, France, Metropolitan

Background: Panitumumab is an antibody targeting the epidermal growth factor receptor (EGFR) to which a role has been suggested in TNBC. Consequently, we evaluated the combination of a standard chemotherapy (FEC 100 followed by T) with panitumumab as neoadjuvant therapy of operable TNBC.

Methods: 60 patients with stage II-IIIa disease were prospectively included in this multicentre pilot study. Systemic therapy (ST) consisted of 4 cycles of FEC 100 (500/100/500 mg/m²) q.3 weeks followed by 4 cycles of T (100 mg/m²) q.3 weeks, in combination with panitumumab (9 mg/kg) for 8 cycles q.3 weeks. All patients underwent surgery at completion of ST. Complete pathologic response (pCR) was the primary endpoint (Sataloff/J Am Coll Surg 1995; Chevallier: Am J Clin Oncol 1993), with toxicity and biologic ancillary studies as secondary endpoints.

Results: Patients characteristics are as follows: mean age 47 [27-72]; T2: 74%, T3: 26% (mean tumor size: 40 mm [20-120]); N0: 65%, N1: 28% and N2: 7%; invasive ductal carcinoma: 96%; Scarff-Bloom-Richardson Grade III: 72%, grade II: 28%. The median number of cycles was: FEC 100: 4 [2-4], T: 4 [0-4], Panitumumab: 7 [1-8]. Pathological response showed a pCR according to Sataloff’s classification of 57.1% [95% IC: 40.7-73.3] and according to Chevallier’s classification of 51.4% [95% IC: 34.8-68.0] with an overall clinical response rate of 60% (29% CR [95% IC: 43.8-76.2].

Conservative surgery was performed in 79% of cases. Skin toxicity was the main side-effect: Cutaneous toxicity grade IV: 12%, grade III: 26%, grade II: 23%. No ocular complications have been reported. Neutropenia grade IV: 23.7%; febrile neutropenia: 4.2%. Infection: 0%. Hand-foot syndrome grade III: 4%. Unusual toxicity grade IV: 2.5%, grade II: 25.5%.

Conclusions: These results suggest that Panitumumab in combination with FEC100 followed by T appears efficacious with acceptable toxicity in the neoadjuvant therapy of operable TNBC.

P3-14-02
Sequential Versus Upfront Intensified Neoadjuvant Chemotherapy in Patients with Large Resectable or Locally Advanced Breast Cancer (INTENS), Toxicity Results from a Phase III Study of the Dutch Breast Cancer Trials' Group (BOOG).
Vriens BE, Van de Vijver KK, Boetes C, van Gastel SM, Wals J, Smilde TJ, van Warmerdam LJ, van Laarhoven HW, van Spreons DJ, Borm GF, Tjan-Heijnen VC. Maastricht University Medical Centre, Maastricht, Netherlands; Comprehensive Cancer Centre the Netherlands, Nijmegen, Netherlands; Atrium Medical Centre, Heerlen, Netherlands; Jeroen Bosch Hospital, ’s Hertogenbosch, Netherlands; Catharina-Hospital, Eindhoven, Netherlands; Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; Canisia-Willheltina Hospital, Nijmegen, Netherlands

Background: Taxanes have an established role as (neo-)adjuvant treatment of breast cancer. In the present study, we compared 4 AC - 4 T with 6 cycles of TAC in the neo-adjuvant setting (A=adriamycine, C=cyclophosphamide, T=docetaxel). Previously, we reported that AC-T resulted in a trend for improved outcome (odds ratio pCR of the breast 1.61; 95% CI 0.79-3.33). Now we report the safety data.

Methods: Women presenting with breast cancer, cT2≥3cm, cT3, cT4 and/or cN+, with measurable disease and no prior treatment, age ≥18 and ≤70 years and Karnofsky Score ≥70% were eligible. Patients were randomized to AC (60/600 mg/m² q3wk x 4 cycles) followed by T (100 mg/m² q3wk x 4 cycles) without primary G-CSF prophylaxis, or to TAC (75/50/500 mg/m² q3wk x 6 cycles) with primary G-CSF prophylaxis. If indicated, trastuzumab and/or endocrine therapy were given as adjuvant treatment. This present analysis focuses on the toxicity profile of the two treatment arms.

Results: In total, 201 patients (n=100 AC-T, n=101 TAC) were included between February 2006 and April 2009. Baseline characteristics (AC-T/TAC) were well balanced. Patients in the AC-T arm had more frequently grade 3 / 4 toxicities as compared to the TAC arm, respectively in 57% and 28% (p=0.001). Grade 3 / 4 neutropenia without fever was more frequently reported with AC-T (35% vs. 4%; p=0.001). Grade 3 / 4 febrile neutropenia was also more frequent with AC-T (17% versus 5%; p=0.0062) and significantly increased during docetaxel treatment after AC. Notably, diarrhea was also more frequently seen in the AC-T arm (4% versus 0%, p=0.0423). Other grade 3 / 4 toxicities more frequently reported in the AC-T arm were neuropathy – sensory (5% vs. 0%; p=0.229) and pain other than muscle or bone pain (4% vs. 0%; p=0.0423). There were no grade 3 / 4 toxicities more frequently observed in the TAC arm.

Conclusion: In the comparison of two taxane-anthracycline-cyclophosphamide regimens in the neo-adjuvant setting, it is observed that the sequential approach with a lower cumulative dose tends to have a slightly better efficacy outcome, but at the cost of increased grade 3 / 4 toxicity. However, considering the use of primary G-CSF prophylaxis in the TAC arm, and the fact that the incidence of febrile neutropenia was higher during taxane containing chemotherapy in the AC-T arm, the difference might (partly) disappear if primary G-CSF prophylaxis would be used in the sequential arm. Primary G-CSF prophylaxis may be considered during docetaxel if used sequentially after anthracycline-containing chemotherapy.

Support: Unrestricted grants from sanofi-aventis NL BV and Amgen BV.
P3-14-03
ABCB1 Single Nucleotide Polymorphisms as a Possible Prognostic Factor in Breast Cancer Patients Receiving Docetaxel and Doxorubicin Neoadjuvant Chemotherapy on Systemic Treatment.

Background
Expression of the adenosine triphosphate-binding cassette B1 (ABCB1) transporter and P-glycoprotein are associated with resistance to anticancer drugs. The purpose of this thesis was to investigate the role of single nucleotide polymorphism (SNP) in the ABCB1 and CYP3A genes in breast cancer patients who were treated with neoadjuvant docetaxel and doxorubicin chemotherapy.

Material and Methods
Patients with histologically confirmed breast cancer, Stage II or III, referred for neoadjuvant chemotherapy were enrolled. Patients were treated with 3 cycles of neoadjuvant and adjuvant chemotherapy with docetaxel and doxorubicin. The polymorphisms of ABCB1 (C3435T, G2677T/A, and C1236T) were genotyped by polymerase chain reaction (PCR) and restriction fragment length polymorphism (RFLP) assays. The genotyping of CYP3A was done by the GoldenGate assay (Illumina Inc). The correlation of genetic polymorphisms of ABCB1, CYP3A, and clinical outcomes was analyzed.

Results
A total of 216 patients were enrolled, and the median age was 44 years (range 25 - 69 years). The overall radiologic response rate (RR) was 76.8% whereas 8.3% of the patients achieved a pathologically complete response. After a follow-up duration of 48.8 months, the median relapse-free survival (RFS) and overall survival (OS) were not reached. ABCB1 3435TT genotype had a longer OS than CT/TT genotype (p=0.045) and a trend toward a lower relapse rate (p=0.284) although it is statistically insignificant. With univariate analysis of the OS, good performance status (PS), invasive ductal carcinoma, initial operable stages, estrogen receptor (ER)-positive, non-triple negative, and the TT genotype of ABCB1 C3435T were associated with a lower risk of death. Multivariate analyses for the OS revealed that PS (HR 4.670, 95% CI=1.066-10.468; p=0.041), initial clinical stage (HR 3.198, CI=1.480-6.907; p=0.003), and triple negative phenotype (HR 3.091, 95% CI=1.245-6.570; p=0.004) were significantly associated with the OS. ABCB1 3435TT genotype was also associated with a lower risk of death with marginal significance not shown to be an independent prognostic factor (HR 0.295 95% CI=0.121-1.122; p=0.071). ABCB1 3435TT genotype had a higher AUC than CC/CT genotype for docetaxel with marginal significance (p=0.054). These higher AUCs in the C3435TT genotype were associated with increased toxicities of neutropenia (p=0.037) and diarrhea (p=0.017). AA (*1/*1)/AG (*1/*3) genotypes of CYP3A5 had a higher AUC than GG (*3/*3) for docetaxel with statistical significance (p=0.024). However, these higher AUCs of CYP3A5*1 allele carrier did not affect the survival and toxicities.

Discussion
This study showed that the genetic polymorphism of ABCB1 C3435T might be associated with a longer OS and have predictive roles after the treatment with the neoadjuvant docetaxel/doxorubicin for stage II and III breast cancer. Our results also suggest that the prediction of docetaxel toxicity might be possible for ABCB1 C3435T polymorphism. Larger prospective studies as well as functional studies in human subjects are warranted.

P3-14-04
Assessment of Genomic Prognostic Signatures as Predictors of Response to Neoadjuvant Chemotherapy in Patients with Early Stage Breast Cancer.
Culakova E, Poniewierski MS, Huang M, Kuderer NM, Ginsburg GS, Barry W, Marcom PK, Ready N, Abernethy A, Lyman GH. Duke University, Durham, NC

Background: Based on results from randomized clinical trials, adjuvant and neoadjuvant chemotherapy (NCT) strategies in early stage breast cancer patients (ESBC) achieve comparable long term results. Recently, a number of genomic signatures have been reported, distinguishing patients with low versus high risk of recurrence. While developed primarily as prognostic assays, these classifiers have also been proposed to be predictive of benefit from systemic chemotherapy. Neoadjuvant studies provide an opportunity to evaluate their predictive value for response to NCT.

Methods: A systematic review of gene expression profile studies in ESBC patients receiving chemotherapy was conducted. Medline search of original research articles of human studies published between January 2000 and February 2011 was based on key words and MeSH heading terms. Publications presenting outcomes for chemotherapy treated patients in groups stratified by multi-gene array signatures and utilizing a new independent cohort of patients compared to the original development cohort were selected. Information from eligible studies was extracted by dual abstraction. Reported results were synthesized into combined diagnostic odds ratio (DOR) using method of Mantel-Haenszel. This analysis is restricted to neoadjuvant studies investigating the association of genomic signature prognostic categories with objective tumor response to chemotherapy.

Results: A total of 42 articles were eligible for data abstraction. Out of these, 6 publications evaluated response to NCT in good (low risk of recurrence) versus poor prognosis groups based on genomic prediction. Since two of the studies analyzed the same signature on a cohort with large overlap, only 5 studies were included in the final analysis, accounting for n=918 patients. Response consisted of pathologic complete response (pCR) in 3 studies, pCR or minimal residual disease (1 study), and clinical complete response (1 study).

Prognostic genomic assays included Oncotype DX (1), MammaPrint (1), Genomic Grade Index (2) and PAM50 Risk of Relapse Score (1). Eight different chemotherapy regimens were utilized. The most common drugs were cyclophosphamide, anthracyclines, taxanes, and 5-fluorouracil. Across all genomic signatures, good prognosis patients, as defined by gene expression data, demonstrated consistently low rates of response to chemotherapy (median 3%, range 0-12%) compared to patients with less favorable prognosis (median 32%, range 19-43%). Odds ratio for response in poor versus good prognosis patients ranged from 3.9 to 21.7 with combined DOR= 6.6 (95% CI 3.9-11.3, P<0.0001). No heterogeneity was determined across studies (P=0.4). The C-statistic estimating assay discriminatory ability was reported in 3 studies ranged from 0.72 to 0.78.

Conclusions: Across all genomic prognostic signatures reported, only a very small proportion of patients with signature predicted good prognosis achieved complete response to NCT. This suggests low sensitivity to chemotherapy among good prognosis patients, as determined by the prognostic genomic signatures. This further confirms the association between poor prognosis tumors and higher responsiveness to chemotherapy.

Evaluation of Residual Cancer Burden Index (RCBI) as a Predictor of Disease Free Survival in a Non-Selected Cohort of Breast Cancer Patients Treated in the Neoadjuvant Setting.

INTRODUCTION: Pathologic complete response (pCR) is associated with long-term survival and is considered as the primary endpoint in neoadjuvant trials. Definition of pCR includes patients without residual disease of the breast, however the presence of nodal metastasis, minimal residual cellularity and residual in situ carcinoma were not consistently defined as pCR. These observations, lead Symmans et al to construct a new prognostic index, the RCBI, in which these important issues were incorporated. RCBI is classified into 4 different response subgroups, from RCB-0 or pCR to RCB-III or absence of response. The aim of our study was to assess the prognostic value for recurrence free survival of the RCBI in a cohort of unselected breast cancer patients treated in our institution. PATIENTS AND METHODS: We performed a retrospective evaluation of samples of breast cancer patients treated with neoadjuvant treatment. RCBI was assessed by two highly trained pathologists. Patients included had a histological diagnosis of breast carcinoma before neoadjuvant treatment and were considered candidate for neoadjuvant therapy. Clinical variables including date and type of recurrence were obtained from clinical records. Prognostic accuracy of RCBI index was evaluated by comparison of the Kaplan-Meier survival curves of the 4 different groups of response by RCBI. Differences were assessed with log-rank. RESULTS: Samples from 70 patients treated in the neoadjuvant setting from January 2003 to December 2006 were included in the analysis. Median age was 54.6 years (range 31-80), histologic subtype was ductal carcinoma (87.1%), lobular carcinoma (8.5%), and other (4.2%). In biopsy, rate of estrogen receptor positive was 72.7%, progesterone receptor positive 62.1%, and rate of HER2 overexpression was 26.2%. Neoadjuvant therapy administered was anthracycline-taxanes chemotherapy (CT) in both sequential or combination schedules in 71.4%, anthracycline-based CT in 15.7%, and other in 12.9%. Most patients received from 6-10 cycles of neoadjuvant CT. 3 patients treated with only 4 cycles received adjuvant complementary CT. All patients with hormone-sensitive tumors received adjuvant endocrine therapy and 20 patients received adjuvant trastuzumab. Number of responses by RCB-group was 5 patients (7.1%) with RCB-0, 12 patients (17.1%) with RCB-I, 35 (50%) with RCB-II, and 18 (25.7%) with RCB-III. With a median follow-up of 41.2 months (range 12.7-120.9 months) 22 patients (31.4%) have relapsed. Ratio of events/patients in each RCB group was 0/5 in RCB-0, 2/12 in RCB-I, 8/35 in RCB-II and 15/18 in RCB-III. Differences in recurrence-free survival in each group was statistically significant with p<0.0002. CONCLUSIONS: Our results suggest that RCBI might be an appropriate prognostic tool to predict disease-free survival in a non-selected population of breast cancer patients. Further validation of our results with a bigger sample size is needed.

P3-14-06
Combined Use of 18F-FDG PET/CT and MRI To Monitor Breast Cancer Response during Neoadjuvant Chemotherapy.

INTRODUCTION: Pathologic complete response (pCR) is commonly used for the evaluation of the therapeutic effect of neoadjuvant chemotherapy (NAC). A recent study demonstrated the relevance of breast cancer subtype with regard to the accuracy of MRI to predict response during NAC. The role of 18F-fluorodeoxyglucose (FDG) positron emission tomography (FDG PET/CT) is under investigation, and varying results have been reported. MRI and 18F-FDG PET/CT, visualize different functional characteristics of the tumor (perfusion and glucose metabolism), but it is unclear if they complement one another to monitor response to NAC, and whether breast cancer subtype plays an independent role.

Method and material
The study group consisted of 65 women with stage II or III breast cancer and measurable FDG tumor uptake, who were treated with NAC and participated in an ongoing MRI/FDG PET/CT study. MRI and FDG PET/CT scans were acquired prior to and during treatment, using prone patient positioning. Written informed consent was obtained. Prior to the start of NAC a biopsy was taken and tumors were divided into three subtypes, using immunohistochemistry: human epidermal growth factor receptor 2 (HER2) amplified (HER2+)(N=18), estrogen receptor positive/HER2 non-amplified (ER+/HER2-)(N=29), and triple negative (TN) tumors (N=18). MRI interpretation included lesion morphology at baseline, changes in morphology, tumor size, and contrast uptake kinetics (initial and late enhancement). At FDG PET/CT the maximum standardized uptake value (SUVmax) at baseline and during treatment was obtained. Tumor response pathologically was stratified to “incomplete response” (substantial presence of vital invasive tumor cells) and “favourable response” (complete absence of invasive residual tumor or only a small number of scattered tumor cells). Appropriate statistical analyses including T-tests, multivariate logistic regression and receiver operating characteristic (ROC) curves were employed to indentify factors associated with incomplete response at pathology. The following imaging and clinical features were candidates for forward feature selection in the multivariate analysis: lesion morphology, largest tumor diameter, pattern of reduction, absolute and relative change in largest tumor diameter at initial and at late enhancement during NAC, SUVmax at baseline; absolute and relative change in SUVmax during NAC; breast cancer subtype; chemotherapy regimen, and age.

Results
At pathology after NAC, 32 tumors (49 %) showed favourable response and 33 (51 %) had residual disease. At multivariate analysis, breast cancer subtype, relative change in the diameter of late enhancement on MRI and relative change in SUVmax on FDG PET/CT were independent markers of tumor response at final pathology. The area under the ROC curve increased from 0.86 for MRI alone to 0.94 (p<0.01) in combination with FDG PET/CT and breast cancer subtype, yielding 84% sensitivity at 95 % specificity.

Conclusion
MRI and FDG PET/CT show complementary potential to predict response during NAC, in addition to breast cancer subtype.

Relative Risk of Recurrence (RR) over Time in ER Positive and Negative T4 Breast Cancer Patients Achieving Less Than pCR (<pCR) after Primary Chemotherapy: A Reversal Trend of Recurrence beyond 60 Months after Diagnosis.
Ionta MT, Atzori F, Pascuccio V, Notari F, Valle E, Guerzoni D, Chiappe A, Marongiu M, Minerba L, Massidda B. University Hospital, Cagliari, Italy; Hospital of Oncology Businco, Cagliari, Italy

Background: It is widely assumed that patients (pts) who achieve a pCR have a good prognosis and better outcomes compared with pts with <pCR, regardless of hormone receptor status. Emerging data suggest that achieving < pCR identifies a heterogeneous group with different risks of recurrence and death, being ER negative the subgroup with the worst prognosis.

Aim of our study was to evaluate the relative risk of recurrence (RR) over time in ER-positive (ER+) and ER-negative (ER-) <pCR patients.

Material and Methods: We analyzed 139 consecutive <pCR T4 pts, of whom 85 were ER+ (cut-off 10%) and 54 were ER-. Median age was 53 y (range 29-73). Median follow up was 137 months (range 8-233). All pts received primary anthra-based chemotherapy with or without taxanes followed by endocrine therapy for 5 years, if hormone receptor positive. We examined the RR of recurrence at 0-24, 25-60, 61-120 and beyond 120 months (m) interval after diagnosis.

Results: For all 139 pts, the total number of pts with recurrence was 95 (68%), 54 (63%) in ER+ and 41 (76%) in ER- tumors. For the entire group and both in ER+ and in ER-, the RR of recurrence was greatest for the interval between 0-24 months, then decreased rapidly in ER- and slowly in ER+ through the 25-120 m interval. For the 0-24 m and 25-60 m intervals the RR of recurrence was higher for ER- pts and after 60 m it crossed and beyond 60 m the RR of recurrence was higher in ER+ than in ER- pts. Notably, beyond 120 months we observed a little second peak of recurrence, higher in ER+ (7%) than in ER- (3%) pts. Nine of these 10 relapses occurred between 120 to 180 m interval, 7 in ER+ (13%) and 2 in ER- (5%) subgroup. In the first 24 m ER- pts were 86% more likely to relapse compared with ER+ vice versa between 61-120 and beyond 120 m intervals, ER- pts were 19% and 18% less likely to relapse, respectively, compared with ER+ pts.

Conclusions: The present study confirmed the previous reports which showed unfavorable prognosis of the <pCR patients with negative ER status, due to their significantly higher relative risk of recurrence between 0 to 60 months interval. The ER+ recurrences occurred more frequently in late follow-up. A reversal of recurrence between ER positive and negative patients beyond 60 months after diagnosis was detected. The fact might indicate the importance of long term adjuvant hormone therapy for T4 ER positive breast cancer patients with <pCR after primary chemotherapy.

A Phase II Study of Gemcitabine and Carboplatin (GC) Plus Iniparib (BSI-201) as Neoadjuvant Therapy for Triple-Negative and BRCA1/2 Mutation-Associated Breast Cancer.

Background: The combination of gemcitabine, platinum and inhibition of DNA repair results in synergistic chemosensitivity in triple-negative and BRCA1-deficient breast cancer cell lines. This study was designed to assess efficacy, safety and predictors of response to iniparib, a small molecule whose mechanism of action is under investigation, in combination with GC in early-stage triple-negative and BRCA1/2 mutation-associated BC.

Methods: This single-arm, phase II study (NCT00813956) enrolled patients with clinical stage I–IIIA (T ≥1cm by MRI) estrogen receptor-negative (≤5%), progesterone receptor-negative (≤5%), and HER2-negative or BRCA1/2 mutation-associated BC. Neoadjuvant gemcitabine (1000 mg/m2; IV; D1, 8), carboplatin (AUC 2; IV; D1, 8), and iniparib (5.6 mg/kg; IV; D1, 4, 8, 11) were given every 21 days for 4 cycles, until the protocol was amended to increase the treatment duration to 6 cycles with enrollment of 36 patients. The protocol was further amended to increase the patient number with expansion to additional centers. Prior to expansion, reporting of interim safety and efficacy results was specified. The primary endpoint is pathologic complete response (pCR), defined as the absence of invasive carcinoma in the breast and axilla. Pathologic response was assessed using the residual cancer burden (RCB) index. Secondary endpoints included safety, radiographic response by MRI, breast conservation eligibility and correlation of baseline gene expression with response.

Results: The pre-expansion cohort consisted of 13 patients assigned to 4 cycles of treatment and 36 patients assigned to 6 cycles of treatment. Among these 49 patients (50 tumors), median tumor size is 35 mm, and median age is 48 years. The overall pCR rate is 34% (95% CI = 22-48); the pCR rate at 6 cycles is 41% (95% CI = 26-57). RCB 0/I was observed in 5/13 pts (38%; 95% CI = 18–64) treated with 4 cycles; 21/37 (57%; 95% CI = 41-71) treated with 6 cycles; and 9/9 pts (100%) with known BRCA1/2 mutations. Two pts experienced disease progression, two locoregional relapse, and three distant relapse. Among 45 tumors with Affymetrix-based RNA microarray gene expression data, 39/45 (87%) are classified as basa-like, 3/45 (7%) luminal B, and 3/45 (7%) normal breast-like. Most common G3/4 adverse events include neutropenia (31%), anemia (10%), and elevated ALT/AST (10%). Alopeica and chemotherapy-induced amenorrhea were uncommon. Analyses of secondary endpoints are ongoing and will be presented.

Conclusions: Preoperative GC plus iniparib is active in the treatment of early-stage triple-negative and BRCA1/2 mutation-associated breast cancer.
P3-14-09
A Phase II Preoperative Study of Dasatinib, a Multi-Targeted Tyrosine Kinase Inhibitor, in Locally Advanced “Triple-Negative” Breast Cancer Patients.
Rimawi MF, Rodriguez AA, Yang WT, Gonzalez-Angulo AM, Nangia JR, Wang T, Speers C, Mills G, Hilsenbeck SG, Brown PH, Chang JC. Baylor College of Medicine, Houston, TX; The Methodist Hospital, Houston, TX; M.D. Anderson Cancer Center, Houston, TX
Background: We previously reported that kinases (Src, Yes-1, cKIT, Abl, and EPH4) were druggable in triple negative breast cancer (TNBC). In this clinical trial, we sought to translate these findings by treating TNBC patients with dasatinib, a multi-targeted kinase inhibitor against these targets.
Methods: Women with stage II-III TNBC were eligible. Patients received dasatinib at 100 mg daily for 3 to 4 weeks before standard-of-care definitive surgery and chemotherapy. Biopsies were performed at baseline, week 1, and at the time of surgery. A cohort of patients had positron emission mammography (PEM; baseline and at 2-3 weeks of dasatinib therapy). This study was designed to detect an increase in clinical response rate from 10% to 25%, using a Simon optimal two stage design, with one-sided alpha=5% and power=80%. At least 3 responses out of 22 patients were needed to proceed to the second stage.
Results: 22 patients were enrolled (Table 1). Median tumor size was 7.0 cm (range 2.4-25 cm). Adverse events were modest, mainly grade 1-2 (headache: 45%, abnormal LFTs: 55%, GI: 23%, fatigue: 18%). One patient had a myocardial infarction 24 hours after starting dasatinib. Out of 22 patients, 2 (9%) had a clinical partial response after 3-4 weeks of therapy, 15 had stable disease (68%), while 5 had progressive disease (23%). Of the 8 patients who received paired PEM imaging, metabolic responses were observed in 2 patients (25%). Conclusion: A short course of dasatinib led to clinical responses in 2 out of 22 patients with TNBC, and the study did not proceed to second stage. Since TNBC is a heterogeneous disease, biomarker studies including sequencing of candidate genes like B-RAF for inactivating mutations might enable selection of those TNBC patients who could benefit from dasatinib.

Early Predictive Value of Non-Responder to Docetaxel in Neoadjuvant Chemotherapy in Breast Cancer Using 18F-FDG-PET.
Hirakata T, Fujisawa T, Yanagita Y, Horikoshi H, Oya N, Akiyoshi T, Kinoshita T, Kikuno H. Gunma Prefectural Cancer Center, Ota, Gunma, Japan; Tsurugaya Hospital, Iseaki, Gunma, Japan; Graduate School of Medicine, Gunma University, Maebashi, Gunma, Japan
Background: Clinical response is determined after several cycles of chemotherapy by changes in tumor size in imaging procedures including ultrasound, MRI or CT. The aim of this prospective study was to early detect non-respondent to docetaxel (DTX) in neoadjuvant chemotherapy using 18F-FDG-PET in patients with breast cancer.
Method: 41 patients were eligible for this study. 37 were assessable (4 were not eligible or not evaluable) with Invasive carcinoma (T1:10%, T2: 83%). All 37 patients were treated with 4 cycles of docetaxel (75mg per square meter) followed by 4 cycles of FEC(cyclophosphamide/epirubicin/fluorouracil: 500/75/500 mg per square meter) before surgery. 18F-FDG-PET response rate was evaluated between before and after the first cycle of DTX. 18F-FDG-PET images were analyzed by standardized uptake value, SUVmax. Clinical response is determined by reduction rate in tumor size with MRI (RECIST criteria) between before the first cycle and after the fourth cycle of DTX. Pathological response evaluated by core needle biopsy after the fourth cycle of DTX.
Result: 18F-FDG-PET response rate after the first cycle of DTX showed correlation with tumor size reduction rate with MRI image after the fourth cycle of DTX (r=0.746)(P<.001). 0 out of 8 patients (0%) revealed cPR with MRI changes in SUV decrease less than 18% (P <.001). 8 out of 13 patients (62%) showed cPR (cCR = 0) with SUV in SUV decrease over 19 to 44% (P <.001). 9 out of 16 patients (56%) were cPR, and 7 out of them (44%) showed cCR with MRI in SUV decrease over 45% (P <.001).
Conclusion: Changes of 18F-FDG SUVs in tumors were statistically significantly different between responding and nonresponding (P <.001). SUV decrease less than 18% after the first cycle indicated potential failure to DTX in neoadjuvant chemotherapy.

P3-14-11
Comparison of Two Nomograms To Predict Pathologic Complete Response to Neoadjuvant Chemotherapy – Evidence That HER2 Positive Tumors Need Specific Predictors.
Aim: The purpose of this study was to compare two different nomograms to predict pathologic complete response (pCR) to preoperative chemotherapy in an independent cohort of 200 patients with breast cancer. The first model was the MDACC nomogram published in 2005 and the other one was a nomogram based on the number of preoperative courses, Ki-67 and steroid hormone receptors expression published by Colleoni et al. in 2010
Patients and methods: Data from 200 patients with breast carcinoma treated with preoperative chemotherapy and operated at Tenon Hospital from 2001 to 2009 were collected. We calculated pCR rate predictions with the two nomograms and compare those predictions with outcome. Patients received between 4 and 8 course of anthracycline/taxanes based chemotherapy. More than 90% of patients with HER2 positive tumors received concomitant trastuzumab with taxanes. Model performances were quantified with respect to discrimination (evaluated by the areas under the receiver operating characteristics curves (AUC)) and calibration.
Results: In the entire population, the AUC for the MDACC nomogram and the Colleoni nomogram were respectively 0.74 and 0.75. Both of them underestimated the pCR rate (p=0.02 and 0.0005). When excluding patients treated with trastuzumab, the AUC were 0.78 for both of them with no significant difference between the predicted and the observed pCR (p=0.14 and 0.15). When analyzing the specific population treated with trastuzumab as preoperative treatment, the AUC for the MDACC nomogram and the Colleoni nomogram were respectively 0.52 and 0.53.
Conclusion: The MDACC and the Colleoni nomograms are accurate to predict the probability of pCR after preoperative chemotherapy in HER2 negative population but did not correctly predict pCR in
HER2 positive patients who received trastuzumab. This suggests that response to preoperative chemotherapy including trastuzumab is biologically driven and that a specific nomogram or predictor for HER2 positive patients has to be developed.

Local Control of Primary Breast Cancer Treated with Radical Radiotherapy Alone after Neoadjuvant Chemotherapy.

Makris A, Li SP, Ravichandran D, Ostler PJ, Pittam M, Mount Vernon Cancer Centre, Northwood, Middlesex, United Kingdom; Laton and Dunstable, Laton, United Kingdom

**Introduction:** The aim of this retrospective study was to evaluate the local recurrence rates in a cohort of patients who achieved a complete clinical response (cCR) to neoadjuvant chemotherapy and did not have surgery.

**Materials and Methods:** 148 women who achieved a cCR to neoadjuvant chemotherapy were identified from a prospectively maintained database (1995-2011) of 667 patients. 122 patients went on to have surgery (either wide local excision or mastectomy) followed by radiotherapy. In 26 patients (median age 49, range 35-72 years; T2-T4, N0-3, M0), no surgery was performed but all received radical radiotherapy. Surgery was avoided due to either physician or patient choice. Recurrence was defined as first relapse of disease, either local (ipsilateral breast and/or axilla) or distant.

**Results:** All 26 patients who avoided surgery had neoadjuvant chemotherapy with 20 patients (77%) receiving anthracycline-based (FEC, FAC, ECF), 5 (19%) MMM and 1 (4%) CMF chemotherapy. The median number of cycles was 6 (range 4-8). Chemotherapy was followed by radical external beam radiotherapy to the breast +/- supraclavicular fossa and axilla (median dose delivered, 60Gy in 2Gy fractions). All were identified as operable at diagnosis including 3 patients who had supraclavicular lymphadenopathy. All 26 patients achieved a final cCR in the breast to chemotherapy. 21 patients had imaging with mammography and/or ultrasonography to assess radiological response at the end of neoadjuvant chemotherapy, 20 of which had a complete response and 2, a partial response. After a median follow-up of 144 months, 10/26 (38%) patients experienced local disease recurrence (2 also had distant recurrence) and 4/26 (15%) patients with distant metastases only. Patients with local recurrence only, went on to have a mastectomy whilst those with distant disease received systemic therapy. There were 10 deaths, 9 of which were breast cancer related (33%).

**Conclusions:** Local recurrence rates were high in patients achieving a cCR following neoadjuvant chemotherapy and who avoided surgery. Our practice has subsequently changed to include clip insertion and surgical excision on completion of chemotherapy. With increasing pathologic complete response rates to more active chemotherapy schedules (including taxanes +/- herceptin), it is being proposed that surgery could be avoided in selected patients. Our study shows that caution should be exercised.

**P3-14-13**

Llombart-Cussac A, Pernas-Simon S, Rezai M, Hauchchild M, Venturini M, Machiels J-P, Paepe S, Luporsi E, Kasiborski F, Kayitalire L, Hospital Armai de Vilanova, Lleida, Spain; L’Hospital de Llobregat, Barcelona, Spain; Luisenkrankenhaus Düsseldorf, Düsseldorf, Germany; Ospedale Sacro Cuore, Negrar (Verona), Italy; Cliniques Universitaires St-Luc, Université Catholique de Louvain, Brussels, Belgium; Technischen Universitat München, München, Germany; Centre Alexis Vautrin, Vandoeuvre-Les-Nancy, France; Cephalon, Maisons-Alfort, France; Frauenklinik und Brustzentrum Rheinfelden, Rheinfelden, Germany

**Background:** The upfront addition of trastuzumab (Herceptin, H) to anthracycline/taxane-based primary chemotherapy significantly increases pathological complete response (pCR) in HER2-positive breast cancer (BC) patients (pts). However, concerns about the cardiac toxicity of concurrent administration of H and standard anthracyclines limited its use (Seidman et al 2002, J Clin Oncol 20:1215-21). MYOCET® (M) has a better cardiac tolerance profile than standard doxorubicin (Adriamycin, A) and might allow to give anthracyclines safely in combination with H. We explored the added benefit of early and longitudinal exposure to the combination of M with H in early-stage HER2-positive BC in a phase II multicentric randomized trial.

**Methods:** Women with stage II or IIIA HER2-positive BC were randomized to receive 4 cycles of either M + cyclophosphamide (C) + H (MCH) or AC every 3 weeks (q3w); then followed by 4 cycles of docetaxel + H (q3w). The primary endpoint was the pCR rate. Secondary endpoints included the overall and cardiac safety (using left ventricular ejection fraction [LVEF] and NYHA classification).

**Results:** Since September 2008, 126 pts with a median age of 51 and stage II (85 pts) or III (39 pts) BC were randomized: 1 pt did not initiate treatment, 12 discontinued treatment prematurely, 21 were still receiving treatment, 91 had completed treatment and 90 underwent surgery, as of January 15th 2011. Pathological responses are under central review.

In the MCH arm, 1 pt reported a NYHA class II cardiac event and 1 pt had asymptomatic LVEF decrease down to 42%. In the AC arm, 2 pts experienced NYHA class II events, 1 pt had LVEF value 17% below baseline, and 1 pt had LVEF value 6% below the lower normal limit. Mean (±SD) LVEF decrease from baseline to endpoint was 0.8% (±6.3) in the MCH arm and 3.8% (±5.8) in the AC arm. Patients tended to report more grade 3 gastrointestinal (GI) adverse event in the MCH arm (8.1% of pts) than in the AC arm (4.8% of pts), mainly diarrhea (6.5% of pts in the MCH arm vs 1.6% in the AC arm). Other grade 3 GI toxicities were infrequent. Hematological toxicity was similar in both arms: 56.4% and 61.9% of pts developed grade 3/4 neutropenia, and 16.1% and 14.3% of pts reported febrile neutropenia, in the MCH and AC arms respectively. No severe case of palmar-plantar erythrodyssaesia syndrome was reported.

**Conclusion:** The concurrent administration of the non-pegylated liposomal doxorubicin MYOCET® and H has an acceptable early safety profile that should be confirmed with longer follow-up. Pathological response data are pending and will be presented at the meeting.

Increased Prevalence of Low Vitamin D Level in Breast Cancer Patients during Neoadjuvant Chemotherapy.

Jacot W, Poudoures S, Thezenas S, Chapelle A, Romieu G, Lamy P-J. CRLC Val d’Aurelle, Montpellier, France

Purpose: Patients with early-stage breast cancer treated with neoadjuvant chemotherapy (NCT) are at risk of bone metabolism changes, resulting in loss of bone mass. Cancer treatment-induced bone loss (CTIBL) increases the risk for skeletal morbidity. An understanding of CTIBL is critical for determining the risk, identifying which patients may benefit from preventive therapy, and for screening patients for early intervention with therapies such as bisphosphonates or anti-RANKL therapies. In addition, considering the bone metabolism profile in early breast cancer patients, only a minority of women had vitamin D levels in the range considered sufficient for optimal health. This vitamin D deficiency may be associated with poor outcomes in breast cancer. In order to study the variation of the bone metabolism markers during NCT, we evaluated 78 early breast cancer patients homogeneously treated in our centre.

Patients and methods: We studied the serum level of a panel of bone metabolism biomarkers (calcium, vitamin D, TRAIL, RANK-Ligand, Osteoprotegerin (OPG), serum bone trap, serum crosslap and DKK1), in a population of 78 early breast cancer patients treated by the association of 3 cycles of FEC100 then 4 taxane cycles between March 2007 and August 2008. Serum samples were withdrawn before the first CT cycle and before surgery. Time course and correlations between these biomarkers levels were evaluated. All computations were carried out using Stata. Two-sided P-values below 0.05 were considered to be statistically significant.

Results: The clinicopathological characteristics of the population were classical of a neoadjuvant setting. 23% of the patients achieved a pCR. At baseline, 79.5% of the patients presented with vitamin D insufficiency (<30 ng/ml). This proportion increased to nearly all the patients before surgery (97.4% p < 0.0001). The same significant decrease in serum levels was found for calcium and RANK-ligand, while a significant increase in serum OPG level was noted, resulting in an increase of the OPG/RANK-Ligand ratio. Serum calcium and vitamin D levels were significantly correlated (Spearman’s coefficient = 0.23), while there was a trend (Spearman’s coefficient = 0.1) for correlation between serum calcium and RANK-Ligand levels.

Conclusion: To our knowledge, this is the first clinical study comprehensively evaluating the changes in bone metabolism during early stage breast cancer NCT. In our study, nearly all the patients suffered from vitamin D insufficiency by the end of NCT. This insufficiency was associated with changes in the calcium / Rank-Ligand / OPG axis, evocative of a functional regulatory mechanism. These results require further analyses in order to define the role of pharmacologic modulation of this regulatory mechanism in the bone wellbeing of early breast cancer patients. A study evaluating the best medical intervention to correct this highly prevalent vitamin D insufficiency in this population is ongoing.

Non-Randomized, Open Label Phase II Trial Evaluating the Safety and Efficacy of Taxotere (T) Followed by Myocet (M) + Cyclophosphamide (C) as First-Line Treatment for HER2-Negative Breast Cancer (BC).

Garcia-Mata J, Calvo L, Lopez R, Ramos M, Castellanos J, Heras L. Complexo Hospitalario de Ourense, Ourense; Spain; Complexo Hospitalario Universitario A Coruña, A Coruña, Spain; Hospital Clínico de Santiago, Santiago de Compostela, A Coruña, Spain; Centro Oncológico de Galicia, A Coruña, Spain; Complexo Hospitalario Universitario Xeral Cies, Vigo, Pontevedra, Spain; Hospital Sociosanitari de l’Hospitalet, Barcelona, Spain

Background: Breast cancer is the most common malignancy in females in Europe and is the most common cause of cancer mortality in women, with doxorubicin playing an important role in chemotherapy (CT) regimens used in this setting but limited by cardiotoxicity. Liposomal encapsulated doxorubicin was designed to minimize healthy tissue distribution by altering pharmacokinetics thus reducing cardiotoxicity while preserving antitumor efficacy. The current study was developed to assess the pathologic complete response (pCR), response rate and safety of treatment with taxotere (T), non-pegylated liposomal doxorubicin (M) and cyclophosphamide (C) in previously untreated patients with BC.

Methods: Patients (pts) with HER2-negative BC receiving 1st-line CT were eligible. On Day 1 of each 21-day cycle for a total of 4 cycles, pts received T 75 mg/m² IV, followed sequentially by M 60 mg/m² and C 600 mg/m² IV every 3 wks for 4 cycles. Breast conserving surgery (BCS) was considered if the response was deemed satisfactory, otherwise mastectomy was performed and pCR was evaluated. Pts must have had LVEF ≥50% at the time of enrolment and had regular cardiac evaluation throughout the study (MUGA or ECHO).

Results: A total of 74 pts (50 stages II and 24 IIIA) over a 30-month period in six centres were accrued with clinical/pathological responses available for 51. The median age was 46 yrs (range 23-75). Histology: lobular 7/ductal 67. Grade I/II/III: 6/27/30. ER+/PR+: 43; ER+/PR-: 13. Triple negative: 18. 50 pts had pre-op CT cycles and were subjected to surgery. No clinically significant change in LVEF was noticed (Pre-CT LVEF 68.5% [CI95%: 66.7-70.4]; post-CT LVEF 68.9% [CI95%: 66.0-71.7]).

On an intent to treat analysis, an objective clinical response was observed for 38 pts: complete (12%) and partial (63%). In addition, 12 pts (23%) demonstrated stable disease and only one progressed (2%). The proportion of patients requiring mastectomy and BCS were 14 (28%) and 36 (72%), respectively. On 33 pts with an axillary dissection, 25 (76%) had involved nodes. After pathological review, 18/50 pts (36%) were devoid of any tumor cells in both breast and axillary dissection, 25 (76%) had involved nodes. On 33 pts with an axillary dissection, 25 (76%) had involved nodes. After pathological review, 18/50 pts (36%) were devoid of any tumor cells in both breast and lymph nodes following CT were 3 (IQR 2-6).

All patients were included for toxicity assessment. Grade 3-4 neutropenia and febrile neutropenia was seen in 23% and 10% pts, respectively. Principal non-hematologic grade 3-4 toxicities included allergic reaction/hypersensitivity in 6% pts, and asthenia, diarrhoea and vomiting in 1%. No pts developed symptomatic CHF. Ten pts discontinued treatment: 5 due to taxane-hypersensitivity reaction, 3 due to disease progression and 2 due to protocol violation.

Conclusions: This multi-centre phase II trial clearly demonstrates significant activity (pCR 36%) for neoadjuvant taxane sequentially followed by non-pegylated liposomal doxorubicin and cyclophosphamide regimen in a HER-2 negative BC population. Overall the treatment regimen was well tolerated. Sequential T→MC is safe and not associated with changes in LVEF. An updated evaluation of efficacy and toxicity profile analysis will be presented.

Molecular Phenotype and the Use of HER-2 Targeted Agents Influence the Accuracy of Breast MRI after Neoadjuvant Chemotherapy.

Moon H-G, Han W, Noh D-Y, Ahn S, Kim J, Shin H, Min J. Seoul National University College of Medicine; Dankuk University Hospital

Background: Improved understanding of factors affecting the accuracy of breast magnetic resonance imaging (MRI) after neoadjuvant systemic therapy (NST) can lead to more tailored use of MRI in deciding surgical extent after NST.

Materials and Methods: We analyzed the imaging and clinicopathologic data of 463 patients who underwent NST. We aimed to investigate whether the molecular subtypes, as well as the use of targeted therapies, were associated with changes in the accuracy of MRI predicting residual tumor extent.

Results: The accuracy of MRI predicting the residual tumor extent was most accurate in triple negative breast cancer and was least accurate in Luminal A subtype (Pearson’s correlation coefficient of 0.754 and 0.531, respectively). Multivariate analysis suggested estrogen receptor status as an independent factor influencing the MRI accuracy. In HER2-amplified tumors, the use of HER2-targeted agents was associated with less accurate MRI prediction. Dual HER2-blockade by using trastuzumab and pertuzumab resulted in lowest MRI accuracy among the patients treated with HER2-targeted agents.

Conclusion: The accuracy of MRI in predicting residual tumor extent was lowest in ER positive tumors treated with NST. In HER2 positive tumors, the use of HER2-targeted agents resulted in less accurate MRI after NST.

P3-14-17
Paclitaxel, Carboplatin, and Trastuzumab in a Neoadjuvant Regimen for HER2-Positive Breast Cancer: The TRAIN Study.

Sonke GS, Mandjes IA, Holtkamp M, Schot M, Oosterkamp HM, Wesseling J, Vranken Peeters M-JT, Rodenhuis S, Linn SC. Netherlands Cancer Institute, Amsterdam, Netherlands

Background: Treatment with trastuzumab is highly active in HER2 positive breast cancer, although cardiotoxicity is a well known side effect. The cardiotoxicity of trastuzumab may be aggravated by combined treatment with anthracyclines. Consequently, treatment with trastuzumab is often delayed pending the administration of anthracyclines. Both in vitro and in vivo data suggest that trastuzumab synergizes with a range of chemotherapeutic drugs, including taxoid drugs and carboplatin. In addition, prolonged pre-operative treatment leads to higher pathologic complete remission (pCR) rates. We report the results of a fase 2 trial integrating trastuzumab at the start of a non-anthracycline containing weekly paclitaxel-carboplatin based neo-adjuvant chemotherapy regimen in HER2-positive breast cancer.

Patients and methods: One-hundred patients with stage II or III breast cancer, including inflammatory disease, with HER2 overexpression (immunohistochemistry and/or in situ hybridization) were treated with 24 weekly administrations of paclitaxel 70 mg/m2, carboplatin AUC=3 mg.ml-1.min, and trastuzumab 2 mg/kg (loading dose 4 mg/kg). In cycles 7, 8, 15, 16, 23, and 24 only trastuzumab was given. The primary endpoint was pathologic complete response (pCR) in both breast and axilla. The trial was preceded by an initial pilot cohort of 55 patients treated with the same regimen.

Results: Final efficacy and safety results of all patients included in the phase 2 trial will be reported at the meeting. In the pilot cohort of 55 similarly treated patients, 33% had stage II disease, 69% was clinically node positive, and 49% was ER and PgR negative. Twenty-four patients (41%) had a pCR in breast and lymph nodes. pCR in ER negative patients was 67%, pCR in ER positive patients was 21%. The most commonly reported grade 3/4 toxicities were neutropenia (30%) and thrombocytopenia (27%). Dose reduction was required in 24% of the patients. Grade 3/4 left ventricular systolic dysfunction was not observed.

Conclusion: A weekly carboplatin-paclitaxel-trastuzumab neoadjuvant regimen is highly active in HER2 positive breast cancer with a good safety profile. A subsequent multicenter phase 3 trial will compare this regimen to a similar 16 week regimen preceded by 4 cycles of anthracyclines plus cyclophosphamide.

The study protocol was developed at the joint ECCO-AACR-EORTC-ESMO Workshop on Methods in Clinical Cancer Research in Flims, Switzerland.

P3-14-18
Primary Tumor Response to Neoadjuvant Chemotherapy Is Significantly Associated with Nodal Pathological Complete Response in Breast Cancer Patients with Cytologically Proven Axillary Node Metastasis.

Hwang H, Park S, Lee JS, Kim S-I, Park B-W. Yonsei University College of Medicine, Seoul, Korea

Background

Axillary node status is the most significant factor for the prediction of outcome in breast cancer patients whether they received neoadjuvant chemotherapy or not. However, a reliable method to predict nodal response to neoadjuvant chemotherapy is not established yet. The aim of this study was to identify the predictive factors of axillary pathological complete response (pCR) after neoadjuvant chemotherapy in breast cancer patients with cytologically proven axillary lymph node metastases.

Patients and methods

A total of 123 patients with axillary metastases confirmed by ultrasound-guided fine-needle aspiration biopsy were subsequently treated with four cycles of anthracycline (60mg/m2) plus cyclophosphamide (600mg/m2) followed by doxetaxel (75-100mg/m2) between August 2008 and March 2011. After neoadjuvant chemotherapy, all patients underwent a definite breast surgery with complete axillary lymph node dissection. Clinicopathological parameters were evaluated using a chi-square test and logistic regression model in association with node pCR.

Results

The mean age at diagnosis was 47.9 years in all patients. Eighty-one (65.9%) patients were preoperative clinical T2 stage, 74 (60.2%) showed estrogen receptor (ER)-positivity, and 36 (29.3%) demonstrated HER2-positivity. A pCR of the axilla and breast was determined in 56 (46%) and 40 (31.7%) patients, respectively. Breast pCR rate is significantly associated with age≤50 at diagnosis, ER(-),PR(-) and higher Ki-67 proliferation. Axillary pCR rate is significantly associated with age at diagnosis of 50 or less, smaller primary tumor size at diagnosis, tumor responsiveness to neoadjuvant chemotherapy, estrogen hormone receptors-negativity, higher Ki-67 proliferative index at diagnosis, and subtypes of HER2-enriched or triple negative breast cancer. When these factors entered logistic regression model, tumor response( SD+PD vs CR+PR: OR 8.603, P=0.007), Ki67((-) vs (+): OR 7.157, p=0.009), ER status((+) vs (-): OR 4.943, P=0.036), pre-operation tumor size(>2cm vs ≤2cm : OR 5.116, p=0.044), HER2 status( (-) vs (+) : OR 5.029, p=0.046) remained to be significant for the prediction of axillary pCR, favorable nodal response.
Conclusion
Our study suggests that primary tumor response to neoadjuvant chemotherapy is significantly associated with favorable nodal response. The factors of tumor and nodal response were similar. There are many issues remained to be determined yet.

P3-14-19
Impact of Chemotherapy-Induced Amenorrhea on Response to Neoadjuvant Chemotherapy in Breast Cancer.
Ahn SK, Moon HG, Kim JS, You JM, Shin HC, Han W, Noh D-Y. Seoul National University Hospital

BACKGROUND: Although chemotherapy and ovarian ablation independently improve the outcome of breast cancer, there is controversy about the benefit of chemotherapy-induced amenorrhea (CIA) in breast cancer. We investigated impact of CIA on response to neoadjuvant chemotherapy in breast cancer patients.

METHODS: We reviewed the records of 198 premenopausal patients with breast cancer treated with neoadjuvant chemotherapy between January 2005 and December 2010. Chemotherapy-induced amenorrhea (CIA) was defined as serum FSH level ≥40 IU/L after completion of all scheduled neoadjuvant chemotherapy and prior to definitive surgery.

RESULTS: Among 198 breast cancer patients, 132 pts (66.7%) developed CIA after neoadjuvant chemotherapy. 156 pts (78%) underwent DA chemotherapy. The age of CIA patients was older than non-CIA patients (41.5±5.55 years vs. 38.27± 6.86 years, p=0.001). The incidence of CIA after neoadjuvant chemotherapy was significantly higher in responder group (responder vs. nonresponder: 87 pts (74.4%) vs. 45 pts (55.6%); p=0.006). Additionally, FSH level after all scheduled neoadjuvant chemotherapy was significantly higher in responder group (FSH 56.41±32.41 IU/L vs. 45.76±30.31 IU/L; p=0.021). In univariate analysis, CIA (p=0.006) and total number of chemotherapy cycle regardless of chemotherapy regimen (p=0.04) were significantly associated with tumor response. CIA was only independent factor for tumor response after neoadjuvant chemotherapy on multivariate analysis (p=0.012).

CONCLUSION: CIA after neoadjuvant chemotherapy was significantly associated with response to neoadjuvant chemotherapy in locally advanced breast cancer.

P3-14-20
Concomitant Taxane-Anthracyclin Regimen for Neoadjuvant Chemotherapy of Primary Breast Cancer: Experience from a Cohort of 223 Patients Treated in a Single Institution.
Coguan E, Guizard A-V, Heutte N, Bor C, Allouache D, Delcambre C, Switser O, Guillot J-M, Leither N, Delozier T, Levy C. François Baclesse Cancer Center, Caen, France

BACKGROUND: Although chemotherapy and ovarian ablation independently improve the outcome of breast cancer, there is controversy about the benefit of chemotherapy-induced amenorrhea (CIA) in breast cancer. We investigated impact of CIA on response to neoadjuvant chemotherapy in breast cancer patients.

METHODS: We reviewed the records of 198 premenopausal patients with breast cancer treated with neoadjuvant chemotherapy between January 2005 and December 2010. Chemotherapy-induced amenorrhea (CIA) was defined as serum FSH level ≥40 IU/L after completion of all scheduled neoadjuvant chemotherapy and prior to definitive surgery.

RESULTS: Among 198 breast cancer patients, 132 pts (66.7%) developed CIA after neoadjuvant chemotherapy. 156 pts (78%) underwent DA chemotherapy. The age of CIA patients was older than non-CIA patients (41.5±5.55 years vs. 38.27± 6.86 years, p=0.001). The incidence of CIA after neoadjuvant chemotherapy was significantly higher in responder group (responder vs. nonresponder: 87 pts (74.4%) vs. 45 pts (55.6%); p=0.006). Additionally, FSH level after all scheduled neoadjuvant chemotherapy was significantly higher in responder group (FSH 56.41±32.41 IU/L vs. 45.76±30.31 IU/L; p=0.021). In univariate analysis, CIA (p=0.006) and total number of chemotherapy cycle regardless of chemotherapy regimen (p=0.04) were significantly associated with tumor response. CIA was only independent factor for tumor response after neoadjuvant chemotherapy on multivariate analysis (p=0.012).

CONCLUSION: CIA after neoadjuvant chemotherapy was significantly associated with response to neoadjuvant chemotherapy in locally advanced breast cancer.

P3-14-21
Neoadjuvant Therapy Response, Subtype and BRCA Status in an Underserved Population.

BACKGROUND: Preoperative (neoadjuvant) chemotherapy is typically used for larger operable breast cancer cases, and the degree of pathological response correlates with long term outcome. Therapeutic response also depends on biological and molecular subtype and is increasingly studied in the research setting to identify prognostic biomarkers and potential therapeutic targets. Little is known about the interactions of neoadjuvant response with biomarker subtypes and genetic predisposition in underserved and minority populations.

METHODS: IRB approval was obtained to capture demographic, clinicopathological and genetic testing data on patients diagnosed with invasive breast cancer and treated with preoperative chemotherapy and definitive surgery between 2005 and 2010 at Los Angeles County Medical Center, which serves a primarily Hispanic and indigent population. Treatment followed NCCN guidelines with the exception that not all patients with HER2+ disease received trastuzumab. Genetic counseling and testing has been available at this center since 2007. Pathological complete response (pCR) was defined as no...
residual invasive disease in breast or nodes. Chi-square or Fisher’s Exact test was used to examine associations between pCR and clinical factors, and logistic regression analyses were applied to assess each variable’s contribution to pCR.

Results: Among 104 patients, of whom 79% were Hispanic, the overall pCR rate was 27%. Significantly higher pCR rates were seen in age ≥50, clinical N0, HER2+, triple negative, and lumpectomy cases. No differences in pCR rate was seen in Hispanics vs. others, Grade III vs. I and II or in the 9 BRC4A mutations carriers among 45 tested compared to no mutation or those not tested. Of the 43 patients with HER2+ disease, the pCR rate was higher in the 32 patients who received trastuzumab (pCR 50.0 vs. 27.3%). Subset pCR rates and odds ratios (OR) of achieving pCR are shown below:

Conclusions: In this underserved cohort, with 43% undergoing genetic testing, significantly higher pCR rates were seen in HER2+ and triple negative and lumpectomy cases, with a trend seen in older patients and smaller tumors. There was an unexpected trend of lower pCR rate seen in BRC4A mutation carriers (pCR OR 0.33), albeit with small numbers. No differences were seen in Hispanic cases compared to other ethnicities. Further tissue analyses are planned to examine established and novel markers and to define exploratory markers that could be used for decision-making and target discovery in larger datasets within this population.

Results: 44 women with a mean age of 74.9 (70-93) years were included. Most tumors were ductal (IDA 88.6%), of grade 3 (79.5%) and hormone-receptor (HR) negative (61.4%). Among the 21 tumors (47.7%) that were HER2+ (immunohistochemistry (IHC) 3+ or 2+ and FISH+), all but 3 received neoadjuvant Trastuzumab. Only 4 patients had no surgery (clinical decision or personal choice) while the remaining 40 patients underwent either breast-conserving surgery (17.5%) or mastectomy (82.5%), 23 patients (52.3%) had pathological partial response, 14 patients (31.8%) pCR and 3 patients no response. pCR was more frequently achieved in HR-negative (44.4%) than in HR- positive patients (11.8%). In both groups HER2 positive tumors had better pathological response than HER2 negative tumors. After a mean follow-up of 41 months (5-120) 29 patients (65.9%) had no evidence of disease, 6 patients (13.6%) had (loco)regional recurrence, 12 patients (27.2%) developed metastatic disease and 6 patients (13.6%) died because of breast cancer. Relapse was more frequently seen in patients with a pPR (47.8%) versus patients with a pCR (14.3%).

P3-14-23 Response to Neoadjuvant Chemotherapy and Survival in Japanese Patients with Triple-Negative Breast Cancer.
Ohtani S, Kochi M, Ito M, Takada S, Matsuura H, Higaki K. Hiroshima City Hospital, Hiroshima, Japan

Background: Triple-negative breast cancer (TNBC) is defined by the lack of estrogen receptor (ER), progesterone receptor (PgR), and human epidermal growth factor receptor 2 (HER2) expression. In this study, we compared response to neoadjuvant chemotherapy and survival between Japanese patients with TNBC and non-TNBC.

Patients and Methods: Analysis of a prospectively collected clinical database was performed. We analyzed 335 Japanese patients who received neoadjuvant chemotherapy at Hiroshima City Hospital for stage I-III breast cancer from 2002-2010. Clinical and pathological parameters, pathological complete response (pCR) rates, survival measurements, and organ specific relapse rates were compared between with TNBC and non-TNBC.

Results: 21.1% had TNBC. Patients with TNBC compared with non-TNBC had not significantly higher pCR rate (28% v 19%; p=0.09), similar disease progression-free survival (DFS) rate (p=0.59), but decreased overall survival (OS) rate (p=0.02). TNBC was associated with increased risk for visceral metastasis (p<0.0001) and shorter postrecurrence survival (p=0.017). If pCR was achieved, patients with TNBC and non-TNBC had similar survival. In contrast, patients with residual disease...
P3-14-24
A Phase II Trial of TS-1 and Docetaxel Followed by 5-FU/Epirubicin/Cyclophosphamide (FEC) as Preoperative Treatment in Women with Stage II/III Breast Cancer.

Hayashi T, Jinno H, Sakata M, Takahashi M, Kitagawa Y. Keio University, School of Medicine, Tokyo, Japan

Background: TS-1 is an oral anticancer drug, composed of tegafur, gimestat and otastat potassium in a molar ratio of 1:0.4:1, based on the biochemical modulation of 5-Fuorouracil. In vivo xenograft model showed a synergistic effect of combination chemotherapy with TS-1 and docetaxel through down-regulation of dihydropyrimidine dehydrogenase (DPD). (Suto et al, Oncology Reports 2006) The sequential combination of anthracycline and taxane is a standard of care in the preoperative setting, as well as the adjuvant setting. This study’s purpose was to determine the efficacy of TS-1 and docetaxel followed by fluorouracil/epirubicin/cyclophosphamide (FEC) in the preoperative setting.

Patients and Methods: Patients with stage II/III breast cancer received 4 cycles of TS-1 (TS-1 80 mg/m² on days 1-14 and docetaxel 40 mg/m² on day 1 every 3 weeks), followed by 4 cycles of FEC (fluorouracil 500 mg/m², epirubicin 100 mg/m², cyclophosphamide 500 mg/m² on day 1 every 3 weeks). The tumor objective response was assessed by both caliper and ultrasound. Primary endpoint was the pathological complete response (pCR) rate. Secondary endpoints were the clinical response rate, adverse drug reactions, and the breast conservation rate.

Results: From November 2009 to December 2010, 39 patients were enrolled and 38 patients were assessable for clinical and pathologic responses. The overall response rate (caliper) was 81.5% and ultrasound response rate was 76.3%. The pCR rate was 13.2% (5/38).

The breast-conserving rate in patients whose tumor size was 3 cm or smaller was 92.9%, and 54.5% of patients whose tumor size was larger than 3 cm underwent breast-conserving surgery. The ratio of Ki-67 positive cell and progesterone receptor (PgR) status were significantly correlated with pCR. Grade 4 neutropenia was observed in a patient (2.6%) at the first cycle. The most common grade 3/4 non-hematologic adverse event was hand-foot syndrome, observed in a patient (2.6%) at the first cycle. The most common grade 3/4 non-hematologic adverse event was hand-foot syndrome, observed in a patient (2.6%) at the first cycle. The most common grade 3/4 non-hematologic adverse event was hand-foot syndrome, observed in a patient (2.6%) at the first cycle. The most common grade 3/4 non-hematologic adverse event was hand-foot syndrome, observed in a patient (2.6%) at the first cycle. The most common grade 3/4 non-hematologic adverse event was hand-foot syndrome, observed in a patient (2.6%) at the first cycle. The most common grade 3/4 non-hematologic adverse event was hand-foot syndrome, observed in a patient (2.6%) at the first cycle. The most common grade 3/4 non-hematologic adverse event was hand-foot syndrome, observed in a patient (2.6%) at the first cycle. The most common grade 3/4 non-hematologic adverse event was hand-foot syndrome, observed in a patient (2.6%) at the first cycle.

Conclusions: These results indicate that the sequential combination of TS-1 and docetaxel followed by FEC is a well-tolerated, effective neoadjuvant treatment for stage II/III breast cancer.

P3-14-25
Neoadjuvant Trastuzumab and Paclitaxel Combination Induces a High Rate of Pathological Complete Responses in Locally Advanced Breast Cancer by Exploiting Host Antitumor Immunity.

Background: A phase II study was performed to assess the role of patients’ immune profile in the activity of a trastuzumab-based, non anthracycline containing neoadjuvant chemotherapy (NC) regimen in locally advanced breast cancer (BC) patients (pts).

Methods: Newly diagnosed T2-T3 HER2+ BC pts received a 12 week NC with weekly paclitaxel and trastuzumab, which was discontinued after further 12 weeks before surgery. The % of patients who showed only one year treatment ± hormonal therapy in case of NC, trastuzumab was discontinued and anthracyclines were planned. Blood samples were collected at diagnosis and every 3 months for 1 year then yearly. The % of NK cells, T cells and Treg cells was evaluated by flow cytometry, and serum levels of 9 cytokines were accessed by SearchLight multiplex array technology. Circulating CD8+ T cells specific for a broad spectrum of tumor-associated antigens (Her2, muc-1, mammaglobulin-A, trag-3, survivin, bcl-xL) were enumerated by IFN-γ ELispot and in vitro T-mediated, antibody-dependent cell cytotoxicity (ADCC) was assessed using patients’ PBMCs.

Results: From July 2006, 34 pts were enrolled, median age 46 yrs (range 30-70). Overall objective clinical response rate was 91%, with 53% of pathological complete responses (pCR) and 38% of partial responses. At a median follow-up of 27 months, 4 relapses were noted (1 brain, 1 local breast, 2 bone). No cardiotoxicity occurred. At diagnosis, pts showed an immune profile similar to that of healthy women, whereas higher numbers of Treg cells (p=0.02), lower T cell numbers (p<0.01) and lower amounts of serum IL-2, IL-6, and IL-8 were found in a concomitant control group of untreated HER2- pts. Moreover, spontaneous CD8+ T cells specific for all 13 HLA-A*0201 epitopes were observed in the whole series, with numbers usually higher than those observed in HER2- cases. Notably, patients with pCR, unlike those showing partial responses, retained high numbers of epitope-specific CD8+ T cells throughout the NC treatment, particularly versus survivin and mammaglobulin-A epitopes. Moreover, pts achieving pCR showed at diagnosis a significantly higher efficiency of trastuzumab-mediated ADCC compared to pts with partial responses (p=0.05). The treatment also induced a progressive increase in the number of NK cells and in the efficiency of trastuzumab-mediated ADCC.

Conclusions: NC with paclitaxel and trastuzumab induces high rates of pCR with no cardiotoxicity. This clinical efficacy is favoured by the retained immunological proficiency of HER2+ pts, who may benefit from the immunological synergism between the two drugs. In fact, the increased number and activation of NK cells promoted by paclitaxel likely favour NK-dependent ADCC responses, known as one of trastuzumab’s main mechanisms of action. The possible role of trastuzumab-mediated ADCC in preserving event-free survival and the involvement of paclitaxel in inducing NK cells’ NF-kB nuclear translocation are under evaluation.
P3-14-26
The Effect of Biologic Subtype in Patients Treated with Neoadjuvant Chemotherapy: A UAB Experience.
Keene KS, De Los Santos JF, Meredith R, Hinton B, Li Y, Krontiras H, Bland K, Carpenter JT, Forero A. University of Alabama at Birmingham, Birmingham, AL

Purpose: Previous studies have suggested that the pre-treatment clinical stage drives loco-regional recurrence (LRR), distant metastasis (DM) and survival in patients treated with neoadjuvant chemotherapy. This retrospective analysis was performed to look at the effect of biologic subtype on patient outcomes. Methods: Between 1999 and 2005, 115 patients treated with neoadjuvant chemotherapy, surgery, and +/-radiation therapy at UAB were identified. Patient, tumor, and treatment characteristics were recorded. Pathologic complete response was defined as resolution of both invasive disease and DCIS in both the primary and nodal disease. Survival was measured using the Kaplan Meier statistics. Univariate and multivariate analyzes of covariates associated with LRR, DM, progression-free (PFS) and overall survival (OS) were performed. Results: The mean age was 49 years, with a mean follow-up of 5.8 years. Subtype distribution was as follows: 52 luminal A, 17 luminal B, 36 triple negative, 9 Her2+ and one patient with an unknown biologic subtype. Distribution of clinical stage was as follows: 40 IIA, 34 IIB, 26 IIIA, 10 IIIB, and 5 IIEC. Tumors were down-staged following neoadjuvant therapy as follows: 18: pCR, 6: residual DCIS, 17: I, 38: IIA, 11: IIB, 13: IIIA, 5: IIIB, and 7: IIIEC. Pre-treatment clinical stage did not significantly influence LRR, DM or progression-free and overall survival; however, final pathologic T, N and group stage were associated with both progression free, p=0.003, 0.011, 0.005 and overall survival, p=0.02, 0.037, and 0.009. Complete resolution of tumor by mammographic or MR imaging to neoadjuvant chemotherapy, was associated with an increased overall survival, p=0.0025. Univariate analysis did not show a significant effect of biologic subtype, age, grade, use of radiation therapy or anti-hormonal therapy. Discussion: In this retrospective series, response to chemotherapy and the final pathologic stage, representing the volume of residual disease, were important predictors of survival. Further study to determine factors predictive of chemotherapy response is needed.

P3-14-27
Pegylated Liposomal Doxorubicin (PLD) as Primary Treatment in Estrogen Receptor (ER) and HER2 Poor Breast Cancer and Risk of Developing Cardiotoxicity or Elderly Patients (pt). Results from the Phase II CAPRICE Study.

Background: Combinations of doxorubicin (DX) and taxanes are considered the standard treatment in high risk breast cancer, but classical DX is not commonly used in elderly pt or in those with risk of developing cardiotoxicity. PLD (Caelyx/Doxil™) is associated with less cardiotoxicity. We present a multicentric phase II trial conducted by SOLTI group. A combination of PLD and cyclophosphamide (CP) followed by paclitaxel (PTX) was tested as primary chemotherapy (CT) in pts with stage II-IIIB breast cancer with poor estrogen receptor positivity (< 50% positive nuclei) and at least one risk factor of developing cardiotoxicity. Our aim was to demonstrate a pathologic complete response (pCR) rate similar of prior DX studies without cardiotoxicity. Method: PLD 35 mg/m^2 + CP 600 mg/m^2 were administered every 4 weeks (w) for 4 cycles followed by PTX 80 mg/m² every w for 12 w. Left ventricular ejection fraction (LVEF), ECG and cardiac questionnaire were performed at baseline and 8, 16, 28, 40 w thereafter. The primary end point was pCR. Secondary endpoints included: cardiac safety, radiological response rate (RRR), breast conserving surgery (BCS) rate, toxicity and overall survival at 5 years. Results: 50 pt were included. Median age: 73 (35-84), 42 pt > 65 years old; 32 pt (64%) suffer from hypertension and 7 had prior cardiac disease. Histological grade III: 36 pts (72%); stage II/III: 24/26 pt respectively; only 13 pts (26%) were candidate for BCS at diagnosis. 46 pt (92%) underwent surgery: BCS 27 (58.6%) and mastectomy 19 (41.3%); 4 pt did not proceed to surgery due to serious adverse events. In an intent-to-treat analysis pCR rate in breast was 32% (95% CI 19.5-46.7%), 22% (95% CI 10.5-33.4%) in breast and nodes. Among triple negative pt (N=48) pCR was 33.3%. Two of seven T4d pt (28.7%) achieved pCR. No significant decrease in LVEF was seen: Mean baseline LVEF was 66.6% (52-86), 66.7 (51-88) after 16w, 62.2 (48-75) after 28w and 64.7 (50-74) after 40 w. Other toxicities: edema 10%, alopecia 10%, neutropenia 10%, stomatitis 8%, neurotoxicity 8%, skin reactions 6%, Hand-Foot Syndrome 6%. Grade III-V toxicities were reported in 10 patients (20%): cardiovascular 3, diarrhea 2, rash 2, lung 2 and neutropenia 1. Three non-cancer deaths occurred: 1 sudden death in a 82 year’s old pt one month after surgery, 1 due to hemorrhagic stroke > 30 days after completing CT pt with prior cerebrovascular disease, and another 84 year’s old due to non-neutropenic pneumonia during CT. Conclusions: This schedule of primary chemotherapy achieves a pCR rate similar to the standard treatment and is feasible in a group of patients for whom DX was contraindicated. This strategy enables to double the BCS rate. Toxicity was acceptable in a very fragile cohort of patients.

P3-14-28
ANZ 0502 NeoGem: A Phase II Trial Evaluating the Efficacy and Safety of Epirubicin and Cyclophosphamide Followed by Docetaxel with Gemcitabine (+ Trastuzumab IF HER2 Positive) as Neoadjuvant Chemotherapy for Women with Large Operable or Locally Advanced Breast Carcinoma.
McCarthy N, Boyle F, Bull J, Leong E, Simpson A, Kannourakis G, Gebski V, Forbes JF, Wilcken N, Lindsay DF, Badger HD, Royal Brisbane and Women's Hospital, Brisbane, Queensland, Australia; The Mater Hospital, Sydney, New South Wales, Australia; Wellington Hospital, Wellington, New Zealand; Ballarat Oncology and Haematology Service, Ballarat, Victoria, Australia; NHMRC Clinical Trials Centre, Sydney, New South Wales, Australia; University of Newcastle, Newcastle, New South Wales, Australia; Calvary Mater Newcastle, Newcastle, New South Wales, Australia; Westmead Hospital, Sydney, New South Wales, Australia; Australian New Zealand Breast Cancer Trials Group, Newcastle, New South Wales, Australia

Background: Neoadjuvant chemotherapy may provide an early indication of treatment effect and pathologic complete response (pCR) rate is a surrogate measure of disease-free and overall survival. Anthracyclines remain an important component of chemotherapy regimens for breast cancer (BC), adding a taxane conveys additional survival benefit. Gemcitabine (G) has established safety and efficacy in metastatic breast cancer (MBC) and combining G with docetaxel...
(D) shows preclinical synergy but not overlapping toxicities. In MBC, efficacy of trastuzumab (T) combined with single agent taxanes and G has been demonstrated for tumours that over-express human epidermal growth factor receptor 2 (HER2+). NeoGem aimed to evaluate the efficacy and safety of neoadjuvant epirubicin (E) and cyclophosphamide (C), followed by D and G +/- T (depending on HER2 status) in women with large operable or locally advanced BC.

**Methods:** Eligible patients (pts), ≥18 years, had unilateral, operable (at presentation) T2 (≥3 cm), T3-4, N0-1, M0 primary BC, no prior chemotherapy or hormonal therapy and ECOG status 0-2. All pts received E (90mg/m^2^ i.v.) in combination with C (600mg/m^2^ i.v.) on day 1 q 21 for 4 cycles followed by D (75mg/m^2^ i.v.) on day 1 in combination with G (1000mg/m^2^ i.v.) on days 1 and 8 q 21 for 4 cycles. HER2+ pts received T (4mg/kg loading then 2mg/kg i.v.) concurrent with DG on days 1, 8 and 15 q 21 for 4 cycles. HER2+ pts received post-surgical T (6mg/kg) 3 weekly, for a total of one year of T therapy. Using a Simon’s 2 stage trial design, the decision to proceed to stage 2 followed interim analysis of stage 1. Primary endpoint, pCR, was defined as no histologic evidence of invasive cancer in the breast. Secondary endpoint, pCRax, was defined as no histologic evidence of invasive cancer in the breast and axilla. EC followed by DG/DGT was expected to achieve a pCR rate of 35% in HER2 negative (HER2-) pts and 40% in HER2+, with the lowest limit of therapeutic efficacy being a pCR rate of 22% (HER2-) and 24% (HER2+). Hence 84 HER2- and 63 HER2+ pts were needed to detect significant differences in pCR rates (power 80%, 95% level of significance).

**Results:** Over 32 months 81 pts (63 HER2- and 18 HER2+) were enrolled, 78 (96%) (61 HER2- and 17 HER2+) proceeded to surgery. Of 78 pts, 21 (27%) achieved pCR and 19 (24%) achieved pCRax. Of the 61 HER2- pts, 12 (20%) (95% CI: 12%-31%) achieved pCR compared with 9 (53%) (95% CI: 31%-74%) of the 17 HER2+ pts. Planned chemotherapy was completed by 67 pts (83%), 9 pts (11%) discontinued due to adverse events. Thirteen pts (16%) required DG dose reductions compared with 7 (8%) pts during EC; 57 (70%) pts had ≥ grade 3 neutropenia.

**Conclusion:** Efficacy in the HER2- cohort did not reach predetermined levels of significance (interim analysis); HER2+ recruitment proved too slow to continue. High haematological toxicity during DG, particularly neutropenia required use of supportive therapy (GCSF). Despite relatively small patient numbers, 53% pCR in the HER2+ cohort warrants further investigation.

**P3-14-29**

**Neoadjuvant Sunitinib Administered with Weekly Paclitaxel/Carboplatin in Patients with Locally Advanced Triple-Negative Breast Cancer: A Sarah Cannon Research Institute Phase I/II Trial.**

**Background:** Angiogenesis plays a substantial role in breast cancer development as well as in triple negative breast cancer (TNBC). Sunitinib is an inhibitor of the tyrosine kinase receptors for VEGF, platelet-derived growth factor (PDGF), KIT, RET, and fms-like tyrosine kinase receptor-3 (FLT3). As monotherapy in heavily pretreated breast cancer patients (pts), sunitinib demonstrated a response rate of 15% in TNBC (11% of all pts) with stable disease or better in 16% of all pts. The combination of paclitaxel and carboplatin is ideally suited for further exploration as neoadjuvant chemotherapy for TNBC, based on the established preclinical and clinical sensitivity of TNBC to these cytotoxic agents. This open label, phase I/II trial was designed to evaluate the combination of sunitinib plus paclitaxel and carboplatin as neoadjuvant treatment for locally advanced breast cancer. The primary objective for the phase I portion was to determine the maximum tolerated dose (MTD); these results are presented.

**Methods:** Women with histologically confirmed invasive triple-negative adenocarcinoma of the breast, (defined as <10% staining by IHC for ER/PR; IHC 0-1+ or FISH negative for HER2), with no evidence of metastatic disease and normal LVEF were eligible. All pts received sunitinib (days 1-28), paclitaxel (days 1, 8, 15), and carboplatin (day 1) in 28-day treatment cycles x6. Following 6 cycles, pts had definitive surgery. After ≥2 weeks and evidence of adequate wound healing, maintenance sunitinib 25mg PO daily was initiated to complete a total of 52 weeks. Three dose levels were evaluated as shown in the table below:

<table>

Doses were escalated in sequential cohorts of pts using standard phase I methodology. MTD was defined as the highest dose level (DL) producing ≤1 dose limiting toxicities (DLTs) in a pt cohort. The MTD identified in the phase I portion of the study will be used in the phase II portion, which will evaluate the efficacy, safety, and tolerability of this combination in pts with locally advanced TNBC.

**Results:** 15 women with TNBC were enrolled between 10/2009 and 2/2011 [median age 53 years (range: 40-78)]. Due to grade 3 neutropenia resulting in the inability to deliver cycle 1 day 15 paclitaxel in the first pt treated at both DLs 1 and 2, these DLs were expanded to 6 pts each. No additional cycle 1 DLTs were noted in the 5 additional pts at either DL. Three pts were accrued to DL 3; there were 2 DLTs noted among these pts (grade 3 febrile neutropenia; grade 3 neutropenia with cycle 2 day 1 treatment delay). However, due to the development of grade 3/4 neutropenia in subsequent cycles in 5 of 6 DL 2 pts, resulting in dose delays and requiring dose reductions, the MTD of this combination was defined as DL 1 (paclitaxel 70mg/m^2^ (Days 1, 8, 15); carboplatin AUC=5 (Day 1); sunitinib 25mg PO daily).

**Conclusions:** The administration of sunitinib with paclitaxel plus carboplatin as neoadjuvant therapy is feasible with neutropenia defining the MTD of this combination. The phase II portion of this study is ongoing.

**P3-14-30**

**Concurrent Celecoxib with FEC Followed by Docetaxel Shows Good Responses and Prognosis in a Neoadjuvant Breast Cancer Study.**

Chow LWC, Tung SY, Ng T-Y, Oh D-Y, Im S-A, Lee M-H, Yip AYS, Toi M, Glück S. Organisation for Oncology and Translational Research, Hong Kong; UNIMED Medical Institute, Hong Kong; Tuen Mun Hospital, Hong Kong; Seoul National University Hospital, Seoul, Korea; Soonchunhyang University Hospital, Seoul, Korea; Kyoto University, Kyoto, Japan; University of Miami Leonard M. Miller School of Medicine, Miami, FL

**BACKGROUND:** Anthracyclines and taxane have been widely used as neo-adjuvant therapy(NAT) for breast cancer. Addition of COX-2 inhibitors might enhance the anti-cancer effect of chemotherapy. This prospective clinical trial studied 5-fluorouracil/Epirubicin/Cyclophosphamide-Docetaxel(FEC-T) with concurrent celecoxib(CXB) as NAT for breast cancer patients(pts). Primary endpoints were pathologic complete response(pCR) and clinical
response (CR), secondary endpoints were safety and breast conservative therapy (BCT) rate. Disease-free survival (DFS) was also determined. METHODS: This study accrued 91 pts among which 87 pts received FEC (F:500mg/m2; E:100mg/m2; C:500mg/m2) followed by T(100mg/m2). In the initial phase, the study randomized 12 and 11 pts to receive 4 cycles of FEC followed by 4 cycles of T with or without concurrent CXB (400mg bid) respectively. Due to possible cardiovascular events from COX-2 inhibitors, the study protocol was revised to a single arm phase II study which recruited another 64 pts who received FEC-T with concurrent CXB at reduced dosage (200mg bid). Primary endpoints were compared between pts with and without CXB using Fisher’s Exact test. All endpoints and survival were evaluated for phase II subjects. RESULTS: Out of 87 pts, 84 invasive breast cancer pts, age ranged 30-62 (mean: 46±6 years) and clinically staged IA (n=48, 57.1%), IIB (n=28, 33.3%) and IIA (n=8, 9.5%), are eligible for comparison between groups (CXB+, n=73 / CXB-, n=11). More CRs were observed in CXB+ than in CXB- (94.5% vs. 72.7%, p=0.044) but pCR did not show statistical difference. In the phase II study, 57/64 pts, including luminal A 35/61 (54%), luminal B 12/21 (57.1%), HER-2 positive 8/14 (57.1%), and triple negative (TPN) 12/30 (40%), completed NAT and definitive surgery. pCR plus near pCR was observed in 18/31 (58%) pts. Excluding TPN subtype, pCR (p=0.761) did not but near pCR (p=0.043) differed among subtypes. Those with HER-2 amplification had higher near pCR than those who did not (6/20 vs. 3/37, p=0.031). Out of 56 pts evaluable for CR, 43 (75.4%) reached complete and partial CR respectively. Over 80% pts received BCT after NAT and that 11/14 (78.6%) pts who initially were unsuitable for BCT with a baseline tumor ≥5cm became eligible after NAT. At a median follow-up of 37 months, 61 pts who completed ≥6 cycles of NAT and surgery were followed and 80% of pts are still disease-free. Pts responding to the NAT has fewer chance of relapse (p=0.03). Neither life-threatening toxicity nor cardiotoxicity was observed. The most commonly observed grade 3/4 adverse events included neutropenia and leukopenia: 39.1% and 20.3% during FEC, and 16.1% and 12.9% during T respectively. Febrile neutropenia was observed in 9.4% pts during FEC, but none during T. Less than 40% of pts required G-CSF support. Other mild toxicities were manageable. CONCLUSIONS: Higher CR was observed in pts receiving neo-adjuvant FEC-T with concurrent CXB which appeared well-tolerated and safe. Rate of BCT is high after the treatment. Pts with HER-2 amplified breast cancer responded better than those who did not. Chance of relapse is significantly reduced for NAT responders. Further investigation of using COX-2 inhibitors with neo-adjuvant chemotherapy is warranted.

P3-14-31
Preoperative Chemotherapy and Bevacizumab for Locally Advanced HER-2 Negative Breast Cancer Followed by Prolonged Postoperative Bevacizumab for Those with Less Than Complete Pathologic Response.
Carpenter JT, Forero A, Falkson CI, Nabell LM, De Los Santos JF, Krontiras H, Bland KD, Li Y. University of Alabama at Birmingham, Birmingham, AL

We studied patients with locally advanced breast cancer (LABC) to evaluate 1) whether adding concurrent bevacizumab to preoperative chemotherapy (CT) would increase the pathologic complete response (pCR) rate, 2) whether a prolonged postoperative course of bevacizumab would prevent or reduce the recurrence rate in patients who did experience pCR after preoperative chemotherapy, and 3) whether use of pegylated liposomal doxorubicin would prove comparably effective to doxorubicin with less toxicity in this setting. From 3/08-12/09 32 patients with HER-2 negative operable (LABC) received sequential preoperative CT with pegylated liposomal doxorubicin 25 mg/M2 every 2 weeks X 3, paclitaxel 175 mg/M2 every 2 weeks X 3, and cyclophosphamide 60 mg/M2 every 2 weeks X 3, all with concurrent bevacizumab 10 mg/kg every 2 weeks. One patient’s disease progressed by the end of CT; 1 patient withdrew after 2 cycles of treatment. All 30 remaining patients had ≥30% shrinkage of tumor at the completion of CT. Left ventricular ejection fractions on the 31 who completed CT were >55% before and after completing CT; no cardiac failure was seen. Grade III toxicities included hypertension >150/90 in 7 and palmar-plantar erythrodysesthesia in 1; other toxicities were grade 1 or II. No proteinuria was seen. Five experienced delayed wound healing after operation. Responses: 9/32 pCR in breast and axillary nodes (2/15 in ER or PR+, 7/17 in ER/PR-), and 3 pCR in breast with ≥1 positive axillary node (2 ER or PR+, 1 ER PR-). Hormonal treatment but no further CT was given after operation. 20/21 patients with residual invasive cancer in breast or nodes started an additional year of bevacizumab 15 mg/kg every 3 weeks; 1 never started bevacizumab due to delayed wound healing- her disease recurred before starting bevacizumab and she died 22 months after diagnosis. All but 6 of these have completed the additional year of bevacizumab (1 withdrew early due to the need for 2 emergency abdominal operations); 1 experienced recurrence in lungs during bevacizumab treatment and subsequently died 24 months after starting treatment (ER+). An additional patient with initial pCR experienced recurrence in brain, then lung 18 months after starting treatment (ER/PR-). With a median followup of 26.5 months since diagnosis, 30 of 32 remain alive, 28 of 32 remain free of recurrence, and 19 of the 20 who started bevacizumab for less than pCR after operation remain free of recurrence. Concurrent bevacizumab did not appear to influence the pCR rate from preoperative CT. The pCR rate observed using pegylated liposomal doxorubicin is comparable to that obtained at UAB with sequential treatment using doxorubicin, but is less toxic. Use of bevacizumab after operation in patients with LABC who do not experience pCR from preoperative chemotherapy may decrease recurrence and appears promising. Further observation in this group and further prospective study will be of interest. Supported by Centocor Ortho Biotech Services and by Genentech.

An Interim Efficacy Analysis of Neoadjuvant Letrozole in the New Primary Endocrine-Therapy Origination Study (NEOS/N-SAS BC06): A Randomized Study of Adjuvant Endocrine Therapy with or without Chemotherapy for Postmenopausal Breast Cancer Patients Who Responded to Neoadjuvant Letrozole.
Iwata H, Yamaguchi T, Masuda N, Toyama T, Kashiwahara M, Yamamoto Y, Taira N, Saiji S, Ohashi Y. Aichi Cancer Center, Nagoya, Japan; Kanto University Graduate School of Medicine, Sendai, Japan; NHO Osaka National Hospital, Osaka, Japan; Nagoya City University Hospital, Nagoya, Japan; Iwate Medical University, Morioka, Japan; Kumanoto University Hospital, Kumanoto, Japan; Okayama University Hospital, Okayama, Japan; Saitama Medical University International Medical Center, Hidaka, Japan; The University of Tokyo, Tokyo, Japan

Background: It has not been established if adjuvant chemotherapy is required for patients with intermediate-risk endocrine-responsive postmenopausal breast cancer. The NEOS is a randomized controlled trial to verify the necessity of adjuvant chemotherapy in patients with node-negative, ER-positive, and HER2-negative postmenopausal breast cancer who responded to neoadjuvant endocrine therapy. For
neoadjuvant letrozole (LET), the protocol specified that an interim analysis should be performed to avoid lack of benefit to patients if no therapeutic effects, which were anticipated before the start of the study, were obtained.

Methods: Patients who complied with the eligibility criteria were administered LET preoperatively in weeks 24-28 after primary enrollment. Patients evaluated as complete response (CR), partial response (PR) or stable disease (SD) underwent secondary enrollment and will be divided at random into two arms, an arm given LET for 4.5-5 years after chemotherapy and another arm given only LET for 4.5-5 years. Patients evaluated as progressive disease during LET treatment will receive discretionary treatment. For neoadjuvant LET, the number of patients requiring interim analysis of efficacy was calculated as 140 based on the assumption that the threshold response rate of CR+PR+SD was 75% and its expected response rate was 85% in patients who completed neoadjuvant LET, and that the one-sided level of significance was 5% and the statistical power was 90%. When the hypothesis that the rate of CR+PR+SD was less than 75% was not rejected at a significance level of 5%, the study was discontinued and when it was rejected, the study was continued.

Results: As of June 2011, 140 patients in 39 centers had completed neoadjuvant LET. The median age was 64 years old (range: 50-75) and the median Body Mass Index (BMI) was 23.90 (±3.77). According to MRI or CT scan, CR occurred in 2 (1.4%), PR in 57 (40.7%), and SD in 59 patients (42.1%). The rate of CR+PR+SD among the 140 patients was 84.3% (90% confidence interval: 78.6-88.7). In ultrasonography, 47 patients (33.6%) showed a decrease in the long diameter of 30% or more in a mono-dimensional measurement and 52 patients (37.1%) showed a decrease in volume of 50% or more in a three-dimensional measurement. The neoadjuvant LET effects showed no differences in patients with a BMI of less than 20, 20-25, and more than 25. No serious adverse events were observed.

Discussion: The rate of patients who achieved CR+PR+SD by neoadjuvant LET complied adequately with the continuation criteria for the study. We will present the results for 205 patients who could be evaluated for efficacy and safety of neoadjuvant LET as of May 2011. This study was supported by Public Health Research Foundation. The Change of Bone Turnover Markers during Neoadjuvant Anastrozole Versus Exemestane: A Randomized Single-Center Study.

Jinno H, Shimada K, Takahashi M, Hayashida T, Hirose S, Ikeda T, Kitagawa Y. Keio University School of Medicine, Shinjuku, Tokyo, Japan; Teikyo University School of Medicine, Itabashi, Tokyo, Japan

Background
Non-steroidal aromatase inhibitors including anastrozole and letrozole have been reported to increase the rate of bone turnover, accelerate loss of bone, and increase the incidence of fractures. Although steroidal inactivator exemestane has similar inhibitory effect on the aromatization, animal studies have shown a weak but potentially important anabolic effect of exemestane metabolites, which might lead to decreased bone resorption. This randomized trial was conducted to compare the effect of exemestane and anastrozole on bone turnover markers.

Patients and Methods
Fifty-two postmenopausal women with ER-positive, HER2-negative, invasive, nonmetastatic, and operable breast cancer were randomly assigned to neoadjuvant exemestane (25 mg daily) or anastrozole (1 mg daily) for 4 months. The primary endpoint was change in bone turnover markers including resorption markers urinary and serum N-telopeptide (NTX) and the formation markers serum bone alkaline phosphatase (BAP). The secondary endpoint was tumor objective response (OR) assessed by both caliper and ultrasound. Comparisons were also made of breast conservation rate and adverse events.

Results
The changes in serum NTX from baseline to week 16 were not statistically different between anastrozole and exemestane. The changes in urinary NTX from baseline to week 16 were also statistically different between both groups. BAP did not show any significant increase in the exemestane group (10.8%; p=0.21), whereas the increase in BAP from baseline to week 16 in the anastrozole group was 15.0% and marginally significant (p=0.05). There were no significant differences in OR in the intent-to-treat population between patients receiving anastrozole or exemestane (45.8% vs. 39.2%; p=0.63). The OR was similar between the patients with a baseline Ki67 index of >15% and <15% in exemestane group (37.5% vs. 41.2%; p=0.86). In anastrozole group the OR in patients with a baseline Ki67 index of >15% and <15% was 44.4% and 53.8%, respectively (p=0.66). Breast conservation rate was similar between anastrozole and exemestane (62.5% vs. 67.9%; p=0.68). Treatment was well tolerated and much the same for both groups.

Conclusions
There is no significant differences of the change in bone turnover markers between anastrozole and exemestane. These results indicate exemestane had no anabolic effects which would lead to fewer adverse effects on bone.

P3-16-01
Safety Profile and Clinical Activity of Single-Agent BKM120, a Pan-Class I PI3K Inhibitor, for the Treatment of Patients with Metastatic Breast Carcinoma.

Rodon J, Bendell JC, Abdul Razak AR, Homji N, Trandafir L, Quadt C, Graha-Suárez B, Siu LL, Di Tomaso E, Demanse D, Massacesi C, Hirawat S, Burtis III HA, Baslega J. Vall d’Hebron University Hospital, Barcelona, Spain; Sarah Cannon Research Institute, Nashville, TN; Princess Margaret Hospital, Toronto, ON, Canada; Novartis Pharmaceuticals, Florham Park, NJ; Novartis Oncology, Paris, France; Novartis Pharma AG, Basel, Switzerland; Novartis Institutes for BioMedical Research Inc, Cambridge, MA; Massachusetts, Boston, MA

Background
Phosphatidylinositol 3-kinase (PI3K) is critical to cancer cell growth, survival, and metabolism. BKM120 is an oral pan-class I (α, β, γ, δ) PI3K inhibitor that has demonstrated in vitro and in vivo tumor cell growth inhibition in a range of cancer types including breast cancer.

Materials and methods: The Phase I study CBKM120X2101 investigating single-agent daily BKM120 in patients (pts) with advanced solid tumors has been recently completed with the maximum tolerated dose established at 100 mg/day. Here, we report the analysis of metastatic breast carcinoma (MBC) pts enrolled in this study.

Results: Overall, 83 pts have enrolled, 21 of whom have MBC. At the cut-off date of 25th February 2011, 20 MBC pts were evaluable: 1 pt at 80 mg, 1 pt at 150 mg and 18 pts at 100 mg. Patient characteristics were as follows: median age 55 years (range 37–71); performance status ECOG 0/1/2 for 7/12/1 pts, respectively; visceral disease was reported in 16 pts, including liver, 10 pts (50%); lung, 9 pts (45%); and pleura, 5 pts (25%); all pts had ≥3 lines of systemic therapy (3–12). The median time from last treatment and study entry was 4.5-5 years. Patients evaluated as progressive disease during LET and after 4.5-5 years after chemotherapy and another arm given only LET for 4.5-5 years. Patients evaluated as progressive disease during LET treatment will receive discretionary treatment. For neoadjuvant LET, the number of patients requiring interim analysis of efficacy was calculated as 140 based on the assumption that the threshold response rate of CR+PR+SD was 75% and its expected response rate was 85% in patients who completed neoadjuvant LET, and that the one-sided level of significance was 5% and the statistical power was 90%. When the hypothesis that the rate of CR+PR+SD was less than 75% was not rejected at a significance level of 5%, the study was discontinued and when it was rejected, the study was continued.

Results
The changes in serum NTX from baseline to week 16 were not statistically different between anastrozole and exemestane. The changes in urinary NTX from baseline to week 16 were also statistically different between both groups. BAP did not show any significant increase in the exemestane group (10.8%; p=0.21), whereas the increase in BAP from baseline to week 16 in the anastrozole group was 15.0% and marginally significant (p=0.05). There were no significant differences in OR in the intent-to-treat population between patients receiving anastrozole or exemestane (45.8% vs. 39.2%; p=0.63). The OR was similar between the patients with a baseline Ki67 index of >15% and <15% in exemestane group (37.5% vs. 41.2%; p=0.86). In anastrozole group the OR in patients with a baseline Ki67 index of >15% and <15% was 44.4% and 53.8%, respectively (p=0.66). Breast conservation rate was similar between anastrozole and exemestane (62.5% vs. 67.9%; p=0.68). Treatment was well tolerated and much the same for both groups.

Conclusions
There is no significant differences of the change in bone turnover markers between anastrozole and exemestane. These results indicate exemestane had no anabolic effects which would lead to fewer adverse effects on bone.
46 days (29–235). The median duration of BKM120 treatment administered was 7.5 weeks (1.0–96.4). The most frequent grade 3 drug-related adverse events (AEs) were: transaminases increase, 4 pts; psychiatric disorders, 3 pts, consisting of anxiety, affective disorder, and mood alteration (1 pt each); diarrhea, 2 pts; fatigue, 2 pts; and hyperglycemia, 1 pt. The only grade 4 drug-related AE was hyperglycemia, reported in 1 pt at 150 mg. Most AEs were manageable with treatment interruption and dose reductions. Eighteen pts were evaluable for objective tumor response by RECIST. Two pts (11%) exhibited partial responses, which were confirmed in a triple-negative MBC pt, and unconﬁrmed in an ER+ HER2– MBC pt. For these 2 pts, the treatment duration was 29+ (ongoing) and 6 months, respectively. An additional 9 pts (50%) had stable disease, lasting >4 months in 7 pts (35%).

Conclusions: This preliminary analysis showed that BKM120 has single-agent activity in heavily pretreated pts with MBC, and an acceptable safety proﬁle. Molecular proﬁling and updated pharmacokinetic results will be presented at the meeting.

Targeting Tumor Initiating Cells with siRNA/Nanotherapy in Triple Negative Breast Cancer.
Granados-Principal S, Deng X, Liu D, Chang JC, Shen H, Dave B. The Methodist Research Institute, Houston, TX; Baylor College of Medicine, Houston, TX
Residual human breast tumor cells after conventional therapies are enriched in tumor-initiating cells (TIC) characterized by CD44+/CD24−/low lineage with self-renewal capacities. Our gene expression analyses in those cells and in breast cancer cells propagated as mammospheres (MSs) reveal an epithelial-mesenchymal-transition (EMT) signature (400 genes) mainly found in claudin-low molecular subtype human breast tumors. We performed lentiviral shRNA knockdown of that signature in MS. Critical shRNAs were found to decrease the TIC subpopulation. Among those genes, we found STAT3 (signal transducer and activator of transcription 3), NTN4 (netrin 4), and RPL39L (ribosomal protein L39-like). Here, we used a multiscale siRNA delivery system targeting those three genes in order to clarify the effect of silencing those genes over the self-renewal capacity on MSs with claudin-low features. To this end, duplex small interfering RNA (siRNA) against STAT3, NTN4, RPL39L, and scrambled siRNA as control, were introduced into neutral nanoliposomes (dioleoyl phosphatidylcholine, DOPC), and using mesoporous microscale biodegradable silicon particles as carriers. This multimodal siRNA delivery system has been reported as a good approach for sustained gene silencing. Claudin-low-like human breast cancer cell lines (SUM159 and BT549) were plated in 24-well ultra-low attachment plates with mammary epithelial growth medium (MEGM) (5,000 cells/well). Both cell lines were then treated with 1 µg/well/6 wells of silicon particles loaded with DOPC nanoliposomes/siRNA. The primary MSs were allowed to grow for 3 days. MSs were counted by day 3 with a GelCount colony counter (Oxford Optronix, Oxford, UK). Mammosphere-Forming Efficiency (MSFE) was calculated by dividing the number of MSs by the number of seeded cells. In addition, established MSs were serially passaged by dissociation, and single cells were replated on fresh 24-well ultra-low attachment plates to form secondary mammospheres, which were counted after 3 days. One-way ANOVA and Tukey test were performed. A p value less than 0.05 was considered as signiﬁcant. Our results show that silencing STAT3, NTN4, and RPL39L signiﬁcantly reduces the MSFE in both primary (1%, 0.9%, and 1.7% respectively) (Figure 1) and secondary MSs (0.49%, 0.51%, and 0.45% respectively) (Figure 2) when compared to the scrambled control (2.4% and 1% respectively) in BT549 cells. For SUM159 cells, we did not ﬁnd any change in primary MSs for STAT3 (2.2%) and NTN4 (2.1%), even we found a higher percentage of MSFE in those cells treated with RPL39L siRNA (3.9%) when compared to the scrambled control (2.1%) (Figure 3). Nevertheless, a lesser MSFE were observed in those cells treated with STAT3 (0.9%, not signiﬁcant), NTN4 (0.8%) and RPL39L (0.78%) in comparison to control (1.1%) (Figure 4). In conclusion, knocking-down of EMT-related genes (STAT3, NTN4, and RPL39L) decreases signiﬁcantly the self-renewal capacity in mammospheres derived from claudin-low-like human breast tumor cells, being BT549 cells more sensitive than SUM159 cells to that silencing with siRNA loaded in DOPC nanoliposomes into silicon particles as carriers.

Enhancing Anti-IGF Directed Therapeutics by Co-Targeting Autophagy.
Oh AS, LaPara K, Yee D. University of Minnesota, Minneapolis, MN
Autophagy (macautophagy) is a cellular mechanism that maintains homeostasis and cell growth by regulating the turnover of damaged proteins. Autophagy has a critical role in maintaining cellular viability during nutrient starvation and metabolic stress by recycling intracellular proteins for nutrient reallocation. Whether the autophagy pathway utilized by breast cancer cells has a survival mechanism or is a feature of cell death is not fully understood. Since the IGF/insulin signaling maintains cellular growth, nutrient utilization, and survival, increased autophagy or autophagic flux might be induced with IGF-1 inhibitors as a compensatory survival mechanism. In breast cancer cells treated with anti-IGF1R kinase inhibitors, we observed an increase in autophagic flux; similar to levels induced by nutrient deprivation.

Objective: In this study, we examined whether IGF1R inhibitor-induced autophagy is cytoprotective or cytotoxic. If autophagy has a protective role in nutrient-depleted conditions it could reduce the long term efficacy of IGF1R inhibition by making cells refractory to blockade of this signaling system. In this study, we hypothesized that blocking autophagy in combination with anti-IGF1R therapies (antibodies or small molecules) would further enhance growth inhibition in a panel of breast cancer cells types (luminal and basal-like/triple negative).

Results: We initially examined whether autophagy inhibitors (chloroquine or bafilomycin A1) had a differential growth effect on breast cancer cells that varied in their sensitivity to IGF1R stimulated growth. We found that low-to-moderate IGF growth dependent MDA-MB-231 and MDA-MB-435A breast cancer cells were more sensitive to chloroquine alone. However, sensitivity to bafilomycin A1 differed between breast cancer cell lines compared to chloroquine. In conditions of cellular stress when autophagy is normally triggered, we observed an increase in autophagic flux; similar to levels induced by nutrient deprivation.

with IGF1R inhibitors, but not in IGF1R inhibitor resistant cancers. Additionally, targeting autophagy as a single agent therapy may be more beneficial in triple negative breast cancer compared to other subtypes of breast cancer.

**P3-16-04**  
**A Novel Monoclonal Antibody to Secreted Frizzled Related Protein 2 Inhibits Triple Negative Breast Carcinoma Growth Rate In Vivo.**

**Background:** Secreted frizzled related protein 2 (SFRP2) is a novel angiogenesis factor expressed in the endothelium of a wide variety of human tumors including triple negative breast cancer and angiosarcoma. We previously reported generating a monoclonal antibody against SFRP2 that inhibits endothelial cell and angiosarcoma tube formation in vitro, and decreased tumor volume of the SVR angiosarcoma in vivo. The objectives of these studies were to determine pharmacokinetic (PK) and pharmacodynamic (PD) parameters of the SFRP2 MAb, and evaluate its efficacy in a triple negative breast cancer xenograft.

**Methods:** I-SFRP2 MAb was administered to nude mice i.v. via tail vein injections at 0.4 mg/kg, 4 mg/kg, or 10 mg/kg in mice with or without tumor. Blood organ, and tumor samples were collected at various time points from 5 min to 21 days. Radiolabeled SFRP2 MAb in serum and tissues was determined using a gamma counter. PK parameters were determined based on mean concentration values for 3-5 animals per time point. In vivo efficacy study: MDA-MB-231 human breast cancer xenografts were established in 6-week-old female nude mice. Mice were inoculated with 1 x 10⁶ cells s.c.. Treatment began on day 16 after tumor inoculation when average tumor size was 200 mm³. Animals were randomly assigned (n = 12 per group) to buffer control, SFRP2 MAb 4 mg/kg iv twice weekly; Avastin (Roch) 5 mg/kg iv twice weekly, or IgG control 4 mg/kg iv twice weekly. Tumors were harvested when the tumor diameter reached 2 cm or at 28 days. Tumor volumes were measured with a caliper. Growth rates (percent change per day) were compared with the formula \( (\text{Final volume} - \text{initial volume}) / \text{initial volume} \times 100 \) / number of days. Differences in growth rate between treated and control were analyzed with a two-tailed t-test.

**Results:** PK and PD: SFRP2 MAb was long circulating in the blood with an average \( t_{1/2} \) in the range of 53-89 hr. In addition, the SFRP2 MAB was found to preferentially target the tumors versus all other organs except for the liver. For example, in tumor bearing mice, the blood/tissue ratio on day 14 was smallest in the liver (16:1) and tumor (39:1 to 255:1) proving that the tumor was a prime organ for accumulation of the SFRP2 MAb. SFRP2 MAb was found to preferentially target the tumors versus all other organs including the liver. For example, in tumor bearing mice, the blood/tissue ratio on day 14 was smallest in the liver (16:1) and tumor (39:1 to 255:1) proving that the tumor was a prime organ for accumulation of the SFRP2 MAb. In tumor bearing and non-tumor bearing mice exhibited dose-independent kinetics as a one-way ANOVA analysis comparing \( t_{1/2} \) at different dose levels was not statistically significant (p=0.2847 and 0.1204, respectively). However, there was statistically significant difference in \( t_{1/2} \) of the SFRP2 MAb in tumor-bearing and non-tumor-bearing mice (p=0.0386). **Efficacy in triple negative breast cancer:** There was a 40% decrease in growth rate between SFRP2 MAb and control (p=0.03) and a 20% inhibition of growth rate between Avastin and control (p=0.40). The IgG negative control had no effect on tumor growth.

**Conclusion:** The SFRP2 MAb was long circulating and the tumor was a prime organ for accumulation of the SFRP2 MAb. SFRP2 MAb slowed the growth of a human triple negative breast cancer xenograft in a tumor model that was not sensitive to Avastin. We conclude that SFRP2 is a novel therapeutic target for breast cancer.

**P3-16-05**  
**A Phase II Trial Expansion Cohort of the PARP Inhibitor Veliparib (ABT888) and Temozolomide in BRCA1/2 Associated Metastatic Breast Cancer.**

Isakoff SJ, Overmoyer B, Tung NM, Gelman RS, Habin K, Qian J, Giranda V, Shepherd S, Garber JE, Ellisen LW, Winer EP, Goss PE. Massachusetts General Hospital Cancer Center, Boston, MA; Dana Farber Cancer Institute, Boston, MA; Beth Israel Deaconess Medical Center, Boston, MA; Harvard Medical School, Boston, MA; Abbott Laboratories, Abbott Park, IL

**Background:** Veliparib (ABT-888) is a novel oral inhibitor of Poly (ADP-Ribose) Polymerase (PARP) 1 and 2. Veliparib and temozolomide (TMZ) are synergistic in breast cancer xenograft models. We recently conducted a phase II study of TMZ and veliparib in 41 patients (pts) with metastatic breast cancer (MBC). Activity was observed only in pts with known BRCA1 or BRCA2 deleterious mutations, with a response rate (RR) of 50% (4/8) and clinical benefit rate (CBR) of 62.5%. In order to further evaluate the activity and safety of TMZ and veliparib, we enrolled an expansion cohort of 20 additional patients with BRCA1 or 2 mutations.

**Methods:** We previously conducted a single arm phase II trial of veliparib and TMZ in 41 MBC pts. Eligibility included measurable disease; ≥1 prior MBC therapy and PS ≤ 2. Available archived tumor samples were collected. In this expansion cohort, first line therapy for MBC and prior PARP inhibitor therapy were allowed, and eligible patients were required to have a known deleterious BRCA1 or BRCA2 mutation identified from prior clinical testing. The dose of veliparib in the original cohort was reduced from 40 mg PO BID to 30 mg PO BID. In the expansion cohort all patients received veliparib (30 mg PO BID days 1-7) and TMZ (150mg/m² PO QD days 1-5) on a 28 day cycle. RECIST response was evaluated every 2 cycles. The primary endpoint was overall response rate. Secondary endpoints included PFS, OS, safety and toxicity.

**Results:** Between June 24, 2010 and Sept 29, 2010, 20 eligible pts (median age 42) were enrolled. Baseline characteristics included: median PS=0 (range 0-2); 9 BRCA1 carriers, 9 BRCA2 carriers, and 2 unknown. 17 pts (85%) received prior adjuvant chemotherapy. 9 patients received a prior platinum chemotherapy. The most common grade 3/4 toxicities included thrombocytope尼亚 and neutropenia. Best response for the 20 patients evaluable at the time of abstract submission includes 3 PR (15%), 6 SD (30%), 11 PD, and a clinical benefit rate of 45%. Combined with the initial cohort of 8 known carriers from the original 41 patients, the total RR is 25% (7/28) and clinical benefit rate of 50% (7 PR, 7 SD). The RR was 40% (6/15) in pts without prior platinum treatment, and 9% (1/11) in pts with prior platinum treatment. The median PFS for the 20 BRCA carriers was 85 days, and among patients with prior platinum treatment compared to no prior platinum, the median PFS was 70 and 179 days, respectively. Three pts remain on study, 1 with a CR for >20 mo.

**Discussion:** We previously demonstrated that veliparib and TMZ is an active combination in BRCA1/2 associated MBC. In this larger expansion cohort of 20 additional patients, the combination continued to show activity, although the response rate was not as robust as previously observed. Differences between the original cohort and the expansion cohort may account for some variation in response, such as prior platinum or PARP inhibitors therapy, number of lines of prior therapy, and the dose of veliparib used (40mg vs 30 mg). These results
support further evaluation of this regimen in the BRCA1/2 carrier population, and provide the opportunity to evaluate potential factors that may predict response or resistance to this regimen.

**P3-16-06**

**Phase II Trial of TS-1 in Combination with Oxaliplatin (SOX) in Patients with Metastatic Breast Cancer (MBC) Previously Treated with Anthracycline and Taxane Chemotherapy [TORCH]**

[Korean Cancer Study Group (KCSG) BR07-03].

Im S-A, Oh D-Y, Lee KS, Ahn J-H, Shon J, Ahn JS, Kim JH, Han SW, Lee MH, Lee KE, Lee K, Kim HJ, Keam B, Kim S-Y, Kim SB, Im YH, Ro J, Park H-S. Seoul National University Hospital, Seoul, Republic of Korea; National Cancer Center, Republic of Korea; Asan Medical Center, Seoul, Republic of Korea; Yonsei University College of Medicine, Severance Hospital, Seoul; Samsung Medical Center, Seoul, Republic of Korea; Seoul National University Bundang Hospital, Seongnam, Republic of Korea; Inha University Hospital, Incheon, Republic of Korea; Ewha Womans University Medical Center, Seoul, Republic of Korea; Seoul National University Hospital, Seoul, Republic of Korea; Hanlim University Pyungchon Hospital, Pyungchon, Republic of Korea; Kyung Hee University Hospital, Seoul, Republic of Korea; Soon Chun Hyang University Hospital, Seoul, Republic of Korea

**Background:** Oxaliplatin, a platinum analogue, is an active drug in advanced anthracycline and taxane-pretreated breast cancer patients as a single agent and with 5-fluorouracil (5-FU) combination. TS-1 was developed by the scientific theory of both potentiating antitumor activity of 5-FU and reducing gastrointestinal toxicity. This trial was performed to evaluate the efficacy and safety of TS-1 in combination with oxaliplatin in metastatic breast cancer (MBC) patients previously treated with anthracycline and taxane chemotherapy.

**Methods:** Between October 2007 and October 2009, MBC patients were enrolled in this prospective multicenter trial. Eligible criteria included age ≥18 years, at least one measurable lesion, prior treatment with anthracycline and taxane chemotherapy, and ECOG Performance Status 0–2. TS-1 40 mg/m² b.i.d. on days 1–14 with oxaliplatin 130 mg/m² on day 1 were administered every 3 weeks till disease progression. Primary end-point was response rate, and secondary end-points were time-to-progression (TTP), overall survival (OS), duration of response (DOR) and toxicities. Response was evaluated every 6 weeks according to the RECIST criteria v.1.0 and toxicity was assessed with NCICTCAE v.3.0. (ClinicalTrials.gov identifier NCT00527930).

**Results:** A total of 87 patients were enrolled. Median age was 48 years (range 30–71 years). Nineteen patients (21.8%) had de novo stage IV and 68 patients (78.2%) had recurrent disease. Thirty-five patients (40.2%) received two-line of prior chemotherapy in palliative setting. Forty-eight patients (55.2%) had ≥3 disease sites. Fifty-five patients (62.1%) were hormone receptor positive, and 25 patients (28.7%) were triple negative. Five patients received prior anti-HER2 therapy. A total of 525 cycles were administered (median 6 cycles, range: 1–22 cycles). In protocol analysis, overall response rate was 38.5% (95% CI: 27.7–49.3) (CR 0%, PR 38.5%) and disease control rate (CR, PR, and SD) was 67.9% (95% CI: 57.5–78.3). Median TTP, OS, and DOR were 6.0 months (95% CI: 5.1–6.9 months), 19.4 months (95% CI: not estimated), and 6.6 months (95% CI: 3.7–9.6 months), respectively. RR was not different by triple negativity (39.1% in TNBC vs. 38.2% in non-TNBC, P=0.361). TTP was not different according to the number of prior chemotherapy regimens. Reported grade 3 or 4 toxicities (per cycle) were neutropenia (10.3%), thrombocytopenia (5.5%), diarrhea (1.9%), vomiting (1.9%), and stomatitis (0.2%). There was no treatment-related death.

**Conclusions:** SOX is an effective regimen in anthracycline and taxane pretreated MBC patients with manageable toxicities.

**P3-16-07**

**Denosumab in Patients with Breast Cancer and Bone Metastases Previously Treated with Zoledronic Acid or Denosumab: Results from the 2-Year Open-Label Extension Treatment Phase of a Pivotal Phase 3 Study.**

Stopeck AT, Lipton A, Martin M, Body J-J, Paterson A, Steger GG, Tonkin K, de Boer RH, Fujiwara Y, Yardley D, Jassem J, Takano T, Solal-Celigny P, Fan M, Braun A. University of Arizona Cancer Center, Tucson, AZ; Penn State Milton S. Hershey Medical Center, Hershey, PA; Hospital General Universitario Gregorio Marañón, Madrid, Spain; CHU Brugmann, Université Libre de Bruxelles, Brussels, Belgium; Tom Baker Cancer Centre, Calgary, AB, Canada; Medical University of Vienna, Vienna, Austria; Cross Cancer Institute, Edmonton, AB, Canada; Western and Royal Hospitals, Melbourne, Australia; National Cancer Center Hospital, Tokyo, Japan; Sarah Cannon Research Institute, Nashville, TN; Tennessee Oncology, PLLC, Nashville, TN; Medical University of Gdansk, Gdansk, Poland; Toranomon Hospital, Tokyo, Japan; Clinique Victor Hugo, Centre Jean Bernard, Le Mans, France; Amsgen, Inc., Thousand Oaks, CA

**Background:** Primary results from a phase 3, randomized, double-blind double-dummy trial showed that compared with zoledronic acid (ZA), denosumab reduced the risk of developing a first on-study SRE by 18% (hazard ratio, 0.82; 95% CI 0.71 to 0.95; P = 0.01), and the risk of multiple SREs by 23% (rate ratio, 0.77; 95% CI 0.66 to 0.89; P = 0.001) in patients with breast cancer and bone metastases. Based on superior efficacy and favorable safety data from the study’s primary analysis (Stopeck et al, 2010), all patients who remained on treatment were offered open-label denosumab in a prespecified 2-year extension treatment phase.

**Materials and Methods:** A total of 2046 patients with breast cancer and bone metastasis were randomized to receive either subcutaneous (SC) denosumab 120 mg and intravenous (IV) placebo or IV ZA 4 mg (adjusted for renal function) and SC placebo Q4W in the double-blinded treatment phase. Patients who completed the double-blinded treatment phase were offered open-label denosumab Q4W for up to 2 years from the start of the open-label treatment phase. Patients who did not participate in the open-label treatment were followed for survival every 12 weeks for up to 2 years after their last dose of investigational product in the double-blinded treatment phase.

**Results:** Of the 752 patients who completed the double-blinded treatment phase, 667 (89%) patients entered the open-label treatment phase: 325 (48.7%) initially randomized to the denosumab group (DD) and 342 (51.3%) to the ZA group in the double-blinded treatment phase (ZD). Demographics were comparable between groups. The total median (Q1, Q3) cumulative denosumab exposure (including extension treatment phase) for DD patients was 19.3 months (9.2, 32.2) (range 0.9–59.8 months). Adverse events (AEs) were comparable between groups (n = 283/318 [89%] for DD patients; n = 303/334 [91%] ZD patients). An additional 20 patients (n = 18 patients in the DD group and 18 patients in the ZD group reported osteonecrosis of the jaw, resulting in a cumulative incidence of 4.7% for DD patients; n = 303/334 [91%] ZD patients). An additional 20 patients (n = 20 patients in the DD group and 18 patients in the ZD group reported osteonecrosis of the jaw, resulting in a cumulative incidence of 4.7% for DD patients; n = 303/334 [91%] ZD patients).

**Conclusions:** Denosumab effectively reduces the risk of SRE by 18% (hazard ratio, 0.82; 95% CI 0.71 to 0.95; P = 0.01) and multiple SREs by 23% (rate ratio, 0.77; 95% CI 0.66 to 0.89; P = 0.001) in patients with breast cancer and bone metastases. Based on superior efficacy and favorable safety data from the study’s primary analysis (Stopeck et al, 2010), all patients who remained on treatment were offered open-label denosumab in a prespecified 2-year extension treatment phase.
Overall survival was similar between groups over the entire study: median 34.4 months (95% CI 31.5 to 39.3) for DD patients, 34.2 months (95% CI 31.0 to 37.6) for ZD patients.

**Conclusion:** A two-year open-label extension treatment phase confirmed the long-term safety profile of denosumab in these breast cancer patients with bone metastases who continued receiving denosumab for up to 5 years or who switched from ZA to denosumab. No new safety signals were observed with up to 5 years of monthly denosumab therapy.

**P3-16-08**

**A Phase 2, Randomized Open-Label Study of Iniparib, Administered Either Weekly or Twice-Weekly in Combination with Gemcitabine Plus Carboplatin in Patients with mTNBC.**

Dièras V, Bonnefoi H, Alba E, Avada A, Coudert B, Pivot X, Gligorov J, Jäger A, Gianni L, Lindeman G, Pham N, Su Y, Gao G, Mery-Mignard D, Paridaens R, Verweij J, Institut Curie, Paris, Cedex 05, France; Université de Bordeaux, Bordeaux, INSERM, France; Hospital Clinico Universitario Virgen de la Victoria, Málaga, Spain; Institut Jules Bordet, Centre des Tumeurs de l’Université Libre de Bruxelles, Brussels, Belgium; Centre Georges François Leclerc, Dijon, France; University Hospital Jean Minjoz, Besançon, France; University Paris VI, Paris, France; Erasmus University Medical Center, Daniel den Hoed Cancer Center, Rotterdam, Netherlands; InSR - San Raffaele, Milan, Italy; The Royal Melbourne Hospital and The Walter and Eliza Hall Institute of Medical Research, Melbourne, Victoria, Australia; Sanofi, Vitry, Paris, France; Sanofi, Great Valley, PA; Sanofi, Cambridge, MA; University Hospital Ghent University, Catholic University of Leuven, Leuven, Belgium; Erasmus University Medical Center; Rotterdam, Netherlands

**Background:** Iniparib (BSI-201) is an investigational anticancer agent whose precise mechanism of action is under active investigation. In breast cancer cell lines and xenograft models of triple-negative breast cancer (TNBC), iniparib exhibits anti-proliferative activity and potentiates the cell cycle effects of some DNA damaging agents. In a randomized, open-label phase 2 study in pts with metastatic TNBC (mTNBC), iniparib combined with gemcitabine (G) and carboplatin (C) (GC) improved efficacy outcomes compared with GC alone. A confirmatory phase 3 study with GCI failed to meet pre-specified criteria for PFS and OS; however, an exploratory subset analysis demonstrated a potential benefit amongst 2/3rd line pts (O’Shaughnessy et al. ASCO 2011). Here we report results of a randomized phase 2 study (NCT01045304) in pts with mTNBC, which assesses efficacy and pharmacokinetics (PK) of iniparib administered either biw or qw in combination with GC.

**Patients and methods:** Eligible pts (N=163; median age 49 yrs) had documented and measurable TNBC, ECOG PS 0-1, normal organ/marrow function, and had received ≤2 prior chemotherapy (CT) regimens for metastatic disease. Pts were randomized (1:1) to receive G (1,000 mg/m², IV, d 1, 8) plus C (AUC 2, IV, d 1, 8) and iniparib either biw (5.6 mg/kg, IV d 1,4,8,11) or qw (11.2 mg/kg, IV d 1,8) on a 21 d cycle. Pts were stratified according to prior CT for mTNBC (0 vs. ≥1). The primary efficacy endpoint was overall response rate (ORR; CR + PR); secondary endpoints included: clinical benefit rate (CBR; CR + PR + SD for 24 weeks), PFS, OS and PK.

**Results:** At the time of analysis, 23% of patients were still on treatment. The median number of cycles administered per patient was 6 in both arms; exposure to iniparib was identical. Safety data are not fully validated. All pts experienced at least 1 treatment emergent adverse event (TEAE). Grade (Gr) ≥3 TEAEs occurred in 94% and 85% of pts in the biw and qw arms, respectively. TEAEs Gr ≥3 occurring in ≥5% of pts regardless of relationship to study drug (biw vs qw) are as follows: blood and lymphatic 71% vs 67%; hepatobiliary 7.5% vs 9.8%; asthenia/fatigue 7.5% vs 11%; GI 8.8% vs 8.5%; infections 7.5% vs 3.7%; respiratory, thoracic and mediastinal 5% vs 8.5%, metabolism and nutrition 4% vs 6%. For response data see table.

**No major difference was observed in drug exposure (based on AUC within one cycle) between the two dosing regimens.**

**Conclusion:** Dosing of GCI on a qw schedule produced a similar ORR to that obtained with the biw schedule. A comparable safety profile in both arms, and consistency with results of previous studies, suggests that the weekly combination of GCI may be an appropriate schedule for further studies evaluating this combination. OS and PFS data are not yet mature; updated efficacy and safety data will be presented.

**P3-16-09**

**Endoxifen, a Newly Developed Breast Cancer Drug, Has Anabolic Actions on the Mouse Skeleton.**

**Background:** Commonly used endocrine therapies for breast cancer, such as aromatase inhibitors in postmenopausal women and tamoxifen in premenopausal women, have deleterious effects on bone mineral density. Therefore, the identification of novel cancer therapies which either maintain or improve bone mass are of clinical need. We have recently demonstrated that endoxifen is the most active tamoxifen metabolite with regard to inhibiting the growth of ERα+ breast cancer cells and these studies have led to the development of endoxifen as a novel anti-breast cancer drug for which first-in-human studies are now underway. At present, there are no data regarding endoxifen’s effects on bone.

**Methods:** The effects of endoxifen on osteoblast (OB) and osteoclast (OC) maturation and gene expression were monitored by cell differentiation assays and real-time PCR. Dual-energy X-ray absorptiometry (DXA), peripheral Quantitative Computed Tomography (pQCT) and micro-Computed Tomography (μCT) were used to determine changes in bone density, mass and architecture following 45 days of oral endoxifen administration (50mg/kg/day) to 3-month-old ovariectomized (OVX) C57BL/6 mice relative to vehicle control treated animals. Alterations in the numbers and activity of OBs and OCs were determined by histomorphometry and serum levels of P1NP and CTX-1 respectively.

**Results:** Endoxifen treatment of mouse derived bone marrow stromal cells and human OBs led to significant increases in the expression of critical bone marker genes such as Runx2, osterix, osteocalcin, osteoprotegerin and alkaline phosphatase in a dose dependent manner. Daily administration of endoxifen to OVX mice led to significant increases in total body bone mineral density (BMD) (6%) and content (BMC) (9%), which was accompanied by a 50% decrease in fat tissue mass as determined by DXA; pQCT analysis of the tibial metaphysis revealed dramatic increases in BMD (35%) and BMC (20%), as well
as trabecular density (52%), cortical content (62%), cortical area (60%) and cortical thickness (78%). μCT analysis of the femoral metaphysis revealed increases in bone volume/total volume (200%), trabecular number (38%) and trabecular thickness (18%), as well as decreased trabecular spacing (29%). Interestingly, there was nearly a 50% increase in the numbers of OCs derived from endoxifen treated mice which was associated with elevated expression of OC marker genes such as NFATc1, RANK, c-fms and cathepsin-K compared to control treated animals. Approximately 4 times as many OBs and OCs were observed on the bone surfaces of endoxifen treated mice which correlated with nearly 2-fold increases in serum levels of the bone formation (P1NP) and resorption (CTX-1) markers.

**Conclusions:** These data are the first to demonstrate that endoxifen has anabolic effects on the mouse skeleton which are similar to that of estrogen. Additionally, these data reveal that endoxifen’s mechanism of action in bone is different than that reported for tamoxifen and other selective estrogen receptor modulators in mice as it increases, rather than decreases, bone formation and remodeling. Therefore, the use of endoxifen for the treatment of endocrine responsive breast cancer may avoid the detrimental skeletal effects of many conventional endocrine therapies.

**P3-16-10**

**The Efficacy of Zoledronic Acid in Breast Cancer Adjuvant Therapy: A Meta-Analysis of Randomized Controlled Trials.**

Lu J, Yan T, Yin W, Zhou Q, Zhou L, Jiang Y, Du Y, Shao Z. Fudan University Shanghai Cancer Center, Shanghai, China; Shanghai Medical College, Fudan University, Shanghai, China

**Background:** The effect of zoledronic acid in breast cancer adjuvant therapy concerning improvement of patient survival has yet to be confirmed. We performed a meta-analysis of published and unpublished randomized controlled trials with the aim of accurate evaluation between clinical outcome and the association of the addition of zoledronic acid to adjuvant therapy.

**Methods:** We searched Pubmed (from 1966 to present) and online abstracts from the proceeding Annual Meetings of the American Society of Clinical Oncology (ASCO) (years 1992-2010) and online abstracts from San Antonio Breast Cancer Symposium (years 2004-2010). A total of five eligible studies including 3676 subjects and 3678 controls met our search criteria and were evaluated. Random and fixed-effects meta-analytical models were used where indicated, and between-study heterogeneity was assessed. The primary study endpoints were the DFS. Secondary endpoints were OS, distant or loco-regional recurrence free survival and bone metastasis free survival.

**Results:** Compared with the control arm, adjuvant breast cancer treatment with zoledronic acid did not significantly improve overall survival (OS), disease free survival (DFS), bone metastasis free survival, distant and locoregional recurrence free survival. However, in the postmenopausal subgroup, the addition of zoledronic acid to standard therapy could significantly improve DFS (RR=0.763, 95%CI 0.658-0.884, p<0.001) and reduce the risk of distant (RR=0.744, 95% CI 0.611-0.906, p=0.003) and locoregional recurrence (RR=0.508, 95% CI 0.340-0.760, p=0.001).

**Discussion:** Adjuvant zoledronic acid may potentially improve the prognosis of postmenopausal patients. Additional studies are needed to evaluate the value of adjuvant treatment of zoledronic acid in premenopausal counterparts, differing disease stages, and various pathological types of breast cancer.

**P3-16-11**

**Prospective Evaluation of Radiation Pneumonitis in Neoadjuvant Concurrent Docetaxel and Radiation Therapy for Locally Advanced Breast Cancer.**

**Background:** Taxanes are known to have radiosensitizing properties, by causing cell arrest in the G2 and M phases of the cell cycle. As taxanes have become integrated into routine oncologic use, concerns have arisen over the association between taxanes and radiation toxicities such as pneumonitis. Pneumonitis has been reported to occur both with taxane administration alone or, more commonly, with concurrent or sequential radiation. The purpose of this study is to evaluate radiation pneumonitis from our institutional phase I/II protocol of neoadjuvant FEC chemotherapy followed by weekly docetaxel concurrent with radiotherapy in the treatment of locally advanced breast cancer (LABC).

**Materials and Methods:** Since August 2009, thirty-two LABC patients with stage IIB, IIIA, IIIB, or IIC invasive breast cancer were enrolled to receive protocol based treatment consisting of 3 cycles of intravenous (IV) fluorouracil 500 mg/m², epirubicin 100 mg/m², and cyclophosphamide 500 mg/m² (FEC) every 3 weeks. Following this, weekly IV docetaxel 35 mg/m² was administered concurrently with locoregional external beam radiotherapy to a total dose of 45 Gy in 25 fractions followed by a boost of 5.4-9 Gy in 3-5 fractions to gross residual disease. Adverse events were scored using the National Cancer Institute Common Terminology Criteria for Adverse Events v3.0. A linear regression model was built used to evaluate potential parameters predictive of clinical pneumonitis (grade ≥2).

**Results:** Of the 32 patients enrolled on this prospective protocol, 7 were excluded from analysis (n = 6, follow-up < 4 weeks; n = 1, converted to palliative radiotherapy due to metastatic disease). Twenty-five patients remained for analysis. The median age was 48 years (range 26 to 64). Thirteen patients were treated with intensity modulated radiation therapy while 12 were treated using 3D conformal radiotherapy. In total 13 patients (52%) experienced clinical pneumonitis with 6 of these patients (24%) transiently requiring supportive oxygen (grade 3). On linear regression modeling, the use of IMRT (p = 0.08), grade 3 skin toxicity (p = 0.08), and baseline left ventricular ejection fraction (LVEF, p = 0.05) were potentially predictive of symptomatic pneumonitis. Conversely, various heart and lung dose-volume histogram parameters, trastuzumab use, bolus use, disease laterality, total docetaxel dose, were not predictive of symptomatic pneumonitis (p > 0.10). In multivariable modeling, the use of IMRT (p = 0.05) and baseline LVEF (0 = 0.03) remained predictive of symptomatic pneumonitis.

**Conclusion:** The use of concurrent weekly docetaxel-based chemoradiotherapy in LABC is associated with significant symptomatic pneumonitis and may be related to low baseline LVEF and the use of IMRT. However, conventional parameters of low dose volumes of lung and heart irradiated were not predictive of pneumonitis. The relationship of the use of IMRT and taxanes in the development of pneumonitis is likely complex and warrants further investigation.

P3-16-13
Cardiac Safety of Non-Pegylated Liposomal Doxorubicin and Docetaxel as 1st Line Treatment in Metastatic HER2 Negative Breast Cancer (Myotax Study).

van Warmerdam L, Schiphorst P, Nieboer P, Derksen M, de Jongh F, Schmidt R, Catharina-Ziekenhuis, Eindhoven, Netherlands; Streekziekenhuis Koningin Beatrix, Winterswijk, Netherlands; Wilhelmina Ziekenhuis, Assen, Netherlands; Maxima MC, Eindhoven, Netherlands; IkaZie Ziekenhuis, Rotterdam, Netherlands; Foundation BO3, Steenderen, Netherlands

Background: Doxorubicin (DOX) is an effective, but cardiotoxic agent in metastatic breast cancer (BC). Incidence of heart failure (HF) is 2-4% and increases considerably with cumulative doses over 450-550 mg/m². In Myocet® DOX is encapsulated in liposomes. It is delivered predominantly to areas with increased capillary permeability such as tumors and reduces cardiac exposure. We conducted an open non-comparative study to assess cardiac safety of Myocet® combined with docetaxel.

Materials and methods: Females with locally advanced or metastatic HER2 negative BC. 6 cycles of Myocet® 60 mg/m² and docetaxel 75 mg/m² q3w as 1st line therapy. Left ventricular ejection fraction (LVEF) and disease status were assessed after cycle 2, 4, and 6. Primary endpoint: signs and symptoms of HF (NYHA III-IV) or LVEF <50% and decrease ≥5% (with symptoms) or ≥10% (without symptoms).

Results: 68 patients (pats) were included. Mean (sd;range) age 56.3 y (10.2;32-79), mean disease duration 5.5 y (5.1 y;1 mo-19 y), 31 pats had anthracyclines (AN) in the past. 49 pats completed all 6 cycles. Mean LVEF (%) over time are presented in Table 1.

Conclusion: Liposomal DOX might provide more cardiac safety than conventional AN and a DNA damage response in HCC1187 (representative of the most resistant group), and induced a strong effect of apoptosis and cell cycle, apoptosis and DNA damage responses were analyzed by western blotting. Studies on the action of TG02 in combination with chemotherapy were performed in MDAMB231 and HBL100 cells, and the potency of the combination was quantitated with the Calcusyn software. In vivo studies on the action of TG02 were performed in mice xenografted with the TNBC cell line MDA-MB231.

Results
The TNBC cell lines analyzed showed high levels of Erk5 expression, and Erk5 was active under resting conditions in some of them. TG02 inhibited the kinase activity of Erk5 even though TG02 did not affect the Erk5 upstream activating kinase Mek5. TG02 showed an inhibitory effect of phosphorylation of residue Thr732 in the C-terminal tail of Erk5 without affecting the phosphorylation of the activation loop TEY motif. Cell proliferation studies indicated that one group of TNBC cells were very sensitive to the action of this compound (IC50 ≤100 nM) and another group were more resistant. TG02 induced cell cycle arrest at the early G1 and G2 phases of cell cycle, and triggered cell death in MDAMB231 (representative cell line of the most resistant group), and induced a strong effect of apoptosis and a DNA damage response in HCC1187 (representative of the most sensitive group). In vitro studies indicated that TG02 sensitizes TNBC cells to chemotherapy, showing additive or synergistic effects depending of the doses. In vivo studies indicated that TG02 exerted a strong antitumoral action in mice bearing MDA-MB231-derived tumours.

Conclusions
TNBC cells are very sensitive to TG02, both in vitro and in vivo. The inhibits the kinase activity of Erk5, which, together with the targeting of other kinases, may contribute to the induction of cell cycle arrest or apoptosis in response to the compound in TNBC cells. TG02 synergized with chemotherapy, supporting the possibility of using this drug in combination therapy. Taken together, these preclinical studies establish the bases for the clinical development of this compound for the treatment of TNBC.

P3-16-14
Effect of TG02, a Multikinase Inhibitor, on Triple Negative Breast Cancer Cells.

Pandiella A, Ortiz-Ruiz MJ, Burrows F, Ocaña A, Esparis-Ogando A. Cancer Research Center, Salamanca, Spain; Hospital Universitario, Albacete, Spain; Tragara Pharmaceuticals, San Diego, CA

Background
Breast cancer is the most common neoplasm in women. Formerly, we reported that the MAPK Erk5 participates in the proliferation of breast cancer cells in vitro, it is overexpressed in the tumours of a number of breast cancer patients, and its overexpression is an independent prognostic marker for disease-free survival. In addition, inhibition of Erk5 sensitized cells to treatments commonly used in the breast cancer clinic. Therefore, Erk5 may represent a novel therapeutic target in breast cancer. Here we describe the preclinical activity of TG02, a novel multi-kinase inhibitor being developed by Tragara Pharmaceuticals, in triple negative breast cancer (TNBC). TG02 presents a unique kinase inhibitory spectrum, combining Erk5 inhibitory properties with inhibition of CDKs and certain receptor tyrosine kinases.

Material and methods
The action of TG02 on cell proliferation of TNBC cell lines was carried out by the MITT-based assay, and its action on cell death and cell cycle progression was analyzed by flow cytometry. The expression of different kinases and other proteins implicated in cell cycle, apoptosis and DNA damage responses were analyzed by western blotting. Studies on the action of TG02 in combination with chemotherapy were performed in MDAMB231 and HBL100 cells, and the potency of the combination was quantitated with the Calcusyn software. In vivo studies on the action of TG02 were performed in mice xenografted with the TNBC cell line MDA-MB231.
Phase I Study with Biomarker Evaluation of Neoadjuvant Sunitinib in Combination with Exemestane in Post-Menopausal Women with Hormone-Sensitive, Her-2 Negative Primary Breast Cancer.

Morales S, Gil M, Llombart A, Garcia M, Urruticoechea A, Pernas S. University Hospital Arnau de Vilanova, Lleida, Cataluña, Spain; University Hospital ICO-Duran i Reynals, Barcelona, Cataluña, Spain

Background: In preclinical models, oestrogen causes a rapid induction of VEGF in mammary tumours leading to tumour angiogenesis, tumor growth and cell migration whereas aromatase inhibitors (AI) have the opposite effect. Exemestane (E) is an AI, effective in metastatic hormone-dependent breast cancer, as well as in the adjuvant and neoadjuvant settings. Sunitinib (S) is an oral multitargeted tyrosine kinase inhibitor with antiangiogenic activities via inhibition of VEGFR, PDGFR, KIT, RET, CSF-1R and FLT-3, and direct antitumor activity shown in heavily pretreated subjects with advanced breast cancer. The use of antiangiogenic agents at initial stages of the disease, when fewer proangiogenic factors are present, may result in significantly greater efficacy than using these agents at a later stage. Safety profiles of both agents indicate only modest toxicity and do not overlap. We hypothesize that since antiangiogenic and hormonal agents use different mechanisms of action, combination will have additive activity. Regarding (S), continuous dosing (CD) at low doses might result in improved efficacy while maintaining good tolerability.

Methods: This is a phase I study to evaluate the safety of (S) in combination with (E) administered for 24 weeks (1 cycle=4 weeks) as neoadjuvant therapy for post-menopausal women with newly diagnosed hormone-sensitive, Her-2 negative primary breast cancer. We report the results of the first dose escalation part of the study intended to determine a safe dose level of (S) that can be combined with (E) at conventional fixed dose of 25 mg/d. Preliminary efficacy data in terms of objective clinical response by WHO criteria will also be reported. Results: 18 postmenopausal women with ER-positive invasive breast cancer, adequate organ function and ECOG 0-1 were enrolled in the study (median age 74, range 57-84) to be treated at two dose levels: 25 mg of (E) with either 25 mg or 37.5 mg of (S) CD. Two DLTs were identified: grade 3 mucositis at level 25 mg of (S) and grade 3 asthenia at level 37.5 mg of (S). Main toxicities were asthenia, leucopenia, mucositis, diarrhoea and HBP. 78% of patients had grade 2 toxicities; 22% had grade 3. There were no serious adverse events reported. Median time on treatment with the combination was 23 weeks (range 2-24). 16% of patients needed one dose reduction of (S), 16% needed two or more and 28% suspended (S) administration due to toxicity. 50% of patients completed 24 weeks of treatment. None of the patients at 37.5 mg (S) level could tolerate full doses for the entire treatment period, therefore in our study the recommended dosage of (S) that can be safely combined with (E) is 25 mg. Concerning efficacy, 11 out of 18 patients had partial response (61%), 6 out of 18 had SD (33%) and only one patient had PD (5%) as best response. Conclusion: Safety profile of the combination seems to be manageable in most patients. Toxicities were observed mainly within the two first cycles. Response rates were similar than those previously observed with (E) as monotherapy in the neoadjuvant setting. Biomarkers information will be provided.

This study was supported by an Independent Investigator Research grant from Pfizer, Inc.

Overcoming EGFR Resistance Using Dasatinib in Combination with Cetuximab and Cisplatin in Triple Negative Breast Cancer Cell Lines.

Kim EMH, Gartner E, Choi L, Boerner J. Wayne State University, Karmanos Cancer Center, Detroit, MI

Background: Patients presenting with triple negative breast cancers (TNBC’s) have a poorer prognosis compared to those with other subtypes of breast cancer, and effective therapeutic targets have yet to be identified. The majority of TNBC’s overexpress EGFR, however studies have demonstrated that EGFR inhibition as a monotherapy is ineffective. Interestingly, adding the EGFR inhibitor, cetuximab to cisplatin chemotherapy doubled both the response rate and time to progression compared with patients only on cisplatin. c-Src tyrosine kinase plays a critical role in signal transduction downstream of growth factor receptors, and has been found to contribute to the resistance of TNBC cell lines through the phosphorylation of EGFR. We hypothesize that dasatinib, a c-Src inhibitor, may help overcome EGFR resistance and in combination therapy enhance the cytotoxic activity.

Material and Methods: A panel of breast cancer cell lines, including 7 triple negative cell lines, were tested using increasing doses of dasatinib (1 nM to 10 µM), cetuximab (1 µg/ml to 100 µg/ml), and cisplatin (10 nM to 10 µM) alone and in combination. Growth inhibition was determined after 3 days of treatment using the MTT colorimetric assay, and apoptosis was assessed through Caspase-3 activation and TUNEL assays.

Results: All cell lines were generally resistant to cetuximab, with 100 µg/ml required to decrease cell viability. Two TNBC lines, SUM149 and SUM229, showed an additional decrease in cell viability with dasatinib added to cetuximab, while SUM102 and BT20 cells showed an additional decrease in viability using the dasatinib and cisplatin combination, compared to single agents. In 4 out of 7 TNBC lines, the combination of dasatinib, cisplatin, and cetuximab showed a significant decrease in cell viability compared to the combination without dasatinib (p-value < 0.02). The decrease in proliferation using the combination of dasatinib, cisplatin, and cetuximab was due to an increase in apoptosis. In contrast, this combination did not increase the loss of cell viability or apoptosis in ER/PR+ and HER2+ breast cancer cell lines.

Discussion: Targeting c-Src family kinases with dasatinib may help overcome the resistance to EGFR inhibition in triple-negative breast cancer. This may have significant clinical implications in treating TNBC patients, and hence further investigation into the mechanism of this effect is warranted.

The Identification of Novel Microtubule Stabilizing Taccalonolides.

Risinger AL, Li J, Peng J, Chen Z, Mooberry SL. University of Texas Health Science Center, San Antonio, TX; Shanghai Institute of Materia Medica, Shanghai, China

Microtubule stabilizing agents, including the taxanes and epothilones, are some of the most important drugs used in the treatment of cancer. All of the microtubule stabilizers used clinically bind within the taxane site on microtubules and work through a similar mechanism of action. We have identified a new class of microtubule stabilizers, the taccalonolides, from plants of the genus Tacca. The most abundant taccalonolides, A and E, are classified as microtubule stabilizers due to their ability to disrupt both interphase and mitotic cellular microtubules, leading to mitotic arrest and apoptosis. However, they are unique from all other microtubule stabilizers in that they do
not bind directly to microtubules or stimulate the polymerization of tubulin in biochemical preparations. The taccalonolide structure is characterized by a highly acetylated pentacyclic steroid skeleton, which is also structurally distinct from all other microtubule-targeted agents. The unique structure and mechanism of action of the taccalonolides, together with their ability to circumvent clinically relevant forms of taxane resistance, prompted our efforts to explore the structure-activity relationship of this class of molecules. We have isolated several novel taccalonolides, designated Z, AA, AB, AC, AF and AG, as well as multiple known taccalonolides. Each of these taccalonolides exhibited cellular microtubule stabilizing activity and antiproliferative actions against breast cancer cells. However, profound differences in potencies were noted with IC50 values ranging from 32 nM to 13 μM. These studies demonstrate that microtubule stabilizing activity is a shared trait among this class of molecules and that significant structure-activity relationships exist. Additionally, in vivo antitumor evaluations of taccalonolides A, E and N demonstrate that each of these molecules has activity in vivo and that taccalonolide A is the most effective against a syngeneic mammary model of breast cancer.

**Phase 2, Open-Label Study of EZN-2208 (PEG-SN38) in Patients with Previously Treated Metastatic Breast Cancer.**

O’Shaughnessy JA, Osborne CRC, Steinberg MA, Holmes FA, Kim HS, Kocs DM, Richards PD, Volkel SJ, Berkowitz N, Buchbinder A. Texas Oncology - Baylor Charles A. Sammons Cancer Center, Dallas, TX; Virginia Oncology Associates, Norfolk, VA; Texas Oncology - Houston Memorial City, Houston, TX; Rocky Mountain Cancer Centers, Denver, CO; Texas Oncology - Austin Midtown, Austin, TX; Oncology & Hematology Associates of Southwest Virginia, Inc., D.B.A. Blue Ridge Cancer Care, Salem, VA; Tyler Cancer Center, Tyler, TX; US Oncology; Enzon Pharmaceuticals, Inc., Piscataway, NJ

**Background:** EZN-2208 is a water-soluble PEGylated conjugate of SN38 that results in parenteral delivery, increased solubility, higher exposure, and longer apparent half-life of SN38, as well as more profound deoxyribonucleic acid (DNA) damage and inhibition of angiogenesis. EZN-2208 results in prolonged exposure of tumors to SN38 via preferential accumulation of EZN-2208 in the tumor and prolonged release of SN38 in the blood.

**Methods:** This trial evaluated EZN-2208 delivered as a 1-h IV infusion weekly for 3 wks in 4-wk cycles. The primary objective was to determine the overall response rate (RR) in female patients with metastatic breast cancer (MBC) who had received prior adjuvant or metastatic therapy with either 1) anthracycline and taxane (AT) or 2) anthracycline, taxane, and capecitabine (Xeloda®) (ATX). Secondary objectives included evaluation of RR based on tumor receptor status, duration of response, progression-free survival (PFS), overall survival (OS), and safety and toxicity. Response was evaluated using RECIST (v1.1).

**Results:** 148 patients received EZN-2208 in the AT (n=65; median age = 56 y [31-84 y]) or ATX (n=83; median age = 55 y [36-83 y]) cohorts. All 65 patients in the AT cohort had received 0-2 lines of prior cytotoxic therapy for MBC; for the ATX cohort, 31 patients (37%) had received 0-2 prior lines of cytotoxic therapy for MBC, 50 patients (60%) had received 3-4 prior lines, and 2 patients (2%) had received 5 prior lines. Preliminary results follow; final data will be presented at the meeting. Median (range) cycles of EZN-2208 was 2.3 (0.3-14) for AT and 2 (0.3-15) for ATX. Best overall response is shown in the table. RR (PR+uPR) was 22% for AT and 10% for ATX. Median (95% CI) time to progression was 3.8 mo (3.6-7.4) for AT and 3.5 mo (1.8-3.7) for ATX. Median (95% CI) duration of response was 4.0 mo (3.7-5.6) for AT and 5.2 mo (1.9-7.3) for ATX. 6-mo PFS (95% CI) was 34% (19%-50%) for AT and 19% (9%-29%) for ATX. Median PFS (95% CI) was 3.8 mo (2.7-5.6) for AT and 2.9 mo (1.8-3.7) for ATX. Median OS (95% CI) was 9.1 mo (6.1-12.7) for AT and 7.9 mo (6.4-12.9) for ATX. Grade 3 or 4 drug-related adverse events (>10% of patients in either arm) included neutropenia (43%, 33%), diarrhea (11%, 8%), and leukopenia (11%, 6%).

*PR = unconfirmed partial response; **Clinical benefit rate (CBR) = CR+PR or SD +6 months.

**Conclusions:** EZN-2208 is active in patients with previously treated MBC. The activity is similar regardless of ER status and is promising in the TNBC population. The safety profile of EZN-2208 is acceptable with good tolerability in most patients. Further evaluation of EZN-2208 in this population is warranted.

**ApoE and Its Receptors (LRP8, VLDLR) Function as Growth Signals for Triple-Negative Breast Cancer and Represent a Novel Therapeutic Target.**

Shiang C, Qi Y, Wang B, Broom B, Pusztai L. UT M.D. Anderson Cancer Center

Triple-negative breast cancers (TNBC) lack the expression of estrogen, progesterone, and the human epidermal growth factor 2 receptors and have limited treatment options. We hypothesized that genes that are frequently amplified or overexpressed in these cancers are functionally important for the growth and survival of triple-negative breast cancer.

**Materials/Methods:** We identified genes overexpressed in TNBC in 3 different human breast cancer gene expression data sets (n=294, n=286, n=198). We assessed the functional importance of the consistently overexpressed genes using siRNA screen on 18 breast cancer cell lines (10 ER-, 8 ER+) in vitro. We targeted each gene with 4 different siRNA constructs separately and each experiment was performed in triplicate. The genes with the greatest TNBC-specific inhibitory effect after siRNA down regulation were selected for further mechanistic and signal transduction studies.

**Results:** 684 genes showed consistent and highly significant overexpression in TNBC compared to receptor-positive cancers in all 3 data sets. siRNA suppression of 161 of these genes inhibited cell growth significantly more in the ER-negative compared to ER-positive cells by at least 1 of the 4 siRNAs. 27 genes showed similar effect with 2 or more siRNAs and for 2 genes 3 of the 4 siRNAs showed preferential growth inhibition in ER-negative cells. These two genes were VLDLR (very low-density lipoprotein receptor) and LRP8 (low density lipoprotein receptor-related protein 8). We validated the siRNA screen results and confirmed down regulation of the mRNA and protein levels for VLDLR and LRP8 in 4 different ER-negative cell lines and showed that siRNA inhibition can be rescued by co-transfection of the receptor genes. Reanalysis of gene expression
data also indicated expression of the LRPI8 and VLDLR ligands, Reelin or ApoE, in both breast cancer tissues and in cell lines. We next demonstrated that exposure to Reelin and ApoE stimulates the growth of ER-negative cells in vitro. The stimulatory effect of ApoE was isoform dependent ApoE2 (Cys112/Cys112) has the lowest receptor binding affinity and showed no growth stimulation, ApoE3 (Cys112/ Arg158) had modest 50-60% growth stimulation and ApoE4 (Arg112/ Arg158) had the greatest stimulatory effect (300-400%). Suppression of the expression of either LRPI8 or VLDLR or exposure to RAP (an inhibitor of ligand binding to LRPI8 and VLDLR) abolished this ligand-induced proliferation. ApoE4 stimulation results in the transcriptional upregulation of genes involved in proliferation, metabolism, and inflammatory signaling pathways. ApoE4 stimulation increases expression of proteins involved in MAPK/ERK pathway, DNA damage repair, and inflammation. **Conclusions:** We show that the ApoE–LRPI8/VLDLR ligand receptor system is overexpressed in human TNBC. We also demonstrated that this receptor system mediates a strong growth promoting and survival function in TNBC cells in vitro. Interestingly, allelic imbalance favoring ApoE4 expression (E3/E4 or E4/E4) has been linked to higher risk of developing early onset breast cancer, which is primarily TNBC. We propose that inhibitors of LRPI8/VLDLR signaling may be clinically useful therapeutic or preventive agents for TNBC.

**Targeting the Autophagy Pathway for Drug Resistance of Breast Tumor-Initiating Cells.**
Zhao H, Li F, Cui K, Sheng J, Landis M, Chang J, Wong S, Dave B. The Methodist Hospital Research Institute, Weil Medical College, Cornell University, Houston, TX; The Methodist Hospital, Weil Medical College, Cornell University, Houston, TX

**Background:** Our clinical data and experimental evidence reveal that the tumor-initiating cells (TICs) in the original tumor are intrinsically resistant to conventional chemotherapy and radiation therapy and greatly enriched in residual breast cancers after such treatments. We have published a gene expression signature of such breast TICs, and our pathway analysis on the gene signature suggests that the activation of autophagy pathway may be an intrinsic characteristic of the TICs. This motivates us to further investigate the role of the autophagy pathway in TICs self-maintenance and their resistance to hormonal and chemo therapies, as well as their response to TIC-targeted therapies.

**Methods:** A collective 84 well-documented autophagy pathway genes were used to compare the activation of autophagy pathway in different microarray datasets, 1) flow-sorted CD44+/CD24−/low cancer cells vs. all other cells (representing 20 patients), and cancer-derived MSs vs. corresponding primary bulk tumors (representing 17 patients), 2) before vs. after letrozole and doxetaxel treatments (representing 30 patient pairs), 3) before vs. after letrozole treatment (representing 176 patient pairs), and 4) before vs. after lapatinib treatment (representing 115 patient pairs). We applied the Significance Analysis of Microarrays (SAM) algorithm to analyze the expression data of 211 normalized probes for the 84 genes. Levels of TGF alpha were measured by ELISA in conditioned media from cell lines (MCF7, T47D, BT474, JIMT-1, SKBR3, MDA-MB-453). Growth inhibitory effects were determined by cell counts and by MTT cell viability assay (Roche), following 5 days post treatment. Levels of TGF alpha were measured by ELISA in conditioned media from cells treated with 1µM WAY for 24 hours. Levels of pEGFR were also measured by ELISA.

**Results:** We analyzed expression of ADAM17 across molecular subtypes for breast cancer. Levels of ADAM17 mRNA were significantly enriched in the basal like subtype (most of which were TNBC) compared to luminal A, luminal B or HER2 positive breast cancers. In vitro, treatment with WAY-180022 alone resulted in growth inhibitory effects ranging from 15–49% in TNBC cells as determined by cell counts. By MTT viability assay, treatment with 1 µM WAY resulted in a significant reduction in cell proliferation compared to vehicle control in MDA-MB-231 (p = 0.007) cells. Addition of WAY to gefitinib resulted in a significant reduction in proliferation in MDA-MB-231 cells compared to either gefitinib or WAY alone.

**Conclusion:** Activation of the autophagy pathway in TICs is a promising target to combat the drug resistance of breast cancer to conventional systemic therapy.

**P3-17-03**

**ADAM17: A Novel Therapeutic Target for Treatment of Triple Negative Breast Cancer.**
McGowan PM, Mullooly M, Sukor S, Madden S, McDermott E, Pierce A, Crown J, O’Donovan N, Duffy MJ. St. Vincent’s University Hospital, Dublin, Ireland; University College Dublin Dublin, Dublin, Ireland; Dublin City University, Dublin, Ireland; Molecular Therapeutics Cancer Ireland, Dublin, Ireland

**Background:** Due to the absence of ER, PR and HER2, targeted therapy is currently unavailable for patients with triple negative breast cancer (TNBC). Although TNBC lack overexpression of HER2, HER1, or EGFR, signaling is active in at least a subset of these cancers. Activation of EGFR is initiated by ADAM17-mediated release of ligands such as EGF, TGFα and HB-EGF. The aim of this study was to test the hypothesis that inhibition of ADAM17 is a novel approach for the treatment of TNBC.

**Methods:** Gene expression data sets were analyzed for ADAM17 expression (3,519 samples across 21 datasets incorporating 10 different microarrays). We used the ADAM17 specific inhibitor, WAY-180022 (WAY: Pfizer), the EGFR inhibitor gefitinib and 5-fluorouracil (5FU) (Sigma Aldrich) to determine their effects on the growth of 7 TNBC cell lines (MDA-MB-231, MDA-MB-468, SUM159PT, HCC1937, BT20, Hs578T, Hs578T) and 6 non-TNBC cell lines (MCF7, T47D, BT474, JIMT-1, SKBR3, MDA-MB-453). Growth inhibitory effects were determined by cell counts and by MTT cell viability assay (Roche), following 5 days post treatment. Levels of TGFalpha were measured by ELISA in conditioned media from cells treated with 1µM WAY for 24 hours. Levels of pEGFR were also measured by ELISA.

**Results:** We analyzed expression of ADAM17 across molecular subtypes for breast cancer. Levels of ADAM17 mRNA were significantly elevated in the basal like subtype (most of which were TNBC) compared to luminal A, luminal B or HER2 positive breast cancers. In vitro, treatment with WAY-180022 alone resulted in growth inhibitory effects ranging from 15–49% in TNBC cells as determined by cell counts. By MTT viability assay, treatment with 1 µM WAY resulted in a significant reduction in cell proliferation compared to vehicle control in MDA-MB-231 (p = 0.007) cells. Addition of WAY to gefitinib resulted in a significant reduction in proliferation in MDA-MB-231 cells compared to either gefitinib or WAY alone.
(p = 0.017 and p = 0.003, respectively). Similarly, addition of WAY to 5FU resulted in a significant inhibitory effect compared to 5FU alone in MDA-MB-468 (p = 0.007) cells. Investigating the functional effects of ADAM17 inhibition on breast cancer cells, we found that levels of pEGFR were reduced by between 26 – 57.6% in 5 of 6 lines examined. pEGFR levels were significantly reduced in MDA-MB-468 (p = 0.01) and MDA-MB-231 (p = 0.01) cells. In addition, levels of TGFα were significantly reduced following treatment with 1 µM WAY (MDA-MB-468, p = 0.008; MDA-MB-231, p = 0.012; HCC1143, p = 0.033; Hs5788, p = 0.036). Conclusion: Based on our findings, inhibition of ADAM17 with WAY-188022 is a potential treatment for patients with TNBC. Acknowledgement: The authors wish to thank Science Foundation Ireland, Strategic Research Cluster award (08SRC/B1410) to Molecular Therapeutics for Cancer Ireland and the Health Research Board Clinician Scientist Award (CSA/2007/11) for funding this work.

CXCR1/2 Regulates Human Breast Cancer Stem Cell Activity Via EGFR/HER2-Dependent and -Independent Pathway.
Singh JK, Farnie G, Clarke RB, Hundred NJ. School of Cancer and Enabling Sciences, University of Manchester, Paterson Institute for Cancer Research, Manchester, United Kingdom; University Hospital of South Manchester, Wythenshawe Hospital, Manchester, United Kingdom

Background: Increasing evidence suggests that breast cancers are sustained by breast cancer stem cells (CSCs). Interleukin-8 (IL-8) via its cognate receptors, CXCR1 and CXCR2, and HER2 regulate CSC activity. Cytokine receptors can trans-activate members of the epidermal growth factor receptor (EGFR) family in normal and malignant tissue. The aims of this study were to determine (1) the effect of the IL-8-CXCR1/2 signalling pathway on human breast CSC activity, (2) the effect of CXCR1/2 inhibition in combination with EGFR/HER-2 inhibition on CSC activity and (3) the interaction of CXCR1/2 and EGFR/HER2 in breast cancer.

Methods: Human breast cancer cell lines used were HER2-18 and SKBR3 (both HER2 over-expressing). Primary human breast cancer cells were extracted from metastatic samples (pleural effusion n=4; ascites n=5; local recurrence n=1) and invasive breast cancers (n=1). CSC activity was investigated in vitro using the mammosphere assay. Mammosphere forming efficiency (MFE) was determined by dividing the number of mammospheres >60µm in diameter divided by the number of cells seeded and expressed as a percentage. Data is represented as mean MFE ± standard error of mean normalised by the number of cells seeded and expressed as a percentage. Data is represented as mean MFE ± standard error of mean normalised by the number of cells seeded and expressed as a percentage. Results: Ganetespib displayed potent, low nanomolar activity in vitro. Anticancer activity of ganetespib was further investigated in vivo using breast cancer xenografts.

P3-17-05
Beyond HER2 and Hormonal Agents: The Heat Shock Protein 90 Inhibitor Ganetespib as a Potential New Breast Cancer Therapy.
Friedland JC, Sang J, Modi S, Bradley R, El-Hariry I, Wada Y, Proia DA. Synta Pharmaceuticals, Lexington, MA; Memorial Sloan-Kettering Cancer Center, New York, NY

Background: Ganetespib is a fully synthetic and selective inhibitor of heat shock protein 90 (HSP90), a molecular chaperone recognized as a key facilitator of breast cancer initiation, progression and metastasis. Methods: Preclinical activity of ganetespib across the four major breast cancer subtypes and inflammatory breast cancer was assessed in vitro and in vivo. Modulation of cell proliferation and viability was determined both in monolayer and three-dimensional cultures. HSP90 client protein expression and activity was monitored by Western blot and protein array. To recapitulate clinical dosing, kinetics of client protein destabilization were measured following short exposures to drug in vitro. Anticancer activity of ganetespib was further investigated in vivo using breast cancer xenografts.

Results: Ganetespib displayed potent, low nanomolar activity in luminal (A and B), basal (A and B) and inflammatory breast cancer cell lines grown as monolayers in vitro. BT-474 (HER2 amplified) luminal cells grown as mammospheres in 3D were equally as sensitive to ganetespib as those grown in monolayer. In luminal cells, ganetespib simultaneously disrupted multiple signaling components including the estrogen and progesterone receptor, several receptor and non-receptor tyrosine kinases, as well as the MAPK pathway. Further, ganetespib effectively inhibited AKT, PDK1 and SGK3 activity in PI3KCA mutant cells suggesting that HSP90 is essential for both AKT-dependent and AKT-independent signaling. Clinically relevant exposure times to ganetespib in vitro resulted in potent, long term degradation of HER2. In the basal-like breast cancer cell line MDA-MB-231, enriched in CD44+CD24- stem like cells that commonly display chemotherapeutic resistance and activated JAK2/STAT3 signaling, ganetespib (50 nM) induced significant degradation of JAK2 concordant with loss of both tyrosine and serine phosphorylation of STAT3, followed by cell death. The potent anticancer activity in vitro translated in vivo, where ganetespib was effective in modulating breast cancer xenograft growth as a single agent in both luminal and basal-like breast cancer models. Finally, ganetespib has demonstrated encouraging signs of clinical activity in breast cancer patients, including confirmed partial responses in both a triple negative breast cancer patient and a HER2 positive breast cancer patient.
Conclusions: Ganetespib is a highly potent HSP90 inhibitor that displays preclinical activity in breast cancer due to its ability to simultaneously perturb multiple oncogenic signaling pathways.

**P3-17-06**

Final Results of a Controlled, Randomized 3-Arm Phase II Trial of EndoTAG™-1, a Cationic Liposomal Formulation of Paclitaxel Targeting Tumor Endothelial Cells, in Advanced Triple-Negative Breast Cancer (TNBC).

Awada A, Bondarenko IN, Tarasova O, Bonneterre J, Novara E, Ferrero JM, Bakshi AV, Weidenthaler H, Wilke C, Piccart MJ. Institut Jules Bordet, Brussels, Belgium; Dnepropetrovsk State Medical Academy, Dnepropetrovsk, Ukraine; Academy of Medical Sciences of Ukraine, Kharkov, Ukraine; Centre Oscar Lambret, Lille, France; Instytut im. M. Sklodowskiej-Curie, Gliwice, Poland; Centre Antoine Lacassagne, Nice, France; Kaushalya Medical Foundation, Thane, India; Medigene AG, Martinsried, Germany

**Background**

EndoTAG™-1 (ET) is an innovative therapy of paclitaxel (P) embedded in cationic liposomes displaying antitumor activity by targeting negatively charged activated endothelial cells of tumor vessels.

**Methods**

140 patients (pts) with locally relapsed (r) or metastatic (m) centrally verified TNBC were randomized to i.v. weekly ET (22mg/m$^2$) plus P (70mg/m$^2$) (ET+P), biweekly ET alone (44mg/m$^2$) or weekly P (90mg/m$^2$) in a 2:2:1 ratio. Pts had ≤ 1 prior chemotherapy (CT) for r or m disease and ≥ 6 months (mo) after taxane. A cycle (cy) comprised 3 weeks (w) of therapy and 1 w rest. Pts were treated for a minimum of 4 cy or until disease progression/unacceptable toxicity.

Primary endpoint was progression-free survival (PFS) rate at week 16 based on blinded central imaging and local assessment. Secondary endpoints included median overall survival (mOS), tumor response (RECIST), Quality of Life (QoL) and safety. The study was not powered for intergroup comparisons.

**Results**

Pts baseline characteristics were overall well distributed. Appr. 80% of all pts were treated 1st line for r or m TNBC. Results of PFS rates at week 16 are shown in table. Based on central review, median PFS at week 16 was 4.2 mo for ET+P (95% Cl: 3.5-9.1), 3.4 on ET (2.0-3.8) and 3.7 on P (1.9-6.7). Antitumor activity was highest for ET+P with a clinical benefit rate (complete response (CR) + partial response (PR) + stable disease (SD)) of 52% (26/49 evaluable pts), 31% (15/49) on ET and 36% (9/25) on P. The best overall response (CR, PR, SD at any time) on ET+P was 80% (39/49), on ET 65% (32/49) and 68% (17/25) on P.

Analysis of median OS is shown in table. Analysis of the not predefined subgroup (centrally TNBC + ECOG 0/1 + first line population) showed an impressive median OS of 17.8 mo for ET+P. No differences were reported for QoL. No additional toxicities to those known for ET and P were observed except uncomplicated grade 3/4 neutropenia in the ET+P arm.

EGCG, a Green Tea Antioxidant Suppresses Breast Tumor Angiogenesis and Growth Via Inhibiting the Activation of HIF-1α and NFκB, and VEGF Expression.

Makey KL, Tucker KB, Chinchar E, Miele L, Pei I, Thomas EY, Gu J-W. University of Mississippi Medical Center, Jackson, MS

**Background:** Cancer cells are under greater oxidative stress than normal cells. Limited studies have showed that epigallocatechin-3-gallate (EGCG), a green tea antioxidant can afford protection against a variety of cancer types. The role of EGCG in breast cancer therapy is poorly understood. The present study tests the hypothesis that EGCG as an antioxidant can inhibit the activation of HIF-1α and NFκB, and VEGF expression, thereby suppressing tumor angiogenesis and breast cancer progression.

**Material and Methods:** 16 eight-wk-old female mice (C57BL/6J) were inoculated with 10^6 E0771 (mouse breast cancer) cells in the left fourth mammary gland fat pad. 8 mice received EGCG at 50-100 mg/kg/d in drinking water for 4 weeks. 8 control mice received drinking water only. Tumor size was monitored using dial calipers. At the end of the experiment, blood samples, tumors, heart and limb muscles were collected for measuring VEGF expression using ELISA and capillary density (CD) using CD31 immunohistochemistry. Cultured E0771 cells were used for determining the direct effects of EGCG on proliferation (3H-thymidine incorporation), migration (Matrigel assay), VEGF expression (ELISA), the activation of HIF-1α and NFκB (motif binding assays, Active Motif). MCF-7 and MDA-MB-231 cells were also used for 3H-thymidine incorporation.

**Results:** Oral EGCG treatment significantly reduced tumor weight over the control (0.37±0.15 vs. 1.16±0.30 g; P<0.01), tumor CD (109±20 vs. 156±12 capillary/mm^2; P<0.01), tumor VEGF expression (45.72±1.4 vs. 59.03±3.8 pg/mg; P<0.01), respectively. EGCG treatment reduced plasma VEGF levels over the control mice (26.48±3.76 vs. 40.79±3.5 pg/ml; P<0.01). However, there were no differences in the body weight and heart weight between EGCG and the control groups. EGCG did not inhibit angiogenesis and VEGF expression in the heart and skeletal muscle of mice, compared to the control. EGCG at 50 mol/L significantly inhibited the activation of HIF-1α (0.11±0.02 vs. 0.24±0.02; P<0.01) and NFκB (1.15±0.21 vs. 1.61±0.32; P<0.01) as well as VEGF expression (1752±49 vs. 2254±91 pg/mg; P<0.01) in cultured E0771 cells, compared to the control, respectively. EGCG caused a dose-related inhibition on the proliferation and migration in cultured E0771 cells. EGCG also caused a dose-related inhibition on the proliferation in cultured MCF-7 and MDA-MB-231 cells.

**Discussion:** These findings support the hypothesis that EGCG, a green tea antioxidant, directly targets both tumor cells and tumor vasculature, thereby inhibiting tumor growth, proliferation, migration, and angiogenesis of breast cancer, which is mediated by the inhibition of HIF-1α and NFκB activation as well as VEGF expression. Interestingly, oral EGCG treatment has no effects on the body weight, heart weight, angiogenesis and VEGF expression in breast cancer progression.
the heart and skeletal muscle of mice. This work will have important implications for translating EGCG therapy to human breast cancer treatment and prevention.

Macroautophagy Protects Breast Cancer MCF-7 Cells from TAM-Induced Apoptosis Via Mitogen-Activated Protein Kinase (MAPK) Pathway.

Hou YF, Ma XY, Liu ZB, Yu SJ, Shao ZM. Cancer Institute, Shanghai, China

Tamoxifen (TAM) has been used ubiquitously for endocrine therapy for the hormone-sensitive breast cancer. Several studies have revealed that tamoxifen treatment induced apoptosis and at the same time tamoxifen increased autophagic levels in MCF-7 cells. The previous studies attempt to elaborate the significance and mechanism of autophagy induced by TAM in breast cancer cells, however, there are contradictions among their conclusions, it is still not clear that autophagy protects MCF-7 from apoptosis or promotes apoptosis. Better understanding of the effect of autophagy induced by TAM in breast cancer cells on apoptosis will be of the important clinical significance in endocrine therapy for breast cancer.

The present study shows that tamoxifen treatment significantly increased autophagic levels by inducing autophagic vacuoles formation in MCF-7 cells observed by means of transmission electron microscopy and enhancing the expression of autophagy marker, microtubule-associated protein light chain 3 measured by Western blot. Our research shows tamoxifen enhanced the phosphorylation of MAPKs when inducing autophagy and autophagy decreased significantly when kinase inhibitors were separately used to inhibit the phosphorylation of ERK, JNK, p38 MAPK. MAPK signal transduction pathway was involved in the process of autophagy in MCF-7 cells.

To investigate whether Estrogen receptor-α participated in autophagy caused by tamoxifen, we constructed Estrogen receptor-α gene ESR/1 shRNA expression vector and it could effectively inhibit the expression of ER-α in MCF-7 cells. Our research shows that autophagy was decreased with the downregulation of ER-α, so we conclude that Estrogen receptor-α also involved in autophagy induced by tamoxifen in MCF-7 cells.

To find out the specific role of autophagy in tamoxifen treated breast cancer cell MCF-7, we inhibited autophagy producing after tamoxifen treatment by pretreating the cells with chloroquine and 3-methyladenine, both commonly used as autophagy inhibitors. Another method for autophagy inhibition was Becline-1 siRNA transfection into MCF-7 cells. Than we stained MCF-7 cells with anti-Annexin V FITC and PI and examined apoptotic rate by flow cytometer and we also detected activity of caspase7 in MCF-7 cells.

The results indicate that inhibition of autophagy by the methods mentioned induced higher apoptotic level, therefore, autophagy protected MCF-7 from apoptosis and inhibiting autophagy may be a new strategy to augment the therapeutic effect of tamoxifen treatment. In our study, we induced breast cancer cell MCF-7 resistant to TAM in vitro and we found much higher autophagic level in TAM resistant cells compared with TAM not resistant MCF-7 cells. We draw the conclusion that inhibition of autophagy induced by tamoxifen may be a new therapy for tamoxifen resistant breast cancer.

Key words: tamoxifen, breast cancer, autophagy, MCF-7 cells, MAPKs, estrogen receptor, inhibition, apoptosis

P3-17-09
Neutralizing the Prolactin Receptor with Therapeutic Antibody LFA102: A Novel Approach for the Treatment of Breast Cancer.

The prolactin receptor (PRLR) is a class I cytokine receptor required for the normal development of the mammary gland and is frequently found to be overexpressed in breast tumors. The polypeptide hormone prolactin (PRL) has been demonstrated to induce PRLR signaling through the Jak/Stat, PI3-kinase/AKT and MAPK pathways, leading to cell proliferation and survival. Mammary gland-specific over-expression of PRL in transgenic mice leads to a higher incidence of ER+ and ER- mammary tumors. In addition, the PRLR locus is the site of frequent viral integrations in MMTV-induced mammary tumors. Elevated serum PRL levels in humans have been correlated with an increased risk for breast cancer, especially for ER+ cases, implicating a role for this hormone in the development of human breast tumors. An analysis of more than 3000 breast tumor specimens indicates that PRLR is expressed with high prevalence (60-70% of tumors) across all breast cancer subtypes, with a trend towards higher expression in ER+ tumors. All of these lines of evidence support the hypothesis that targeting the PRL/PRLR axis may be a new approach for addressing unmet medical need in breast cancer. LFA102 is a Human Engineered™ anti-PRLR antibody of the IgG1 isotype that neutralizes the function of PRLR through a non-ligand competitive binding interaction. LFA102 blocks PRL-induced signaling and proliferation in T47D and MCF7 ER+ human breast cancer cells in vitro, and abolishes PRL-induced phosphorylation of Stat5 in T47D xenograft tumors in vivo. An examination of disaggregated primary human breast tumors ex vivo has indicated that PRL frequently induces signaling through Stat5 in the cells and that LFA102 is capable of completely antagonizing this signaling. LFA102 also neutralizes rat PRLR and the antibody potently regresses PRL-dependent Nb2-C11 pre-T cell lymphoma tumors in vivo. Preliminary data suggests that LFA102 is also capable of inhibiting the growth of carcinogen-induced rat mammary tumors. In vitro studies have shown that LFA102 can also mediate antibody-dependent cellular cytotoxicity (ADCC) and inhibit the PRL-dependent release of the pro-angiogenic factor VEGF from breast cancer cells. Thus, there are multiple potential mechanisms through which LFA102 could show anti-tumor activity in vivo. Preclinical toxicological studies of LFA102 indicate that this therapeutic is well tolerated and exhibits a normal pharmacokinetic profile in relevant animal species. The safety and pharmacokinetics of LFA102 in humans are currently being evaluated in a phase I healthy volunteer trial. At the three dose levels explored so far, no infusion reactions or severe adverse events related to the drug have been reported. Preliminary results suggest that LFA102 has an adequate pharmacokinetic profile for further clinical development. An assessment of LFA102 in a population of metastatic breast cancer patients predicted to have the highest probability of benefit is imminent.

P3-17-10
EpCAM as a Target for Chemical Antibodies in Metastatic Breast Cancer.

Shigdar SL, Duan W. Deakin University, Geelong, Victoria, Australia

EpCAM is a 40kDa glycoprotein that functions as an adhesion molecule in benign epithelium. However, it is over-expressed in nearly all carcinomas, including breast carcinomas, and has been
implicated in the pathogenesis and progression of cancer. In primary breast carcinoma, its over-expression correlates with a diminished overall survival in patients with node-positive disease. Indeed, recent evidence has shown that EpCAM is expressed at a higher level in metastases than in matched primary breast carcinoma. This has led to the suggestion that EpCAM over-expression is associated with aggressive behaviour, and that it could be considered a promising therapeutic target for breast cancer. Several immunotherapy trials are ongoing, though there are limitations to their delivery and distribution, suggesting a smaller and more effective EpCAM targeting molecule is required.

Aptamers, also known as chemical antibodies, are short-stranded DNA or RNA molecules and are selected via the systematic evolution of ligands by exponential enrichment (SELEX). They are 10 to 20 times smaller than antibodies and exhibit superb tissue penetration, thereby indicating their suitability in cancer targeting. In addition, aptamers are more stable, non-immunogenic and non-toxic. Following 12 rounds of SELEX using EpCAM protein as a target, we generated several EpCAM specific RNA aptamers. These were investigated using flow cytometry and confocal microscopy for their ability to bind to three breast cancer cell lines, MCF-7, T47D and MDA-MB-231. Our 19-nt aptamer showed specific binding to all three cell lines. In addition, it also showed superior penetration of breast cancer 3-D spheroid tumor models, as compared to a control aptamer and negative cell lines. This aptamer has also shown efficient internalisation via receptor-mediated endocytosis, suggesting it to be a suitable targeting moiety for drug delivery to both primary and metastatic tumors. The usefulness of this aptamer in clinical applications is being actively investigated.

Dovitinib (TKI258), a Dual Inhibitor of FGFR and VEGFR, Induces Tumor Growth Suppression in Xenograft Models of Primary Human Breast Cancer:
Shi MM, Linnartz R, Versace R, Graus Porta D, Kay A, Dugan M, Novartis Oncology, East Hanover, NJ; Novartis Institutes for BioMedical Research, Basel, Switzerland

**Introduction:** The objective of this study was to evaluate the efficacy of dovitinib (TKI258), a small-molecule dual inhibitor of fibroblast growth factor receptor (FGFR) and vascular endothelial growth factor receptor (VEGFR) in mouse models of human breast cancer. Molecular epidemiological studies have implicated that FGFR1 and FGFR2 gene amplification plays a critical role in breast cancer tumorigenesis. FGFR1 gene amplification correlates with gene expression and is associated with poor prognosis in patients with estrogen receptor-positive (ER+) tumors. Dual FGFR/VEGFR inhibitory activities of dovitinib make it an attractive molecule for targeting breast cancer. **Experimental Design:** Dovitinib was evaluated in 3 primary human breast carcinoma xenograft models with different histological and molecular profiles: a triple-negative breast cancer model (HBCx-15), a HER2+ model (HBCx-5), and an ER+ model (HBCx-3). Dovitinib was administered orally at 20- and 40-mg/kg dose levels (n = 8-10/group), once daily for 21 consecutive days. **Results:** At a dose of 40 mg/kg, dovitinib demonstrated strong antitumor efficacy as a single agent, particularly in the ER+ HBCx-3 and the HER2+ BCx-5 tumor models (AT/TO = −26.42% and AT/AC = 5.09%, respectively), whereas the response was less significant in the triple negative breast cancer HBCx-15 model (AT/AC = 31.7%). **Conclusion:** Dovitinib showed significant antitumor effect in human breast cancer xenograft mouse models. This study provides a strong rationale for clinical investigation of dovitinib in patients with advanced breast cancer, particularly in patients with ER+ and HER2+ disease.

cMET Inhibitor and the Inhibition of Growth of Breast Cancer Cells in Bone Marrow Matrix Environment.
Ye L, Mason MD, Bramble P, Jiang WG. Cardiff University School of Medicine, Cardiff, Wales, United Kingdom; Pfizer Limited, Walton Oaks, Surry, United Kingdom

Background: Hepatocyte growth factor (HGF) is a cytokine that has a diverse but potential role in cancer including breast cancer. HGF, which action is mediated by its specific receptor, cMET, stimulates the aggressiveness of cancer cells by increasing the invasiveness and cellular migration. HGF is also a potent angiogenic factor. Small inhibitors to the HGF receptor are currently investigated in clinical trials of various cancers. In solid tumours which have potency of bone metastasis, HGF and particularly the HGF receptor, cMET, have been found to be particularly over-expressed in tumour cells metastatised to bones.

Materials and Methods. A panel of breast cancer cell lines were used. Cell growth was determined using a colorimetric method. Cell adhesion and migration were investigated using a ECIS model. Bone matrix proteins were prepared from fresh bones. A small inhibitor to human cMET, PF02341066 was used in the present study in all the cell models.

Results. Depending on cell types, cancer cells tended to grow at a faster rate in bone marrow microenvironment than under normal conditions (12% higher for MDA MB 231 cells, for example). While PF02341066 have a concentration dependent effect on the growth of breast cancer, this effect became more marked when cells were growing in the bone marrow matrix. Breast cancer cells migrated rapidly in the presence of bone marrow environment, in comparison with controls. This was also inhibited by the cMET inhibitor. The study further showed that cells over-expressing a molecule linked to bone metastasis, namely ALCAM (1,2), responded more vigorously to cMET inhibitor in the matrix adhesion and cellular migration.

Conclusions. The present study has shown that the HGF receptor inhibitor has an inhibitory effect on breast cancer cells. This is particularly so when cells are grown in bone matrix microenvironment. It is concluded therefore that inhibitors to the HGF receptor may have a particular role in the management of bone metastasis in breast cancer.

A Combination of Pathway-Targeted Inhibitor with DNA-Repair Inhibitor: Preclinical Efficacy of Zactima and Olaparib in Triple Negative Subset of Breast Cancer.
Dey N, Wu H, Sun Y, De P, Leyland-Jones B. Emory University, Atlanta, GA

**Introduction:** Pathway-targeted therapy has not been established for the treatment of Triple Negative (TN) subset of breast cancer (BC). Despite emerging data supporting the use of polyADP-ribose polymerase (PARP) inhibitors, complete and durable responses are rare in TNBC and exploration of additional pathway-targeted...
therapies is needed. The high frequency (72-75%) of EGFR expression in TNBCs suggests that loss of BRCA1 may be coupled, either directly or indirectly, with EGFR overexpression in breast cancer (Van der Groep et al., 2006), and a recent report shows that even a partial loss of BRCA1 leads to an overall increase in EGFR expression in mammary epithelial cells (Burga et al., 2011). We hypothesize that the combined inhibition of growth factor driven EGFR pathway (by Zactima, a small molecule kinase inhibitor of EGFR and VEGFR-2) and DNA-repair pathway (by Olaparib, PARG inhibitor) in the presence of DNA-damaging agent (carboplatin) will have anti-proliferative and anti-migratory effects on triple negative breast tumor (TNBT) cells.

Methods: The effects of Zactima, Olaparib (single or in combination) and carboplatin were studied on: (a) the cell survival/proliferation (MTT, SRB, & cell titer-GLO assay), (b) EGF-induced upregulation of downstream proliferation markers, (c) the cellular signals for apoptosis, (d) fibronectin-directed migration (scratch-assay), (e) the vascular mimicry, and (f) the clonogenic survival (3D-ON-TOP assay) in different TNBT cell lines.

Results: Our in vitro data show that, (1) Zactima (10 µM) blocked EGF-induced phosphorylation of AKT (S473 & T308), S6RP, 4EBP1 and ERK as early as 1 hr (after the treatment), (2) the range of EC50's for Zactima (96 hrs) varied from 5 uM -15 uM (HCC70, HCC1937, MDA-MB231, MDA-MB468, BT20), (3) EGFR over-expressing, PTEN-null, and ATM kinase mutated MDA-MB468 cell line exhibited lowest EC50 for Zactima as compared to other TNBT cell lines and was found to be the most sensitive cell line to Zactima (~0.05 uM) when combined with 10 uM fixed dose of Olaparib, (4) a combination of Zactima with Olaparib plus carboplatin altered an adhesion-dependent cell-survival, increased caspase3 activity (expression of cleaved caspase3 and cleaved PARP) time dependently, inhibited vascular mimicry (at 6 and 24 hrs), blocked fibronectin-directed migration (scratch assay, 24 hrs), changed the organization of actin-cytoskeleton, and suppressed clonogenic growth in different TNBT cells lines.

Conclusion: Zactima alone showed anti-proliferative/pro-apoptotic, and anti-migratory effects in TNBT cells. The combination of Zactima with Olaparib plus carboplatin was most effective in blocking the clonogenic growth of TNBT cells. We are currently pursuing studies to, (1) delineate the relationship between the anti-proliferative effects (clonogenic assay) of Zactima (alone or in combination) and the status of the EGFR/ PI3K pathway using PIK3CA-mutated, PTEN-null and EGFR overexpressed TNBT cell lines, and (2) determine the effect of Zactima on angiogenesis using HUVEC cells, the results of which will be presented in the meeting. This work was generously supported by AVON foundation.

P3-18-04 Pathway Guided Selection of Targeted Inhibitors for Breast Cancer Treatment.

Background: The ability to functionally profile a whole spectrum of pathway proteins in tumor may provide valuable information about the likelihood of drug response and potential mechanisms for drug resistance in breast cancer (BCA) patients. Here we report a comprehensive pathway analysis of membrane associated kinases such as HER1, HER2, HER3, cMET, IGF1R, PI3K and downstream signal transduction proteins including Shc, AKT, ERK, MEK, PDK1, PRAS40, p70S6K and eIF4e in breast cancer cell lines and xenografts as in response to inhibitors targeting the Her1/Her2 and PI3K/AKT and MAPK pathways. For comparison we also analyzed NSCLC lines driven by other receptor tyrosine kinases like EGFR and MET.

Methods: Lysates prepared from KPL4 cells and MCF7 cells both harboring PIK3CA mutations (with HER2-amplification and low level HER2 expression, respectively) treated with 6 inhibitors (an allosteric AKT inhibitor, Lapatinib, Regorafenib, MET inhibitor, an allosteric MEK inhibitor or PI3K inhibitor) targeting PI3K/AKT and MAPK pathways were analyzed for modulations of pathway signal transduction proteins including Shc, AKT, ERK, MEK, PDK1, PRAS40, p70S6K and eIF4e in breast cancer cell lines and xenografts.

Results: Treatment of ER+ and HER2+ cell lines with INK128 in vitro showed that 1) cell lines were sensitive to single agent INK128 with 50% inhibitory concentration ranging from 15 nM-10 µM in ER+ cell lines and 20 nM -50 nM in HER2+ cell lines, 2) 70-80% anti-proliferative activities were observed on 3D-ON-TOP colony formation assay in both ER+ and HER2+ cells, 3) INK128 dose- and time-dependently blocked downstream effectors of mTOR1/2 pathway i.e. p-AKT (at Ser473), p-p70S6K, p-S6 ribosomal protein, p-4EBP1 (interestingly, potent inhibition was also observed in cell line resistant to trastuzumab), 4) INK128 also blocked AKT phosphorylation at Thr308 (although in lesser extent than at Ser473), 5) rapalog-mediated AKT activation was blocked when cells were treated with INK128, 6) in ER+ cell lines INK128 more efficiently blocked p-4EBP1 than rapalog, 7) HER3 expression was significantly upregulated following treatment of trastuzumab-resistant cells (BT474HR) with INK128, and 8) integrin-dependent cell migration was significantly abrogated with INK128 in association with inhibition of RAC1-GTP.

Conclusion: Our preclinical in vitro data demonstrate that concurrent inhibition of mTOR1 and mTOR2 is likely to be more effective in both ER+ and HER2+ breast cancer cells than the inhibition of mTOR1 alone. We are currently studying the effect of INK128 on downstream apoptotic signals in ER+ and HER2+ cell lines, the results of which will be presented in the meeting.

INK128 was generously supplied by InKellikine, San Diego, CA.

In Vitro Potency of mTOR Kinase (TOR1/TOR2) Inhibitor, INK128 in ER+ and HER2 Overexpressing Breast Cancer Cells.

De P, Sun Y, Dey N, Leyland-Jones B. Emory University, Atlanta, GA

Background: Persistent activation of the PI3K-AKT-mTOR1/2 signaling pathway drives aberrant cell growth and proliferation in a variety of tumor types including breast tumors. Recent works have demonstrated a strong association between mutational activation of PIK3CA or loss of function of PTEN and resistance to therapies targeted against the ER or HER2 pathway.

Purpose: Since PI3K-AKT-mTOR is one of the major signaling pathways responsible for the progression of breast cancer, as well as appears to be upregulated during development of the resistance to the endocrine and trastuzumab treatment, suppression of this pathway by administration of INK128 (mTOR1/2 kinase inhibitor) may therefore be efficacious in ER+ and HER2+ breast cancer models.

Experimental Design: To examine this possibility, INK128 was treated in ER+ (MCF7, BT483, T47D and MDA-MB-415), trastuzumab-sensitive HER2+ (BT474), trastuzumab-resistant (BT474HR), and PIK3CA mutated/HER2+ breast cancer cells (HCC1954 and UACC893). We have tested the effects of INK128 on the, (a) cell survival/proliferation, (b) integrin-directed cell migration, and small GTP-ase activation, (c) downstream signaling pathways for proliferation and apoptosis, and (d) 3D ON-TOP-colony formation.

Results: Treatment of ER+ and HER2+ cell lines with INK128 in vitro showed that 1) cell lines were sensitive to single agent INK128 with 50% inhibitory concentration ranging from 15 nM-10 µM in ER+ cell lines and 20 nM -50 nM in HER2+ cell lines, 2) 70-80% anti-proliferative activities were observed on 3D-ON-TOP colony formation assay in both ER+ and HER2+ cells, 3) INK128 dose- and time-dependently blocked downstream effectors of mTOR1/2 pathway i.e. p-AKT (at Ser473), p-P70S6K, p-S6 ribosomal protein, p-4EBP1 (interestingly, potent inhibition was also observed in cell line resistant to trastuzumab), 4) INK128 also blocked AKT phosphorylation at Thr308 (although in lesser extent than at Ser473), 5) rapalog-mediated AKT activation was blocked when cells were treated with INK128, 6) in ER+ cell lines INK128 more efficiently blocked p-4EBP1 than rapalog, 7) HER3 expression was significantly upregulated following treatment of trastuzumab-resistant cells (BT474HR) with INK128, and 8) integrin-dependent cell migration was significantly abrogated with INK128 in association with inhibition of RAC1-GTP.

Conclusion: Our preclinical in vitro data demonstrate that concurrent inhibition of mTOR1 and mTOR2 is likely to be more effective in both ER+ and HER2+ breast cancer cells than the inhibition of mTOR1 alone. We are currently studying the effect of INK128 on downstream apoptotic signals in ER+ and HER2+ cell lines, the results of which will be presented in the meeting.
TRAIL on CSCs derived from CRL-2335 and MDA-MB-468 TNBC

and BSI-201), paclitaxel, docetaxel, cisplatin and cisplatin plus breast tumors. We studied the effects of PARP inhibitors (AZD2281 stem cells compared to ER-positive, PR-positive and HER2-negative Results: TNBC tumors express relatively higher levels of cancer evaluated using Nod/Scid mice. Cancer stem cell levels in human nondifferentiated conditions. Apoptosis was assessed using the Cell ability to form mammospheres, are generated in nonadherent and positive population by fluorescence-activated cell sorting. CSCs Materials and Methods: Cancer stem cells were identified by ALDH- CSCs leading to tumor recurrence.

bulk of tumor cells, but it has a minimal effect on cancer stem cells despite initial response to neoadjuvant chemotherapy. The aim of this study was to determine whether current drug treatment(s) eliminates because of the loss of target receptors such as ER, PR and HER-2 have a worse prognosis compared with other breast cancer subtypes. Hormonal or Herceptin-based therapies were found to be ineffective for the loss of target receptors such as ER, PR and HER-2 amplification. TNBC has increased recurrence and poor survival, despite initial response to neoadjuvant chemotherapy. The aim of this study was to determine whether current drug treatment(s) eliminates bulk of tumor cells, but it has a minimal effect on cancer stem cells (CSCs) leading to tumor recurrence. Materials and Methods: Cancer stem cells were identified by ALDH-positive population by fluorescence-activated cell sorting. CSCs ability to form mammospheres, are generated in nonadherent and nondifferentiated conditions. Apoptosis was assessed using the Cell Death Detection ELISAPLUS kit. Xenograft tumor formation was determined by western blot analysis. Mode of action was explored by cell cycle FACS-analysis. Cleavage of PARP was explored by Western blot. Cytotoxic efficacy was evaluated by MTT assay. Additionally it was explored if inhibition of classical apoptosis could abrogate the effect of AEZS-131.

Results: The level of phosphorylated AKT (pAKT) was reduced when MCF7 cells were treated with AKT inhibitor as well as PI3K inhibitor. However, compensatory AKT activation was observed when these cells were treated with BRAF or MEK inhibitor. KPL4 cells also showed reduction of pAKT when treated with Lapatinib, AKT inhibitor or PI3K inhibitor. Compensatory hyper-phosphorylation of ERK (pERK) was observed in both cell lines and KPL4 xenografts with AKT inhibitor treatment while PI3K inhibition did not induce hyper-ERK phosphorylation. Reduction of pERK level was observed when both cell lines were treated with MEK inhibitor. Downstream analytes like PRAS40 and RPS6 summarize PI3K/AKT pathway activity and correlate well with response to treatment whereas elf4e is a good final readout for activity in the RAS/RAF/MEK/ERK pathway. Treatment with single agents often even shows adverse profile shift through feedback or pathway cross-talk. The comparative analysis of pathway modulation in BCA models to other tumor types in response to drug treatments revealed several adaptive drug resistance mechanism with different oncogenic backgrounds. Discussion: Evaluation of drug specific pathway modulations in cancer cells provided comprehensive information on efficacy of specific agents on target protein and pathway inhibition. Multiplexed pathway analysis provides valuable information for drug resistance mechanisms due to either redundant pathway activation, cross-talk or through feedback mechanism and may guide appropriate selection of targeted drug-combinations or drug-sequencing in clinical setting. For example, the observed increase in ERK phosphorylation due to AKT inhibition could be blocked by combination therapy with a MEK inhibitor.

P3-18-06

Introduction

Overexpression of MAPK has been detected in 34 % of TNBC and has been found to be associated with anthracycline resistance (1). AEZS-131 is a highly selective orally active ERK1/2-inhibitor, which has shown in vivo activity (first in class) in colon cancer. The following study explores mode of action and efficacy in models of TNBC.

Study design

AEZS-131 was tested in a kinase panel of 36 STK, 26 TK and 7 PIK to check for selectivity. Inhibition of Rsk-phosphorylation (cellular substrate of ERK) was evaluated by western blot analysis. Mode of action was explored by cell cycle FACS-analysis. Cleavage of PARP was explored by Western blot. Cytotoxic efficacy was evaluated in 5 TNBC, of which 2 had mutations in the MAPK signal transduction pathway lines, by MTT assay. Additionally it was explored if inhibition of classical apoptosis could abrogate the effect of AEZS-131.

Results

AEZS-131 selectively inhibited ERK with an IC50<4nM. Phosphorylation of Rsk-1 the cellular substrate of ERK was inhibited with an IC 50 of 158 nM. AEZS-131 induced cell cycle arrest in G1 dose-dependently and cleavage of PARP. EC 50 was 0,739 µM for MDA-MB-231 (Ras-mutated), 0,137 µM for MDA-MB-435s (B-RAF mutated), 17,5 µM for MDA-MB-468 (PTEN loss), 25 µM for HCC 1937. HCC 1937 were not inhibited by the compound. Of note, inhibition of classical apoptosis did not alter the cytotoxic effect of the compound in MDA-MB-468 and HCC-1806 cells.

Conclusions

AZS-131 was shown to selectively inhibit ERK at low nM concentrations and to induce G1-arrest. Accordingly, the cytotoxic effect most pronounced in TNBC cell lines with mutations in the MAPK pathway. If classical apoptosis is inhibited, cytotoxic effects remain unchanged, suggesting that AEZS-131 can also induce non-
classical forms of programmed cell death. AEZS-131 should be further explored in TNBCs with overexpression of MAPK or mutations in the MAPK-pathway.

*Äterna Zentaris GmbH, Frankfurt/M, Germany.

(1): MAPK overexpression is associated with antracycline resistance and increased risk for recurrence in patients with triple-negative breast cancer.

P3-18-07
Multiplex RTK Inhibitor Screening Utilizing a Plate-Based Immunoassay with Near-Infrared Detection.
Finkel DJ, James AE, Felix RA, Wegner GJ. R&D Systems Inc., Minneapolis, MN; Toceis Bioscience, Bristol, United Kingdom
Receptor-tyrosine kinases (RTKs) are transmembrane proteins that have been implicated in various cancers and are considered therapeutic targets. The phosphorylation of RTKs on tyrosine residues leads to their activation. We have previously used the Proteome Profiler™ 96 Human Phospho-RTK Antibody Array, a plate-based multiplex immunoassay, to determine the phospho-tyrosine profile of RTKs in MDA-MB-453 breast cancer cells. Most notably, the ErbB family of RTKs were shown to be hyperactivated in this cell line. In this study, we use the same multiplex assay to screen a small molecule kinase inhibitor library (TOCRIS, Catalog # 3514) to identify inhibitors with selectivity towards the ErbB receptors. MDA-MB-453 cells were treated with the kinase inhibitor library prior to treatment with ligands to stimulate ErbB receptor tyrosine phosphorylation and subsequently lysed. The lysates were analyzed with the Proteome Profiler 96 Human Phospho-RTK Antibody Array using near-infrared fluorescent detection. Ligand-dependent tyrosine phosphorylation of all four ErbB receptors was monitored simultaneously and the effects of different kinase inhibitors were determined. While several known ErbB inhibitors blocked ErbB phosphorylation, our screen also identified several inhibitors reported to be selective for other kinases that effectively inhibited ErbB activation. The activation of ErbB2 was selectively inhibited by NH125, GF 109203X, SB 202190, and ligands that effectively inhibited ErbB activation. The activation of ErbB2 was selectively inhibited by NH125, GF 109203X, SB 202190, and ZM 306416 hydrochloride. The results obtained with this multiplex assay were confirmed by singleplex ELISA for ErbB receptors. Hence, the data collected with our multiplex assay provides a rapid method for the analysis of inhibitor effects on a defined signaling pathway. This may facilitate a faster identification of selective kinase inhibitors that have therapeutic potential for treating ErbB-overexpressing cancers.

P4-01-01
Preclinical and Clinical Studies of Estrogen Deprivation Support the PDGF/Ab1 Pathway as a Novel Therapeutic Target for Overcoming Resistance.
Wegel MT, Banerjee S, A'Hern R, Arnedos M, Ghazoui Z, Dumbier AK, Dowsett M, Martin L-A. Institute of Cancer Research, London, United Kingdom; Royal Marsden Hospital, London, United Kingdom
Aim: To determine the relevance of PDGF/Ab1 signaling pathway as a therapeutic target in endocrine resistance in vitro and in vivo.
Rationale: Targeting estrogen stimulation reduces mortality from ER-positive (ER+) breast cancer (BC) but resistance remains a major clinical problem. To identify the molecular mechanisms associated with resistance to estrogen-deprivation, we previously assessed the temporal changes in gene expression during adaptation to long-term culture of MCF7 human breast cancer cells in the absence of estradiol (E2) (LTED), modeling resistance to an aromatase inhibitor (AI). Platelet-derived growth factor (PDGF)/Ab1 signaling was the top adaptive pathway at the point of resistance (p=1.15 E-07), but there is limited evidence for it playing a role clinically.
Methods: Gene expression data from postmenopausal women with ER+ BC at pre-treatment and at 2-week on-treatment with neoadjuvant anastrozole were interrogated. Immunohistochemical staining using antibodies against PDGFRα, β and Ab1 and Ki67 was assessed in paired clinical specimen of 45 patients who had received an AI and presented progressive disease. Proliferation assays, immunoblots and ChIP assays were carried out using either the PDGFR/Ab1 inhibitor nilotinib or siRNA knockdowns in LTED and wild-type MCF7 cells.
Results: In vitro: PDGFRβ and Ab1 expression and phosphorylation were elevated in LTED cells. Cell proliferation was decreased in LTED cells by siRNA knock-down of either PDGFRβ (50% p=0.01), Ab1 (40% p=0.01) or the combination (70% p=0.01). Inhibition of Ab1 activity using nilotinib decreased ER protein levels and suppressed ER-mediated transcription by reducing recruitment of AIB1 and CBP to the promoter of E-responsive genes TFF1 and GREB1. Clinical: Data from 81 patients treated with an AI in the neoadjuvant setting, showed increases in PDGFRα gene expression after two weeks (1.25 fold, p=0.003). Low PDGFRα at baseline was associated with a better response. Of note, paired pre-AI-treatment and relapse clinical specimens from a cohort of patients treated in the primary or advanced setting revealed increases in tumor protein expression of PDGFRα (1.39 fold, p=0.0065), PDGFRβ (4.32 fold, p=0.006) and Ab1 (1.8 fold, p=0.001) at the point of relapse. Tumor (T) and stromal (S) expression of PDGFRα as well as PDGFRβ was significantly correlated in pre-treatment and relapse samples (Table 1).

<table>

<tr>
<td>T-PDGFRα vs T-PDGFRβ</td>
</tr>
</tbody>
</table>

High post-treatment tumor and stromal PDGFRβ levels were associated with a short time to treatment failure (TTF) (T: Rs -0.284, p=0.066; S: Rs -0.307, p=0.046). Expression of PDGFRα in relapsing tumor specimens was correlated with Ab1 expression (Rs 0.342, p=0.027) and Ki67 levels (Rs 0.39, p=0.01). Furthermore, changes in Ab1 correlated significantly with changes in ER expression (Rs 0.307, p=0.048).
Discussion: These in vitro and clinical data support a biological interaction between PDGFR/Ab1 and ER-signaling and suggest that the PDGFR signaling pathway warrants clinical evaluation as a therapeutic target in endocrine resistant breast cancer.

Morrison GD, Fu X, Ithimakin S, Rimawi MF, Wicha MS, Osborne CK, Schiﬀ R. Baylor College of Medicine, Houston, TX; University of Michigan, Ann Arbor, MI
Background: Endocrine therapy is the most effective therapies for estrogen receptor positive (ER+) breast cancer, but resistance is still a major clinical problem. Tumor initiating cells (TICs) in drug resistant tumors are believed to be part of the contributing factors for tumor relapse. Here we focused on the TICs and how they are related to HER2 expression and its downstream factors in acquired endocrine resistance models.
Materials and Methods: We have established a panel of endocrine resistant cell models through long-term treatment with tamoxifen (Tam, 10^-7 M, >6 months). Resistance to tamoxifen treatment in cells (TamR) was conﬁrmed by growth curve assays (Celigo, Cyntellect...
Inc., San Diego, CA). In vitro mammmosphere assays were applied to assess the mammosphere forming ability of parental and resistant cells. Aldefluor assays (StemCell Technology) were performed to measure the aldehyde dehydrogenase (ALDH-1) expressing cell population as a marker of TICs. Flow analysis was performed to evaluate HER2 expression in the ALDH subpopulations of both parental and TamR cells. Immunofluorescence staining was further used to detect the expression of ER, HER2, phosphorylated STAT3, and β-catenin in sorted ALDH+/− subpopulations.

Results: We found that endocrine resistant cells have a higher mammosphere forming ability than their parental counterparts. In addition, we showed that the ALDH+ subpopulation was significantly upregulated in all TamR derivative lines.

Further analysis of the ALDH populations indicated that HER2, as well as downstream survival factors such as pSTAT3s727 and β-Catenin, are upregulated in the ALDH+ populations as compared to the ALDH-population, especially in TamR derivatives.

Discussion: Our data suggest that deregulated HER or other growth factor receptor signaling can potentially lead to the enrichment of TICs as a potential contributor to endocrine resistance. We will further investigate the role and molecular signaling of TICs in endocrine resistance of breast cancer, as well as whether and to what extent more potent anti-HER inhibitors can improve endocrine sensitivity and circumvent resistance.

Establishment and Characterization of an Endocrine Resistance Model In Vitro and In Vivo by Inducible PTEN Knockdown.
Fu X, Shea M, Biswal NC, Mitchell T, Giuliano M, Healy NA, Meerbrey KL, Joshi A, Westbrook T, Hilsenbeck SG, Osborne CK, Schiff R. Baylor College of Medicine, Houston, TX; National University of Ireland, Galway, Ireland

Background: Growth factor receptor and estrogen receptor (ER) are two major driving pathways for initiating and sustaining breast cancer (BC) development and progression. We have previously shown that an inverse correlation exists between the PI3K pathway and ER expression/activity in luminal type BCs. High PI3K activation signaling correlates to the luminal B subtype of BC with low ER expression/activity. However, the involvement of the PI3K pathway tumor suppressor PTEN in resistance to endocrine therapy is less clear. Here we attempt to develop an experimental system to better understand the role of PTEN in this resistance.

Materials and Methods: Two luminal BC cell lines, MCF7L and ZR75-B, were stably infected with a lentivirus pINDUCER (Meerbrey et al., PNAS, 2011), containing Tet-on responsive shPTEN, turboRFP (tRFP) as an inducible tag, and enhanced GFP (eGFP) as a constitutive expressed tag for positive cells selection. Immunoblotting of PTEN, phosphorylated (p) Akt, pMAPK, pc-Jun, ER, and ER’s downstream gene products (PR, IGF-1R) was performed on cells after 6 days of growth factor receptor and estrogen receptor (ER) signaling correlates to the luminal B subtype of BC with low ER expression/activity. However, the involvement of the PI3K pathway tumor suppressor PTEN in resistance to endocrine therapy is less clear. Here we attempt to develop an experimental system to better understand the role of PTEN in this resistance.

P4-01-04
Effects of CYP2D6 Phenotype and Drug Adherence on Tamoxifen Metabolite Levels.
Sousa B,1, Namin S,2 Cole DE,3 Wong BY,1 Hill K,2 Pritchard KL,1 Trudeau M,1 Vernia S,4 Dent RA,5 Petrella T,1 Gandhi S,4 Ueng S,2 Vandenbergh U,3 Romaschin A,1 Warner E,1 Sunnybrook Health Sciences Odette Cancer Centre, Toronto, ON, Canada; Li Ka Shing Research Institute, Biochemistry, Toronto, ON, Canada

Background: Although the activity of cytochrome P450 2D6 (CYP2D6), the enzyme responsible for conversion of tamoxifen (TAM) to its most important active metabolite endoxifen, varies significantly with genotype. Routine genotype testing in patients on TAM has recently been discouraged. Conflicting results in publications regarding the prognostic utility of this test remain unexplained. Confounding factors could be lack of predicted correlation between CYP2D6 genotype and TAM active metabolites, or variability of patient compliance.

Methods: Consecutive breast cancer patients on TAM were asked to enroll in a study to examine the relationship between CYP 2D6 phenotype, patient-reported treatment adherence, and TAM metabolites levels. Patients were genotyped for CYP2D6 polymorphisms using long-range PCR allele-specific amplification and single-nucleotide primer extension assay. From the genotypes, four phenotype groups were defined: Ultra rapid Metabolizer (UM), Extensive Metabolizer (EM), Intermediate Metabolizer (IM) and Poor Metabolizer (PM). Plasma was collected after at least 6 weeks of TAM (20 mg daily). The parent drug TAM, as well as 4-hydroxy N-desmethyl tamoxifen (endoxifen), 4 hydroxy tamoxifen (4OHtam) and N-desmethyl-tamoxifen (NDtam), were determined by Liquid Chromatography tandem mass-spectrometry (LC-MS/MS). Patients also completed a questionnaire about ethnicity, side effects, concurrent medications and tamoxifen adherence. Correlation between plus and minus Dox groups under E2, Tam, or Ful treatment is ongoing.

Discussion: These data further support the existence of crosstalk between PI3K and ER pathways in luminal type BC. Decreasing PTEN levels by shRNA renders the luminal type BC cells de novo resistant to endocrine therapy both in vitro and in vivo. The pINDUCER PTEN knockdown system combined with live animal imaging offers successful real-time, noninvasive tracking of endocrine sensitivity by controllably manipulating the level of target gene. Combination therapies to overcome endocrine resistance under PTEN knockdown conditions are currently underway.
between metabolite/TAM ratio and phenotype was tested by Spearman correlation test. Relationship between metabolite levels and adherence was tested by Wilcoxon rank sum test. Chi square test was used to compare proportions.

**Results:** Of the 100 patients enrolled there were 62 Caucasians, 25 Asians, 4 Africans and 6 Unknown. We found a strong correlation between ratio of endoxifen/TAM and phenotype (p <0.001) (Table 1) Over a 2 week period 68 never missed a TAM dose, 25 missed 1-2 times, 2 missed 3-5 times and 2 >5times (2 missing data). In EM group we found significantly lower levels of TAM (p <0.001), NDtam (p=.008), 4OHtam (p=.003) in less adherent patients. A trend to decreased levels was also shown for endoxifen (p=.081). No associations were found between adherence or phenotype activity and side effects.

**Conclusions:** Our data suggests the predicted association between endoxifen levels and genotype. However, non-adherence may have a significant confounding effect. Prospective studies to evaluate the prognostic impact of CYP2D6 variants for patients on adjuvant tamoxifen should be done but results could be confounded by variable drug adherence if this is not measured concurrently.

**P4-01-05**

**Background:** Resistance to antiestrogens is a major problem in metastatic breast cancer. Preclinical data suggest that growth factor signaling and angiogenesis may promote endocrine resistance and blocking such pathways may delay resistance.

**Methods:** We conducted a phase II clinical trial of adding sorafenib, a VEGFR and Ras/Raf/MAPK inhibitor, to antiestrogen therapy in patients with metastatic ER-positive breast cancer. Patients were required to have progressive disease on an anstiestrogen or have maximum response with residual measurable disease. A core biopsy of accessible breast disease was offered at entry and after 28 days of sorafenib. Microarray experiments were performed on frozen tissue obtained from 4 paired biopsies using Affymetrix Gene Chip HG-U133 Plus 2. Data was normalized based on the GCRMA method and Expression values of each gene were analyzed based on the significant analysis of microarray (SAM) method for paired data. Gene set analysis on KEGG pathways was performed using the gene set enrichment analysis (GSEA) method, where genes were ranked based on the absolute values of their SAM test statistics. Serum was collected on day 1 and day 28 for biomarker comparison using ELISA. Primary study endpoint was response rate by RECIST criteria after 3 months of sorafenib and secondary endpoints were safety, time to progression (TTP), and biomarker assessment.

**Results:** Planned sample size was 43 but the study closed after 11 patients because of slow accrual. Median age was 45 years (Range 39-72). 7 patients were on tamoxifen, 3 on an aromatase inhibitor, and 1 on fulvestrant. Of the 11 patients enrolled, 8 had progressive disease (PD) on entry and 3 had confirmed stable disease (SD) on antioestrogen alone. One patient with SD at entry discontinued sorafenib after 2 weeks because of a grade 3 rash. Of the 10 patients evaluable for response, 7 had SD (70%) and 3 had PD. Median TTP after adding sorafenib was 182 days (6 months) and in the 8 patients who entered the study with PD, 5 converted to SD (62%) with a median TTP of 192 days (6.4 months). One patient remains on treatment after 16 months of enrollment. Most common adverse events were rash in 9 patients, weight loss in 8 and hypertension in 6. Hypophosphatemia was seen in 11 patients, hypokalemia in 9, and elevated ALT/AST in 4. The majority of toxicities were grade 1. There were 6 grade 3 toxicities; rash, anorexia, hypokalemia, colitis, and 2 hypophosphatemia. No grade 4 toxicities occurred. Microarray analysis identified 29 enriched pathways with a false discovery rate of less than 25%. There was a significant reduction in mean serum Transforming growth factor beta (TGF-β) and platelet derived growth factor receptor alpha (PDGFRα) on day 28 (P values =< 0.0001 and 0.017, respectively). Tissue and serum biomarker correlates will be presented in detail at the meeting.

**Conclusions:** Sorafenib can overcome resistance to antiestrogens, particularly tamoxifen, and may help avoid the routine early use of chemotherapy for endocrine resistant disease. Further study of strategies to overcome endocrine resistance is warranted to help preserve patient quality of life and to investigate mechanisms of resistance.

**P4-01-06**

Global Characterization of the SRC-1 Transcriptome Identifies Disintegrin C as an ER-Independent Mediator of Endocrine Resistant Breast Cancer. 
Bolger JC, McCartan DP, McIlroy M, Byrne C, Fagan A, Xu J, O’Gaora P, Hill ADK, Young LS. Royal College of Surgeons in Ireland, Dublin, Ireland; University College Dublin, Dublin, Ireland; Dan L. Duncan Cancer Center, Baylor College of Medicine, Houston, TX

**Background:** The development of breast cancer resistance to endocrine therapy results from an increase in cellular plasticity leading to the development of a steroid independent tumour. The p160 steroid coactivator protein SRC-1 drives this tumour adaptability. SRC-1 is central to the development of the endocrine resistant phenotype and is an independent predictor of disease free survival in tamoxifen-treated patients. Here, using discovery studies we identify Disintegrin C (DC), a multidomain transmembrane glycoprotein as a direct, ER-independent target of SRC-1.

**Methods:** SRC-1-ChIP sequencing was performed in endocrine resistant (LY2) cells. Microarray experiments were performed on LY2 cells transfected with scrambled siRNA or SRC-1 siRNA, +/- 4-OHT to assess SRC-1-dependent gene expression. Combining the ChIP-seq and expression array datasets, a total of 2,065 genes were significantly downregulated (p<0.05) following SRC-1 knockdown. DC transcript levels were measured following knockdown and over-expression of SRC-1 and ERα. Mouse xenograft and SRC-1 knockout models were used to examine DC expression in vivo. A TMA comprising 560 patients was stained for DC. Functional validation studies were performed using 3D culture and migration assays, with transient knockdown of DC and treatment with JC1, an inhibitory peptide against DC.

**Results:** Treatment with 4-OHT significantly increased the number of ChIP-enriched intervals identified. The majority of peaks in the 4-OHT treated sample were close to the transcriptional start site, in the promoter, first exon or upstream of the promoter. As a defined
ER coactivator, an overlap between ER binding sites and those identified for SRC-1 is expected. 43% of high confidence SRC-1 peaks in 4-OHT-treated lymphocytes contained an ERE binding motif. This raises the possibility that, in endocrine resistance, SRC-1 can drive transcription independent of ER. Treatment with 4-OHT resulted in substantial recruitment of SRC-1 to the DC promoter. In primary tumours there was a significant association between transcript levels of SRC-1 and DC. Cells derived from mammary tumours of the SRC-1+/−/PyMT mouse lacked DC, but there was high expression in the wild type PyMT mouse. Knockdown of ERα in LY2 cells did not alter DC expression. Knockdown of DC reduced cell migration and restored cell differentiation in resistant cells. In xenograft studies treatment with 4-OHT increased tumour volume in the resistant tumours and induced DC expression. Treatment with recombiant JCl1 reduced cellular migration in endocrine resistant cells. Kaplan-Meier estimates of disease free survival show that DC is a strong predictor of disease free survival in breast cancer (p<0.0001). SRC-1 and DC are significant independent predictors of disease recurrence (odds ratios 2.10 and 2.44).

Conclusion: Our discovery studies have uncovered a steroid independent SRC-1 mediated network in endocrine resistant breast cancer. We identified a new SRC-1 target, DC. DC represents a rational new therapeutic target with a robust companion biomarker for treatment of endocrine resistant tumours.

Results: Expression of Hhg signaling molecules and the targets are significantly activated in OHTR cells resistant to 0.5 and 1μM tamoxifen. Serial passage of the resistant cells in mice resulted in aggressive transformation of tumors that micro-metastasized to lung and liver. Concurrent increase in Hhg marker expression, TICs and acquisition of epithelial mesenchymal transition were observed in the cells derived from these tumors. Depletion of GLI1 in OHTR cells resulted in reduced proliferation, colony formation and mamsphere formation and increased apoptosis in presence of tamoxifen. Treatment of OHTR cells with GDC-0449 and tamoxifen inhibited cell proliferation in vitro and supressed tumor growth and distant metastasis of tamoxifen resistant xenografts in mice. Primary human breast tumors expressing higher level of GLI1 demonstrated a trend towards increased risk of recurrence (p=0.08) after tamoxifen therapy.

Conclusions: Our work has demonstrated for the first time that activated Hhg signaling is an alternate survival mechanism for tamoxifen resistant breast cancer. Furthermore, targeting these tumors with a combination of tamoxifen and anti-Hhg therapy inhibited tumor growth and development of distant metastases demonstrating efficacy of this approach. Clinical trials using this combination in patients with advanced ER+ breast cancer are warranted and are under development.

P4-01-08
The Role of Ser991 PELP1 Phosphorylation in Therapy Resistance and Metastasis of Breast Cancer.
Sareddy GR, Nair BC, Krishnan SR, Gonugunta VK, Vadlamudi RK. UTHSCSA, San Antonio, TX

BACKGROUND: Growth factor induced activation of MAPK pathway is suggested to play a critical role both in invasive and hormone therapy resistant breast cancer via ligand independent activation of ERα. Proline Glutamic acid Leucine Rich Protein (PELP1) is a well established ER-coregulator that plays a critical role in ER’s nuclear and extra-nuclear functions. PELP1 functions as a proto-oncogene and deregulation of PELP1 expression is linked to increased proliferation, metastasis and therapy resistance. The objective of this study is to examine, whether growth factor signaling modulates PELP1 mediated ER coactivation functions via MAPK pathway.

METHODS: Bioinformatics and phosphopeptide specific antibodies were employed in this study. In vitro kinase assays and MAPK inhibitors were used to confirm MAPK phosphorylation of PELP1. Site directed mutants and ERE reporter gene assays were used to demonstrate the significance of MAPK site in PELP1. Growth factor and estrogen regulation of PELP1 phosphorylation at Ser991 was validated in therapy sensitive (MCF7, ZR75) and resistant (MCF-7 HER2, MCF7-Tam and MCF-7Ca-LTLT cells using PELP1 specific phosphoantibody. Breast cancer model cells stably expressing PELP1 mutant or PELP1 peptides encompassing MAPK phosphorylation site were used to test the significance of this MAPK site in PELP1 using proliferation, migration, and invasion assays. IHC analysis using PELP1 phospho antibodies was performed using murine xenograft tumors and human breast tumor arrays (TMA).

RESULTS: Growth factors (EGF, Heregulin) induced Ser991 phosphorylation of PELP1 in murine mammary epithelial cells and also in human breast cancer cell lines. Growth factor mediated Ser991 PELP1 phosphorylation was abrogated by ERK1/2 MAPK pathway inhibitors including PD98059 and U0126. In ERE-reporter luciferase assays using ZR75 cells, PELP1 (WT) but not the ser991Aa mutant of PELP1 corroborated growth factor-ER crosstalk. Therapy resistant model cells (MCF-7-Tam, MCF-7-LTLT-ca and MCF-7...
HER2) exhibited enhanced Ser991 PELP1 phosphorylation compared to parental MCF7. TAT-Peptide encompassing Ser991 inhibited growth factor-mediated phosphorylation of PELP1 and revealed a potent ability to inhibit the growth of therapy resistant cells. Xenograft tumors of hormone therapy model cell lines showed increased Ser991 PELP1 phosphorylation and enhanced nuclear localization compared to hormonal sensitive xenograft tumors. IHC analysis of human breast invasive TMA revealed enhanced PELP1 ser991 phosphorylation in advanced metastatic tumors with prominent nuclear/nucleolar localization compared to normal and benign tumors.

CONCLUSIONS: In this study, we identified that growth factor-MAPK pathway modulate ER coregulator PELP1 functions via phosphorylation and demonstrated that Ser991 phosphorylation of PELP1 has the potential to govern the growth Factor-ER cross talk leading to therapy resistance and metastatic phenotype of breast cancer. Peptides encompassing Ser991 PELP1 site and Phospho-antibodies targeting Ser991 represent a novel therapeutic target and diagnostic markers in breast cancer. **P4-01-09**

**Reduced CYBA Expression Leads to the Development of Fulvestrant Resistance in a Breast Cancer Cell Line.**

Skerry BJO, Ramsahoye BH. The University of Edinburgh, Edinburgh, United Kingdom

**Background:** Acquired resistance to endocrine therapy is an important problem in the management of advanced breast cancer. In this study we used a cell line model to investigate the evolution of fulvestrant resistance. We examined gene expression and promoter methylation in estrogen-dependent MCF7 cells and compared two derived cell lines, estrogen-hypersensitive LCC1 and fulvestrant-resistant LCC9, using array technology. Thus we determined the epigenetic changes associated with the evolution of estrogen independence and fulvestrant resistance, which revealed a role for CYBA/p22phox in the acquisition of resistance.

**Material and Methods:** Estrogen-dependent gene expression was measured in MCF7, LCC1 and LCC9 cells using Illumina HT-12 microarrays. In parallel, differential methylation between MCF7, LCC1 and LCC9 cells was examined using Illumina Infinium methylation 27 arrays.

**Results:** Despite marked physiological differences between MCF7, LCC1 and LCC9 cells there were few genes which were both differentially methylated and differentially expressed. However, CYBA was underexpressed in LCC1 (p<10^-5) and LCC9 (p<10^-4) and had a methylated promoter in LCC1 (p<10^-5) and LCC9 (p<10^-5), with reduced expression correlated to increased estrogen independence. This gene codes for the protein p22phox, a critical component of membrane NADPH oxidase. We verified expression by qRT-PCR and Western blot, and methylation by CpG island bisulphite sequencing, demonstrating significant and biologically relevant changes. Fulvestrant-resistant LCC9 cells exhibited a 20-fold reduction in CYBA expression compared to MCF7, corresponding to undetectable levels of p22phox. Due to its role in the generation of reactive oxygen species (ROS), we investigated the cellular response to oxidant damage, finding that LCC9 cells showed reduced sensitivity to oxidant damage when compared to MCF7 (p<10^-5), in keeping with impaired NADPH oxidase function. We then treated MCF7 cells with a ROS scavenger, N-acetyl cysteine, which reduced their sensitivity to fulvestrant (p<10^-13). Using siRNA, we knocked down CYBA expression, which conferred slight fulvestrant resistance on MCF7 cells, mitigating fulvestrant-induced growth arrest (p<10^-7).

**Discussion:** The striking differences in methylation in the CYBA promoter and gene expression between these cell lines lead us to conclude that the repression of this gene represents an important step in the development of fulvestrant resistance. As these cells develop estrogen independence and fulvestrant resistance, CYBA/p22phox levels drop, making the cells more resistant to oxidant damage caused by estrogen deprivation and, ultimatey, providing a selective advantage against fulvestrant-induced growth arrest and cell death. CYBA/p22phox may represent a novel druggable target in breast cancer, either in the prevention of the acquisition of fulvestrant resistance, or the further treatment of resistant tumours.

**P4-01-10**

**The Role of the Steroid Receptor Coactivator SRC1 and Its Functional Partner HOXC11 in the Development of Endocrine Resistant Breast Cancer.**

Walsh CA, McCartan D, Hill ADK, Young LS. Royal College of Surgeons in Ireland, Dublin, Ireland

**Background:** The steroid receptor coactivator; SRC1, has been well described in the development of endocrine resistant breast cancer. SRC1 associates with clinically aggressive tumours and promotion of distant metastasis. It directly interacts with the developmental transcription factor, HOXC11 and together they are found to strongly predict poor disease-free survival in breast cancer patients (hazard ratios: 5.79; P < 0.0001). In this study, we investigate the mechanism of SRC1 and HOXC11 action in tumour adaptability and subsequent resistance to endocrine therapy.

**Materials and Methods:** Cells which are resistant to tamoxifen (LY2s) have enhanced SRC1 and HOXC11 mRNA and protein expression in comparison to their endocrine sensitive parent cells (MCF-7s). ChIP-sequencing data for SRC1- and HOXC11- DNA interactions in conjunction with DNA microarray and RNA-sequencing data identified potential signalling targets at play in the LY2 model of endocrine resistance. Real-time analysis and flow cytometry confirmed these interactions at a transcriptional and protein level. These observations were further confirmed in primary breast cancer cultures using flow cytometry.

**Results:** SRC1 and HOXC11 interactions are driven in tamoxifen treated LY2 resistant cells. Combined SRC1 ChIP-sequencing and expression array data analysed in conjunction with HOXC11 ChIP-sequencing and RNA-sequencing data reveal that the SRC1/ HOXC11 transcriptional process can orchestrate the loss of luminal cell markers such as ERα, CD24 and PTCH1 whilst concomitantly upregulating mediators of tumourigenicity such as CD44 and MSI2. Primary breast cancer cultures confirm the loss of CD24 in tamoxifen resistant patients. In these patients, loss of CD24 was accompanied by loss of steroid receptor expression (ERα and PR) and by a gain of the basal marker CD44.

**Discussion:** Here, we describe a new signalling pathway where SRC1 and HOXC11 regulate two distinct but complementary mechanisms to drive tumour adaptability. Silencing of luminal cell markers and a concomitant increase in a basal cell phenotype has the potential to alter the survival mechanism of breast cancer cells to evade targeted therapy.
P4-01-11
Autocrine Human Growth Hormone (hGH) Reduces the Sensitivity of Breast Cancer Cells to Treatment with Tamoxifen and Fulvestrant.

Perry JK, Chen H, Bougen NM, Liu D-X, Lobie PE. University of Auckland, Auckland, New Zealand; National University of Singapore, Singapore

Despite recent advances in breast cancer treatment regimes, intrinsic or development of resistance to conventional breast cancer therapies is still a significant clinical challenge. Expression of growth factors by tumour cells has been proposed as one mechanism for developing resistance to radiotherapy and chemotherapeutic agents. The growth hormone/insulin-like growth factor-1 axis is emerging as an important mediator of tumour development in human breast cancer. Recent studies have demonstrated that humans with growth hormone receptor deficiency are protected from developing cancer. Studies investigating human growth hormone (hGH) expression in human breast cancer have demonstrated that hGH expression is associated with specific histopathological features and survival outcomes for patients. Increased hGH expression is significantly associated with lymph node metastasis, tumour stage, proliferative index, worse relapse free survival and reduced overall survival in mammary carcinoma. In recent studies we have demonstrated that autocrine hGH promotes cell proliferation, cell survival and oncogenicity of human mammary carcinoma cells, enhancing anchorage independent cell growth, and supporting tumour formation in immunodeficient mice. Autocrine hGH also promotes mammary carcinoma cell migration/invasion and epithelial to mesenchymal transition and tumour vascularisation in xenograft studies. In this study we investigated whether autocrine hGH promotes resistance to anti-estrogen therapeutic drugs, sensitivity to tamoxifen and fulvestrant using the human breast cancer cell lines MCF-7, T47D and BT474. Stable transfection with an expression vector containing the hGH gene enhanced MCF-7, T47D and BT474 cell viability, total cell number and anchorage independent growth following treatment with tamoxifen or fulvestrant when compared to control transfected cells. Conversely, treatment of BT474 cells with an hGH receptor antagonist (B2036), increased BT474 cell sensitivity to treatment with tamoxifen or fulvestrant. Using an estrogen response element (ERE) luciferase assay, we observed that autocrine hGH enhanced basal estrogen receptor (ER)-mediated transcriptional activity. Our results demonstrate that forced expression of hGH in mammary carcinoma cells enhances ER-mediated signal transduction and promotes resistance to tamoxifen and fulvestrant, while functional antagonism of hGH increased cell sensitivity. Consequently, antagonism of the hGH receptor may help maintain sensitivity to anti-estrogen therapy and improve the prognosis of patients with hormone sensitive breast cancer.

P4-01-12
The Unfolded Protein Response (UPR) and Pro-Survival Autophagy Contributes to Antiestrogen Resistance in Breast Cancer.

Clarke R, Shajahan AN, Cook KL, Hickman FE, Facey CO. Georgetown University, Lombardi Comprehensive Cancer Center, Washington, DC

In 2011, most of the 192,000 newly diagnosed cases of invasive breast cancer will be estrogen receptor alpha positive (ER+). Endocrine therapy, administered as an antiestrogen, e.g., Tamoxifen (TAM) or Faslodex (FAS; Fulvestrant; ICI 182,780) or an aromatase inhibitor (AI), e.g., Letrozole or Exemestane is the least toxic and most effective means to manage the hormone-dependent breast cancer in such patients. However, resistance to endocrine therapy remains a significant clinical problem. Previously, we have shown that antiestrogen resistant breast cancer cells over-express X-Box Binding Protein 1 (XBP1), a transcription factor that belongs to the basic region/leucine zipper (bZIP) family. XBP1(U) and XBP1(S) variants result from an unconventional splicing of the XBP1 mRNA by IRE1alpha. In the unfolded protein response (UPR), endoplasmic reticulum proteins (IRE1alpha, ATF6 and PERK) sense cellular stress to regulate the accumulation of unfolded proteins. Initially a compensatory mechanism allowing cells to recover normal endoplasmic reticulum function, prolonged UPR may induce cell death; this is often dependent upon which arm of the UPR predominates. XBP1 is an obligate component in both the IRE1alpha and ATF6 arms of the UPR. In this study, we show that in MCF7/LCC9 [FAS resistant; TAM cross-resistant] cells, there is an increase in UPR signaling as detected by increased expression of BiP/GRP78. Transient expression of XBP1(S) in MCF7/LCC1 [antiestrogen sensitive] cells show decreased sensitivity to FAS that correlated with increased levels of both basal and FAS-induced autophagy as measured by cleaved LC3BII protein fragment, GFP-LC3 activity, and reduced expression of p62/SQSTM1. Furthermore, we show that MCF7/LCC9 cells survive by activating pro-survival autophagy through UPR that is regulated by the transcription factor c-MYC. An inhibitor of c-MYC, 10058-F4, synergized with FAS to inhibit proliferation in MCF7/LCC9 cells by preventing pro-survival autophagy and increasing apoptosis. Thus, our study shows that antiestrogen resistant breast cancer cells evade cell death by activating XBP1-mediated UPR that results in c-MYC-mediated prosurvival autophagy.

P4-01-13
Biology of Aggressiveness and Tamoxifen Resistance in Hormone Receptor-Positive Very Young Age Breast Cancer.

Han W, Ro J, Jung S. Seoul National University Hospital, Seoul, Korea; National Cancer Center, Goyang, Kyungi, Korea

It has been known that young breast cancer patients have worse outcomes compared with older premenopausal or postmenopausal patients. Survival difference between young and older breast cancer patients is evident only in hormone receptor positive breast cancer regardless of tamoxifen treatment according to our previous report. However, the biology of aggressiveness and endocrine resistance of breast cancer in very young women is largely unknown. The purpose of this study is to find molecular characteristics of hormone receptor positive breast cancers of very young age women (<35) compared with those of older premenopausal women.

We extracted mRNA from fresh frozen hormone receptor positive primary breast cancer tissues of 24 young age breast cancer patients (<35 years) and 31 older premenopausal women (40 to 49 years) by standard method. All tumor specimens analyzed contained more than 50% tumor cells. Hormone receptor status was determined by immunohistochemistry (IHC). Gene expression microarray experiment was done in the 55 samples using Illumina HumanRef-8 v3 Expression BeadChip (Illumina, Inc., San Diego, CA). Functional and pathway analysis of differentially expressed genes were done using DAVID (http://david.abcc.unc.edu/home.jsp) and Ingenuity pathway analysis (IPA, http://www.ingenuity.com). Ki-67 assay was done using IHC in 4,957 ER+ breast cancer patients of Seoul National University cohort and 1,863 ER+ patients from National Cancer Center, Korea.
355 genes were upregulated (>1.5 fold) and 209 genes were downregulated in breast cancer tissues of young age patients (<35) compared with those of older patients. In pathway analysis of the highly expressed genes in young patients, cell cycle function and pathway was significantly activated. The genes of central role in this pathway were MYC and CCND1. In IHC assay for 4,957 ER+ Seoul National University dataset, the proportion of high Ki-67 expression (>=10%) was positively correlated with decreasing age: 26.4%, 24.0%, 21.3%, 14.8%, 12.0% of women aged <30, 30-34, 35-39, 40-49, 50-59, respectively (p<0.001). The same correlation pattern between younger age and high Ki-67 expression was also seen in another 1,863 patient cohort.

In conclusion, we showed that genes involved in cell cycle pathway were upregulated in very young age (<35) ER+ breast cancer using microarray study. It was validated in large data set using Ki-67 IHC assay. High proliferation and fast cell cycle could be a mechanism of worse outcome and tamoxifen resistance of ER+ very young age breast cancer patients.

P4-01-14
Fulvestrant Regulates Epidermal Growth Factor (EGF) Ligands and Induces EGF Receptor Activation in MCF-7 Breast Cancer Cells.
Zhang X, Diaz MR, Yee D. University of Minnesota, Minneapolis, MN
Selective Estrogen Receptor Modulators (SERMs) 4 Hydroxy Tamoxifen (4-HT) and fulvestrant (fulv) inhibit estrogen receptor α (ER) positive breast cancer growth. We have observed that treatment (24 to 48 hours) of fulv in MCF-7 cells induced a 190kDa tyrosine phosphorylated band, which was blocked by EGFR and HER-2 tyrosine kinase inhibitors erlotinib and lapatinib. Immunoprecipitation showed EGFR, HER-2, and HER-3 were all phosphorylated after fulv treatment. 4-HT and estradiol did not cause this phosphorylation. No changes in receptor level after fulv treatment were noted. Downstream MAPK signaling was also blocked by erlotinib and lapatinib. Fulv induced activation of EGFR was ER dependent, since fulv treatment in C4-12, an ER negative cell line derived from MCF-7 cells, did not induce EGFR activation. Co-treatment with estradiol and fulv prevented EGFR activation. To explore the possibility that fulv enhanced ligand expression, we collected conditioned media (CM) from MCF-7 cells after 48 hours of treatment. pEGFR was lost when CM was removed, but recurred within 30 minutes. Cycloheximide abolished the ability of fulv to activate EGFR suggesting autocrine production of EGF ligands was induced by fulv. To detect specific EGFR ligands, we used qPCR to measure various EGFR ligand mRNA levels in MCF-7 and C4-12 cell at 1, 4, 24 and 48 hours after fulv treatment. TGF-α and HB-EGF mRNAs were upregulated over 48 hours, which correlated well with pEGFR activation. 4-HT did not affect mRNA levels of these ligands. In contrast, amphiregulin (AREG) mRNA levels were substantially reduced 48 hours after fulv treatment. A similar trend was seen for AREG mRNA levels in 48HT treated cells but to a much lesser extent. There was no change in any EGF ligand mRNA levels in ER negative C4-12 cells. These qPCR data suggested differential regulation of EGFR ligands by fulv treatment contributed to EGFR family member activation and was dependent on ER expression. Upon fulv treatment, levels of ER were diminished with decreased detection of S167 and S118 ER phosphorylation sites. Monolayer cell growth analysis showed that while fulv treatment in SFM reduced MCF-7 cell numbers compared to control treatment, erlotinib plus fulv significantly reduced cell numbers below the level of cells maintained in fulv alone. In conclusion, we show that fulv, but not E2 or 4-HT, activates EGFR family members accompanied by upregulation of ligands. Since SERM resistance has been associated with EGFR family member activation, differential control of EGFR ligand gene expression by ER may contribute to the development of fulvestrant resistance in breast cancer.

P4-01-15
Alteration of Y-box Binding Protein-1 Expression Modifies the Response to Endocrine Therapy in Estrogen Receptor Positive Breast Cancer.
Ito T, Kamijo S, Isumi H, Kohno K, Ito K-I. Shinshu University School of Medicine, Matsumoto, Nagano, Japan; University of Occupational & Environmental Health, Kitakyushu, Fukuoka, Japan
Y-box binding protein-1 (YB-1) plays an important role in tumor progression and drug resistance. This study examined whether YB-1 is involved in the alteration of response to endocrine therapy in ER-positive breast cancer cells. MCF7 cells that stably expressed YB-1 (MCF7-YB-1) and vector control cells (MCF7-vector) were established. These cells were used to analyze the expression of the factors related to the ER and growth factor receptor signaling pathways, response to the antiestrogens (tamoxifen and fulvestrant), and estrogen responsive element (ERE) activity. The effect of knocking down endogenous YB-1 expression was tested in wild-type MCF7 cells. In addition, the expression of the YB-1 and the factors related to the ER and growth factor receptor signaling pathways were evaluated in the clinical breast cancers treated with preoperative chemotherapy. The expression of HER2, ALB1, p-Erk and c-Myc were increased in the MCF7-YB-1 cells. In contrast, knocking down of YB-1 decreased the expression of these factors, but increased the expression of ERα in the wild-type MCF7 cells. Furthermore, sensitivity to antiestrogens was decreased in the MCF7-YB-1 in comparison to those in the MCF7-vector cells. In the MCF7-YB-1 cells, the expression levels of p-Erk and c-Myc were continuously upregulated when the cells were treated either with tamoxifen or fulvestrant. The ERE activity was decreased in the MCF7-YB-1 cells in comparison to the MCF7-vector cells, and the ERE activity of the MCF7-YB-1 cells was inhibited by fulvestrant at a lower concentration than that which inhibited the ERE activity of the MCF7-vector cells. In the ER-positive clinical breast cancers treated with preoperative chemotherapy, significantly more of the specimens that showed increased or positive nuclear YB-1 expression after the chemotherapy were positive for HER2 expression. These data suggest that alteration of YB-1 may modify the crosstalk between the ER pathway and HER2 pathway in ER-positive breast cancer cells, and consequently may alter the response to endocrine therapy in these cells.

P4-01-16
The Influence of CYP2D6 Genetic Polymorphisms on Variability of Tamoxifen Metabolism in the Lebanese Breast Cancer Population.
Introduction The selective estrogen receptor modulator tamoxifen is commonly used for the treatment and prevention of breast cancer. Tamoxifen needs to be converted by the highly polymorphic enzyme, CYP2D6, to its active metabolites (4-hydroxytamoxifen and endoxifen) to exert its anti-estrogenic effect. Several clinical trials have shown that CYP2D6 poor metabolizers have decreased benefit from tamoxifen compared to extensive metabolizers. Large ethnic variations have been noticed in the frequency and effect of CYP2D6 polymorphisms.
Objectives To assess for the frequency of CYP2D6*3, *4, *5 (nonfunctional alleles with *5 being a gene deletion), *41 (reduced functional allele) as well as CYP2D6*1N (allele copy number) in a sample of Lebanese participants receiving maintenance doses of tamoxifen for early stage breast cancer, and to assess the effect of these polymorphisms on tamoxifen metabolism in the same subjects.

Methods 111 (median age = 48.7 ± 8.6 years) Lebanese breast cancer women were recruited. Blood for isolation of DNA and measurement of tamoxifen metabolites was collected. CYP2D6 genotyping was performed using real-time PCR. Plasma levels of tamoxifen were being measured using HPLC.

Results The allele frequencies of CYP2D6*3, *4, and *41 were 0.9, 15.9 and 12.1 respectively. 18.9% of patients had more than 2 CYP2D6 copies and 9% had only 1 copy. Tamoxifen plasma concentration didn’t significantly vary among the 4 phenotypic groups, although there was a trend observed whereby PMs had the highest tamoxifen plasma concentrations and UMs had the lowest tamoxifen plasma concentrations (Tamoxifen median plasma concentrations in µg/L: PM=290, IM=210, EM=190 and UM=170). Furthermore, there was a statistically significant variation of Z-tamoxifen plasma concentrations among the phenotypic groups when PMs and IMs were grouped together: Z-tamoxifen median plasma concentrations in µg/L: PM=IM=130, EM=90 and UM=62 (P=0.03).

Conclusion This is the first study in the Middle East that evaluates the frequencies of CYP2D6 polymorphisms in a Lebanese breast cancer population and the effect of these polymorphisms on tamoxifen metabolism. We have shown that CYP2D6 phenotype is significantly correlated with Z-tamoxifen levels. PMs and IM group had the highest Z-tamoxifen plasma concentrations; in contrast UMs had the lowest Z-tamoxifen plasma concentrations. Further recruitment and follow up are being performed to assess for the role of these polymorphisms in disease outcome.

P4-01-17 TIMP-1 Over-Expression Confers Resistance of MCF-7 Breast Cancer Cells to Fulvestrant.

Bjerre CA, Vinther L, Belling K, Schroih Rasmussen A-S, Li J, Lin X, Han Z, Wang J, Boland L, Jensen V, Nielsen BS, Soekilde R, Gupta R, Lademann U, Brünnen N, Stenvang J. Faculty of Life Sciences, University of Copenhagen, Copenhagen, Denmark; Technical University of Denmark, Lyngby, Denmark; Aarhus University, Aarhus, Denmark; BGI-Shenzhen, Shenzhen, China; Exiqon A/S, Vedbeak, Denmark

Background: Endocrine resistance represents a major challenge in the management of estrogen receptor (ER) positive breast cancer. Currently no predictive biomarkers for endocrine resistance in ER-positive breast cancer patients are in clinical use. In a clinical study, patients with metastatic breast cancer and high levels of serum Tissue Inhibitor of Metalloproteinases-1 (TIMP-1) had less benefit from endocrine therapy than patients with a lower level of serum TIMP-1 [1].

Therefore, we evaluated the association between TIMP-1 and response to endocrine therapy using an in vitro approach. We have previously presented initial results on TIMP-1 and response to endocrine therapy [2].

Materials and Methods: MCF-7 cells were stably transfected with pcDNA3.1(Hyg)-TIMP-1 plasmid, and a panel of 11 subclones with different expression levels of TIMP-1 was generated. TIMP-1 expression levels were confirmed using enzyme-linked immunosorbent assay (ELISA).

Four subclones with high or low TIMP-1 expression were analyzed for the growth response to estrogen, 4-hydroxytamoxifen and fulvestran. These four subclones were analyzed for protein expression by western blotting. All subclones were analyzed by whole human genome oligo microarrays 4x44K for determination of gene expression levels. Data were analyzed using the limma R/Bioconductor package. Pair-end Solexa sequencing was applied to selected subclones with high and low TIMP-1 levels to identify transcriptional changes.

Results: High expression of TIMP-1 was associated with resistance to fulvestran, whereas growth response to either estrogen or 4-hydroxytamoxifen was independent of TIMP-1 expression levels. High expression of TIMP-1 protein and mRNA was associated with undetectable levels of progesterone receptor (PgR) protein and mRNA whereas ER protein and mRNA levels were unaffected by TIMP-1. To characterize the potential role of TIMP-1 in estrogen signaling we analyzed the expression of reported estrogen-responsive genes and no general change was observed. We identified genes that correlated positively or negatively to TIMP-1 expression. Among the identified genes was PgR, which is a direct target for ER.

Conclusion: Our data suggest that a high expression of TIMP-1 in vitro is associated with resistance to fulvestran but not to 4-hydroxytamoxifen. Estrogen-regulated genes are not generally affected by changes in TIMP-1 expression levels and therefore TIMP-1 appears to affect endocrine resistance through other mechanisms than globally regulating ER signaling. However, high expression of TIMP-1 is associated with loss of PgR and this may be related to the resistance towards fulvestran.

P4-01-18 AP-1 Blockade Potentiates the Anti-Tumor Effect of Endocrine Treatment and Reverts the Resistant Phenotype in Hormone Receptor-Positive Breast Cancer.

Malorni L, Giuliano M, Migliaccio I, Wang T, Creighton C, Lupien M, Hilsenbeck SG, Healy N, Mazumdar A, Trivedi MV, Jeselsohn R, Fu X, Gutierrez C, Brown M, Brown PH, Osborne CK, Schiff R. Baylor College of Medicine, Houston, TX; Hospital of Prato, Italy; The University of Texas M.D. Anderson Cancer Center, Houston, TX; Dana-Farber Cancer Institute and Harvard Medical School, Boston, MA; Dana-Farber Cancer Institute, Boston, MA; Beth Israel Deaconess Medical Center, Boston, MA; Dartmouth Medical School, Lebanon, NH; UH College of Pharmacy, Houston, TX

Background: Resistance to endocrine therapy is a major clinical issue. The transcription factor AP-1 is a key regulator of cell growth and survival as well as a downstream signaling component of several pathways deregulated in endocrine-resistant breast cancer. We have previously shown that acquired endocrine resistance is associated with increased AP-1 activity. AP-1 has also been shown to interact with and modulate the ER network and transcriptional program, especially under hyperactive growth factor signaling, which is commonly associated with endocrine resistance. We hypothesized that interfering with AP-1 function would circumvent endocrine resistance possibly due to its role in modulating ER transcriptional activity.

Methods and results: We inhibited AP-1 function by a genetic approach. We used two different MCF7 clones stably transfected...
with a Doxycycline (Dox)-inducible dominant-negative (DN) c-Jun (MCF7/Tet-Off Tam67 clones 62 and 67) and two vector-alone control MCF7 clones. Xenografts of these clones were established in ovariectomized nude mice supplemented with estrogen (E2). Mice were then randomized to continued E2 supplementation (control) or to endocrine therapy with either estrogen deprivation (ED) or tamoxifen (Tam), all in the presence or absence of Dox to induce the DN c-Jun expression. AP-1 blockade in both MCF7/Tet-Off Tam67 clones significantly enhanced sensitivity to Tam by reducing time to tumor size halving (p=0.014 and p=0.006 for clone 62 and 67, respectively) and time to complete tumor disappearance (p=0.001 and p=0.0034 for clone 62 and 67, respectively). Similar results were obtained with ED treatment. In addition, AP-1 blockade significantly delayed the onset of Tam resistance by increasing time to tumor size doubling (p=0.028). Furthermore, induction of DN c-Jun resulted in a dramatic shrinkage of growing tumors after long-term Tam treatment, suggesting reversal of endocrine resistance with AP-1 blockade. None of the above effects was observed in control clones upon Dox removal. Interestingly, no significant effect of AP-1 blockade was observed on E2-stimulated tumor growth. IHC analysis showed that AP-1 blockade induced tumor response by reducing proliferation (i.e., decreased % of Ki67- and phospho-Histone 3-positive cells) and by inducing apoptosis (i.e., increased % of cleaved caspase 3/7-positive cells). Bioinformatic analyses were conducted to intersect our MCF7 xenograft/Tam-resistant gene signature and the datasets of genes associated with ER DNA-binding sites obtained by whole-genome ER cistrome analysis under estrogen or epidermal growth factor (EGF) stimulation of MCF7 cells. A significant enrichment of the genes associated with the EGF-unique ER DNA-binding sites was observed within our Tam-resistant signature (p=2E-16). Remarkably, 90% of these DNA binding sites harbored an AP-1 motif. Conclusions: We show that AP-1 blockade increases tumor sensitivity and circumvents resistance to endocrine therapy, thus warranting the development of AP-1-targeted therapy to improve endocrine treatment outcomes. Overall, we suggest that AP-1 is critical in induction of a switch in the ER transcriptional program and may be a new hallmark of endocrine resistance.

P4-01-19
SRC-1 Expression Is a Prognostic Factor of Breast Cancer-Specific and Disease-Free Survival in Inflammatory Breast Cancer.

Arias-Pulido H, Ahmed RD, Chaher N, Vargas J, Joste N, Lomo L, Qualls C, Azziez S, Terki N, Bouzid K, Prossnitz E, Royce M. University of New Mexico, Albuquerque, NM; Centre Pierre et Marie Curie, Algiers, Algeria

Background: Steroid receptor coactivator (SRC-1 to 3) proteins drive nuclear receptor transcriptional activity by modulating transcriptional processes such as chromatin modification, transcription initiation, chain elongation, and RNA splicing. In patients who display resistance to endocrine treatment, SRC-1 has been implicated in the conversion of tamoxifen anti-agonist activity to its agonist profile. SRC-1 expression is a prognostic of DFS in breast cancer, but its role in inflammatory breast cancer (IBC) remains unknown.

Materials and Methods: SRC-1 protein levels were measured by immunohistochemistry in 103 IBC and 11 normal, non-cancer related samples, diagnosed at the Centre Pierre & Marie Curie (Algiers, Algeria). Staining results were correlated with protein levels of ER, PR, and HER2, and clinico-pathological variables, breast cancer-specific (BCSS) and disease-free survival (DFS), and response to tamoxifen treatment.

Results: SRC-1 was positive in all normal breast tissue, as well as in 66% of IBC samples. SRC-1 positivity was associated with worse OS (P<0.001) and DFS (P=0.004). SRC-1 expression correlated with worse BCSS (P=0.011), and marginally with DFS (P=0.046) in tamoxifen-treated patients, but strongly with DFS (P=0.007) in patients who received no endocrine therapy as indicated by Kaplan-Meier and log-Rank analyses. Multivariate analysis showed that SRC-1 (Hazard Ratios (HR): 5.2; 95%CI: 2.0-13.6; P<0.001) and Her2 (HR: 3.1; 95%CI: 1.2-8.1; P=0.02) expression were independent prognostic markers of BCSS. SRC-1 (HR: 4.8; 95%CI: 1.9-12.2; P<0.001), Her2 (HR: 2.4; 95%CI: 1.0-5.7; P=0.05), and hormone treatment (HR: 0.4; 95%CI: 0.2-0.8; P=0.01) were independent prognostic markers of DFS.

Discussion: Determining prognosis and predicting response to endocrine treatment is of paramount importance in the search for personalized treatment. SRC-1 expression predicts worse OS, DFS, and, similar to non-IBC, predicts DFS independently of endocrine therapy. This study highlights the importance of SRC-1 expression as a strong prognosticator of BCSS and disease recurrence in IBC patients.

Supported by an Ulcc Icref Fellowship (Icr/09/043) to Dr. Chaher) and by New Mexico State Ibc funding (New Mexico Senate Bill 532).

P4-01-20
Specific Anti-Proliferative Profile of Endoxifen for MCF-7 Cell Compared to 4-OH Tamoxifen.

Saji S, Hirose M, Hayashi S-I, Kuroi K. Saitama Medical University, IMC, Saitama, Japan; Tokyo Metropolitan Komagome Hospital, Tokyo, Japan; Tohoku University Graduate School of Medicine, Sendai, Japan; Kyoto University, Graduate School of Medicine, Kyoto, Japan

Background: Endoxifen and 4-hydroxy tamoxifen are both active metabolites of tamoxifen and exert anti-tumor activity for ER+ breast cancer. However, only small numbers of paper reported biological profile of endoxifen.

Methods: Cells were incubated with various concentration of endoxifen (Z)4-Hydroxy-N-desmethyl Tamoxifen (<10% with (E)-form) for 6 days and viability (anti-proliferative index) was assessed by cell counting kit-8. For seeking the influence of ERβ, two independent ERβ expressing clones of MCF-7 cells were established by stable transfection of ERβ vector to MCF-7. Western blotting was done with ERα, ERβ, PgR and HER2 antibodies.

Results: IC50s of endoxifen for MCF-7 were 100 nM in estradiol (E2) deprivation condition and 500 nM in the presence of 1nM E2. These are significantly higher than those of 4-OH tamoxifen, which are 10 nM without E2 and 50 nM with E2, respectively. From the previous reports, plasma endoxifen concentrations in breast cancer patients were ranged from 20 to 200 nM according to CYP2D6 phenotype. Anti-proliferative index of 20 nM endoxifen for MCF-7 was 0.7 (indicating 30% reduction in proliferative activity), and 200 nM endoxifen was 0.5 in the absence of E2. These were 0.95 (20 M) and 0.75 (200M), respectively, when incubated with 1 nM E2. 10 nM 4-OH tamoxifen, which is mean concentration in patient plasma, showed about 0.6 anti-proliferative index with no regards to E2 condition. Without E2, endoxifen reduced ERα expression as previously reported, however, endoxifen increased ERα amount in the presence of E2 accompanied with decrease of HER-2 expression. This alteration of ERα and HER2 expression were identical to those
observed using 4-OH tamoxifen. There was a weak tendency that ERβ expressing MCF-7 clones showed favorable response to endoxifen compared to parent MCF-7, but this was not significant.

Conclusion:
Endoxifen is active agent for MCF-7 cell, however, it requires 10-fold higher concentration compared to 4-OH tamoxifen to achieve IC 50. Difference of anti-proliferative effect between 20 nM and 200 nM of endoxifen are relatively small, and it might result in minor difference for clinical response, as expected from recent clinical studies of CYP2D6. This is the first time to show that endoxifen has opposite effect to ERα protein level depending on the presence or absence of E2. ERβ expression did not enhance activity of endoxifen in contrast to previous report.

P4-01-21
An Estrogen-Inducible Transcription Factor FOXP1 Promotes Estrogen-Dependent Cell Proliferation of Breast Cancer Cells and Is Associated with 5-Year Disease-Free Survival in Patients with Tamoxifen-Treated Breast Cancer.
Shigekawa T, Iichii N, Ikeda K, Horie-Inoue K, Shimizu C, Saji S, Aogi K, Tsuda H, Osaki A, Saeki T, Inoue S. Tokyo Metropolitan Cancer and Infectious Disease Center; Komagome Hospital; Research Center for Genomic Medicine, Saitama Medical University; International Medical Center, Saitama Medical University; National Cancer Center Hospital; National Shikoku Cancer Center; Graduate School of Medicine, The University of Tokyo

Estrogen signaling pathways are involved in the growth and development of breast tumors through the activation of estrogen receptor α (ERα). ERα is expressed in most breast cancers and involves estrogen-dependent proliferation by acting as transcription factors activating the expression of target genes. Various coregulators and transcription factors are associated with ERα-mediated transcriptional control of target genes. Therefore, a comprehensive understanding of estrogen signaling pathways in breast cancer is required for both treatment and diagnosis of the disease. Forkhead box P1 (FOXP1) is a member of the forkhead box transcription factor family and has been reported to be associated with various types of tumors. Here, we investigated the expression pattern of FOXP1 by immunohistochemistry in a series of 133 invasive breast cancers and compared it with clinicopathological factors. The expression of FOXP1 was detected in nuclei in 89 cases (67%) and correlated positively with tumor grade and hormone receptor status, including ERα and progesterone receptor (PgR), and negatively with pathological tumor size (pT). And in ERα-positive MCF-7 breast cancer cells, we demonstrated that FOXP1 mRNA was upregulated by estrogen and that ERα recruitment to ER binding sites within the FOXP1 gene region identified by ChIP-chip analysis was increased. We also demonstrated that proliferation of MCF-7 cells was increased by exogenously transfected FOXP1 and decreased by FOXP1-specific siRNA. Moreover, in MCF-7 cells, FOXP1 enhanced estrogen response element (ERE)-driven transcription. Finally, FOXP1 immunoreactivity was significantly more elevated in relapse-free breast cancer patients treated with tamoxifen than in relapse patients treated with it. Taken together, these results suggest that FOXP1 plays an important role in proliferation of breast cancer cells by modulating estrogen signaling and that FOXP1 immunoreactivity might be associated with the estrogen dependency of breast cancer clinically, which may predict favorable prognosis in the patients treated with tamoxifen.

P4-01-22
Cyclin D1 and Its Prognostic Value in Planning of Endocrine Therapy for Women of Postmenopausal Age with Breast Cancer.
Skvortsov V, Manikhas A, Manikhas G, Oganesyan A, Raskin G. City Clinical Oncology Dispensary, St. Petersburg, Russian Federation; Pavlov State Medical University of St. Petersburg, St. Petersburg, Russian Federation

Background: Nowadays tamoxifen still remains the primary drug in breast cancer endocrine therapy. However, its application is limited due to the resistance of tumor cells. The search of adequate biomarkers is one of the most actual problems in prognosis of effectiveness of tamoxifen adjuvant therapy. The most prospective biomarker is cell cycle regulator cyclin D. Besides its central role in cell cycle regulation cyclin D1 modulates the estrogen receptors activity and can influence on the effectiveness of treatment with antiestrogens and aromatase inhibitors.

The objective of our work was to evaluate the effectiveness of tamoxifen in adjuvant therapy of hormone-receptor-positive breast cancer in women of postmenopausal age with cyclin D1 expression. Material and Methods.
To evaluate the effectiveness of tamoxifen adjuvant application in women with cyclin D1-positive T1-4N0-3M0 breast cancer we have researched 2 retrospective groups of 70 patients that have been on regular medical check-up for a period of 5 years or that had previously undergone treatment. On the basis of the archive histological material we have revealed cyclin D1 in tumor cells.

Results: The expression of cyclin was classified in 4 levels: negative, low, moderate and high. Patients with lack of cyclin D1 expression or with low qualitative value (according to our data less than 30%) have no neoplastic process progression throughout the 5 years of tamoxifen adjuvant therapy. These women were both with axillary lymph nodes affection and without it (+N; -N). On the contrary, women with moderate and high cyclin D1 expression (more than 30%) had a relapse of tumor and distant metastasis is prognosed in 5 years of observation (p=0,005). Moderate level of cyclin D1 expression was observed in 45 (64%) patients and 28 (62%) of them had progression with metastasis in bones, 9 (20%) metastasis in soft tissues, 2 (4%) metastasis in lungs and 6 (14%) relapse in postoperative scar. High expression was revealed in 25 (35%) women and 17 (68%) of them had bone affection, 7 (28%) soft tissue metastasis and 2 (4%) tumor relapse in postoperative scar. Lung metastasis were not observed. The average period of tumor relapse and progression of neoplastic process in patients with cyclin D1-positive breast cancer is 20 months.

Discussion: The results of our work suggest that women with hormone-receptor-positive cyclin D1-negative breast cancer on early stages have more prolonged non-relapse period during the tamoxifen adjuvant therapy. Patients with cyclin D1-positive breast cancer are less sensitive to tamoxifen treatment and in adjuvant regime should receive therapy with other effective equivalent drugs (aromatase inhibitors).

P4-02-01
Bis(2-Ethylhexyl) Phthalate: A Potential Endocrine Disruptor Confers Letrozole Insensitivity and Induction of Aromatase Activity in Breast Cancer Cells.
Nair HB, Bhaskaran SS, Krishnegowda NK, Tekmal RR, VandeBerg JL. Texas Biomedical Research Institute, San Antonio, TX; University of Texas Health Science Center, San Antonio, TX

Exposure to endocrine disrupting compounds (EDC’s) is an important determinant of mammary gland development and mammary tumor pathogenesis. The risk of breast cancer in adulthood is known to
be influenced by environmental factors experienced as a fetus. Fetal exposure to dietary factors or certain pharmaceuticals and environmental chemicals that affect or mimic steroid hormones increase predisposition to breast cancer. The mechanisms by which EDC’s alter epigenetic programming, differentiation and deregulation of ductal branching of mammary glands are poorly understood. A high ratio of estrogen receptor α (ERα) to ERβ has been recently found to be associated with poor prognosis and aggressive disease in breast cancer patients. Preliminary studies from our laboratory revealed that bis(2-ethylhexyl) phthalate (DEHP) is a possible EDC which induces cell proliferation in T47D, MCF7, MCF7/Aro breast cancer cells in vitro and confers insensitivity to letrozole, a third generation aromatase inhibitor. DEHP increased cell proliferation (MTT assay) in a dose dependent manner and was non toxic to T47D, MCF7 and MCF7 7 Aro cells. 1, 10 and 100 nM concentrations of DEHP up regulated ERα and down regulated ERβ at the mRNA level. Hypermethylation in the estrogen receptor beta (ERβ) promoter was observed after treatment with 1nM DEHP for 24 h, suggesting that DEHP alter epigenetic programming through changes in the DNA methylation to modify the chromatin structure and change the accessibility of DNA to transcription factors. When breast cancer cells were treated with letrozole (200nM) and DEHP (1nM) together, they survived, whereas those treated with letrozole alone did not survive. Aromatase mRNA and enzyme levels were higher in the DEHP treated cells by comparison with sham control MCF7/Aro cells. Nonmalignant MCF-10A breast epithelial cells showed a proliferation advantage (MTT assay) by up regulation of ERα as well as aromatase expression when treated with 1nM DEHP. Aromatase transgenic mice treated with 10μg/kg b.wt of DEHP over a period of 30 days resulted in the excessive ductal branching density and epithelial outgrowth in the mammary gland. The present data suggest that dietary accumulation of DEHP through plastic food containers, water bottles, etc. may contribute to risk of hormone sensitive breast cancer in women and chemoinosensitivity and or drug resistance in breast cancer patients.

The Natural Fetal Estrogen Estetrol (E4), Causes Anti-Estrogenic Effects in Women with Endocrine-Responsive Positive Early Breast Cancer.

Singer CF, Natter C, Steurer S, Rudas M, Moiifar F, Appels NRCA, Visser M, Kabista E, Benningk C. Medical University of Vienna, Wien; Medical University of Graz, Wien; Pantheorie Bioscience

Background: Estetrol (E4) is a natural fetal estrogen which exerts estrogenic effects on reproductive organs and on the bone, and effectively reduces menopausal symptoms. In contrast to other estrogens, however, E4 has estrogen-antagonistic effects on breast cancer cell lines in vitro and in the rat DMBA model, which would make it a suitable Hormone Replacement Therapy (HRT) in breast cancer patients, particularly in women who are being treated with aromatase inhibitors. Patients and Methods: We have investigated the effect of 14 days pre-operative treatment with 20 mg E4 per day on tumor proliferation, apoptosis, ER-receptors, PgR receptor and several endocrine parameters in a prospective, randomised, double-blind, placebo-controlled, neo-adjuvant study in 15 pre- and 14 postmenopausal women with estrogen-receptor positive early breast cancer. Results: Estetrol induced a significant increase of SHBG, a significant decrease of FSH in postmenopausal women and no increase of gonadotrophins in premenopausal women. Estetrol had no effect on Ki67 expression and on apoptosis-related Bax and Bcl-2, but the apoptosis index in tumor tissue increased significantly. Systemic IGF-1 levels decreased significantly. Surprisingly the intratumoral epithelial ER-alpha expression decreased significantly, whereas the ER-beta expression showed a trend to increase. Conclusion: Our data suggest that E4 may be suitable and safe for HRT in women with spontaneous or induced menopausal symptoms, since apoptosis increases, IGF-1 decreases and no unfavourable effects are observed on Ki67, Bax and Bcl-2. The decrease of ER-alpha and the increase of ER-beta suggest a mechanism of action, explaining why the natural fetal estrogen E4 has estrogen-antagonistic effects on breast cancer tissue.

Biological Functions of Estrogen Receptor-beta and Its Variants in Breast Cancer.

Hawse JR, Wu X, Cicek M, Subramanian M, Negron V, Lingle WL, Goetz MP, Spelsberg TC, Ingle JN, Mayo Clinic

Background: The role of estrogen receptor alpha (ERα) in breast cancer has been studied extensively; yet, much less is known about full-length ERβ (ERβ1) and even less about its 4 variant forms (ERβ2-5). We have recently implicated a role for ERβ1 in sensitizing ERα expressing breast cancer cells to anti-estrogens. However, the ability of ERβ2-5 to modulate ERα and ERβ1 activity, and their association with cancer development, progression, and response to estrogen and anti-estrogens are not well understood. Here, we provide evidence that the presence of ERβ variants may be of diagnostic and clinical relevance for breast cancer patients and describe the development and characterization of a novel, highly specific monoclonal antibody (MC10) that is able to detect their expression in tumor biopsies. Methods: Transient transfection and luciferase assays were used to determine the transcriptional activity of ERβ2-5 in response to E2 and anti-estrogens alone or in combination with ERα and ERβ1. A novel monoclonal antibody targeting all ERβ variants (MC10) was developed and characterized. The sub-cellular localization of ERβ2-5 was determined via confocal microscopy. Finally, the MC10 antibody was used to assess ERβ positivity in breast tumors and was compared to that of another monoclonal antibody which only detects ERβ1. Results: Unlike ERβ1, ERβ2-5 do not activate an estrogen response element (ERE) in response to E2 and instead, slightly repress the activity of this reporter construct. Expression of ERβ2-5 does not significantly alter the transcriptional activity of ERβ1 following E2 treatment. However, ERβ2, 3 and 5, but not ERβ4, significantly enhance the E2-induced transcriptional activity of ERα. Interestingly, expression of ERβ3, 4 and 5, but not ERβ2, enhance the ability of anti-estrogens to block ERα mediated transcriptional activity. Confocal microscopy revealed that ERβ1 and 2 are almost exclusively localized to the cell nucleus. However, ERβ3-5 exhibit significant cytoplasmatic and peri-nuclear localization. Immunohistochemistry of breast cancer biopsies using the MC10 antibody revealed multiple staining patterns including tumors which exhibit primarily nuclear staining and others primarily cytoplasmatic, both in the presence and absence of ERα. These results are in contrast to the almost exclusive nuclear staining obtained on the same tumors with an ERβ1-specific antibody. Conclusions: ERβ variants exhibit variable sub-cellular localization patterns and can influence the function of ERα, both in response to E2 and anti-estrogens. Therefore, the differential expression of ERβ variants and their cellular localization may influence breast cancer progression and/or therapeutic responses. The use of ERβ antibodies which do not detect all ERβ variants, or the use of a single ERβ antibody which does not discriminate between ERβ1 and its variants,
is unlikely to reveal the complete biological significance of total ERβ expression in breast cancer and may in part explain the conflicting studies which have been reported for ERβ in the field.

**P4-02-04**

Androgen Receptor (AR) Expression in a Cohort of Patients (pts) with Triple Negative Breast Cancer (TNBC).

**Background:** TNBC, defined by the absence of ER, PR, and HER2, is associated with higher risk of recurrence and BC-related mortality, earlier age at diagnosis, menarche, and 1st pregnancy, increased parity, higher BMI, and African-American/Hispanic race. TNBC is a heterogeneous group. Using gene expression analysis, our group described a subset of AR+ ER/PR- BC that exhibits androgen-dependent growth. *In vitro* studies confirmed the functional role of AR and showed that growth could be abrogated by antiandrogens.(Doane et al 2006) We translated this work into a phase II trial of bicalutamide in pts with AR+ ER/PR- metastatic BC (MBC). (NCT00468715) We now describe the prevalence and clinicopathological characteristics of AR+TNBC in primary disease in a single-institution retrospective cohort.

**Methods:** We identified 1,032 pts with resectable, TNBC (ER/PR<1%; HER2<2+/FISH<2.2) who had surgery at MSKCC from 1998-2006. Exclusion criteria: neoadjuvant chemotherapy, prior radiation, inflammatory/MBC. IRB approval was obtained. We constructed tissue microarrays (TMA) from 210 primary tumors (>1 cm) with each tumor represented by three 0.6mm cores. AR was tested with DAKO antibody (Clone AR441; dilution 1:500). TMAs were digitized with a Mirax scanner. MetaMorph image analysis software was used to quantify the ratio of DAB staining to hematoxylin signal. A ratio >1 SD above mean was defined as AR+. AR+ cores were manually reviewed; false positives due to core artifact were excluded. To evaluate clinicopathological variables and differences in recurrence-free survival (RFS) and overall survival (OS) by AR status we used chi-square/t-tests and Kaplan-Meier methods/log-rank test, respectively.

**Results:** 169 pts had adequate cores for image analysis/quantification of AR. 10% of pts tested AR+ (17/169). Median (med) followup: AR++=6 years (yr), AR+=5.6yr. Demographic/clinicopathological variables: Table 1 (ages in med yr). Overall med age=54yr (29-84). Adjuvant chemotherapy received: AR+ 82%, AR- 87%, p=0.40; 77% received anthracycline/taxane-based therapy. Med time to distant metastasis (DM)=2.1yr (0.2-6.2yr). We were unable to demonstrate a difference in 5yr RFS (69% vs. 77%; p=0.37) or OS (68% vs. 84%; p=0.25) between AR+ and AR- TNBC.

**Conclusions:** Consistent with our prospective study, AR is expressed in ~10% of TNBC tumors in this retrospective cohort. The pts in our dataset may be older, postmenopausal, more likely to self-report white race and have T1-2/N0-1 BC. No statistically significant differences were observed in demographic/clinicopathological variables or survival outcomes between AR+ and AR- TNBC. Additional TMA data from our database will be presented.

The Regulation of Artemin Signalling by IGF-1 in Mammary Carcinoma Cells.

Yip C, Liu D, Llobie PE, Perry JK. University of Auckland, Auckland, New Zealand; National University of Singapore, Singapore

Artemin is a neurotrophic signalling factor which belongs to the glial-derived neurotrophic factor (GDNF) family of ligands. Artemin acts as a survival, proliferation and migration factor for a number of neurological cell types, by signalling through the RET (rearranged during transfection) receptor and, in most cases, the GDNF receptor (GFR)-α3 co-receptor. Recently, a number of published studies have implicated Artemin as a potential oncogene in several cell types, including mammary carcinoma cells. Other studies further indicate that Artemin may influence cancer progression and tamoxifen resistance in some breast cancers. Available clinical data has demonstrated that increased Artemin expression is correlated with decreased overall patient survival in breast cancer patients and a poor outcome in tamoxifen treated breast cancer patients.

Here we investigate interaction between the Artemin and the insulin-like growth factor-1 (IGF-1) signal transduction pathways. Using mammary carcinoma cell lines, we demonstrate that IGF-1 treatment increases the endogenous expression of both Artemin and its endogenous receptors, RET and GFRα3. Semi-quantitative RT-PCR assays demonstrated that IGF-1 stimulated mRNA expression of Artemin as well as RET and GFRα3 in wild-type MCF-7 and ZR-75-1 cells in a time-dependent and dose-dependent manner. The same effect was not observed in wild-type T47D cells where IGF-1 did not increase Artemin mRNA expression.
We also demonstrated that forced expression of Artemin in MCF-7 cells consistently enhanced the response of these cells to IGF-1 in a number of cell function assays. Forced expression of Artemin significantly enhanced IGF-1-mediated stimulation of total cell number in MCF-7 cells. Consistent with this, Artemin enhanced IGF-1-mediated stimulation of S-phase entry and cell survival. In a soft agar assay, forced expression of Artemin also enhanced IGF-1-mediated stimulation of colony formation. Conversely, depletion of Artemin expression using siRNA abrogated the response to IGF-1 stimulation in MCF-7 cells. Artemin depletion significantly decreased IGF-1-stimulated increase in total cell number by decreasing IGF-1-stimulated cell proliferation and protection from apoptotic cell death. In addition, forced expression of Artemin in MCF-7 cells reduced cell sensitivity to the IGF-1 receptor small molecule inhibitor, AG1024. In conclusion, we have demonstrated that IGF-1 increases Artemin mRNA and protein expression in the breast cancer cell lines MCF-7 and ZR-75-1 and have identified potential cross-talk between the Artemin and IGF-1 signalling pathways in MCF-7 cells.

P4-02-06

Progestrone Receptor Expression Predicts Poor Outcome in Estrogen Receptor Positive, Lymph Node Negative Breast Cancer – A Population Based Study.

Purdie CA, Quinlan P, Jordan LB, Ashfield A, Baker L, Dewar JA, Thompson AM. Ninewells Hospital & Medical School, Dundee, United Kingdom; University of Dundee, Dundee, United Kingdom

Background: Estrogen receptor (ER) positive, lymph node (LN) negative breast cancer usually carries a good prognosis; endocrine therapy is often the only adjuvant treatment. However, a small proportion of such patients do badly (possibly representing those with luminal B cancers identified by gene expression profiling). A clinically applicable method for identifying this subgroup of poor prognosis ER+, LN- patients is required to offer them more intensive adjuvant therapy.

Material and methods: A consecutive, unselected series of 1072 new, operable breast cancer patients diagnosed between 2000 and 2004 was studied for ER and progestrone receptor (PR) expression, HER2 status and standard pathological and demographic parameters. ER and PR expression were scored on immunohistochemistry (IHC) on preoperative, diagnostic core biopsies using the “Quickscore” method. This ensured optimal fixation and tissue processing avoiding the variable fixation of resection specimens and the well-described sampling error of tissue micro-array (TMA) methodologies. PR expression is frequently heterogeneous resulting in false negative scores in at least 12% of cases by TMA analysis. HER2 status was assessed using IHC with dual color FISH for cases scoring 2+.

Adjuvant therapy was prescribed using standard protocols; all patients with ER+ disease received adjuvant endocrine therapy. Follow up data were obtained from the oncology database, and the registrar of deaths for the date and cause of death. All deaths not attributable to breast cancer were censored at the date of death. Accordingly, the primary end-point was breast cancer-specific overall survival. Survival analysis was carried out by Kaplan-Meier survival curves analysed by the Log-Rank test. Multivariate analysis was carried out using Cox’s regression.

Results: Overall, PR- cancers had a worse prognosis than PR+ (p<10^-12, Hazard Ratio 3.40), even in the ER+ (p=0.006, HR 1.86), LN- (p=10^-4, HR=5.33) and LN+ (p=10^-11, HR=3.26) sub-groups. In the ER+ LN- group, the absence of PR expression predicted worse prognosis (88% vs 96% 8 year survival, p=0.0003) with a hazard ratio of 3.75. This is considerably more significant than Ki67 IHC scoring reported for a similar group of patients in other studies (HR 2.22). Multivariate analysis demonstrated that PR expression was an independent prognostic variable second only to LN status and more powerful than ER.

Discussion: Patients with ER+, LN-, PR- breast cancers have a significantly worse prognosis than those with ER+, LN-, PR+ cancers. Unlike Ki67, PR IHC uses a simple, cost effective, standard methodology (as for ER) and should identify patients who may require chemotherapy in addition to endocrine therapy in this group of otherwise good prognosis patients.
tumors have a significantly deteriorated prognosis and seem to be a patient group, which should be investigated concerning drug resistance mechanisms.

**Obesity-Induced Aromatase Expression in the Breast Microenvironment Promotes Estrogen Receptor Activity Independent of Circulating Estradiol Levels.**

Bowers LW, Brenner AJ, Li R, Tekmal RR, deGraffenried LA. The University of Texas at Austin, Austin, TX; The University of Texas Health Science Center at San Antonio, San Antonio, TX

Epidemiological studies indicate that obesity increases the risk of postmenopausal breast cancer by approximately 50%. In the past, researchers have hypothesized that elevated estrogen synthesis by the peripheral adipose tissue may be the principal mediator of breast tumorigenesis in this population, which primarily develops estrogen receptor alpha (ERα) positive breast cancer. However, obesity is also accompanied by an elevation in growth factor and cytokine signaling, and these pathways have been linked to tumorigenesis. In addition, certain growth factor and cytokine family members can promote aromatase expression in both the epithelial and stromal tumor compartments. Consequently, we hypothesized that obesity increases the risk of postmenopausal breast cancer via elevated aromatase expression and/or activity in the local mammary tissue.

To test our hypothesis, we investigated how ERα activity in mammary epithelial cells was influenced by adipose stromal cells (ASC) cultured under obesity-associated conditions, including high cell density and exposure to elevated levels of circulating growth factors and cytokines. For the latter condition, sera was obtained from postmenopausal women, pooled by BMI category (lean: 18.5-24.9; obese: ≥30), and applied to the ASC, which were originally derived from women undergoing reduction mammoplasty. High ASC density was achieved via the protocol previously published by Dr. Li. Preliminary data indicated that both elevated cell density and sera from obese postmenopausal women induces greater aromatase expression in ASC, indicating that multiple factors may be contributing to the increased local aromatase expression seen with obesity. We are currently exploring the signaling pathways responsible for obesity’s upregulation of ASC aromatase expression and will present these results at the meeting. Intriguingly, exposure to conditioned media from both the high density and obese sera-exposed ASC enhanced ERα activity in MCF-7 mammary epithelial cells, independent from exogenous estradiol but dependent on the presence of androgens, suggesting an important role for the aromatase enzyme in this observation. To expand on this finding, we plan to investigate the effect of ASC conditioned media on different markers of cancer aggression, including proliferation and survival, and assess the degree to which these effects depend on estradiol. Through further examination of obesity’s impact on signaling pathways in both the epithelial and stromal tumor compartments, we ultimately hope to identify more effective chemopreventive and therapeutic regimens for the high-risk obese postmenopausal population.

**Estrogen-Related Receptor α Mediates Insulin-Like Growth Factor-1 Dependent Migration in Breast Cancer Cells.**

Fettig-Anderson LM, Oh AS, Yee D. University of Minnesota, Minneapolis, MN

The orphan nuclear estrogen-related receptors (ERR) have homology to steroid hormone receptors. Unlike classical steroid hormone receptors, ERs do not have known ligands but are transcriptionally activated upon binding to nuclear receptor coregulators such as PGC1α, PGC1β, and PPRC1. ERRs regulate energy metabolism and are accordingly expressed in tissues that require high energy production. ERRs recognize their own ERRE (estrogen-related receptor response element) gene promoters, but can also activate transcription viaERE (estrogen receptor response element) promoters, representing the ability of ERRs to cross participate in ERα regulatory pathways in the absence of estrogen. Of the three family members (α,β,γ), ERRα is the most highly expressed in breast tissue. ERRα expression was found to be increased in ERα negative breast cancers and associated with poor prognoses. ERRα and its coactivators can increase the expression of a critical mediator of breast tumor angiogenesis and metastasis, VEGFA. We have previously shown that VEGFA is regulated by insulin and IGF receptor activation and hypothesized that ERRα may be a mediator of this finding. We therefore explored whether ERRα and its coactivators are necessary for IGF-1/insulin dependent regulation of VEGFA and cell migration. REDa was expressed in breast cancer cell lines, but no correlation was observed with breast cancer subtypes. Reducing endogenous ERRα levels by shRNA reduced IGF-1-dependent migration in MDA-MB-231 cells. These results were confirmed using an ERRα specific inverse agonist (XCT-790), which also inhibited MDA-MB-231 cell migration. Modulating ERRα mRNA levels via shRNA resulted in decreased VEGFA mRNA levels in MCF7L cells and increased VEGFA mRNA levels in MDA-MB-231 cells, while the inverse agonist XCT-790 caused an increase in VEGFA mRNA levels in both cell lines. Reducing ERRα levels did not affect the expression of the IGF1R, IRS, IRS-1, IRS-2, PI-3K-Akt-mTOR dependent signaling pathway. Neither ERRα protein nor mRNA levels were modulated by IGF-I or insulin. We conclude that ERRα is important for mediating IGF-1 dependent migration, but have shown that ERRα is not directly regulated by the IGF signaling. We will next explore the role of ERRα’s coregulators (PGC1α, PGC1β, and PPRC1) in the regulation of VEGFA by the IGF/insulin pathway given their central role in regulating ERRα’s function.

**The Relationship between Estrogen Receptor Gene Polymorphism and Mammographic Density in Postmenopausal Women.**

Baldisserrato FDG, Elias S, Silva IDG, Nazario ACP. Universidade Federal de Sao Paulo - UNIFESP-EPM, Sao Paulo, SP, Brazil

**Background**

Assess the relation between the presence of PVUII and XBAI polymorphisms in the estrogen receptor alpha gene and mammographic density in postmenopausal women.

**Methods**

For the present analysis, 189 postmenopausal women who had never used hormonal therapy and who did not have clinical or mammographic features were selected. Based on the ACR-BIRADS 2003 classification, the mammographic density was determined by three independent readers (two subjective ratings and one computerized – Adobe Photoshop 7.0 software). Blood samples were available to extract DNA according to KIT GFX â protocol. PCR-RFLP (Polymerase Chain Reaction – Restriction Fragment Length Polymorphism) was then used to identify the polymorphisms. PCR-RFLP (Polymerase Chain Reaction – Restriction Fragment Length Polymorphism) was then used to identify the polymorphisms.

**Results**

There was a high degree of agreement among the three readers for mediating IGF-1 dependent migration, but have shown that ERRα is not directly regulated by the IGF signaling. We will next explore the role of ERRα’s coregulators (PGC1α, PGC1β, and PPRC1) in the regulation of VEGFA by the IGF/insulin pathway given their central role in regulating ERRα’s function.
be classified in dense breasts group (p=0.003) and the presence of both wild alleles was associated with fibro glandular tissue replacement by fat (p=0.02).

Conclusions There was no significant association of the PVUII polymorphism in the estrogen receptor alpha gene with mammographic density (p=0.34). However, the XBAI polymorphism was observed at a higher mutated homozygous frequency in women with dense breasts and there was an increased frequency of wild-type homozygous and heterozygous women with fat-replaced breasts (p=0.01).

Insulin-Like Growth Factor I Promotes Estrogen Receptor Positive Breast Cancer Cell Proliferation, in Part, through CYP1A1 Signaling.
Rodriguez M, Becker M, Yee D, Potter D. University of Minnesota, Minneapolis, MN

Activation of the transmembrane tyrosine kinase insulin-like growth factor 1 receptor (IGF-1R) contributes to breast cancer progression. Nonetheless, the mechanisms by which the IGF-1R contributes to breast cancer progression need to be better characterized to further develop therapeutic strategies that target this pathway. It is known that cytochrome P450 monoxygenases synthesize metabolites from endogenous and exogenous sources that promote breast cancer proliferation. Here we propose that activity of the IGF-1R modulates the activity of CYP1A1 to promote breast cancer cell proliferation. We have found that IGF-1R activation by treatment with IGF1 (5nM) for 4hrs induces cytochrome P450 1A1 (CYP1A1) mRNA levels in estrogen receptor (ER) positive line T47D-CO, but not ER negative line MDA-MB-231. Treatment with IGF1 promotes the proliferation of ER positive lines T47D-CO and MCF7. Interestingly, we found that treatment with IGF1 only partially compensates the growth-inhibition induced by CYP1A1 knock down by siRNA, suggesting that IGF1 requires CYP1A1 for full promotion of cell growth. These preliminary data suggest that IGF-1 signaling functions, in part, through CYP1A1 to promote ER positive breast cancer cell proliferation. The mechanism of IGF-1 signaling through CYP1A1 is novel and may represent an effector mechanism for IGF-1. Further understanding of the role of CYP1A1 downstream of the IGF-1R may allow novel approaches for inhibition of breast cancer cell proliferation downstream of the IGF-1R.

P4-02-12
Plasma Estradiol Levels and Degree of Estrogen Receptor Positivity by Image Analysis in a Large Cohort of Breast Cancer Cases: Results from the Nurses’ Health Study.
Collins LC, Frieling GW, Ahern TP, Hu R, Hankinson SE, Tamim RM, Beth Israel Deaconess Medical Center, Boston; Harvard Medical School, Boston; Channing Laboratory, Brigham and Women’s Hospital, Boston; Harvard School of Public Health, Boston

Background: Breast cancer risk is strongly associated with endogenous reproductive hormones. There is also good evidence to suggest that endogenous estradiol levels are more strongly associated with the development of estrogen receptor (ER) positive breast cancers than with ER negative cancers. However, the degree of ER positivity in those cancers that develop is not yet established. Therefore, we sought to evaluate the proportion and intensity of tumor cells demonstrating ER positivity using image analysis in a large cohort of breast cancers for which we also had plasma estradiol levels.

Design: Tissue microarray (TMA) sections of breast cancers from women enrolled in the Nurses’ Health Study were immunostained for ER (1D5, Dako Corporation, Carpinteria, CA). Slides were then scanned using the ScanScope slide scanning system (Aperio Technologies Inc., Vista, CA) and ER staining was assessed for both intensity and percent of nuclei staining positively using a specific algorithm, Nuclear v9, which evaluates nuclear size, intensity, roundness, curvature, compactness, and elongation. Plasma samples were collected prior to the date of diagnosis for all women in the study and estradiol levels were determined by radioimmunoassay following extraction and celite column chromatography.

Results: Image analysis data for ER was available for 691 breast cancers. The mean percent of tumor cell positivity was approximately uniformly distributed, with a mean of 44.5%, (median=41.3%, max=99.6%). The proportion of tumor cells staining for ER from the TMA cores was positively associated with patient age (p=0.0001), and postmenopausal status (p=0.008), while inversely associated with tumor grade (p=0.0001). Among women with image analysis data for ER, plasma estradiol data were also available for 320 postmenopausal women. Estrogen receptor positivity (by proportion or intensity) did not vary according to plasma estradiol levels (p=0.17).

Conclusion: While high concentrations of plasma estradiol are more strongly associated with the development of estrogen receptor positive breast cancer versus estrogen receptor negative cancers, the degree of estrogen receptor positivity in the breast cancers that develop is not influenced by this variable.

P4-03-01
Stat5 regulates the P13-Kinase/Akt1 pathway during mammary gland development and promotes neoplastic transformation in a mouse model for Cowden syndrome.
Schmidt JW, Sakamoto K, Creager BA, Leone G, Wagner K-U. University of Nebraska Medical Center, Omaha, NE; Ohio State University, Columbus, OH

Background: The Jak/Stat pathway responds to extracellular signals (i.e. cytokines) to promote physiological responses at the transcriptional level. In the developing mammary gland, Jak2/Stat5 activity has also been shown to cause mammary tumors in a number of transgenic models and we have previously shown it plays a crucial role in the early neoplastic events of prolactin and ErbB2-induced tumorigenesis. However, the mechanisms and target genes by which Stat5 promotes cell survival and neoplastic transformation remain to be elucidated and are the focus of this current study.

Materials and Methods: To assess the functions of Stat5 during mammary development, gain-of-function Stat5 was expressed in a number of transgenic models and we have previously shown it plays a crucial role in the early neoplastic events of prolactin and ErbB2-induced tumorigenesis. However, the mechanisms and target genes by which Stat5 promotes cell survival and neoplastic transformation remain to be elucidated and are the focus of this current study.

Materials and Methods: To assess the functions of Stat5 during mammary development, gain-of-function Stat5 was expressed in a spatial and temporal manner within the mammary epithelial cells of double transgenic females (Wap-TATet-Ostat5SS710F model) during lactation and involution in a doxycycline (dox)-inducible manner. Mammary tissues were collected for histological examination along with mRNA, protein, and chromatin immunoprecipitation (ChIP) analyses. HC11 mouse mammary epithelial cells were infected to overexpress wildtype or gain-of-function Stat5, a constitutively active prolactin receptor, or combinations of both. Finally, the functional cooperation between Stat5 and P13-kinase/Akt signaling in promoting mammary cancer was assessed by expressing hyperactive Stat5.
specifically within the mammary epithelium of females harboring a knock-in PtenG129E mutation found in patients with Cowden Syndrome (PtenG129E MMTV-TATA TetO-Stat5S710F model).

Results: Dox-induced expression of active Stat5 during involution overrides pro-apoptotic signaling and sustains p-Akt1 levels along with expression of the PI3-kinase and Akt1, which are normally downregulated at the transcriptional and protein levels during involution. ChIP analysis revealed that Stat5 binds two consensus sites in the Akt1 promoter during lactation whereas this is lost by the second day of involution. Furthermore, Stat5 promotes the transcriptional activation of Akt1 through a novel mammary-specific promoter and this suggests a mechanism for Stat5 in cell survival both in mammary development and breast cancer. Preliminary results also suggest that forced expression of active Stat5 in the mammary glands of PtenG129E females accelerates the development of mammary intraepithelial neoplasia (MIN) lesions predisposed by the loss of PI3K/Akt inhibition.

Discussion: In this study we demonstrate that Stat5 regulates PI3-kinase/Akt1 signaling during mammary gland development and this provides a mechanism for enhancing cell survival during lactation and for allowing apoptosis through loss of this regulation during involution. These findings further suggest that Jak2/Stat5 signaling may play an important role in the development of breast cancers induced through aberrant PI3-kinase/Akt signaling (i.e. Cowden Syndrome) and that targeting Jak2/Stat5 activity might be a suitable strategy for prophylyactic intervention.

P4-03-02
High Fat Diet-Induced Postmenopausal Obesity Promotes Tumor Angiogenesis and Breast Cancer Progression in Age- Relevant Ovariectomized Mice.
Gu J-W, Young E, Patterson SG, Makey KL, Huang M, Tucker KB, Chinchar E, Miele L. University of Mississippi Medical Center, Jackson, MS

Background: Obese postmenopausal women have 50% higher risk of breast cancer than non-obese women. The mechanisms of postmenopausal obesity-induced breast cancer are poorly understood due to lack of the established animal model that mimics postmenopausal obesity related to breast cancer progression.

Material and Methods: Using age-relevant C57BL/6 mice, this study determined whether postmenopausal obesity increases VEGF expression, tumor angiogenesis, and breast tumor growth. Ovariectomy (OVX) was performed in 12 sixty week-old female mice (life span is about 140 weeks), then followed by a low-fat (5%, LF, n=6) or a high-fat (60%, HF, n=6) diet for 12 weeks. In the 8th wk of the dietary program, 10^6 E0771 (mouse breast cancer) cells were injected in the left fourth mammary gland. Tumor size was monitored using dial calipers for 4 wk. Body weights were monitored weekly. At the end of the experiment, blood samples, visceral fat, and tumors were collected for measuring VEGF expression using ELISA and intratumoral microvessel density (IMD) using CD31 immunochemistry.

Results: Body weight was significantly increased in OVX/HF mice, compared to OVX/LF group (55.3±1.7 vs. 41.5±1.5 g; P<0.01). There was a two-fold increase in the ratio of visceral fat/BW in OVX/HF mice, compared to those in OVX/LF group (0.062±0.005 vs. 0.032±0.003; P<0.01). Postmenopausal obesity significantly increased breast tumor weight over the control (4.6±2.63 vs. 1.98±0.27 g; P<0.01) and IMD (173±3.7 vs. 139±4.3 IM#/mm²; P<0.01). Tumor VEGF levels were higher in OVX/HF mice, compared to OVX/LF group (73.3±3.8 vs. 49.5±4.3 pg/mg protein; P<0.01). Plasma VEGF levels (69±7.1 vs. 48±3.5 pg/ml) and visceral fat VEGF levels (424.4±39.5 vs. 208.5±22.4 pg/mg protein) were significantly increased in OVX/HF mice, compared to OVX/LF group, respectively (n=6; P<0.01). Interestingly, adipose tissue primary culture showed that subcutaneous fat released more VEGF, compared to visceral fat (6.7±3.14 vs. 0.9±0.16 pg/mg tissue; n=6; P<0.01). The abdominal subcutaneous fat expressed more VEGF proteins than visceral fat in OVX/HF mice (692±72 vs. 431±44 pg/mg protein; n=6; P<0.01). There was a strong positive linear correlation between increased breast tumor weight and visceral fat weight in OVX mice (R²=0.7379; N=12; P<0.01). However, there was no significant difference in heart, or kidney weight/body weight ratio between postmenopausal obesity (OVX/HF) mice and the control mice (OVX/LF).

Discussion: Our observations indicate that ovariectomy plus a high fat diet with the inoculation of E0771 (mouse ER+ breast cancer) cells in female wild type >60 week old mice can mimic human obesity-induced postmenopausal breast cancer. The increased tumor angiogenesis in postmenopausal obese mice was correlated with increased breast tumor growth, adipose tissue mass, and adipokines such as VEGF. These findings support the hypothesis that postmenopausal obesity promotes tumor angiogenesis and breast cancer progression, possibly through increased adipose tissue mass and adipokines such as VEGF that could systemically and locally affect breast cancer progression.

P4-03-03
Therapeutic Sensitivities of Mouse Models of Human Breast Cancer.
Usary JE, Darr DB, Zhao W, Balletta LD, Aparicio AP, Karginova OA, Jordan JL, Perou CM. University of North Carolina, Chapel Hill, NC

Genetically engineered mouse (GEM) models have provided a wealth of information regarding the genetic causes of cancer, but their utility for preclinical drug evaluation has not been well examined. Here we have used three mammary tumor GEM models that represent three human breast cancer subtypes and have evaluated their sensitivities to chemotherapy and to three biologically targeted agents. We have selected three mouse models that resemble human breast cancer subtypes based upon common gene expression profiles; Basal-like tumors are represented by the C3(1)-T-antigen (C3-TAg) model, Luminal B tumors are represented by the MMTV-Neu model, and the P53 null transplant T11 line represents the newly described Claudin-low breast tumor subtype. On each of these models we have tested the therapeutic efficacy of: four chemotherapeutics (doxorubicin, carboplatin, paclitaxel, and cyclophosphamide), two chemotherapy combinations (carboplatin/paclitaxel and doxorubicin/cyclophosphamide), and three biologically targeted agents (erlotinib, lapatinib, and ABT-888, alone and combined with selected chemotherapy). The results from individual models were as follows: The MMTV-Neu tumors were sensitive to the single-agent chemotherapeutics carboplatin and cyclophosphamide, and cyclophosphamide dramatically increased overall survival of the MMTV-Neu mice. The targeted agents lapatinib and erlotinib were extremely effective; lapatinib produced a near complete regression in every MMTV-Neu mouse tested and both compounds lead to greatly increased survival times. In the Claudin-low T11 line, the tumors were very sensitive to cyclophosphamide. Alone and in combination with doxorubicin, cyclophosphamide was the only chemotherapeutic able to successfully cause tumor regression in this model. None of the biological inhibitors were effective as single agents in these mice, nor were they effective
in combination with chemotherapeutics other than cyclophosphamide. In the C3-Tag basal-like model, carboplatin alone and in combination with other drugs caused volume reduction in some of the tumors. Erlotinib was able to cause volume reductions in a third of the treated C3-Tag tumors, which revealed a heterogeneity of response within this GEM strain. None of the single agent treatments significantly increased overall survival in these mice. Those combination treatments that were effective showed a range of responses from tumor regression to slowed progression.

Finally, we closely examined the heterogeneous responses of the C3-Tag tumors to carboplatin/paclitaxel and performed expression profiling of sensitive and resistant tumors. We identified a gene signature from these treated mouse tumors that was able to predict pathological complete response of human patients receiving multagent taxane-containing neoadjuvant chemotherapy regimens. These results show that genomically selected GEM models can recapitulate findings seen in human tumors (like lapatinib responsiveness in HER2+ tumors and carboplatin sensitivity in basal-like tumors) and that GEM models can potentially be used to develop biomarkers and to test new drug combinations prior to their being tested in humans.

P4-03-04
Identification of Molecular Targets for Cancer-Initiating Cells Using a Triple-Negative Breast Cancer Mouse Model.
Kai K, Iwamoto T, Pusztai L, Hortobagyi GN, Saya H, Ueno NT. The University of Texas MD Anderson Cancer Center, Houston, TX; Institute for Advanced Medical Research, Shinjuku-ku, Tokyo, Japan

Background: Triple-negative breast cancer (TNBC), which is negative for estrogen receptor, progesterone receptor, and HER2, cannot be targeted with hormonal or anti-HER2 agents and frequently relapses. Thus, innovative molecular targeted therapies for TNBC are needed. Cancer-initiating cells (CICs) play a crucial role in tumor recurrences. TNBC has a much higher proportion of CICs compared with the other breast cancer subtypes, reflecting TNBC’s clinical aggressiveness. However, qualitative or molecular traits of TNBC CICs have not been fully elucidated. We established a TNBC mouse model that successfully recapitulated human-like TNBC in vivo (SABCs 2010 abstract P1-03-02). We here report the phenotypes and molecular features of CICs in our TNBC mouse model. Methods: We created this animal model by transferring Hras(L146V) into Ink4a/Arf-knockout (KO) mouse mammary epithelial cells (MECs) in vitro and inducing tumors in mammary fat pads of recipient mice. The induced TNBCs were digested, and single suspended cells were reacted with antibodies to candidate CIC markers CD29, CD24, CD44, Sca1, CD61, and CD49f. Expression patterns of the tumor cells were analyzed by FACS. The induced TNBCs were CICs in our model. Genome-wide expression patterns for CD49f dividing cells than that of CD49f dividing cells. We thus determined that CD49f cells were CICs in our model. Genome-wide expression patterns for CD49f cells and CD49f cells were compared by paired t-test, and over- and underexpressed genes in CD49f cells were functionally annotated by Ingenuity pathway analysis. The top-ranked bioprocess of overexpressed genes in CD49f cells was hepatic satellite cell activation (HSMA), followed by pantothenal and Coenzyme A biosynthesis, and HER2 signaling in breast cancer. HSMA is known to result in liver fibrosis due to collagen deposits in response to liver damage. In CD49f cells in our model, collagen family proteins and the upstream endothelin-A receptor were overexpressed and significantly correlated with HSMA. Conclusion: We identified CICs in a mouse TNBC model and revealed their molecular profile. We plan to analyze expression of HSMA-associated proteins in human TNBC. Our first step is to determine whether endothelin-A receptor is a therapeutic target in human TNBC.

P4-03-05
Development of an Inducible Estrogen Receptor Co-Activator PELP1 Mammary Tumor Model.
Cortez VA, Newallo D, Chodosh LA, Tekmal RR, Vadlamudi RK. The University of Texas Health Science Center at San Antonio, San Antonio, TX; University of Pennsylvania School of Medicine, Pennsylvania, PA

Despite treatment advances, breast cancer remains the second most lethal malignant disease for women worldwide. Given the importance of estrogen receptor (ER) and hormone-dependent nature of breast cancer, pharmacologic agents were developed to either modulate ER functions or reduce circulating estrogens levels. Although targeted endocrine therapies significantly reduce mortality in patients with estrogen sensitive (ER+) tumors, both de novo and acquired resistance limits efficacy. A critical need for identifying more precise diagnostic/prognostic biomarkers and novel therapeutic targets prompted deeper investigation into ER-coregulatory protein function and regulation. ER-coactivator PELP1 mediates both nuclear and extra-nuclear estrogen signaling and crosstalk with growth factors. PELP1 is deregulated in hormone-driven cancers, associates with undifferentiated invasive breast adenocarcinomas and an independent prognostic biomarker in assessing clinical outcome of luminal-like breast cancer patients. Collectively, several studies suggest PELP1 is an ERζ co regulator with tumorigenic potential. However, the in vivo significance of PELP1 deregulation during initiation and progression of breast cancer is unknown. To determine the role of PELP1 overexpression in mammary tumorigenesis, we generated an inducible transgenic murine model. Transgene construct (pTetOPELP1) consists of a full-length human PELP1 cDNA linked to luciferase gene reporter through an internal ribosomal entry site (IRES). PELP1 transgene was purified and microinjected into mouse zygotes to generate pTetOPELP1 mice. Founder mice were identified by Southern blot analysis, of genomic DNA extracted from tail biopsies, for transgene integration through germline transmission. pTetOPELP1 mice were bred with mammary gland-specific rTA mice (MMTVrTA) to produce MMTVrTA-TetOPELP1 hitransgenic mice. Potential founder mice were identified by polymerase chain reaction and breed to establish two independent transgenic lines. Transgene expression was induced in adult female hitransgenic animals with 200mg/ mL of doxycycline administered in drinking water. Concurrent expression and activity of the luciferase gene reporter was detected specifically in the mammary gland by in vivo bioluminescence imaging, luciferase assay and RT-PCR. Mammary epithelial-specific expression of PELP1 was validated by immunohistochemistry.
and Western blot analysis. PELP1-mediated morphological and histological changes were analyzed by examining carmine-stained whole mounts and H&E-stained mammary glands sections. Our early findings with MMTVrtTA-TetOPELP1 bitransgenic mice (n=30) early preneoplastic changes and hyperplasia were evident as early as 12 weeks and the formation of mammary tumors by 8 months of age following PELP1 induction by doxycycline treatment. By utilizing the tetracycline-regulatory system, we created a novel, inducible and mammary gland-specific PELP1-expressing transgenic model for future in vivo studies into molecular mechanisms of PELP1-mediated mammary tumorigenesis.

Identification of a Unique Mammary Cell Type Expressing Mesenchymal Markers, but Capable of Multilineage Epithelial Differentiation.
Landua JD, Lewis MT. Baylor College of Medicine, Houston, TX
We have identified a previously uncharacterized cell population within the epithelial compartment of the post-pubertal mouse mammary gland. These cells can be found as singlets or as like pairs in both the cap and body cell layer of terminal end buds (TEB) of developing ducts, and are ultimately localized in a suprabasal position distributed throughout the mature mammary ductal tree. In differentiated ducts, these cells typically extend long processes that contact multiple surrounding luminal epithelial and myoepithelial cells suggesting a function in cell-cell communication. In younger animals, identified cells do not express epithelial markers including the major cytokeratins (CK) 5, 6, 8, and 14, or E-cadherin, nor do they express myoepithelial cell markers such as smooth muscle actin or p63. However, in 20 week old non-parous females, these cells can give rise to epithelial cell types expressing CK 5, 6, 8, or 14. In transplantation assays, epithelial fragment and whole mammary gland transplantation did not indicate a major role in regenerative growth of mammary ducts. Transplantation of dissociated epithelial cells and wound-healing assays are in progress. Taken together, these observations suggest that this unique cell population possess stem cell-like features in that they are capable of self-renewal, and of giving rise to all major differentiated cell types within the mouse mammary gland.

Smoothened Function as a G-Protein Coupled Receptor in Mammary Epithelial Cells.
Villanueva H, Vishal AP, Birnbauer L, Plummer NW, Lewis MT. Baylor College of Medicine, Houston, TX; National Institute of Environmental Health Sciences, Research Triangle Park, NC
Background: Hedgehog signaling orchestrates many key developmental processes, including cell fate determination and tissue patterning in the embryo, as well as tissue homeostasis and stem cell maintenance in the adult. Aberrant hedgehog signaling has been implicated in several cancers including skin, brain, prostate and breast. Previous work in our laboratory demonstrated that overexpression of activated Smoothened (SMO), a key effector in hedgehog signaling, leads to mammary hyperplasia, and is overexpressed in DCIS and IBCs.

Hypothesis: Smoothened promotes mammary gland proliferation by functioning as a G-protein coupled receptor(GPCR) and couples to one or more members of the PTX-sensitive Gα, family of heterotrimeric G-protein subunits.

Experimental Design and Methods: Expression of Gα1, subunit(s) was tested by qRT-PCR & immunofluorescence microscopy of mammary epithelial cells (MECs) and whole mammary glands from SMO and WT mice. We analyzed mammary glands from single Gα1, subunit null mice for developmental abnormalities. Genetic studies are underway in which SMO mice are crossed to Gα1, 2, and 3 null mice.

Development and Comparative Characterization of Metastasis in Newly Developed Pre-Clinical Models of Inflammatory Breast Cancer.
Chu K, Mu Z, Alpaugh KR, Fernandez S, Freiter EM, Wu H, Zook MB, Barsky SH, Cristofanilli M, Robertson FM. The University of Texas MD Anderson Cancer Center, Houston, TX; Fox Chase Cancer Center, Philadelphia, PA; University of Nevada School of Medicine, Reno, NV; Nevada Cancer Institute, Las Vegas, NV
Background: Inflammatory breast cancer (IBC) is the most metastatic variant of breast cancer. It is associated with a poor survival rate (40% 5-year survival) despite appropriate multidisciplinary care. For such an aggressive type of cancer, IBC has been understudied, in part due to the lack of adequate numbers of cell lines and mouse models that recapitulate the human disease. To expand our understanding of IBC, we have obtained all of the previously developed and characterized IBC cell lines and models including Mary-X, SUM149, SUM190, KPL-4, MDA-IBC-3 and have developed two new IBC models, designated as FC-IBC01 and FC-IBC02, using tumor cells derived from pleural effusion of IBC patients.

Materials and Methods: Each of these IBC cell lines has been luciferase (LUC)-tagged, allowing the growth of orthotopic injection or subcutaneous implantation to be evaluated by bioluminescent imaging (BLI). Alternatively, the LUC-tagged IBC cells can be injected via either intra-cardiac or intravenous route of delivery, which promotes rapid tumor colonization, resulting in both visceral and skeletal metastasis. Growth of IBC tumors can then be monitored immediately using BLI, thus eliminating the lag time needed for the physical detection of palpable tumors. BLI imaging also allows for monitoring of the kinetics and location of development of metastatic lesions. Whole transcriptome analysis was performed on IBC cell lines and xenograft tissues to define the heterogeneity of IBC as a distinct variant of breast cancer.

Results: These models have allowed us to identify micro-metastatic foci in multiple sites distant from the IBC primary tumor in each of these models of IBC and allow the quantitation of anti-tumor and anti-metastatic effects of targeted therapeutics as single agents and as the potential synergy of combinations of agents. As an example, injection of LUC-tagged IBC cell lines such as SUM149-Luc, into the left ventricle of NOD.Cg-Prkdc<sup>scid</sup> Il2rg<sup>tm1Wjl</sup>/SzJ mice allows the metabolic tumor burden to be monitored longitudinally by whole animal BLI, which can be validated at necropsy and by immunohistochemical analysis. Whole transcriptome analysis of pre-clinical models of IBC reflect the molecular subtypes observed in IBC patients, with the majority of IBC models being of the basal like, luminal B and Her2 amplified. Discussion: First time analysis of known and newly developed pre-clinical models of IBC allows a more complete analysis of IBC as a distinct variant of breast cancer. Furthermore, these approaches allow rapid evaluation of the promising targeted therapeutics identified based on whole transcriptome analysis of both IBC patient tumors and pre-clinical models developed from IBC patients. We believe that this extensive collection of LUC-tagged IBC cell lines is an invaluable tool for IBC research since the cell lines encompass the broad spectrum of IBC heterogeneity.
To elucidate downstream signaling events triggered by SMO activation, we are treating SMO derived MECs cultured in a 3D matrix and whole gland organ cultures with inhibitors of Gαi effector molecules and assessing proliferation status. We will also employ GTPγS binding assays using primary MECs from SMO overexpressing mice to test whether SMO can activate Gαi proteins in mammary gland epithelium.

**Results and Discussion:** Treatment of MMTV-Cre dependent SMO hyperplasias with pertussis toxin (PTX), a potent inhibitor of Gαi family of G-protein signaling, significantly attenuates mammary gland hyperproliferation. This result supports the hypothesis that Smoothened functions as a GPCR interacting with one or more members of the Gαi family.

We have now found that Gαs and Gαi3 null mice display an increased number of terminal end buds and a more completely filled fat pad relative to WT control littermates. Our data suggest that SMO-expressing cells induce proliferation of neighboring WT cells and that low-level proliferation in SMO-αi3 null mice should provide evidence that these two proteins interact in the developing mammary gland. When associated with biochemical data, these studies ought to provide functional insight into the mechanism behind SMO-driven mammary hyperplasias.

This work offers potential clinical implications towards breast cancer treatment as there exist therapeutic agents targeting the hedgehog signaling pathway in clinical trials that were developed by solely treating SMO derived MECs cultured in a 3D endocytic machinary and can have a huge impact on the cellular and coordinately elevated in ER+ve breast cancers. Specifically in the luminal B subtypes, they are significantly associated with a markedly worsened outcome. In vitro, in MCF7 cell line, we observe an increased EGFR stability and MAPK signaling in Rab25 overexpressing stable clones which could be reversed with shRNA knockdown of Rab25. Loss of either Rab25 or RCP inhibited survival and growth of MCF7 lines under serum free conditions suggesting that Rab25 can potentially facilitate growth factor independence in cancer cells. Most importantly, we report that Rab25 enhances mitochondrial ATP production in breast and ovarian cancer cells and significantly reduces acidification of the ECM. Our ongoing experiments are directed towards understanding the mechanistic link between Rab25 mediated effects on EGFR/pERK signaling and its effects on cellular metabolism.

**P4-05-02 Early Developmental Exposures to a High Carbohydrate/High Fat Diet Affect Glucose Metabolism and Mammary Cancer Susceptibility.**

*Berton TR, Lambertz I, Tian J, Johanning G, Conti C, Fuchs-Young R. UT MD Anderson Cancer Center, Smithville, TX; UT MD Anderson Cancer Center, Bastrop, TX*

**Background:** The obesity epidemic in the U.S. has substantially increased the number of people with altered glucose metabolism. Alterations in metabolic programming, resulting from early exposures can affect development, metabolism as well as propensity to later diseases, including cancer. The Warburg effect describes a mechanism by which diet-induced hyperglycemia and hyperinsulinemia can contribute to cellular transformation. To investigate the effect of a hyperinsulinemia-, hyperglycemia-inducing (HI/HG) diet on metabolic programming and susceptibility to mammary cancer, we exposed developing mouse pups during three developmental stages: gestation, lactation and post-weaning.

**Materials and Methods:** Female SENCAR mice were fed either a mildly restricted, defined, “chow like” control diet (DR) or a HI/HG, high sucrose/high fat (HS/HF) diet. At 14 weeks, both DR and HS/HF fed female mice were bred and the resulting offspring were randomized into 8 groups to model all combinations of gestational, lactational and post-weaning dietary exposures. Body weights (BW) were recorded weekly and Glucose Tolerance Tests (GTTs) were conducted on the female offspring at 10-12 weeks of age. Starting at 7-9 weeks of age, mice received 20 μg/day of DMBA or vehicle by daily gavage to induce mammary carcinogenesis.

**Results:** Animals in the DR/DR/DR (gestational diet/nursing diet/post-weaning diet) and HS/DR/DR groups had the lowest average BW and retained normal response to glucose, while mice in the DR/HS/HS and HS/HS/HS groups had the highest average BW. Interestingly, animals born to DR-fed and nursed by HS/HF mothers and weaned...
onto a HS/HF diet (DR/HS/HS) were the most glucose intolerant. In response to DMBA, animals in the different dietary regimens partitioned into high, moderate or low mammary tumor incidence groups. Mice fed consistent diets throughout gestation, lactation and post-weaning (DR/DR/DR or HS/HS/HS) had intermediate tumor incidence. However, mice exposed to DR during gestation and/or lactation and then switched to a HS/HS diet at weaning had the highest tumor incidence and shortest latency. Mice exposed to a HS/HF diet during gestation and/or lactation and then switched to a DR diet at weaning had the fewest mammary tumors and longest latency.

**Conclusion:** Our data indicate that substantial changes in the type and abundance of calories during gestation and/or lactation had long-lasting impacts on BW, glucose metabolism, and mammary tumorigenesis. Since BW did not consistently correlate with GTT results, the effects of dietary manipulation on obesity and glucose metabolism appear to be distinguishable. Results also indicate that diet-induced changes in the glucose metabolism of the mother profoundly affected tumor susceptibility in the exposed female offspring. These findings support the contention that rising levels of obesity, metabolic syndrome, and diabetes, especially in young individuals, may contribute to the increasing incidence of early onset breast cancer.

**P4-05-03**

**Mechanism Underlying Metabolic Heterogeneity in Breast Cancer Subtypes.**

Molina JR, Dennisson JB, Zhang F, Mills GB. MD Anderson Cancer Center; Houston, TX

**Background:** Several distinct subtypes of breast cancer (Luminal, Basal-like and Her-2+) have been identified by gene expression profiling of breast cancers and cell lines. Although much is known about the regulation of cell signaling in each breast cancer subtype, little is known about subtype-specific energy metabolism and its regulation. The majority of cancers, including breast cancer, acquire an accelerated metabolic index as part of the transformation process. One of the most studied metabolic changes in cancer, referred to as the Warburg effect, is the increased uptake of glucose and its conversion to lactate; which is released from the cell, thus creating an astringent tumor microenvironment with high lactate and low pH. Accumulation of lactate in the tumor microenvironment presents cancer cells with a potential rich carbon source that could be exploited when the preferred nutrient sources, glucose and glutamine, are not abundant or available. Thus uptake and conversion of lactate to pyruvate and then entry into the TCA cycle and oxidative phosphorylation could generate energy that could potentially allow cancer cells to survive until other nutrients become available or until the cancer cells can invade and migrate toward nutrient rich environments, in other words, until they spread locally and metastasize.

**Methods and Results:** Examination of 59 breast cancer cell lines shows differences in expression of numerous proteins and enzymes involved in cellular metabolism, including the lactate transporters (MCT), the enzyme lactate dehydrogenase (LDH), and glucose transporter proteins (GLUT). We found that MCT1 expression is lost in the Luminal subtype and correlates with loss of LDHB and the regulator and chaperone of MCT1, CD147 (Basigin). Conversely, MCT1 is highly expressed in Basal-like and normal cell lines, along with CD147 and LDHB. While monocarboxylate transporter proteins can transport bi-directionally, MCT1 preferentially transports lactate into the cell, while MCT4 transports lactate out of the cell. The loss of MCT1 in luminal cells suggests a distinct energy metabolism in this subtype versus basal-like cells. The basal-like subtype has been further categorized into Basal and Claudin-low subtypes. Claudin-low cells express stem-like markers such as CD44+/CD24-, EMT markers such as vimentin, and are low expressers of the Claudin proteins. We found that MCT1 and CD147 are highly expressed and differentially regulated in Claudin-low cell lines as compared to normal cells. We have evidence that high lactate (10 mM) as a sole energy source delays ATP loss and apoptosis in MCT1 expressing cells, but not in luminal cell lines that lack MCT1. Thus, claudin-low tumors may benefit from local lactate production providing an unexpected energy source.

**Arachidonic Acid-Induced Elevated Expression of 5-Lipoxygenase Is Linked to Metastatic Migration of Breast Cancer Cells.**

Roy D, De Chatterjee A, Pal R, Roychowdhury S, Das S. University of Texas at El Paso, El Paso, TX

**Background:** In invasive breast cancers, cancerous cells spread outside the ducts of the breast and metastasize to lung and other tissues. Although the rapid arachidonic acid (AA) metabolism and concomitant increase of eicosanoid molecules are involved in the proliferation and invasion of breast cancer cells, the exact mechanism by which AA metabolites regulate these phenomena are not well understood. Here, we show that leukotriene B4 (LTB4), one of the metabolites of AA, which is produced by the action of 5-lipoxygenase (5-LOX), causes the proliferation and metastatic migration of breast cancer cells.

**Material and Methods:** MDA-MB-231 (invasive breast cancer cells) and MCF7 (non-invasive breast cancer cells) were used in this study. Briefly, cells were treated with AA (100 μM) and nordihydroguaiaretic acid (NDGA, 10 μM), and the secreted eicosanoids were characterized by HPLC. Immunofluorescence microscopy was performed to elucidate the expression and intracellular localization of 5-LOX. The metastatic migration was analyzed by wound-healing assays.

**Results:** Our results suggest that while MDA-MB-231 cells produce high levels of PGE2 and PGD2, MCF7 cells synthesize excess HETE compounds (HETE5 and HETE8). Interestingly, MDA-MB-231 cells, when stimulated with AA, show the increased syntheses of LTB4 (~3 fold) and decreased PGE2 and PGD2 (~2 fold). In MCF7, on the contrary, AA treatment reduced the syntheses of all eicosanoids. Furthermore, the expression of 5-LOX in MDA-MB-231 cells was also increased by ~2 fold. We observed that AA promotes cell migration in MDA-MB-231 cells, which could be blocked by NDGA, a generic inhibitor of LOX enzymes. Because LTB4 production and its binding with BLT receptors are linked to IL-8 secretion, we measured the level of IL-8 synthesized by both MCF7 and MDA-MB-231 cells. The results suggest that MDA-MB-231 cells secrete excess IL-8 (~2 fold) when stimulated with AA, suggesting that LTB4 and IL-8 interactive pathways are important for cancer metastasis.

**Discussion:** Our results demonstrate that LTB4 synthesis is linked to the metastatic migration of MDA-MB-231 cells, and that it therefore should be considered as a target for developing new drugs for the treatment of invasive breast cancers.
P4-05-05
Imaging Mass Spectrometry Based Lipid Metabolites Analysis for Breast Cancer.
Ide Y, Nishio T, Hosokawa Y, Matsunuma R, Koizumi K, Ogura H, Shiiya N, Setou M. Hamamatsu University School of Medicine, Hamamatsu, Japan

Background:
Activation of lipid metabolism is an early event of carcinogenesis and a central hallmark of many cancers including breast cancer. Recent findings argue that stearoyl CoA desaturase-1 (SCD1), a key regulator of the fatty acid (FA) composition and the endoplasmic reticulum resident enzyme that converts saturated FA (SFA) into monounsaturated FA (MUFA) is a novel regulator of carcinogenesis. The distinctive lipids composition of membrane in cancer cells and the biological functions of SCD1, however, still remain uncertain. Imaging mass spectrometry (IMS) is a mass spectrometry-based analyzing technique that enables visualization of the individual molecules without requiring antibodies. It allows comprehensive detection of a wide range of biomolecules, such as lipids. We attempted to visualize the localization of lipids in breast cancer by IMS for better understanding of cancer proliferation.

Materials and methods:
13 specimens were obtained from the primary breast cancer patients. All were Japanese woman and aged 41-86 years (mean 61.5y.o.). Only one patient received preoperative systematic therapy. 6 were estrogen receptor (ER) and/or progesterone receptor (PgR) positive and human epidermal growth factor receptor 2 (HER2) negative, 2 were ER and/or PgR positive and HER2 positive, 2 were both ER and PgR negative and HER2 positive and 2 were triple negative. IMS:
Samples were immediately chilled in liquid Hexan and stored at -80°. All specimens were sliced into 10 μm thin sections, mounted onto one indium-tin oxide-coated glass slides (Bruker Daltonics) and then sprayed by 2,5-Dihydroxybenzoic acid. Matrix assisted laser desorption ionization (MALDI) technique was used as a soft ionization method. We used time of flight (TOF)/TOF type instrument (Ultraflex, Bruker Daltonics) and all the spectrum were acquired automatically using Fleximaging software (Bruker Daltonics). Each spectral intensity at any mass-to-charge ratio (m/z) was measured at 16 regions of interest (ROI); 13 ROI were picked up from cancerous parts and 3 were from non-cancerous parts. Spectral intensities were compared and statistical analysis was performed by Mann Whitney test. The software was also used to create two-dimensional ion-density maps.

Results:
In the cancerous parts of all the 13 specimens, two distinct peaks of the molecular ions were detected at m/z 798.5 and 810.5, which were not found in the non-cancerous parts. Median intensity of the molecular ions at m/z 798.5 and 810.5 were 38.9 and 3.18 in the cancerous part, while they were 0.84 and 1.02 in the non-cancerous part (p=0.010 and 0.015, respectively). Tandem mass spectrometry analysis for these two molecules revealed that they were two kinds of phosphatidylcholine (PC), PC (16:0/18:1) and PC (18:0/18:1). Localization of the individual PC was visualized by means of IMS, which showed that in cancerous part accumulation of PCs containing MUFA was more pronounced than those containing SFA only.

Conclusions:
Two kinds of PC containing MUFA were found to highly accumulate in cancerous parts, which may suggest involvement of SCD1 in the membrane composition regulation and cancer proliferation. Further studies may thus be warranted to explore the relation between PC localization and the SCD1 expression.

Microscopic Disease in Blood and Bone Marrow Predicts Survival in Early Stage Breast Cancer.
Lucci A, Krishnamurthy S, Lodhi A, Bhattacharyya A, Hall C, Anderson A, Bedrosian I, Singh B, Kuerer H. University of Texas MD Anderson Cancer Center, Houston, TX

Background: Disseminated tumor cells (DTCs) in the bone marrow have been identified in 30% of stage I-III breast cancer (BC) patients and predict survival. Circulating tumor cells (CTCs) in the blood predict outcome in metastatic BC, but their prognostic significance in primary BC is unclear. This study determined whether: 1) DTCs and CTCs could be identified in significant numbers of non-metastatic BC patients and 2) if these cells predict relapse-free (RFS) and overall survival (OS).

Methods: Clinical stage I-III BC patients seen at a single tertiary cancer center provided informed consent to participate in an IRB-approved study involving collection of blood (7.5 ml x 2 tubes) and bone marrow (10 ml from bilateral iliac crests), and at the time of surgery for their primary BC. DTCs were assessed using an anticytokeratin antibody cocktail (MNF 116, CK 8,18, and 19, CAM 5.2, and AE1/AE3) following ficoll enrichment and cytoospin. A positive result for DTCs was defined by presence of one or more CK-positive cells meeting morphologic criteria for malignancy. CTCs were detected using the Cell SearchTM system. A positive result was defined as the presence of one or more cells per 7.5 ml blood since a threshold for positivity has not been established in non-metastatic BC. Statistical analyses used chi-square and Fischer’s exact test.

Results: We prospectively evaluated 313 patients. Mean age was 53 years, and median follow-up was 32 months. Forty-two percent of patients (131) had T1 tumors, 36% (112) T2, 10% (30) T3, and 13% (40) had T4 disease. Forty-five percent of patients (141/312) had positive lymph nodes. DTCs were identified in 29% (91/313) and CTCs in 25% (79/313) of all patients. Seven percent (21/313) of patients had both DTCs and CTCs. In the overall cohort, 26% (83/313) patients relapsed and 15% (48/313) died. Ten percent (9/91) of DTC positive patients died compared to 3% (6/222) of those who did not have DTCs (p=0.01). Similarly, 6% (7/79) of those who had CTCs died compared to 3% (8/234) of those who did not (p=0.03). Fifteen percent (12/79) of CTC positive patients relapsed compared to 6% (14/234, P=0.01) of those who were CTC negative. Simultaneous presence of DTCs and CTCs in 25% (79/313) of all patients. Seventy percent (91/313) of patients had both DTCs and CTCs. In the overall cohort, T2 tumors had 15% (40) had T4 disease. Forty-five percent of patients (141/312) had T1 tumors, 36% (112) T2, 10% (30) T3, and 13% (40) had T4 disease. Forty-five percent of patients (141/312) had positive lymph nodes. DTCs were identified in 29% (91/313) and CTCs in 25% (79/313) of all patients. Seven percent (21/313) of patients had both DTCs and CTCs. In the overall cohort, 26% (83/313) patients relapsed and 15% (48/313) died. Ten percent (9/91) of DTC positive patients died compared to 3% (6/222) of those who did not have DTCs (p=0.01). Similarly, 6% (7/79) of those who had CTCs died compared to 3% (8/234) of those who did not (p=0.03). Fifteen percent (12/79) of CTC positive patients relapsed compared to 6% (14/234, P=0.01) of those who were CTC negative. Simultaneous presence of DTCs and CTCs was a strong predictor of RFS (log rank p=0.030, HR= 2.8, 95% C.I. 1.20- 8.10) as well as OS (log rank p=0.026, HR= 3.66, 95% C.I. 1.03- 13.00) at 2 years. Combined presence of DTCs and CTCs was a predictor of outcome and these findings persisted after adjusting for variables including hormone receptor status, HER2 status, primary tumor size, grade, and preoperative lymph node status. There was no significant correlation between DTCs and/or CTCs with other primary tumor characteristics.

Conclusions: Circulating and disseminated tumor cells can be identified in a significant number of non-metastatic breast cancer patients. Both CTCs and DTCs predicted outcome, and their combined presence was an independent predictor of survival.
**P4-06-03**  
Multiplex Gene Expression of Disseminated Tumor Cells in the Bone Marrow of Breast Cancer Patients Identifies Novel Therapeutic Targets.  
Afni R, Mudalagiriyappa C, Pillai S, Fleming T, Watson M. Washington University, St. Louis, MO  
**Background:** Disseminated tumor cells (DTCs) are detected in the bone marrow (BM) of up to 40% of breast cancer patients at the time of diagnosis and are an independent prognostic factor for recurrent disease. Present techniques for detection of DTC are often laborious, and insensitive due to the molecular heterogeneity of the DTCs. We have previously optimized and validated a novel, multiplexed gene expression technology platform, Nanostring nCounter™ (NC) which counts single molecules of RNA, for the multi-marker detection of DTCs in BM at a sensitivity of 1 cancer cell per 1 million nucleated BM cells. We now validate a 36 gene panel for the detection and molecular characterization of DTCs in BM.  
**Methods:** Hybridization probes for 36 genes whose expression are associated with breast cancer, metastasis, and/or the cancer stem cell phenotype, and which exhibit no or low expression levels in normal bone marrow by qRT-PCR were developed for the NC assay. Total RNA was isolated from whole BM collected from the right and left iliac crest from breast cancer patients and healthy volunteers. 5 ug of RNA was analyzed, in duplicate with the NC assay. BM was scored positive for expression of an individual gene if expression in duplicate samples was 2 standard deviations above mean expression in a set of 11 independent normal BM samples.  
**Results:** Bilateral BM samples were analyzed prior to any therapy from 20 patients: 8 developed metastatic disease within 2-48 months (mean of 23 months) after diagnosis, and 12 had no evidence of metastatic disease with 3-5 years follow-up. Overall, expression of at least one gene in the 36-gene multi-marker panel was detected in 17 patients (85%). There was excellent correlation between individual gene expression in both the right and left iliac crest samples from the same patient. Six of the 8 patients (75%) who developed metastatic disease had detectable expression of 1-3 genes. Two genes were commonly associated with metastatic disease development. 50% (3 of 6) of the patients who had detectable expression of EBB2 in their BM developed metastatic disease, although this did not correlate with expression in the corresponding primary tumor from the same patient. 80% (4 of 5) of the patients who expressed the hedgehog pathway gene, Ptch1, in their BM developed metastatic disease.  
**Conclusions:** Our data demonstrate the feasibility of using a 36-plex NC assay to detect gene expression associated with BM DTCs in breast cancer patients. We found expression of 2 targetable genes associated with the development of metastatic disease, ERBB2 and Ptch1. ERBB2 expression in BM did not correlate with expression in the primary tumor. The molecular diversity of gene expression observed underscores the need for a multiplexed gene expression panel. Ongoing studies are evaluating the clinical utility of this assay to detect DTCs relative to existing techniques, for predicting relapse-free survival, molecular classification, and selecting appropriate targeted therapeutics based on BM DTC profiles in breast cancer patients.

Detection of HER2 Gene Amplification in Circulating Tumor Cells and Disseminated Tumor Cells by Fluorescence In Situ Hybridization Using OncoCEE™.  
Krishnamurthy S, Bischoff FZ, Mayer JA, Wong K, Pham T, Kuerer HM, Lodhi AK, Bhattacharyya A, Hall CS, Lucchi A. University of Texas M.D. Anderson Cancer Center, Houston, TX; Biocept Laboratories, San Diego, CA  
**BACKGROUND:** The status of HER2 gene amplification in circulating tumor cells (CTCs) and disseminated tumor cells (DTCs) might provide useful information for monitoring response to trastuzumab therapy, and may provide a basis for consideration of trastuzumab in patients with HER2 negative primary tumors who have HER2 positive CTCs and/or DTCs. The majority of techniques utilized for detection of minimal residual disease are limited in their ability to allow detailed phenotypic and genotypic evaluation of the cells. We report the utility of a microfluidic platform (OncoCEE™, Biocept, San Diego) for detecting HER2 gene amplification in CTCs and DTCs in patients with non-metastatic breast cancer.  
**METHODS:** Peripheral blood (10ml) and bone marrow (BM) (1-2ml) were collected from patients with clinical stage I-III breast cancer in acid citrate dextrose solution (BD, Franklin Lakes, NJ) and anti-clumping reagent (OncoCEE-Sure™). Mononuclear cells were recovered using a Percoll density gradient method, incubated with a mixture of 10 primary capture antibodies (Abs), introduced into CEE™ microchannels, stained with fluorescent anti cytokeratin (CK) and CD45 abs and finally processed for fluorescence in situ hybridization (FISH) using probes specific to centromere 17 (spectrum green) and HER2 (spectrum range). The ratio of HER2:CEP17 >2.2 in any CK+/CD45- and CK-/CD45- cell was regarded as positive for HER2 gene amplification.  
**RESULTS:** Peripheral blood and/or BM from 78 patients (65 BM; 70 blood; 57 matched blood and BM) with T1NO(39), T1N1 (8), T2N0(12), T2N1 (2), T2N2 (1), T2N3 (3), T3N0 (2), T3N1 (2), T3N2 (1), T4N0(5), T4N1 (3), with HER2+ (n=12) and HER2- (n=58) primary invasive breast tumors were studied. The 12 patients with HER2+ primary tumors had HER2+ DTCs in 3/12 (25%) and HER2+ CTCs in 1/9 (11%) cases respectively. HER2+ DTCs and HER2+ CTCs occurred in 12/55 (24%) and in 4/63 (6%) of the patients with HER2- primary breast tumors. HER2+ CTCs and DTCs occurred simultaneously in only 2 patients and in either blood (3) or BM (13) in the remaining patients.  
**CONCLUSION:**  
1. The cell enrichment and extraction microfluidic technology (OncoCEE™) provides a sensitive platform for evaluation of HER2 gene amplification of CTCs and DTCs.  
2. HER2+ primary tumors were associated with either HER2+ CTCs or DTCs in 25% of the patients.  
3. HER2+ CTCs or DTCs occurred in 28% of patients with HER2- primary tumor.  
4. Discordant HER2 status was contributed mainly by HER2+ DTCs occurring in HER2- primary tumors.  
5. The clinical significance of evaluating the status of HER2 gene amplification in CTCs and DTCs in the management of patients with breast cancer needs to be evaluated prospectively in larger clinical trials.
P4-06-05
Prognostic Impact of Disseminated and Circulating Tumor Cells in Patients Treated for Locally Advanced Breast Cancer.
Mathiesen RR, Nesland JM, Renolen A, Lokkveik E, Anker G, Østensen B, Lundgren S, Riisberg T, Myaaland I, Kvalheim G, Lønning PE, Naume B. Oslo University Hospital The Radium Hospital, Oslo, Norway; Oslo University Hospital, Oslo, Norway; University of Bergen, Bergen, Norway; Haukeland University Hospital, Bergen, Norway; St. Olav University Hospital, Trondheim, Norway; Norwegian University of Science and Technology, Trondheim, Norway; University Hospital of Northern Norway and Institute of Clinical Medicine, University of Tromsø, Tromsø, Norway; Stavanger University Hospital, Stavanger, Norway; Oslo University Hospital, The Radium Hospital, Oslo, Norway; University of Oslo, Oslo, Norway

INTRODUCTION:
Neoadjuvant systemic therapy (NST) in breast cancer patients is an established approach to reduce tumor size prior to surgery and to assess the clinical effect of therapy on the breast cancer disease. The current study was designed to identify primary tumor resistance factors to epirubicin and paclitaxel therapy in patients with locally advanced breast cancer (Chrisanthar et al PLoSOne 2008 and 2011). As a sub-study, the incidence of disseminated tumor cells (DTCs) and circulating tumor cells (CTCs) before and after therapy, was investigated. The aim was to evaluate the prognostic impact of DTCs and CTCs as well as to evaluate the effect of NST on DTCs and CTCs.

PATIENTS AND METHODS:
Patients with locally advanced non-inflammatory breast cancer (T3-4 and/or N2) were included in the study. The patients were randomly allocated to primary treatment either with epirubicin 90mg/m² or paclitaxel 200mg/m², with cross-over design if no response/progression, followed by mastectomy and axillary dissection. Bone marrow (BM) aspiration and peripheral blood (PB) samples were collected before NST (BM1/PB1)(n=230), at the time of surgery (BM2/PB2)(n=69; logistic reasons caused reduced sampling) and 12 months after randomization (BM3/PB3)(n=162). Detection of DTCs/CTCs was performed by standard immunocytochemical analysis of 2x10⁶ mononuclear cells stained for cytokeratin by AE1AE3 antibodies. Patient outcomes were evaluated over a 10-year follow-up period. Univariate and multivariable proportional hazards models were estimated to assess the prognostic significance of DTC for disease-free survival (DFS) and overall survival (OS).

RESULTS:
Before NST (BM1) 21.3% were DTC positive, compared to 15.9% and 26.5% at BM2 and BM3, respectively. Of those that both had BM1 and BM3 performed, 68% concordance and 22% overlap among positive cases was observed. Presence of DTCs in BM3 predicted reduced DFS (HR 2.2; 95% CI 1.3-3.7; p=0.007) and OS (HR 3.0; 95% CI 1.8-5.2; p=0.001). DTC status before NST had no impact on outcome. No difference in the results was observed after exclusion of patients with limited M1 status at diagnosis (25 and 13 of those analysed for BM1 and BM3, respectively). The incidence of CTCs before NST was 4.9% compared to 1.4% and 4.3% at PB2 and PB3, respectively. Presence of CTC before NST was associated with reduced overall survival (HR 2.4; 95% CI 1.2-5.0; p=0.018), but CTC status was not significant for DFS or at other time points. In the multivariable analysis, DTC status at BM3 remained as a prognostic factor for both DFS (HR 2.0; 95% CI 1.1-3.6) and OS (HR 2.1; 95% CI 1.04-4.2).

CONCLUSION:
In patients with locally advanced breast cancer, the presence of CTCs at the time of diagnosis identified high risk patients. However, the sensitivity of the performed CTC analysis was too low for further interpretation. Presence of DTCs 12 months after neoadjuvant therapy increased the risk for relapse and death. The best clinical utility of DTC analysis appears to be as a monitoring tool during follow up, in a “window of opportunity” for selection of patients to secondary adjuvant treatment intervention within clinical trials.

P4-06-06
Morphological Categories of ICC-Detected CK+ Cells in Bone Marrow Have Different Prognostic Impact in Breast Cancer.
Borgen E, Synnestvedt M, Schirmer CB, Schlichting E, Nesland JM, Naume B. The Radium Hospital, Oslo University Hospital, Oslo, Norway; The Radium Hospital, Oslo University Hospital, Oslo, Norway; Ullevål Hospital, Oslo University Hospital, Oslo, Norway; University of Oslo, Oslo, Norway

Introduction: Morphological evaluation increases the specificity of immunocytochemical analysis (ICC) of disseminated tumor cells (DTC) in bone marrow (BM). In the Oslo1 cohort of primary breast cancer (BC) patients (pts), ICC-positive cells detected in BM were prospectively classified into 4 morphological groups: Tumor cells (TC) and un-interpretable cells (UIC, i.e. degenerated/fragmented cells), both significantly associated with reduced survival; and hematopoietic cells (HC) and questionable HC (Q-HC), not affecting outcome (Borgen 1999, Naume 2004). The present study revisits these categories, comparing their significance according to therapy and tumor subtype.

Materials and methods: Mononuclear cells (MNC) from BM collected at surgery of 761 pts were analyzed by standard ICC, including 2x10⁶ BM MNC stained for cytokeratin by AE1AE3 monoclonal antibodies, and corresponding isotype specific negative controls (neg co; 2x10⁶ BM MNC for most). Cells were classified as TC, UIC, Q-HC or HC. Primary tumor analyses included ptPn stage, grade, hormone receptor (HR) and HER2. Patients were followed for median 99 months. Survival analyses were performed by Kaplan Meyer and Cox regression analysis.

Results: Frequency of TC in specific test (AE1AE3) was 16.9%, UIC 14.0%, Q-HC 23.4% and HC 27.2%. By analyzing the entire cohort and numerically correcting for similar cells in neg co, only cells classified as TC or UIC predicted systemic relapse. Analysis of no adjuvant treated (NO-ADJ; n=390) and adjuvant treated (ADJ; n=361) pts separately, revealed that in NO-ADJ pts only those harboring Q-HC experienced reduced survival (DDFS: HR 2.2, 95% CI 1.2-4.1, p=0.01; BCSS: HR 2.7, 95% CI 1.3-5.5, p=0.006). In ADJ pts, only TC and UIC predicted relapse (HR 1.8, 95% CI 1.2-2.9, p=0.004) and death (HR 2.0, 95% CI 1.3-3.1, p=0.003). In multivariable analysis for NO-ADJ pts, presence of Q-HC by AE1AE3 remained significant (DDFS: HR 2.1, 95% CI 1.1-4.1, p=0.031; BCSS: HR 2.4, 95% CI 1.1-5.1, p=0.024). By subgroup analysis according to HR and HER2 (where available), prognostic impact of TC and UIC were observed only in HR+/HER2- subgroup (n=538; DDFS:HR 1.9, 95% CI 1.2-3.2, p=0.006; BCSS:HR 3.3, 95% CI 1.9-5.6, p=0.001), and not in HER2+(n=80), or triple negative pts (p=0.17). In contrast, presence of Q-HC was associated with worse outcome in triple negative pts (n=115; DDFS:HR 2.9, 95% CI 1.4-6.1, p=0.005; BCSS:HR 2.4, 95% CI 1.1-5.2, p=0.026), with no significant prognostic impact in the other two pts groups. Interestingly, pts harbouring ≥ 3 HC in AE1AE3 and in neg co together (8.5% of pts), had improved DDFS (HR 0.60, 95% CI 0.41-0.88, p=0.008) and BCSS (HR 0.57, CI 0.36-0.91, p=0.018) compared to those with fewer or no HC (p=0.029). Only 4.7% of pts with ≥ 3 HC experienced metastasis, versus 20.8% of the other.
Conclusion: Morphological DTC subgroups may differ in clinical significance according to biology/primary tumor subtype and therapy status. This emphasizes the importance of separate analyses of DTC categories and further DTC characterization. False positive cells, probably in the B-cell lineage, might signify an immune-related favorable clinical outcome.

P4-07-01
Circulating Tumor Cells, Disease Recurrence and Survival in Newly Diagnosed Breast Cancer.
Franken B, de Groot MR, Terstappen LWMM, Mastboom WJB, Van der Palen J, Tibbe AGJ. Medisch Spectrum Twente, Enschede, Overijssel, Netherlands; University of Twente, Enschede, Overijssel, Netherlands

Background: The presence of circulating tumor cells (CTC) is an independent prognostic factor for progression-free survival and overall survival (OS) for patients with metastatic breast cancer beginning a new line of systemic therapy. The current study was undertaken to explore whether the presence of CTC at the time of diagnosis was associated with recurrence free survival (RFS) and breast cancer related death.

Materials and Methods: In a prospective single center study, CTC were enumerated with the CellSearch system in 4 aliquots of 7.5 ml of peripheral blood of 504 patients before undergoing surgery for breast cancer between September 2003 and January 2009. Four hundred four had stage I-III disease and were followed for 6-90 months (median 48). One hundred had a benign tumor and served as a control group. Results: In the control group 15 (15%) had ≥1 CTC / 30 mL of blood. In stage I-III patients 76 (19%) had ≥1 CTC in 30 mL of blood of whom 16 (21.1%) developed a recurrence. In 328 patients with 0 CTC 38 (11.6%) developed a recurrence. Four year RFS was 88.4% for favorable CTC and 78.9% for unfavorable CTC (p =0.038). Breast cancer related death was 4.3% (14 of 328 patients) for favorable and 14.5% (11 of 76 patients) for unfavorable CTC (p = 0.001). CTC, PR receptor and stage were independent predictors of breast cancer related death in multivariate analysis. The corrected odds ratio after multivariate analysis for breast cancer related death in patients with CTC versus patients without CTC was 3.47.

Discussion: Presence of CTC in breast cancer patients before undergoing surgery with curative intent is associated with an increased risk for recurrence and breast cancer related death. This supports the notion that the presence of CTC is also important in the primary disease setting. In this study the sensitivity of the CellSearch assay was increased by a fourfold increase in blood volume and a threshold for unfavorable of ≥1 CTC in 30 mL of blood, which lead to a relatively high background in the control group. Thus an increase in specificity is desired before initiation of prospective multicenter trials as well as a more practical way to process larger blood volumes.

P4-07-02
Detection, Enrichment, Characterization and Propagation of Circulating Tumour Cells from Patients with Advanced Metastatic Breast Cancer.
MihalciouC, Lian J, Bertos N, Omeroglu A, Sebag M, DiBattista J, Li J, Chuangtai N, Park M, Kremer R. Royal Victoria Hospital/McGill University, Montreal, QC, Canada; McGill University, Montreal, QC, Canada

Background: Circulating tumour cells (CTCs) have attracted much attention lately due to their potential utility in diagnostic, therapeutic and prognostic applications. Characterization of these cells may indeed permit more targeted and individualized therapeutic approaches, as well as provide a means to monitor treatment response. Although detection of CTCs in peripheral blood (PB) is relatively easy using current methodologies, characterization of the CTC pool has proven more challenging due to their low abundance. Furthermore, in-vitro expansion of this elusive cell pool in mammospheres cultures has not yet been reported. In order to achieve a more complete characterization of CTCs and attempt to obtain live cells in sufficient quantity for in vitro expansion, we have used aphaeresis as a means to collect a large initial cell fraction from which to enrich CTCs from peripheral blood.

Methods: A cohort (n=17) of late stage breast cancer patients were first screened using 10ml PB. Peripheral blood mononuclear cells (PBMCs) were isolated using a Ficoll gradient and then enriched for CTCs by anti-CD45 negative selection using an automated system (RoboSep) based on magnetic bead separation. CTCs were detected by immunocytochemistry (ICC) for cytokeratin expression and patients classified as CTC-positive were selected for the aphaeresis procedure. Following collection of aphaeresis material (APM), PBMCs were isolated using a Ficoll gradient, enriched by automated anti-CD45 negative selection and characterized for a variety of markers by ICC, immunofluorescence and flow cytometry. CTCs were then cultured in serum-free medium as monolayers and suspensions. Recovery at the various steps of the isolation process was determined using PB from healthy subjects spiked with MCF-7 breast cancer cells and processed using the same approach.

Results: Recovery of spiked MCF-7 cells was about 40% after Ficoll and magnetic bead separation. Using this negative selection procedure 17/17 (100%) of subjects tested were positive at screening. Most patients (14/17) underwent aphaeresis and a large number (9,600 to 108,000) of enriched CTCs was recovered from APM in all patients tested, either as individual cells or as CTC clusters. Using dual immunofluorescence labelling, co-localization of the epithelial cell marker CK8 and the chemokine receptor CXCX4 was observed within CTCs. Furthermore, over 20% of CTCs were positive for both CK8 and ALDH1, indicative of a stem-like phenotype. APM-derived CTCs from all patients (14/14) could be propagated, both as attached cells and in suspension culture. They formed colonies in monolayer culture, and clusters in mammosphere culture, indicating stem cell-like properties. They replicated for at least three passages in mammosphere culture.

Conclusion: Our CTC detection and enrichment method using negative selection offers a distinct advantage over current methodologies, including collection of clusters, and the ability to grow and expand CTCs in serum-free culture conditions. Furthermore, these cells demonstrate breast cancer stem cell-like characteristics, the ability to replicate for multiple passages as mammospheres in suspensions and a metastatic signature.

P4-07-03
Identification of Triple-Negative Primary Breast Cancer Xenograft Models with High Numbers of Circulating and Disseminated Tumor Cells.
Giuliano M, Christy PI, Zhang X, Mao S, Contreras A, Lewis MI, Rimawi MF, Osborne CK, Schiff R, Trivedi MV. Baylor College of Medicine, Houston, TX; UH College of Pharmacy, Houston, TX

Background: Primary breast cancer xenografts, in which tumors are grown directly from patients and which maintain their original genotype and phenotype, have the potential to facilitate the study of tumor biology and progression. These models can also be instrumental in the discovery of novel therapeutic targets especially for the triple-negative (ER-, PR- and HER2-negative, TN) breast cancer.
TN breast cancer is associated with high numbers of circulating and disseminated tumor cells (CTCs and DTCs), which predict poor outcome in patients and may play a role in tumor progression. However, isolation and detection of human CTCs and DTCs in these xenograft models have been challenging even with EpCAM-based enrichment methods. The goal of this study was to determine if CTCs and DTCs could be identified using human pan-CK staining in a panel of triple-negative primary breast cancer xenograft lines, which could then be employed to study the biology of these cells and to test novel therapies.

**Methods:** We screened 13 stable primary transplantable xenograft lines (1-6 mice per line), established by directly transplanting ethnically diverse triple-negative tumor samples into the epithelium-free mammary fat pads of SCID/Beige mice, for the presence of CTCs and DTCs. The triple-negative status was maintained in these xenograft lines over serial passages. To detect CTCs, peripheral blood mononuclear cells (PBMCs) were isolated from the blood collected from the inferior vena cava either by Ficoll gradient or RBC lysis, with a typical yield of 500,000 PBMCs in 500 μl of blood. Subsequently, PBMCs were immunostained for the presence of CTCs, which were defined as the cells positive for cytoplasmic human pan-cytokeratin staining and nuclear (DAPI/hematoxylin) counter stain. We also flushed the femurs and tibias of 7 xenograft lines to harvest bone marrow cells (BMCs) for the detection of DTCs using the same staining procedure. A xenograft line was considered positive for CTCs or DTCs if they were detected in at least 25% of mice. The presence of lung metastases was assessed in all the xenograft lines by histological examination.

**Results:** We detected CTCs (range: 1-128/20,000 PBMCs) in 6 out of 13 xenograft lines (46%) and DTCs (range: 1-21/20,000 BMCs) in 5 out of 7 (71%) lines. Interestingly, 4 of the 5 DTC-positive lines also had detectable CTCs. High numbers of CTCs (>20/20,000 PBMCs) were found in 3 xenograft lines, one of which also had high numbers of DTCs (>20/20,000 BMCs). No human pan-CK+ cells were detected in PBMCs and/or BMCs from 5 control mice without tumors. Among 13 xenograft lines, lung metastases were found in 5 lines (38%), of which 3 had detectable CTCs or DTCs. Of the 3 xenograft lines containing high CTCs and/or DTCs, 2 had lung metastases.

**Conclusion:** In summary, human pan-CK staining can effectively detect CTCs and DTCs in isolated PBMCs and BMCs of mice bearing triple-negative primary breast cancer xenografts. These xenograft lines with detectable CTCs and DTCs may represent a valuable preclinical model for detailed characterization of human CTCs and DTCs and for the discovery of new therapeutic targets for the triple-negative breast cancer.

**P4-07-04**

**Nomogram Including Circulating Tumor Cells (CTC) Count before and during Chemotherapy for Individual Survival Prediction of Metastatic Breast Cancer Patients.**

**Bidard F-C, Hajage D, Bachelot T, Delaloge S, Brain E, Campone M, Wolp-Diniz R, Dieras V, Mathiot C, Asselin B, Pergo J-Y. Institut Curie, Paris, France; Centre Leon Berard, Lyon, France; Institut Gustave Roussy, Villejuif, France; Institut de Cancérologie de l’Ouest, Nantes, France**

**Background:** CTC count before a new line of treatment and CTC count early changes under chemotherapy have been reported as an independent prognostic marker in metastatic breast cancer in a recent pooled analysis in 841 pts (Liu M. ASCO 2011). The aim of this study was to build a prognostic tool including CTC and other parameters to assess its predictive value for progression-free survival (PFS) and overall survival (OS).

**Methods:** Data from the IC 2006-04 study were used. This prospective multicentre study included 267 metastatic breast cancer patients treated by first line chemotherapy with or without targeted therapy, in whom appropriate pre-treatment prognostic variables (age, performance status, number of metastatic sites, disease-free interval, ER, PR and HER2 status, tumor grade, LDH, serum markers, CTC count by CellSearch technique before treatment and before cycle 2) were available for statistical analysis. We constructed a multivariate Cox regression model for PFS and OS prediction. A stepwise selection process was applied to achieve the most informative and parsimonious models. Performance was measured with the C-index statistic. Internal validation was performed using leave-two-out technique.

**Results:** Four nomograms have been obtained, in two clinical settings: at inclusion (before the start of any treatment) taking into account the initial CTC count, and during treatment (before cycle 2) taking into account CTC changes under treatment. Their accuracy was good for PFS and OS prediction, with C-index ranging from 0.72 to 0.88. Internal validations allow considering a good accuracy of the models in an external population.

**Conclusion:** These clinically relevant nomograms are a simple tool for a personalized prognostic assessment including CTC assessment. Validation on independent series of patients are ongoing.

**P4-07-05**

**Comparison of PIK3CA Hot Spot Mutations in the Primary Tumor or Metastases with PIK3CA Mutations or PIK3CA Over-Expression in Circulating Tumor Cells of Metastatic Breast Cancer Patients under Sequential Palliative Therapy.**

**Aktas B, Kasimir-Bauer S, Kasper S, Derks C, Kimmig R, Schuler M, Tewes M. West German Cancer Center, University Hospital Essen, University of Duisburg-Essen, Essen, Germany**

**Background:** Stem cell like tumor cells have been implied as the active source of metastatic spread in primary tumors. To disseminate and metastasize, these cells may undergo phenotypic changes, known as epithelial-mesenchymal transition (EMT). The PI3K/AKT signaling pathway has been identified as one of the most important and most frequently mutated pathways involved in these processes. Assuming that metastasis requires a dissemination of tumor stem cells or tumor cells showing EMT, we studied 174 blood samples of 43 metastatic breast cancer patients under follow-up of palliative chemotherapy or antihormonal therapy for the presence of stemness like circulating tumor cells (sCTCs). Further, we correlated these data with the occurrence of PIK3CA mutations in sCTCs and with the detection of hot spot mutations as well as PTEN loss in primary tumors or metastases.

**Materials and Methods:** All blood samples underwent immunomagnetic enrichment using the AdnaTest BreastCancerSelect (AdnaGen AG, Germany). RNA was recovered and reverse transcribed for analysis using the AdnaTest EMT (multiplex RT-PCR for TWIST, AKT2, PI3K), and separately for the stem cell marker ALDH1 applying the AdnaTest StemCell. The identification of EMT markers was considered positive if at least one of the three markers was detected in the sample. The expression of CD34 was analyzed in a subset of samples to exclude potential interference of normal hematopoietic stem cells. The analysis of PCR products was performed by capillary electrophoresis on the Agilent Bioanalyzer 2100. The PIK3CA 3140 G/A mutation in sCTC-derived cDNA was identified by direct sequencing. PIK3CA hot spot mutations in primary tumors or
metastases were identified by direct sequencing from microdissected FFPE tumor tissue. PTEN loss (as defined as <10% of cells exhibiting positive staining) was detected by immunohistochemistry.

Results: During follow up, sCTCs were detected in 23/43 (53%) of the patients at least at one time point. ALDH1 was present in 18/43 (42%) patients, and at least one of the EMT markers was detected in 22/43 (51%) of the patients with the over-expression of PI3K (87%), AKT (96%) and TWIST (22%), respectively. Positivity for both, ALDH1 and EMT markers, was found in 15/23 (65%) of the patients. So far, analyzing one sample of each sCTC-positive patient during follow-up of the disease, there seems to be an occurrence of PIK3CA 3140 G/A mutation in sCTCs in about 25% of the patients. Examining the tissue samples, PTEN loss was found in 3/43 (7%) patients, in two of which sCTCs were present. DNA has been extracted from the dissected tumor tissues of all patients and is currently analyzed for PIK3CA mutations. The results will be available for presentation during the SABCS.

Conclusion: This study provides evidence for the presence of therapy-resistant breast cancer stem-like cells in the blood, possibly derived from the tumor or the metastases. Specific PI3K pathway inhibitors, alone or in combination therapy, may provide a therapeutic strategy for eliminating these cells to improve the prognosis of these patients.

P4-07-06
Correlation of Two Analytical Methods for Circulating Tumor Cells in Peripheral Blood of Patients with Primary Breast Cancer.
Jaeger BAS, Rack B, Jueckstock J, Salmen J, Ortman U, Lorenz R, Rezai M, Beck T, Schneeveis A, Zwingers T, Beckmann MW, Friese K, Janni W. Klinikum der Ludwig-Maximilians-Universität - Campus Innenstadt, Munich, Germany; Heinrich Heine-Universitetas, Duesseldorf, Germany; Gemeinschaftspraxis Lorenz-Hecker-Wesche, Braunschweig, Germany; Lisenkrankenhaus, Duesseldorf, Germany; RoMed Klinikum Rosenheim, Rosenheim, Germany; University Hospital Heidelberg, Heidelberg, Germany; Estimate, Augsburg, Germany; Frauenklinik der Universitaet Erlangen, Erlangen, Germany

Background: While the evidence for circulating tumor cells (CTCs) as a prognostic marker in metastatic breast cancer has been well established, there is still a lack of data in primary disease. In the SUCCESS A trial two different techniques for the detection of CTCs in early breast cancer were prospectively evaluated.

Material and Methods: SUCCESS A compared FEC-Docetaxel vs. FEC-Docetaxel-Gemcitabine and 5 vs. 2 years of treatment with zoledronic acid in primary breast cancer patients and node positive or high-risk node negative disease. Two different techniques to detect CTCs were prospectively evaluated in two consecutive, but comparable subgroups of the whole study population.

In 3515 samples the CellSearch® System (Veridex, Warren, USA) was used for CTC detection. Immunomagnetic enrichment with an EPCAM-antibody was followed by labeling with monoclonal antibodies specific for cytokeratin (8, 18, 19) and leukocytes (CD45). 2165 samples were evaluated with a manual immunocytochemistry (MICC) protocol. Cytopsins were prepared after mononuclear cell enrichment based on Oncoquick® centrifugation (greiner bioone, Friekkenhausen, Germany). Staining was performed with the monoclonal pancytokeratin antibody A45-B/B3 (Micromet, Munich, Germany) and the APAAP technique. Conventional light field microscopy (Axiohot; Zeiss, Oberkochen, Germany) was used for the detection of stained cells.

For both methods, the cut-off value for positivity was ≥ 1 CTC. All events were evaluated by two independent observers.

Results: CTCs were examined in a total number of 3243 patients before and after chemotherapy (CHT). The two subgroups evaluated with one or the other method were well-balanced regarding clinical parameters as tumor size, grading, lymph node-status, hormone receptors and Her2. Furthermore there was no significant correlation between the CTC positivity and one of these clinical parameters using CellSearch or the MICC, respectively (p > 0.05 using the chi square test each time).

Before adjuvant CHT 21.3% (424 out of 1994) and 21.1% (264 out of 1249) of the patients were found positive for CTCs using CellSearch® or the MICC, respectively, with a mean CTC level of 5.9 (range: 1 to 827) and 3.1 (range: 1 to 256).

Immediately after CHT 21.9% (333 out of 1521) and 16.5% (151 out of 916) of the patients were positive for CTCs using CellSearch® or the MICC. The mean CTC level decreased to 3.0 (range: 1 to 124) and 2.1 (range: 1 to 23) in both analytical methods.

Using CellSearch® there was a significant correlation between the presence of CTCs before CHT and disease progression (p = 0.0044), as well as survival (p = 0.0001), whereas the MICC did not predict any of these (p = 0.3143 and p = 0.0801 respectively; the chi-square test was used each time).

Conclusion: We found comparable prevalence of CTCs before and after adjuvant chemotherapy both with the CellSearch® System or the MICC. However, prognostic relevance could only be shown for CTCs detected with the CellSearch® System. This may be attributed to the high standardization and reproducibility of the automated system, as well as the additional CD45 counterstaining. According to our findings, the FDA approved CellSearch® System should be used as gold standard for CTC detection in future clinical trials.

P4-07-07
Circulating Tumor Cells Predict Survival in Non-Metastatic Breast Cancer.
Lucel A, Krishnamurthy S, Bhattacharyya A, Lodhi A, Hall C, Singh B, Anderson A, Bedrosian I, Kuerer H. University of Texas MD Anderson Cancer Center, Houston, TX

Background: Circulating tumor cells (CTCs) predict outcome in metastatic breast cancer (BC), but their prognostic significance in non-metastatic BC is unclear. This study determined whether CTCs could be identified in non-metastatic BC patients and 2) if CTCs predict relapse-free and overall survival.

Methods: Clinical stage I-III BC patients seen at a single tertiary cancer center provided informed consent to participate in an IRB-approved study involving collection of blood (7.5 ml x 2 tubes) before systemic therapy and at the time of surgery for their primary BC. CTCs were detected using the Cell SearchTM System. A positive result was defined as the presence of two or more cells per 7.5 ml blood since a threshold for positivity has not been established in primary BC. Statistical analyses were done using STATA-IC 11 software.

Results: We prospectively evaluated 291 patients. Mean age was 54 years, and median follow-up was 30 months. 54% (157) had T1 tumors, 36%(104) T2, 6% (18) T3, and 4%(12) had T4 disease; 37% (107/287) were clinically node-positive (LNs) by axillary ultrasound and FNA. Two or more CTCs were identified in 10% (29) patients. Seventy-seven percent (225) patients were hormone receptor positive, 11% (32) were HER2 positive while 16% (48) expressed no receptors. Sixteen percent (48) were tumor grade 1, 50% (143) were grade 2 and 34% (98) were grade 3. Systemic chemotherapy and/or endocrine therapy were administered in 80% (233/289) of patients. Sixty-eight
percent (167/244) of patients were post-menopausal. Additionally, there was no significant correlation between CTCs with primary tumor size, lymph node status, estrogen or progesterone receptor status, HER2 amplification or tumor grade. Thirty-eight percent (6/16) of all relapses occurred in patients with 2 or more CTCs (HR: 4.48 (95% CI 1.61-12.45), Logrank P 0.002) while 40% (4/10) of all deaths occurred in patients with 2 or more CTCs (HR: 4.54 (95% CI 1.27-16.25), Logrank P 0.011).

Conclusions: CTCs were a significant predictor of disease-free and overall survival in non-metastatic breast cancer.

P4-07-08
Subsets and Molecular Signatures of Circulating Tumor Cells in Breast Cancer Brain Metastasis.
Marchetti D, Zhang L, Wetzel M, Zaidi T, Ridgway W, He W, Groves MD, Katz RL. Baylor College of Medicine, Houston, TX; MD Anderson Cancer Center, Houston, TX

Background: Circulating tumor cells (CTCs) represent the “seeds” of intractable brain metastatic breast cancer (BMBC); however, properties of CTCs targeting the brain remain elusive. For example, the FDA-approved CTC platform (CellSearch™, Veridex, LLC) detects only CTCs positive for epithelial cell adhesion molecule (EpCAM) and cytokeratins (CKs), but is unable to capture any other CTC subtypes or analyze biomarkers of brain-homing CTCs. We hypothesized that profiling CTCs from BMBC patients might result in the identification of brain-colonizing CTC signatures.

Materials and Methods: We employed CellSearch™ and a novel technology that uses analysis of specific antigenic markers by immunofluorescence, coupled with detecting gene amplification by fluorescence in situ hybridization on the same cells; and quantification of the signal via automated scanning (FICTION; BioView Duet-3™ system).

Results: We established that our approach was feasible by performing CTC analyses on peripheral blood mononuclear cells isolated from BMBC patients or patients not possessing overt metastatic disease. We detected a differential gene amplification for human epidermal growth factor receptor1 and 2 (EGFR and HER2, respectively). Second, the number of EpCAM-positive CTCs visualized by the BioView™ platform was at least three orders of magnitude higher than one obtained from CellSearch™ CTC analyses using the same specimen. Third, we identified the presence of CTCs positive for CKs but negative for EpCAM. Conversely, high levels of pro-metastatic heparanase, in conjunction with the expression of aldehyde dehydrogenase-1 (ALDH1), a known cancer stem-cell marker, were detected in CTCs from BMBC patients; with a correlation between heparanase, ALDH1, and high EGFR amplification. Finally, extensive flow cytometric/FACS analyses validated the presence of CTC subsets negative for EpCAM and CD45, a hematolymphoid marker, however enriched for heparanase/ALDH1 expression.

Discussion: These findings indicate that the BioView™ platform not only captures more EpCAM-positive CTCs than CellSearch™ but also allows the detection of novel CTC subtypes possessing varying EpCAM levels. Importantly, they suggest that profiling CTC subtypes in patients with BMBC can be relevant towards the discovery of BMBC founder CTCs. Work is ongoing to further characterize these CTC subtypes, and to assess their abilities to metastasize to brain in xenotransplantation studies using immunodeficient mice.

P4-07-09
Automated Quantitative Assessment of HER2 Expression of Circulating Tumor Cells (CTC) in Metastatic Breast Cancer (IC 2006-04 Study).
Bidard F-C, Ligthart ST, Decraene C, Bachelot T, Delalage S, Brain E, Campone M, Pieta J-Y, Terstappen LWM, Institut Curie, Paris, France; University of Twente, Enschede, Netherlands; Centre Leon Berard, Lyon, France; Institut Gustave Roussy, Villejuif, France; Institut de Cancérologie de l’Ouest, Nantes, France

Background: Beyond quantitative CTC analysis for outcome assessment, their qualitative analysis could predict drug response and resistance. Classification of CTC and quantification of treatment targets on CTC can be subjective as they are morphologically heterogeneous. Current HER2 fluorescence assessment methods rely on a visual comparison between CTC images and external controls (cells lines) and are poorly reproducible. We report an automated classification and quantification of HER2 expression on CTC in a large cohort of metastatic breast cancer (MBC) patients (pts).

Materials and Methods: CTC enumeration and HER2 assessment was performed with the CellSearch® system in pts with MBC included in the prospective IC 2006-04 study (Piera, Ann Oncol 2011), before first line chemotherapy. The FITC conjugated antibody CB11 was used to identify HER2. For quantitative assessment of HER2 the breast cancer lines SKBR3 and MCF7 with known HER2 status were spiked in blood of normal donors and processed with the CellSearch system. Digital images of Cytokeratin-PE, DAPI, CD45-APC, and HER2-FITC from these samples were stored. An algorithm, previously developed in prostate cancer (Ligthart, AACR 2011), was applied on these images to automate identification of CTC. The fluorescence of the HER2 FITC channel for each CTC as well as the CD45+, DAPI+ leukocytes contained within each sample were also quantified using this algorithm. HER2 fluorescence levels of CTC were compared to HER2 status of status of pts. Results: Among 267 pts included in this study, 103 had at least 1 CTC/7.5 ml and HER2 fluorescence assessment. In these pts, correlation analysis between automated (aCTC) and manual (mCTC) CTC counts showed an excellent correlation (R²=0.978). HER2 fluorescence of CTC, varied greatly within and between pts, whereas leukocyte fluorescence was more homogeneous. The vast majority of CTC exhibited less fluorescence than SKBR3 cells, even in HER2+ pts. Primary tumor was HER2+ and HER2- in 36 and 58 pts respectively. Percentage of HER2+ CTC was higher in pts with primary HER2+ status.

## Table 1

<table>

Although a rare event, the presence within a sample of at least 1 CTC whose HER2 expression is superior to SKBR3 cells was also strongly associated with HER2+ primary tumor (N=15/36 vs. 3/58; p=0.001).

Conclusion: This study was the first to assess HER2 staining intensity in each CTC isolated from a large number of MBC pts. This was made possible by the aCTC count that was highly correlated with the mCTC count in our cohort and permitted HER2 quantification. Our study shows that HER2 staining is highly heterogeneous among CTC within each pt. These findings demonstrate the feasibility of real time quantitative assessment of treatment targets on CTC and opens a path towards personalized treatment.
P4-07-10 Circulating Tumor Cells in Newly Diagnosed Inflammatory Breast Cancer.
Mego M, Giordano A, De Giorgi U, Hsu L, Lucci A, Dawood S, Woodward WA, Ueno NT, Valero V, Andreopoulou E, Hortobagyi GN, Reuben JM, Cristofanilli M. Comenius University, School of Medicine, Bratislava, Slovakia (Slovak Republic); UT MD Anderson Cancer Center, Houston, TX; Fox Chase Cancer Center, Philadelphia, PA

Background: Inflammatory breast cancer (IBC) is one of the most aggressive forms of breast cancer and is associated with special clinical and biological features. Circulating tumor cells (CTC) are an independent prognostic factor in metastatic breast cancer for progression-free and overall survival. Previously, we showed that metastatic IBC patients treated with first and subsequent lines of chemotherapy had a lower number of CTC when compared with CTC levels of non-IBC patients; hence, the prognostic value of CTC in mIBC patients is limited. In the present study, we investigated the prognostic value of baseline CTC in newly diagnosed IBC patients.

Patients and methods: This retrospective study included 84 newly diagnosed IBC (37 stage III B or C and 47 stage IV) patients treated with neoadjuvant therapy or first line chemotherapy before January 2004 and July 2009 at the MD Anderson Cancer Center. The median age was 55 years (range, 23-78). Twenty-four (28.8%) patients were HER2 positive, 36 (42.9%) hormone receptor positive and 33 (39.3%) were triple receptor negative. CTC were detected and enumerated using the CellSearch® system before patients started chemotherapy.

Progression free survival (PFS) and overall survival (OS) were calculated from the date of CTC measurement and estimated by the Kaplan-Meier product limit method.

Results: At baseline, 64 (76.2%) patients had at least ≥1 CTC and 29 (34.5%) ≥5 CTC. Proportions of patients with stage III IBC with ≥1 CTC and ≥5 CTC were lower than those of newly diagnosed stage IV IBC patients (67.6% vs. 86%; p = 0.12 and 24.3% vs. 42.6%; p = 0.11, respectively). At a median follow up of 22.4 months (range: 4.8 – 58.3 months), 48 (57.1%) patients experienced disease progression and 26 (31.0%) had died. Patients with < 5 CTC had similar PFS (p = 0.36) and OS (p = 0.80) to those of patients with ≥5 CTC, respectively. We investigated the prognostic value of CTC ≥ 1 in stage III IBC patients, as well. There was no difference in PFS (p = 0.71) and OS (p = 0.15) in patients with CTC = 0 vs. those of patients with CTC ≥ 1, respectively. Moreover, we correlated CTC levels with prognosis, using different CTC threshold, but we observed no correlation between baseline CTC and patients’ outcome (Table 1).

Conclusions: CTC can be detected in a large proportion of patients with newly diagnosed IBC; however, baseline CTC was not prognostic for PFS and OS. Collective dissemination of cancer cells with newly diagnosed IBC; hence, the threshold for positivity has not been established in non-metastatic breast cancer.

Statistical analyses used chi-square and Fisher’s exact test.

Results: One hundred and twenty patients were prospectively enrolled. Median age was 50 years and median follow-up was 33 months. Eight percent of patients had T1 disease, 35% T2, 18% T3, and 39% T4. Fifty-three percent of patients (63/120) had hormone receptor positive disease. Thirty-two percent of patients (38/120) were HER-2 positive. Thirty percent (36/120) were triple negative. Seventy-eight percent (91/120) had lymph node positive disease. Two or more CTCs were present in 9% of patients (11/120). Of the 11 patients who died, 3 had 2 or more CTCs (P = 0.08). Of the 20 who relapsed, 6 had 2 or more CTCs (P = 0.0019).

Conclusions: Presence of two or more CTCs after NACT predicted worse relapse free survival in patients with stage I-III breast cancer.

P4-07-11 Circulating Tumor Cells after Neoadjuvant Therapy Predict Outcome in Stage I to III Breast Cancer.
Gainer S, Krishnamurthy S, Bhattacharyya A, Lodhi A, Hall C, Kuerer H, Bedrosian I, Anderson A, Singh B, Lucci A. The University of Texas MD Anderson Cancer Center, Houston, TX

Introduction: Circulating tumor cells (CTCs) predict outcome in metastatic breast cancer, but their significance is unclear in non-metastatic patients. Furthermore, it is unclear if the presence of CTCs after completion of neoadjuvant chemotherapy (NACT) predicts worse outcome. The purpose of this study was to determine if CTCs after NACT predicts worse outcome.

Methods: Clinical stage I-III breast cancer patients seen at a single tertiary cancer center provided informed consent to participate in an IRB-approved study involving collection of blood (7.5 ml x 2 tubes) at the time of surgery for their primary breast cancer. CTCs were detected using the CellSearch® system. A positive result was defined as the presence of one or more cells per 7.5 ml blood since the threshold for positivity has not been established in non-metastatic breast cancer. Statistical analyses used chi-square and Fischer’s exact test.

Results: At baseline, 64 (76.2%) patients had at least ≥1 CTC and 29 (34.5%) ≥5 CTC. Proportions of patients with stage III IBC with ≥1 CTC and ≥5 CTC were lower than those of newly diagnosed stage IV IBC patients (67.6% vs. 86%; p = 0.12 and 24.3% vs. 42.6%; p = 0.11, respectively). At a median follow up of 22.4 months (range: 4.8 – 58.3 months), 48 (57.1%) patients experienced disease progression and 26 (31.0%) had died. Patients with < 5 CTC had similar PFS (p = 0.36) and OS (p = 0.80) to those of patients with ≥5 CTC, respectively. We investigated the prognostic value of CTC ≥ 1 in stage III IBC patients, as well. There was no difference in PFS (p = 0.71) and OS (p = 0.15) in patients with CTC = 0 vs. those of patients with CTC ≥ 1, respectively. Moreover, we correlated CTC levels with prognosis, using different CTC threshold, but we observed no correlation between baseline CTC and patients’ outcome (Table 1).

Conclusions: CTC can be detected in a large proportion of patients with newly diagnosed IBC; however, baseline CTC was not prognostic for PFS and OS. Collective dissemination of cancer cells via lymphovascular tumor emboli and/or epithelial-mesenchymal transition accompanied by inadequate detection of CTC due to lack of sensitivity of current assays may account for limited prognostic value of CTC in newly diagnosed IBC. Nevertheless, sample size and study power could influence study results as well.

P4-07-12 Identification of p53 Mutation in Whole Genome DNA from Single Circulating Tumor Cells (CTCs) and Primary Breast Cancers (BC) from Patients (pts) with Metastatic Breast Cancer (MBC).

Background: CTCs represent the source of distant metastases, and are also implied in the growth/re-growth of primary BC. Molecular/gene-level characterization of similarities and discords between CTCs and BCs in pts with MBC may provide useful information for individualized treatment. Since somatic p53 mutations are frequently observed in primary BCs, we set out to assess the feasibility of identifying such mutations in CTCs from pts with MBCs, and compare the findings with those of the primary BCs from the same pts.

Material and Method: Fiber-optic Array Scanning Technology (FAST) was used for identification and location of CTCs on large glass substrates. CTCs were identified after blood samples (10 ml) from MBC pts were stained to detect CTCs via automated digital microscopy by morphology, based on immunofluorescence staining for cytokeratin and nucleus, and the absence of CD45. Single CTCs from 10 pts with MBC were identified and removed from the glass substrates. DNA was extracted, and the whole genome of isolated CTCs was amplified by using whole genome amplification method (Sigma). P53 mutations in exons 5, exon 6, exon 7 and exon 8 were assessed. As comparison, genomic DNA from formalin-fixed and paraffin-embedded (FFPE) from primary BCs of the same pts, was amplified using the same method.
Results: p53 mutations were found in 8 out of 10 CTCs, and in 4 out of 10 in primary BC samples. Of 8 mutations detected in CTCs, one silent mutation and 7 missense mutations were seen. One particular point mutation, R181L, previously assessed as functional mutation, was observed in 4 out of 8 CTCs. None of the 4 mutations (a silent mutation, one missense mutation and two different deletions) detected in tumor samples were found in CTCs. We validated that the mutations detected in CTCs were not artifacts occurring during genome amplification, by comparing p53 mutations between unamplified tumor genomic DNA vs. amplified samples.

Conclusion: Whole genome amplification based on extracting DNA from single CTCs using FAST, and identification of mutations such as those in p53, is feasible. The quantitative and qualitative discordance in detecting p53 mutations between CTCs and primary BCs may be due to CTCs acquiring new—as possible epithelial-mesenchymal transition-like-characteristics with metastatic potential as they evolve from the primary tumors or metastatic sites, or, technical issues (analyzing FFPE-preserved vs. CTCs, tumor heterogeneity) may contribute to our findings. Further assessment of the functionality of high frequent functional mutations such as R181L is warranted.

P4-07-13

Mueller V, Riethdorf S, Rack B, Wolfgang J, Fasching PA, Solomayer E, Aktas B, Kasimir-Bauer S, Mury D, Pantel K, Fehm T; University Medical Center Hamburg-Eppendorf; LMU Munich; University Medical Center Düsseldorf; Hospital Erlangen, Friedrich-Alexander University Erlangen Nuremberg, Erlangen; University Medical Center Homburg/Saar; University Medical Center Essen; University Medical Center Tübingen, All Authors on Behalf of the DETECT Study Group

Background: Over the last decade circulating tumor cells (CTC) were established as a prognostic factor in breast cancer patients. However, there are very limited studies comparing different test methods, although several are available. The DETECT trial for metastatic breast cancer patients was designed to investigate the prognostic impact of CTC. Here, we report on the prognostic relevance of CTC testing with different detection methods.

Material and Methods: Patients with primary metastatic breast cancer or metastatic recurrence were prospectively enrolled in this multicenter trial. CTC were detected using the FDA-approved Cell Search® assay applying immunocytochemistry and the RNA-based Adna Test Breast Cancer™. After a median follow-up of 11 months the first survival data are now presented.

Results: Both methods could be performed in 221 patients. Using the CellSearch™ assay 116 of 221 patients were CTC-positive based on the cut-off level of 5 cells. Presence of CTC was associated with the site of metastatic disease. The OS was 15.4 months in CTC positive pts. (95%-CI: 13.5-17.1 mths) compared to 20.4 mths. in CTC negative pts. (19.1-21.9 mths. ; p=0.001). In the multivariate analysis presence of CTC was the only independent predictor for overall survival (HR: 3.4, 95%-CI: 1.7-6.3) including tumourbiological factors, menopausal status, number and sites of metastatic disease. The progression-free survival was not correlated with CTC status in our cohort receiving different types of systemic treatment (p=0.197). When the AdnaTest Breast was performed, 88 of 221 (40%) patients were CTC positive. Except for HER2 status, no correlation could be observed between CTC positivity and any of the clinicopathological factors. CTC positivity assessed by the AdnaTest Breast has no impact on PFS and OS. A multivariate analysis was therefore not performed.

Conclusions: Currently, several different tests are available for CTC detection. Only a few tests have been approved by the FDA and been validated in large clinical trials. Therefore, it will be important to compare new techniques with the Cell Search assay.

P4-07-14
Circulating Tumor Cells (CTCs) Detection and HER2 Profiling by CellSearch® in Non-Metastatic Breast Cancer: An International Ring Study To Assess Inter-Reader Variability.

Ignatiadis M, Pierga J-Y, Campion M, Fehm T, Payne R, Rack B, Mavroudis D, Riethdorf S, Rothe F, Bessi S, Arau CM, Sandri MT, Borgen E, Kraan J, Terstappen LWM, Piccart M, Sotiriou C, Michiels S, Pantel K, Institut Jules Bordet, Brussels, Belgium; Institut Curie, Paris, France; Mayo Clinic, Rochester; Universitèts-Frauenklinik, Tübingen, Germany; Hammersmith Hospital, Imperial College, London, United Kingdom; Ludwig-Maximilians-Universität, Munich, Germany; University of Crete, Crete, Greece; University Medical Center Hamburg-Eppendorf, Hamburg, Germany; Hospital of Prato, Prato, Italy; Vall d’ Hebron, Barcelona, Spain; European Institute of Oncology, Milan, Italy; Oslo University Hospital, Oslo, Norway; Erasmus Medical Center, Rotterdam, Netherlands; University of Twente, Twente, Netherlands

Background: Preliminary results from the Success and Remagrus trials showed that CTC detection by CellSearch® has adverse prognostic value in non-metastatic breast cancer. Moreover, several investigators have characterized HER2 expression on CTCs in early breast cancer. Since the majority of CTC-positive women with non-metastatic breast cancer have only 1 CTC detected/blood volume analyzed, we wanted to evaluate the inter-reader variability in this setting. This is a crucial step before moving forward with multi-lab/multi-center prospective testing of the clinical utility of the CellSearch® technology in non-metastatic breast cancer.

Methods: Five galleries of CellSearch® images from 3 European and one US institution (a total of 307 images) were mailed to 22 independent readers from 14 European and US academic laboratories and 8 readers from two CellSearch® Veridex laboratories in a blinded fashion. These images came mainly from studies on CTC and/or HER2-positive CTC detection in breast cancer and included healthy women (negative controls), women with metastatic (positive controls) and non-metastatic disease (Pierga et al SABCS 2010, Pierga et al ASCO 2011, Riedthorf et al CCR 2010, Ignatiadis et al PLoS ONE 2011). Each reader reported the images as either CTC-negative or CTC-positive/HER2-negative or CTC-positive/HER2-positive. Kappa statistics were used to assess inter-reader agreement. The 8 Veridex readers were summarized by a majority voting system to derive a gold standard in order to compare each independent reader using discordance rates.

Results: Kappa statistics showed moderate to good agreement between independent readers depending on the gallery evaluated (gallery 1 K: 0.55, gallery 2 K:0.57 gallery 3 K:0.64, gallery 4 K:0.72, gallery 5 K:0.85). These differences were attributed to differences in scoring difficulty of each gallery. Discordances in CTC-positive vs CTC-negative events between each reader and the gold standard ranged from 2.3%-31.3% with 7 readers showing discordance rates <5%, 11 readers between 5-10%, 10 readers between 10-14% and only 2 readers showing discordance rates >14% as compared to the gold standard (median discordance rate: 9.3%). Image analysis showed that investigators with high discordance rates compared to the Veridex gold standard were not always taking into account “morphological characteristics” for defining an event as CTC-positive. Discordant
results between readers were mainly due to discordance in CTC definition and to a lesser extent in the definition of HER2-positivity. Indeed, discrepancies in assigning a CTC-positive event as either HER2-negative or HER2-positive ranged from 0.3-13.7% with 19 readers showing discordance rates <5%, 7 readers between 5-10% and 4 readers with discordance rates >10% (median discordance rate: 3.9%).

Conclusion: In non-metastatic breast cancer, we observed low discordance between most independent readers and the gold standard for defining a CellSearch® event as CTC with very few readers showing high discordance rates. Concordance can be improved through appropriate training and the use of all the tools provided by the CellSearch® system for image interpretation.

P4-07-15
Insulin-Like Growth Factor Receptor I (IGFIR) Expression in Circulating Tumor Cells (CTCs) of Patients with Early and Metastatic Breast Cancer (BC).

Spiliotaki M, Markomanolaki H, Kokotsaki M, Kallergi G, Movroudis D, Georgoulias V, Agelaki S. School of Medicine, University of Crete, Heraklion, Crete, Greece; University General Hospital of Heraklion, Heraklion, Crete, Greece

Background: Components of the insulin-like growth factor system are deregulated and IGFIR overexpression is commonly observed in BC, however the expression of the receptor in CTCs of patients with BC has not been studied.

Methods: IGFIR expression was assessed in CTCs from 65 patients with early and 101 with metastatic breast cancer before the start of adjuvant and first-line chemotherapy, respectively. Peripheral blood mononuclear cells’ (PBMCs) cytospins were stained with a monoclonal A45-B/B3 anti-cytokeratin (CK) antibody and IGFIR β-subunit anti-rabbit antibody. IGFIR(+)CK(+) CTCs were detected using immunofluorescent microscopy (Ariol system). Phosphorylated IGFIR was also evaluated after staining with phospho-IGFIR-β (Tyr1131)/Insulin Receptor-β (Tyr1146) antibody.

Results: CK(+) CTCs were detected in 23 (35.3%) patients with early and 48.5% with metastatic BC. IGFIR(+) CTCs were identified in all (100%) patients with early and in 38 (78%) out of 49 patients with metastatic BC (p=0.014). Eighteen (78%) out of 23 patients with early disease had exclusively IGFIR(+) CTCs and 5(22%) had both IGFIR(+) and CK(+) CTCs. There were no patients in whom exclusively CK(+) CTCs were identified. The respective values in patients with metastatic disease were 19 (39%), 19 (39%) and 11 (22%) (p=0.004, compared to early disease). The median percentage of the expression of IGFIR(+) and IGFIR(-) CTCs per patient was 100% (range 25-100) and 0% (range 0-75), in early and 68% (range, 0-100) and 32% (range 0-100), in metastatic disease, respectively (p=0.003). A total of 222 and 386 CTCs were detected in patients with early and metastatic disease, respectively. IGFIR expression was observed in 84% and 64% of all detected CTCs in adjuvant and metastatic patients, respectively (p=0.001). Phosphorylated IGFIR has been evaluated in PBMCs’ cytospins from 6 patients with adjuvant and 6 with metastatic disease. Interestingly, among 18 CTCs detected in early BC, all expressed phosphorylated IGFIR, whereas, among 34 CTCs identified in metastatic patients, none expressed the phosphorylated form of the receptor. The evaluation of phosphorylated IGFIR is ongoing and updated results will be presented.

Conclusions: IGFIR expression is commonly observed in CTCs of patients with BC. IGFIR expression is detected in a higher proportion of patients and in a higher proportion of the total number of CTCs identified in early compared to metastatic disease. The above observations suggest that metastatic progression is associated with loss or downregulation of IGFIR expression in breast cancer.

P4-07-16
Development of Circulating Tumor Cell-Endocrine Therapy Index in Metastatic Breast Cancer Patients.

Paolotti C, Connelly MC, Chianese DA, Brown ME, Muiñó MC, Rae JM, Thomas DG, Hayes DF. University of Michigan Comprehensive Cancer Center, Ann Arbor, MI; Veridex, LLC a J.&J. Co., Huntingdon Valley, PA

Introduction: Only ~ 50% of patients (pts) with estrogen receptor (ER) positive metastatic breast cancer (MBC) benefit from endocrine therapy (ET). Currently only clinical judgment can be used to identify pts with endocrine-refractory MBC, who are better palliated with chemotherapy. Circulating Tumor Cells (CTC) are reliably enumerated using an automated immunomagnetic system (CellSearch®; Veridex LLC). High CTC levels predict rapid progression in pts with MBC. We have developed a multi-parameter assay, the CTC-Endocrine Therapy Index (CTC-ETI) using CellSearch® that may identify pts with ER positive MBC who are unlikely to benefit from ET and may be better served with chemotherapy. CTC-ETI scores are assigned based on CTC levels coupled with the relative percent and degree of marker positivity on the CTC. We report preliminary results from a pilot single institutional study.

Methods: CellSearch® has 4 fluorescence channels. Three distinguish CTC from WBC (DAPI, anti-cytokeratin, anti-CD45). The 4th “empty” channel was used to measure ER, BCL-2, HER-2, and Ki-67 expression with fluorescent-labeled antibodies. These 4 markers reflect sensitivity (ER, BCL-2) or resistance (HER-2, Ki-67) to ET. Forty ml of blood was drawn into 4 CellSave® tubes from pts with progressive MBC. Whole blood from 4 tubes was pooled and divided into 4 different 7.5 ml aliquots of blood, which were processed and characterized for CTC counts and each of the four molecular markers using the CXC CellSearch® kit.

Results: 21 pts have been accrued to the feasibility study. One patient was ineligible. Five of 20 pts had low CTC counts (<5 CTC/7.5ml whole blood), and are expected to have a relatively favorable prognosis. CTC-ETI was successfully determined in 10 pts (50%): 2 pts had low, while 3 had intermediate, and 5 had high CTC-ETI. Technical difficulties precluded accurate CTC-ETI in the remaining 5 patients. Of note, expression of the biomarkers among CTC in single patients was heterogeneous, suggesting that future iterations of the CTC-ETI will have to consider expression variability. Further exploratory results regarding associations between CTC-ETI and outcomes will be presented.

Conclusions: ER, BCL-2, HER-2, and Ki-67 can be accurately determined on CTC using the 4th channel in the CellSearch® system to calculate CTC-ETI. We predict that lower CTC-ETI scores (low or no CTC, or CTC with high CTC ER and BCL-2 and low CTC HER-2 and Ki-67) could be associated with favorable response to ET. Successful completion of the feasibility study will lead to a prospective trial to determine if high CTC-ETI at baseline predicts resistance and rapid progression on ET in women starting a new endocrine therapy for MBC.

P4-07-17
Isolation of Highly Pure Circulating Tumor Cells (CTCs) from Metastatic Breast Cancer (MBC) Patients for Gene Expression Analysis.

Background: The paucity of information regarding the molecular nature of CTCs can be largely attributed to the difficulty of isolating these rare cells. As such, efforts on RNA profiling of CTCs have been limited to studies using immuno-enriched samples containing a high background of leukocytes.

Methods: We developed a two-step process: immunomagnetic enrichment followed by fluorescence activated cell sorting (IE/FACS) to isolate CTCs away from leukocytes and performed expression analysis on a limited panel of genes. Magnetic beads coated with EpCAM mAb were used to enrich for tumor cells. Enriched samples were then subjected to FACS using fluorescently labeled mAbs to distinguish tumor cells (EpCAM+) from leukocytes (CD45+) during sorting. CTCs and matched leukocytes were isolated from 67 sequential patients with MBC. Total RNA from isolated 20-50 cells was reverse-transcribed into cDNA. Sixty four (64) CTC-related genes from previous published reports were chosen for expression analysis. cDNA of these genes were pre-amplified and analyzed in triplicate via Taqman®-based RT-PCR in a low density array format. Statistical analysis of gene expression data was performed using Realtime Statminer®.

Results: Unsupervised hierarchical clustering analysis showed that CTCs clustered away from the leukocytes. Differential gene expression analysis revealed the up-regulation of several genes including EPCAM, MUC1, and KRT19 in CTCs (adjusted p<0.05). In addition, CTCs showed a significant down-regulation of the leukocyte-specific marker PTPRC (CD45) as well as CD44 and VIM, markers associated with stem cellness and epithelial to mesenchymal transition, respectively.

Discussion: We demonstrate the feasibility of isolation and gene expression analysis of CTCs. Molecular profiling confirmed that isolated CTCs were highly pure with little or no evidence of leukocyte contamination. This approach can serve as a non-invasive source of tumor tissue for further molecular characterization of CTCs and for monitoring of therapeutic efficacy of targeted therapies in clinical trials. This study was supported by CALGB and BCRF.

P4-07-18
Prospective Assessment of Circulating Tumor Cells and Serum Markers for PFS Prediction in Metastatic Breast Cancer.
Bidard F-C, Hajage D, Bachelot T, Delaloge S, Brain E, Campone M, Cottu P, Beuzeboc P, Mathiot C, Pierga J-Y, Institut Curie, Paris, France; Centre Léon Bérard, Lyon, France; Institut Gustave Roussy, Villejuif, France; Centre René Gauducheau, Nantes, France

Purpose: Circulating tumors cells (CTC) have been recently proposed as a new dynamic blood marker whose positivity at baseline is a prognostic factor and whose changes under treatment are correlated with progression-free survival (PFS) in metastatic breast cancer patients. However, serum markers levels are also used for the same purpose, and no clear comparison as been reported to date.

Patients and methods: The IC 2006-04 enrolled prospectively 267 metastatic breast cancer patients treated by first line chemotherapy and confirmed that CTC levels are an independent prognostic factor for PFS and Overall survival (OS). A pre-planned endpoint was to compare prospectively the positivity rates and the value of CTC (CellSearch®), of serum tumor markers (CEA, CA 15-3, CYFRA 21.1), and of serum non-tumor markers (LDH, ALP) at baseline and under treatment for PFS prediction, independently from the other known prognostic factors, using univariate analyses and concordance indexes.

Results: Table 1 shows the incidence of each of the 6 blood markers. Assessing all the 6 markers retrieved 90% of patients with at least one elevated marker at baseline. Interestingly, a combination of two markers (CA 15-3 and CYFRA 21.1, often used in lung cancer) retrieved 86% of patients with at least one marker elevated at baseline. All 6 markers were correlated with poor performance status, high number of metastatic sites and with each other. Each marker was associated, when elevated at baseline, with a significantly shorter PFS in univariate analysis.

Discussion: Markers change during treatment, assessed either between baseline and week 3 or between baseline and week 6-9, were significantly associated with PFS, as reported for CTC. Concordance indexes comparison showed no clear superiority of any of the serum marker or CTC for PFS prediction.

Conclusion: In the largest prospective CTC study in metastatic breast cancer, we previously reported that CTC count, but not serum markers, is an independent prognostic factor for PFS and overall survival. However, for the purpose of PFS prediction by measuring blood marker changes during treatment, currently available blood-derived markers (CTC and serum markers) had globally similar performances. Besides CEA and CA 15-3, CYFRA 21.1 is commonly elevated in metastatic breast cancer and has a strong prognostic value.

P4-07-19
Bone Marrow Involvement Is Associated with High Numbers of Circulating Tumor Cells in Peripheral Blood of Metastatic Breast Cancer Patients.
Grisantis S, Consoli F, Almici C, Bertagna F, Verardi R, Ungari M, Amoroso V, Pedersini B, Vassalli L, Montani E, Simoncini EL, Spedali Civili di Brescia, Brescia, Italy; University of Brescia, Brescia, Italy

Introduction: Circulating Tumor Cells (CTCs) levels are dynamic indicators of prognosis and response to therapy in metastatic breast cancer (MBC) patients (pts). CTCs levels have been reported to be higher in pts with bone than visceral metastases, respectively. However, little is known about CTCs levels in pts with BM involvement. We analysed CTC patterns in patients with either visceral, bone or BM to test the hypothesis that BM involvement would facilitate tumor cells to enter the systemic circulation as CTCs. Patients and methods: Sites and extension of metastatic disease were identified with conventional imaging. Bone metastases were diagnosed with either bone scintigraphy or CT-PET and the BM involvement was documented histologically by BM biopsy and metabolically by CT-PET. A training set of 10 pts was evaluated by both BM biopsy and CT-PET to verify the diagnostic performance of CTC-PET in identifying BM metastases (M+). We found a 100% concordance between BM biopsy and CT-PET and we therefore used CT-PET for further analyses. The CellSearch System (Veridex LLC, Raritan, NJ, USA) was used for the isolation and enumeration of CTCs in peripheral blood. The Student’s t-test and the two-way ANOVA test were used to compare means of CTCs among patients with different metastatic patterns.
Results: The CTCs mean and median scores of 129 MBC pts were analysed. Final analysis focused on 101 pts with bone M+. Thirty-three pts had bone M+ alone and 68 pts had bone and visceral M+ (including lymphnodes, brain, liver and lung/pleura). Number of metastatic sites was 1, 2, 3, 4, 5 in 30%, 37%, 25%, 6% and 2% of pts, respectively. BM involvement was documented in 27 (27%) of pts in the whole series and in 12 (33%) of pts with bone M+ alone. Mean CTCs score in the whole series was 392 (0-9993) and the median number of CTCs was 20. In the whole series, BM involvement was associated with higher mean CTCs scores (1350 vs 42, p = 0.014). In pts with bone M+ alone, mean CTCs score was 696 (0-7000) and pts with BM involvement had higher mean CTCs scores (1846 vs 39, p = 0.37). Among the different metastatic patterns, the association of bone with BM involvement and liver M+ was correlated with the highest CTCs numbers. We could not perform comparisons in the 68 pts with both bone and visceral localizations because of the variety of metastatic patterns. However, the two-way ANOVA showed a significant influence of BM involvement on mean CTCs scores in pts with different metastatic patterns (p = 0.001).

Conclusions: This work confirms that pts with bone metastases have higher numbers of CTCs than pts with visceral metastases. Extensive bone disease with BM involvement is characterized by an increase in CTCs numbers compared to bone disease without BM involvement. Bone marrow metastases are metabolically more active by CT-PET and can be accurately detected by metabolic imaging without need of BM biopsy. Further studies are ongoing.

P4-07-20
Apoptosis in Circulating Tumor Cells (CTCs) of Early and Metastatic Breast Cancer Patients.
Kallergi G, Konstantinidis G, Papadaki M, Agelaki S, Mavroudis D, Stournaras C, Georgoulas V. School of Medicine, University of Crete, Heraklion, Crete, Greece; University General Hospital of Heraklion, Heraklion, Crete, Greece.

Background: Metastasis has been associated with the presence of circulating (CTCs) and disseminated (DTCs) tumor cells in peripheral blood and bone marrow of breast cancer patients, respectively. Recent studies have confirmed that the detection of CTCs and DTCs represents a strong and independent prognostic factor for decreased disease-free and overall survival. However, it is not clear so far whether all CTCs are capable to generate metastasis or some of them are destined to die. The aim of the present study was to analyze the presence of apoptotic CTCs in patients with early and metastatic breast cancer. Patients and methods: Double staining immunofluorescent (IF) experiments were performed in peripheral blood mononuclear cells (PBMC) cytospins of patients with early (n=23) and metastatic breast cancer (n=29), prior to the initiation of adjuvant and first-line chemotherapy, respectively. Pancytokeratin A45-B/B3 antibody (as a marker of CK-positive cells) was coupled with either M30 (marker of apoptotic cells) or Ki67 (marker of proliferating cells) antibodies. Apoptotic CTCs were also evaluated using a polycaspase detection kit. Results: Significantly lower proportions of apoptotic CTCs were detected in metastatic compared to early breast cancer patients using the polycaspase kit (3% vs 49%, p = 0.0001). These results were confirmed with M30 staining (32% vs 67%, in metastatic and early disease, respectively, p = 0.023). The median percentage of apoptotic CTCs per patient was also lower in advanced compared to early disease patients (0% vs 100% with the polycaspase kit and 15% vs 70% with M30 staining). Ki67 positive CTCs were identified in 56% of early and metastatic patients, while the ratio of Ki67-positive/Total CTCs was 15% and 36% respectively. Conclusions: Apoptotic CTCs are more commonly observed in early compared to metastatic breast cancer, whereas, Ki-67 positive CTCs are more frequently encountered in metastatic disease. The differential incidence of apoptotic and proliferative CTCs in early and metastatic disease is probably related to disease progression. The evaluation of these markers in CTCs from patients with breast cancer may provide useful prognostic information and could be used to monitor the effectiveness of therapy.

P4-07-21
A Comparison of Two Methods for the Detection of Circulating Tumor Cells (CTCs) in Patients (pts) with Early and Metastatic Breast Cancer (BC): RT-PCR for Cytokeratin (CK) -19 mRNA Versus the CellSearch System.
Politaki E, Agelaki S, Apostolaki S, Perraki M, Hatzidakis D, Lianidou ES, Mavroudis D, Georgoulas V. University General Hospital of Heraklion, Heraklion, Crete, Greece; University of Athens, Athens, Greece.

Background: Different methods are available for the detection of CTCs in pts with BC, however, the variable performance of these assays, the heterogeneity of CTCs, and the possible treatment-induced alteration of the markers evaluated, imply that no ideal method currently exists. We compared the efficiency of two methods to detect CTCs in pts with BC.

Patients and Methods: Blood was obtained from 200 pts with early and 164 with metastatic BC before the start of adjuvant or first-line chemotherapy, respectively. Different aliquots of the same sample were evaluated by RT-PCR for CK-19 mRNA and by the CellSearch System. Blood samples were available after the end of adjuvant or first-line therapy in 99 and 93 pts, respectively. CTCs in 23 and 7.5 ml of blood were enumerated by CellSearch, in adjuvant and metastatic pts, respectively. Cut-off values of ≥ 1 and ≥ 2 CTCs/23 ml and ≥ 2 and ≥ 5 CTCs/7.5 ml were used. Twenty ml of blood were obtained for mRNA extraction in all RT-PCR experiments.

Results: In early BC, 18.0% of samples were positive prior to therapy by RT-PCR and 37.0% (CTC≥ 1) and 16.5% (CTC≥ 2) by CellSearch. Blood samples were available after the end of adjuvant or first-line therapy in 99 and 93 pts, respectively. CTCs in 23 and 7.5 ml of blood were enumerated by CellSearch, in adjuvant and metastatic pts, respectively. Cut-off values of ≥ 1 and ≥ 2 CTCs/23 ml and ≥ 2 and ≥ 5 CTCs/7.5 ml were used. Twenty ml of blood were obtained for mRNA extraction in all RT-PCR experiments.

Conclusions: This work confirms that pts with bone metastases have higher mean CTCs scores (1846 vs 39, p = 0.001). Overall agreement was 60.6% (CTC≥ 2) by CellSearch and 11.6% by RT-PCR (Spearman, R = -0.031, p = 0.761). Overall concordance was 62% for CTC≥ 2 (Chi-Square, p = 0.161 and p = 0.307). Post-chemotherapy, the positivity rate was 33.6% (CTC≥ 1) and 18.8% (CTC≥ 2) by CellSearch and 11.6% by RT-PCR (Spearman, R = -0.031, p = 0.761). Overall agreement was 60.6% (CTC≥ 1) and 71.4% (CTC≥ 2) (Chi-Square, p = 0.771 and p = 0.708). In the metastatic setting, 37.8% of the samples were positive by RT-PCR, and 50% (CTC≥ 2) or 32.3% (CTC≥ 5), by CellSearch (Spearman, R = 0.373, p = 0.0001). Overall agreement was 70.0% for CTC≥ 5 (Chi-Square, p = 0.0001). Post-chemotherapy, 21% were positive by RT-PCR and 13.7% and 8.4% by CellSearch for CTC≥ 2 and ≥ 5, respectively (Spearman, R = -0.194, p = 0.063). Overall concordance for CTC≥ 5 was 79.6% (Chi-Square, p = 0.017). Agreement was also observed for CTC≥ 2, pre-and post-chemotherapy (Chi-Square, p = 0.0001 and p = 0.010). The concordance rates in the adjuvant and metastatic settings are shown in Table 1.
Predictive Value of HER2 Serum Levels in Patients Treated with Lapatinib or Trastuzumab – A Translational Project in the Neoadjuvant “Geparquinto” Trial.

Witzel ID, Loibl S, von Minckwitz G, Abdallah A, Kähn T, Overkamp F, Fehm T, Schrader I, Ueber C, Kohls A, Stürbmer S, zu Eulenburg C, Unnich M, Müller V. University Medical Center Hamburg-Eppendorf, Hamburg, Germany; German Breast Group, Neuss, Germany; Helios Klinikum Berlin Buch, Berlin, Germany; University Medical Center Tübingen, Tübingen, Germany; Hospital Gelsenkirchen, Gelsenkirchen, Germany; Hospital Esslingen, Esslingen, Germany; Oncologianova, Recklinghausen, Germany; Gynäko-Onkologische Praxis Hannover, Hannover, Germany; Gynäkologische Gemeinschaftspraxis, Hildesheim, Germany; Ev. Krankenhaus, Ludwigsfelde-Teltow, Germany; Frauenklinik Rheinfeld, Rheinfeld, Germany

Background: Neoadjuvant chemotherapy (NT) has become an important approach to assess therapeutic efficacy of new treatment strategies. We observed a predictive role of serum HER2 (sHER2) with neoadjuvant trastuzumab treatment in the previous trial “Geparquattro”. Predictive markers for response to new HER2-targeted therapies are still lacking. Therefore, we investigated the role of sHER2 in the context of trastuzumab and lapatinib treatment.

Methods: The clinical trial Geparquinto incorporated either trastuzumab or lapatinib treatment combined with chemotherapy for HER2-positive breast cancer patients. Serum samples were taken at three different time points: before initiation of NT, after 4 cycles of chemotherapy with epirubicin and cyclophosphamide, and after finalization of NT with 4 cycles of docetaxel (pre-surgery). Only those patients were included in the analysis with serum available at all three time points. sHER2 levels were measured by a commercially available ELISA in 159 patients with a HER2-positive primary tumor, 77 (48%) patients were treated with trastuzumab, 82 (52%) with lapatinib. Pathological complete remission (pCR) was defined as no microscopic evidence of invasive residual tumor cells in the breast and lymph nodes.

Results: Overall pCR rate in this cohort was 28%. sHER2 levels were higher in patients with larger tumors (>5 cm), p=0.012) and positive nodal status (p=0.001). Higher pre-chemotherapy sHER2 levels were associated with higher pCR rates in the entire study cohort (OR 2.9, 95% CI 1.3-6.7, p=0.012). Additionally, in the lapatinib treated patient group, a decrease of serum levels of more than 20% after 4 cycles of chemotherapy showed a tendency to be associated with higher pCR rates (OR 7.7, 95% CI 0.8-70, p=0.071). In contrast to the finding of the previous trial Geparquattro, this was not the case in the trastuzumab-treated patient group (p=n.s.).

Conclusions: Results of this study demonstrate pre-chemotherapy sHER2 levels to be an independent predictor of response to NT with both trastuzumab and lapatinib treatment.

P4-08-02
Estradiol (E2) Mediated Secretion of Vascular Endothelial Growth Factor (VEGF) and Stimulation of T-Regulatory Cells (T-Regs): Their Role for the Worse Prognosis of Breast Cancer (BC) in Premenopause.

Roccia F, Candeloro G, Desideri G, Necoziene S, Recchia COC, Rea S. Civilized Hospital, Avezzano, AQ, Italy; University, L’Aquila, AQ, Italy

Background: E2 plays a key role in all the phases of human reproduction, including promotion of uterine basal membrane erosion, embryo implantation, placental villi development, and pregnancy maintenance. E2 mediates all these functions through the induction of VEGF secretion and stimulation of T-Regs with increased tolerance for the eutrophic embryo. BC might utilize the same pathways for its growth and for disease progression: Modulation of VEGF expression in BC cells through transcriptional activation and regulation of the peripheral development of CD4+CD25+ T-Regs cells. Both VEGF and T-Regs are important prognostic factors: In fact high levels of VEGF expression are associated with significantly worse survival in breast cancer patients, even in sub-groups expected to have a better prognosis and T-Regs quantification in breast tumors is valuable for assessing disease progression and prognosis. However few clinical studies investigated the association between E2, VEGF and T-Regs in humans. Objective of this study was to evaluate whether E2 suppression with an LH-RH analogue was able to down regulate VEGF expression, and decrease T-Regs in premenopausal patients with high-risk estrogen receptor positive (ER+) and negative (ER-) early BC. Material and Methods: From 04-2003 to 10-2008, 100 premenopausal early BC patients were entered into the study. At baseline, in the follicular phase of the menstrual cycle, after surgery, plasma E2, VEGF and T-Regs were measured. Measurements were repeated every six months. Treatment: LH-RH analogue for 5 years, chemotherapy tailored to the biological characteristics of each patient, radiation therapy, and 5-year hormonal therapy in ER+ tumors. Primary end-point was the evaluation of VEGF and T-Regs. Secondary end points were progression-free survival (PFS) and overall survival (OS). Results: Median age was 43 years (range 26-45). Median number of positive axillary nodes was 3. Thirty-eight-three patients were ER+, 17 were ER- and progesterone receptor negative (PGR-), 10 were triple negative, 20 were Herb-2 positive. Median Ki-67 was 33% (range 15%-100%). A statistically significant decrease of E2, VEGF and T-Regs was observed after 1 and 5 years, in ER+ and ER- patients. In particular, VEGF (P<0.001) and T-Regs (P<0.001) decreased in 95% of patients that were disease-free. No unexpected toxicity of chemotherapy was observed, while hot flashes and G1 osteopenia occurred after LH-RH analogues administration. After a median follow-up of 55 months (range 30-95), 5-year PFS and OS rate were 95% and 100%, respectively. Discussion: E2 deprivation with an LH-RH analogue is able to decrease plasma VEGF and T-Regs levels in premenopausal high risk ER+ and ER- BC patients. These data show how E2, through VEGF and T-Regs modulation, may be responsible for the worst prognosis that is observed in premenopausal BC.
Serum Autoantibodies to Breast Cancer Associated Antigens Reflect Tumor Biology: An Opportunity for Early Detection & Prevention?

Eiermann W, Jackson L, Murray A, Chapman CJ, Peek LJ, Widschwendter P, Allen J, Graham H, Robertson JF. Fauieklinik vom Roten, Munich, Munich, Germany; University of Nottingham, Nottingham, United Kingdom; Oncimmune Ltd, Nottingham, United Kingdom; Oncimmune LLC, De Soto, KS.

Autoantibodies (AABs) are produced as an immune response to abnormal (‘non-self’) cancer antigens. Previous studies have reported that AABs can be measured in the blood long before cancers are presently diagnosed, e.g., up to 4 years before screening mammography identified breast cancers and up to 5 years before screening CT detected lung cancers. EarlyCDT™-Lung is currently available as an aid to early detection of lung cancer in high risk patients and measures a panel of seven AABs to general cancer antigens and also lung cancer (LC) specific antigens. These AABs have previously been reported to be associated with the two main types of LC i.e., non-small cell and small cell LC. This study looked at AABs to 4 general cancer antigens to evaluate whether their levels reflected different biology in primary breast tumors.

Methods
770 patients presented with primary breast cancer to three centers (Nottingham, UK n=323; Munich, Germany n=320; Oklahoma, USA n=127); the median ages and ranges were 61 (26-82), 61 (20-88) & 65 (54-84) years, respectively. All had serum samples taken post-diagnosis and pre-treatment. The tumors were well characterized for histological grade, estrogen receptor (ER), progesterone receptor (PgR) and HER2 status. Serum samples were tested for AABs to four generic cancer antigens (Aggs) (p53, SOX2, NY-ESO-1 and Annexin1) originally included as part of Oncimmune’s EarlyCDT™-Lung assay. The AABs were measured by ELISA on the Oncimmune platform, and the EarlyCDT™-Lung cutoffs were used to determine positivity.

Results
131/770 (17%) of primary breast cancers showed elevated AAB levels to one or more of the limited panel of four generic antigens. Positivity for each AAB was correlated with histological grade, ER, PgR and HER2 status. The results, which were similar for each of the three centers, were combined, and the results are shown in Table 1 below.

Table 1.

</tbody>
</table>

p53 AAB positive cancers tended to be hormone receptor negative and HER2 positive. NY-ESO-1 positive tumors were almost all higher grade with the majority hormone receptor and HER2 negative. SOX2 positive cancers tended to have a hormone sensitive phenotype (i.e., hormone receptor positive and HER2 negative). Annexin1 positive cancers also tended to have a hormone sensitive phenotype as well as HER2 negative. The pattern was statistically different for the four AABs (p<0.001). The autoantibody profile for ER positive tumors was not statistically different from PgR positive tumors.

Conclusions
These data show that specific AABs measured in the serum reflected the biology of the breast cancers. Confirmation of this finding could, in the future, lead to using immuno-biomarkers such as these to guide early therapeutic intervention (e.g. prevention) in a targeted group of women.
P4-08-05
Diagnostic Significance of Exosomal miRNAs in the Plasma of Breast Cancer Patients.

Kwong A, Ng EKO, Leung CPH, Chan V, Li R, Wong CLP, Ma ESK. The University of Hong Kong, Pokfulam, Hong Kong; Hong Kong Sanatorium & Hospital, Hong Kong

Background and Aims: Emerging evidence that microRNAs (miRNAs) play an important role in cancer development has opened up new opportunities for cancer diagnosis. Recent studies demonstrated that released exosomes which contain a subset of both cellular mRNA and miRNA could be a useful source of biomarkers for cancer detection. Here, we aim to develop a novel biomarker for breast cancer diagnosis using exosomal miRNAs in plasma.

Methods: We have developed a rapid and novel isolation protocol to enrich tumor-associated exosomes from plasma samples by capturing tumor specific surface markers containing exosomes. After enrichment, we performed miRNA profiling on four sample sets: (1) Ep-CAM marker enriched plasma exosomes of breast cancer patients; (2) breast tumors of the same patients; (3) adjacent non-cancerous tissues of the same patients; (4) Ep-CAM marker enriched plasma exosomes of normal control subjects. Profiling is performed using PCR-based array with human microRNA panels that contain more than 700 miRNAs.

Results: Our profiling data showed that 15 miRNAs are concordantly up-regulated and 13 miRNAs are concordantly down-regulated in both plasma exosomes and corresponding tumors. These account for ~25% (up-regulation) and ~15% (down-regulation) of all miRNAs detectable in plasma exosomes. Our findings demonstrate that miRNA profile in EpCAM-enriched plasma exosomes from breast cancer patients exhibit certain similar pattern to that in the corresponding tumors. Based on our profiling results, plasma signatures that differentiated breast cancer from control are generated and some of the well-known breast cancer related miRNAs such as miR-10b, miR-21, miR-155 and miR-145 are included in our panel list. The putative miRNA biomarkers are validated on plasma samples from an independent cohort from more than 100 cancer patients. Further validation of the selected markers is likely to offer an accurate, noninvasive and specific diagnostic assay for breast cancer.

Conclusions: These results suggest that exosomal miRNAs in plasma may be a novel biomarker for breast cancer diagnosis.

P4-09-01
Identification of Poor Prognosis T1T2N0 Luminal ERBB2-ve Breast Carcinomas.

Background: To identify ER+ve ERBB2-ve duc tal T1T2N0 carcinomas associated with a poor prognosis remains challenging. We have previously demonstrated that the number of chromosomal breakpoints assessed by CGH could be a marker of worse outcome for breast carcinomas. Our aim was to validate the CGH based signature in a series of luminal duc tal and T1T2 N0 carcinoma patients with long-term clinical follow-up. Patients and methods: We analyzed 214 patients treated for an invasive ductal ER+ve ERBB2-ve carcinomas, smaller than 30mm. The training set was composed of 109 patients (10.9 years of median follow-up; 30 cases associated with a metastatic event within less than 4 years/79 control cases with no metastasis event at 5 years) and the validation set of 105 patients (10.5 years of median follow-up, 30 relapses including contra-lateral breast carcinomas, loco-regional relapses and 8 metastatic events). None of the patient received adjuvant chemotherapy. 16 received an adjuvant hormonotherapy (10 in the training and 6 in the validation groups). We genotyped the sample set with the SNP6.0 affymetrix array. After RNA normalization using Genotyping console, segmentation was performed according to the Zhang and Siegmund maximum method. In the training data set, the number of breakpoints was assessed, linked to outcome and the threshold optimising the sensitivity and specificity was determined (ROC curve). The threshold prognostic value was then tested on the validation series (Kaplan Meier analysis, log rank test, determination of relative risk and its confidence interval with a Cox model). Results: In the training set, median numbers of breakpoints were 7 in cases that experienced a metastatic event after more than 5 years and 40.5 in cases that experienced a metastatic event in less than 4 years. The threshold (Younden index) was 34 breakpoints with a sensitivity of 0.57 and a specificity of 0.94 (AUC: 0.81[0.71;0.91]). In the validation set, the outcome of patients with more than 34 breakpoints was poorer than that of patients with less than 34 breakpoints (<34 breakpoints: 19 events in out of 83 patients; >34 breakpoints: 11 events out of 22 patients with a median time to progression of 108 months; p=0.001 (logrank test); RR: 3.7 [1.73; 7.92]). In multivariate analysis, the number of breakpoints (>34 versus <34) remained the only significant parameter for prediction of outcome (RR: 3.12, CI[1.33; 7.31]. p = 0.009). Histoprostagrade, significant in univariate analysis, was not significant in multivariate analysis but was correlated with the number of breakpoints. The number of breakpoints was statistically significant for prediction of metastatic free interval (<34 breakpoints: 4 events in out of 83 patients; >34 breakpoints: 4 events out of 22 patients with a median time to progression of 108 months; p=0.009 (logrank test); RR: 5.29 [1.32; 21.26]). Conclusion: We demonstrated that patients with T1T2 (<3cm) N0 ER+Ve ERBB2-ve invasive duc tal carcinomas harboured a shorter disease free and metastatic free intervals based on genomic profiles assessed by SNP6.0 with a threshold of more than 34 breakpoints. This new approach to assess prognosis in luminal carcinomas is based on a single genomic platform, could allow identification of future therapeutic targets.

P4-09-02
G Protein-Coupled Estrogen Receptor 1 Positively Correlates with Estrogen Receptor α Expression and Increased Distant Disease-Free Survival of Breast Cancer Patients.

Background: Endocrine therapy is an important therapeutic choice for patients with estrogen receptor (ER)-α-positive breast carcinoma and functions by blocking proliferative estrogen signalling through the classical nuclear ERα. G protein-coupled estrogen receptor 1 (GPER1) is a novel membrane estrogen receptor responsible for unique estrogen responses in vitro and in vivo and that is activated by tamoxifen. The aim of this study was to determine the correlation of GPER1 with clinicopathological variables and distant disease-free survival (DDFS) in breast cancer patients treated with and without adjuvant tamoxifen, and whether the prognostic impact is dependent on ERα-status.

Material and Methods: GPER1 was investigated by immunohistochemistry in tissue microarrays of breast tumors from 208 premenopausal node-negative patients (median age 47 years; range 30-57), mainly (87%) not subjected to any adjuvant systemic treatment, and from 273 stage II patients (median age 63 years; range...
26-81), all treated with adjuvant tamoxifen for 2 years. Because almost 90% of the samples had a high percentage (>50%) GPER1-stained cells, we decided to evaluate only the staining intensity (negative, very weak, weak, moderate, and strong) for this variable. Pearson’s χ2 test for trend was used for analyzing association between GPER1 and categorical clinicopathological variables, a test for trend based on ranks for association with age and tumor size, and a log-rank test for trend for evaluating the impact of GPER1 on DDFS after 5 years of follow-up.

Results: GPER1 positively correlated with ERα (P=0.0005 and P=0.01, respectively) and progesterone receptor expression (P=0.004 and P=0.01, respectively) in both the premenopausal and tamoxifen-treated groups, but not with HER2 expression (P=0.45 and P=0.42, respectively). In the premenopausal group, GPER1 negatively correlated with tumor size (P=0.02) and positively with age (P=0.003), whereas in the tamoxifen group GPER1 did not correlate with either tumor size or age. During 5 years of follow up, 64 patients were diagnosed with distant recurrences in the tamoxifen group and 34 patients in the premenopausal group. In univariate analysis, GPER1 positively correlated with DDFS in the tamoxifen group (P=0.04), but non-significantly in the premenopausal group (P=0.08). When stratifying for ERα-status, GPER1 was a prognostic factor in the ERα-positive subgroup (P=0.02 in tamoxifen group and P=0.08 in premenopausal group), but not in the ERα-negative subgroup (P=0.57 and P=0.95, respectively).

Conclusion: We propose that GPER1 is a prognostic marker for increased DDFS in ERα-positive breast cancer. While our results suggest that GPER1 is also a tamoxifen-predictive factor, this needs to be further studied, ideally in a randomized trial comparing clinical outcome for patients treated with and without adjuvant tamoxifen.

P4-09-03
Clinical Significance of HER2+ and Triple-Negative Status in Patients with Tumor Size ≤ 1 cm and Node Negative Breast Cancer.
Shao T, Booolok SK, Boachie-Adjei K, Klein P. Beth Israel Medical Center, Continuum Cancer Centers of New York, New York, NY

Background: Data regarding the clinical significance of HER2 and triple negative status in patients with small node negative tumors is limited. Several small case series have suggested an increased risk of recurrence in patients with T1abN0M0 HER2+ or triple negative (TN) tumors. Conversely, a recent study reported that the recurrence risk for T1abN0M0 HER2+ tumors was too low to justify any adjuvant chemotherapy or trastuzumab. Therefore it remains unclear who among those with small lesions might possibly benefit from more aggressive adjuvant therapy.

Methods: We identified all node negative breast cancer patients with tumor size ≤ 1 cm diagnosed between 1/1/1995 and 12/21/2008 through our institutional breast service database. Patients were classified according to their receptor status into three groups: 1) Hormone receptor (HR)+ (ER or PR positive, HER2 negative); 2) HER2+ (IHC 3+ or FISH ≥2); and 3) TN (ER, PR, and HER2 negative). Disease-free survival (DFS) was calculated using Kaplan-Meier methods. Cox proportional hazards models were used to estimate the association between breast cancer subtypes with DFS adjusting for patient and disease characteristics.

Results: Among 658 patients with tumor ≤ 1 cm, 494 (75%) of the patients were HR+, 109 (17%) were HER2+, and 55 (8%) were TN. Two hundred thirty-two tumors were classified as T1a, and 426 were classified as T1b. Median age was 58 years (27-92). Median follow-up was 3.5 years. The 5-year DFS rates were 97.9%, 95.6%, 93.5% in patients with HR+, HER2+, and TN, respectively (P=0.026).

In multivariate analysis, TN status was associated with worse DFS (HR 3.13, 95% CI 1.26-7.73), while HER2+ was not (HR 1.64, 95% CI 0.73-3.69). In the HER2+ group, 5-year DFS was also not different between patients who received chemotherapy +/- trastuzumab (32%) and those who did not (P=0.588). We also analyzed T1aN0 and T1bN0 patients separately in order to differentiate the sub-populations of patients more likely to benefit from systemic adjuvant chemotherapy. TN status remains an independent risk factor for worse DFS in T1bN0 (HR 3.68, 95% CI 1.17-11.6), but not in T1aN0 patients.

Conclusion: TN, but not HER2+ status was associated with worse DFS in patients with T1aN0M0 tumors, and adjuvant chemotherapy should be considered in TN breast cancer patients who have T1bN0 tumors.

P4-09-04
Do Decreased CEP17 Signals Indicate the Presence of “Monosomy” in Breast Cancer? A Study of HER2 Gene Status and HER2 Immunohistochemistry.
Tse CH, Hwang HC, Goldstein LC, Kandalafy PL, Duesterhoeft SM, Kussick SL, Gown AM. PhenoPath Laboratories, Seattle, WA

Background: Detection of HER2 gene amplification by fluorescence in-situ hybridization (FISH) is one of the key tests predicting clinical response of breast cancer to trastuzumab. According to the recent ASCO/CAP guidelines for HER2 testing, the tumor is considered positive for HER2 gene amplification when the HER2/CEP17 ratio is greater than 2.2, negative if less than 1.8, and equivocal if the ratio is between 1.8 and 2.2. The need to use CEP17 as reference for HER2 assumes that the copy number of CEP17 is equivalent to “polysomy”. This study aims to examine the effect of decreased CEP17 signals interpreted as “monosomy” on HER2 protein expression and gene amplification, and to test the hypothesis that a subset of these cases may be inappropriately classified as amplified or equivocal.

Material and Methods: A total of 57 breast cancer cases were tested for HER2 gene status and HER2 Immunohistochemistry. 45 cases were stained in parallel by IHC and FISH and were selected based on HER2 signals > 2 and CEP17 signals < 1.5. To further examine chromosome 17 copy number, FISH mapping studies were performed on 5 cases, using probes for SMS, RARA, and TP53 loci which are telomeric to the CEP17 and HER2 loci. Chromosome 17 status was determined by correlating the mean copy numbers of HER2, CEP17, SMS, RARA, and TP53. A gene locus with signal number/cell between 1.4 and 2.4 was considered consistent with eusomy.

Results: Of the 57 cases, 54 were included in the HER2 ≥ 2 group (457s). Of these 54 cases, 49 cases tested positive for HER2 amplification when the HER2/CEP17 ratio was greater than 2.2, 3 cases were negative if less than 1.8, and 2 cases were equivocal if the HER2/CEP17 ratio was between 1.8 and 2.2. We performed additional FISH hybridization (FISH) to alternative chromosome 17 genes (SMS, RARA, and TP53). The number of CEP17 signals/cell of these 5 cases ranged from 1.01 to 1.15 and the HER2 signals/cell ranged from 2.05 to 2.84. In these cases when additional probes to
chromosome 17 were used as reference genes, 4/5 cases remained amplified or equivocal. One case with HER2 signals of 2.05 changed from equivocal to negative. 4/5 of these cases showed equivocal IHC (2+).

Discussion:
Application of strict ASCO-CAP guidelines on 59 “monosomy” cases showed that all were either amplified or equivocal by FISH, with the vast majority showing equivocal (2+) IHC. In cases with decreased CEP17 signals, most cases remained as “monosomy” using the alternative chromosome 17 reference genes. This may be due to deletion of the short arm of chromosome 17 or true monosomy of chromosome 17. Further studies are warranted on the cases with 2-4 HER2 signals per cell and “monosomy” in order to permit accurate determination of HER2 gene status and appropriate treatment with anti-HER2 therapy.

P4-09-05
CA15-3 Adds Prognostic Information in “Luminal” Type Breast Cancer – A Single Center Experience Evaluating 700 Patients with a Median Follow-Up of 5 Years.
Kantelhardt EJ, Vetter S, Steer S, Ruider T, Holzhausen H-J, Strauß H-G, Große R, Thomassen C, GYN/OB, Halle (Saale), Germany; Inst. of Pathology, Halle (Saale), Germany

Background: Prognostic markers are essential for the decision about individual therapy for patients with newly diagnosed breast cancer. Biological meaningful cancer types are revealed by gene expression analysis. Steroid hormone receptor (HR) and HER2 status of the tumor by immunohistochemistry (IHC) are more easily available and predominantly resemble these cancer types. The “luminal” type as HR pos. and HER2 neg., the “luminalHER2” type as HR pos. and HER2 pos., the “HER2” type as HR neg. and HER2 pos. and the “triple neg.” type as HER neg. and HER2 neg. were evaluated. Preoperative serum CA 15-3 and CEA within IHC-cancer types and outcome using our own cohort from 1999-2010.

Material and Methods: Since 1999 all patients with breast cancer were entered in our tumor registry. Patients were treated by surgery and adjuvant therapy according to national guidelines (www.ago-online.de). Data was entered into SPSS by a specially trained study nurse. Follow-up was obtained yearly using our own out-patient clinic, information from general practitioners and the general cancer registry. Informed consent was taken from the patients at time of diagnosis. CA 15-3 and CEA were defined elevated if above 25 U/ml or 4.6 µg/l respectively.

Results: Preoperative serum CA15-3 available for 1149 patients. Patients with elevated results showed a reduced 5 year disease-free survival (DFS) of 74.4% as compared to 84.7% (p=0.001). CA15-3 remained an independent prognostic factor in multivariate analysis (nodal status, grading, HR). Within HR positive disease, normal CA15-3 values predict a significantly better 5 year DFS of 89.9% compared to 79.7% (p=0.001). No significant difference was seen in HR negative patients (5 year DFS 57.5% vs 68.4%; p=n.s.). Patients with HER2 status available (n=700) were classified into biological tumor types by IHC. Significant differences in DFS were seen for “luminal” (n=435) tumors only (5 year DFS 81.0% vs 91.8% (p=0.001). Only trends of differences in DFS were seen in the other less frequent tumor types “luminalHER2” (n=90) or “triple neg.” (n=112) types. Within the “HER2” (n=63) group no discrimination by serum levels of CA15-3 was seen. CEA did not add information on prognosis.

Discussion: Decision on adjuvant therapy is increasingly based on tumor biology. Particularly, in “luminal” tumors additional prognostic information is needed to decide on adjuvant chemotherapy. CA15-3 may be an easily available, independent marker to identify patients with a higher risk of recurrence within this group. Prospective validation and comparison to molecular typing is needed.

P4-09-06
The Prognostic Value of Tumour-Stroma Ratio in Triple Negative Breast Cancer.
Moorman AM, Vink R, Heijmans HJ, van der Palen J, Kounenhoen EA. Hospital Group Twente, Almelo, Netherlands; Pathology Laboratory East Netherlands, Enschede, Netherlands; Medical Spectrum Twente, Enschede, Netherlands; Hospital Group Twente, Hengelo, Netherlands

Background: Triple-negative breast cancer constitutes one of the most challenging groups of breast cancer given its aggressive clinical behaviour, poor outcome and lack of targeted therapy. Until now, profiling techniques have not been able to distinguish between patients with good and poor outcome. Recent studies suggested an important role for stroma in tumour growth and progression. In colorectal-, oesophageal- and breast cancer, the tumour-stroma ratio was found to be of prognostic value.

Objective: to evaluate the prognostic value of the tumour-stroma ratio in triple-negative breast cancer.

Methods: During the period January 2004-2008, 124 consecutive triple negative breast cancer patients treated in our hospital were retrospectively evaluated. Routine Haematoxylin-Eosin (H&E) stained histological sections were evaluated by two investigators (kappa 0.735) for stroma percentage, growth pattern (pushing margin), necrosis and amount of lymphocytic infiltrate. Patients with less than 50% stroma were classified as stroma-low and patients with ≥50% stroma were classified as stroma-high.

Results: of 124 triple-negative breast cancer patients, 50 (40%) had a stroma-high and 74 (60%) had a stroma-low tumour. Survival analysis revealed a 5 years relapse free period (RFP) of 85% in the stroma-low and 45% in the stroma-high group. Overall survival (OS) was 89% for stroma-low and 65% in the patients with a stroma-high tumour. Both RFP and OS were significantly worse in patients with stroma-high tumours compared to stroma-low. In a multivariate cox-regression analysis, tumour stroma remained an independent prognostic variable for RFP (HR 2.39; 95% CI 1.07-5.29; p=0.033) and OS (HR 3.00; 95% CI 1.08-8.32; 0.034) when corrected for other clinical-pathological variables. In addition, tumour-stroma proved to be a strong prognostic variable when compared to nodal status, tumour grade and tumour size, with respectively a HR of 2.39 (95% CI 1.37-6.26) versus HR 2.18 (95% CI 1.06-4.48), HR 2.10 (95% CI 0.89-4.91) and HR 0.53 (95% CI 0.70-3.91) for RFP with comparable numbers for OS.

Conclusion: Tumour-stroma ratio is a strong independent prognostic variable in triple-negative breast cancer. It is easy to determine, reproducible (kappa 0.735) and can be easily incorporated into routine histological examination. This parameter optimizes risk stratification and could be target for future therapies.
P4-09-07

Breast Cancer Outcome by Combined Immunohistochemical ER/PR/HER2 Receptor Phenotype.

Introduction: We previously reported that molecular prognostic subgroup classification of operable breast cancers resembles the classification based on combined immunohistochemical expression of ER, PR and HER-2 receptors. This update represents a larger cohort with more detailed follow-up (median 5.5y).

Patients and methods: A prospective cohort of 4334 breast-cancer patients primary operated at our institution between 2000 and 2009. Steroid receptors were considered positive for any nuclear staining, HER-2 for strong (3+) membrane staining or positive fluorescence in situ hybridization. Survival curves were calculated for six predefined breast cancer subgroups: ER + PR + HER-2 - (PPN), ER + PR - HER-2 - (PNN), ER + PR + HER-2 + (PPP), ER - PR - HER-2 - (NNN), ER - PR - HER-2 + (NPP), and ER + PR + HER-2 + (PNP) (figures not allowed in abstract). Disease free interval (DFI), distant metastasis free interval (DMFI), overall survival (OS) and breast cancer specific survival (BCSS) were calculated. A long-rank test was used for testing the null hypothesis of no difference between the groups.

Results: We previously reported that molecular prognostic subgroup classification of operable breast cancers resembles the classification based on combined immunohistochemical expression of ER, PR and HER-2 receptors. This update represents a larger cohort with more detailed follow-up (median 5.5y).

Conclusion: Combined receptor expression for ER/PR/HER2 determines specific breast cancer subtypes with significant different clinical behavior. Both predictive and prognostic factors need to be considered when interpreting these results.

P4-09-08

Secretory Leukocyte Protease Inhibitor as a Diagnostic Differential Biomarker of Tumor Emboli in Inflammatory Breast Cancer.

Robertson FM, Ye Z, Chu K, Luo AZ, Wright MC, Jin J, Barsky SH, Cristofanilli M, Krishnamurthy S. The University of Texas MD Anderson Cancer Center, Houston, TX; University of Nevada School of Medicine, Reno, NV; Nevada Cancer Institute, Las Vegas, NV; Fox Chase Cancer Center, Philadelphia, PA

Background: Inflammatory breast cancer (IBC) is the most aggressive and lethal variant of locally advanced breast cancer. Pathologically, IBC is characterized by the presence of nests of cells, defined as tumor emboli, that undergo lymphovascular invasion into the skin and chest wall and represent the metastatic lesion of IBC. Due to the distinct presentation of IBC, it is often misdiagnosed due to a lack of defined biomarkers that are specific for tumor emboli in biopsy samples of IBC patients. To date, the only validated marker that has shown to consistently identify IBC tumor emboli is the surface glycoprotein E-cadherin.

Materials and Methods: With the goal of identifying genes specifically expressed by IBC tumor emboli, the present studies performed whole transcriptome analysis of tumor emboli from skin punch biopsy samples from IBC patients and tumor emboli from the Mary-X pre-clinical model of IBC which were isolated using laser capture microdissection.

Results: Secretory leukocyte peptidase inhibitor (SLPI) was a gene identified as being highly expressed by tumor emboli. This gene was previously identified as a metastasis related gene, has been reported to be associated with poor prognosis in serous ovarian carcinoma and is implicated in mediating resistance to paclitaxel. Immunofluorescence staining and confocal microscopy revealed that SLPI is a robust marker of tumor emboli in skin punch biopsy from IBC patient and in Mary-X tumor emboli. SLPI differentially delineates between IBC tumor emboli and hair follicles present in the skin, which also stain with E-cadherin. An additional marker, Cytokeratin 15 (CK15), can be used in combination with SLPI to differentially identify the components of the skin that are CK15 positive, and IBC tumor emboli that reside within the skin, which are CK15 negative. Use of podoplanin antibodies, which stain lymphovascular endothelium, demonstrate that IBC tumor emboli that express SLPI protein, are completely encircled within the dermal lymphovasculature.

Conclusions: These studies are among the first to identify SLPI as a potential biomarker of tumor emboli in skin punch biopsy samples from IBC patients and in pre-clinical models of IBC. Studies are ongoing to establish the molecular function and role of SLPI in mediating the survival and invasion of IBC tumor emboli. Collectively, these studies are the first to identify SLPI as a potential biomarker of IBC tumor emboli in skin punch biopsy samples. In addition to serving as a potential biomarker of tumor emboli, SLPI may also serve as a therapeutic target for development of approaches to eradicate IBC tumor emboli.

P4-09-09

Raghav KP, Wang W, Liu S, Chavez-MacGregor M, Menc X, Hortobagyi GN, Mills GB, Meric-Bernstam F, Blumenschein GR, Gonzalez-Angulo AM. MD Anderson Cancer Center, Houston, TX

Background: c-MET is a tyrosine-kinase membrane receptor and its dysregulation is involved in tumor proliferation, survival, angiogenesis, and migration. High levels of c-MET have been
observed in various tumor types and correlate with adverse outcome. The purpose of this study was to evaluate levels of total cMET and phospho-cMET (p-cMET) in breast cancer and their impact on survival outcomes.

**Materials and Methods:** We measured quantitative expression of cMET and p-cMET in a cohort of 257 breast cancer primary tumor samples using reverse phase protein array. The level of cMET/p-cMET in each sample was expressed as a log-mean centered value after correction for protein loading with the use of the average expression levels of > 50 proteins. The regression tree method and Mantingale residual plots were applied to find the best cutoff point for high and low levels of each protein. Linear regression models were used to determine if mean expression was different among breast cancer subtypes. The Kaplan-Meier method was used to estimate relapse-free survival (RFS) and overall survival (OS) by cMET and p-cMET levels. Cox proportional hazards models were fit to determine the association of cMET and p-cMET levels with the risk of recurrence and death after adjustment for other patient and disease characteristics.

**Results:** Median age was 51, (range 23-85) years. There were 140 (54.5%) hormone receptor (ER/PR)-positive, 53 (20.6%) HER2-positive, and 64 (24.9%) triple-negative tumors. There were no significant differences in the mean expression of cMET (P=0.128) and p-cMET (P=0.088) by breast cancer subtype. Dichotomized cMET and p-cMET expression was a significant prognostic factor of RFS (HR: 0.41, 95% CI: 0.23-0.75, P=0.004, and HR: 0.61, 95% CI:0.38-0.96, P=0.033, respectively) and OS (HR: 0.31, 95% CI:0.14-0.70, P=0.005, and HR: 0.52, 95% CI:0.29-0.93, P=0.025, respectively). Within breast cancer subtypes, high cMET expression was associated with worse RFS (P=0.02) and OS (P=0.01) in ER/PR-positive tumors, and high p-cMET expression was associated with worse RFS (P=0.03) and OS (P=0.03) for patients with HER2-positive breast cancer. Multivariable model after adjustment for patient and tumor characteristics showed that patients with tumors with high cMET levels had a significant higher risk of recurrence (HR: 0.28; 95% CI, 0.36-0.80) and death (HR: 0.24; 95% CI, 0.09-0.65). Similarly, patients with tumors with high p-cMET levels had a significant higher risk of recurrence (HR: 0.53; 95% CI, 0.29-0.97).

**Conclusion:** In this cohort of patients, high expression of cMET and p-cMET was seen in all subtypes of breast cancer. High levels of cMET and p-cMET had a significant impact on breast cancers survival outcomes. cMET inhibition may a be promising novel target for therapy in breast cancer and deserves investigation.

**P4-09-10**

**Assessment of Circulating Immune Parameters in Patients with Metastatic Breast Cancer Improves Survival Prediction.**

**Background:** Prediction of survival for metastatic breast cancer (MBC) patients (pts) remains a major clinical challenge. Most studies proposed prognostic scores based on clinical criteria that are often subjective. We already demonstrated that low lymphocyte count is a prognostic factor in various pts populations, and we recently showed that low CD4 lymphocyte count is a prognostic factor for overall survival (OS) in MBC pts. In this study, we evaluate the plasma levels of various cytokines and chemokines to improve our immune-based prognostic model.

**Methods:** The first cohort (A) consisted of 39 pts with MBC treated with first line chemotherapy between Sep. 04 and Oct. 07. The second cohort (B) consisted of 114 pts with MBC who relapsed after at least one line of chemotherapy between Dec. 2000 and Nov. 05 and who received further chemotherapy. In the cohort A the blood samples were drawn before administration of any chemotherapy. In the cohort B the samples were drawn after white blood cell recovery. Fresh cells have been used for extensive phenotypic analyses. Plasma cytokines levels have been measured using commercially available Lumineux-based multiplex kits. Cytokines were clustered into 3 groups based on biological pathways, group 1: Th1 response and T-cell proliferation (IL-2, IL-7, IL-15, IFNγ, IL-12p40, IFNα2, GM-CSF); group 2: Th2 response (IL-10, IL-13, CCL22), and group 3: inflammatory response (IL-1b, IL6, IL-17, TNFα).

**Results:** In the cohort A: CD4+ T cell levels <450/µL were associated with worse OS (HR=2.46 [95%CI=1.21-5.01], p=0.013). In the cohort B, 48% of pts had received one previous line of chemotherapy; 52% had received more than one. CD4+ T cell levels <450/µL were also associated with worse OS (HR=1.70 [95%CI=1.04-2.78], p=0.036). Analyzing cytokines by clusters, elevation in group 1 (Th1 response) was associated with poor OS for both cohorts (A=HR=1.055 [95%CI=1.002-1.111], p=0.041) and B (HR=1.12 [95%CI=1.01-1.24], p=0.032). Conversely, the group 2 (Th2 response) was not associated with OS for both cohorts. For the group 3 (inflammatory response), the increase of these cytokines values was a prognostic factor of OS only for the cohort B (HR=1.10 [95%CI=1.02-1.18], p=0.009). In multivariate analysis: in the cohort A, CD4+ T cell levels <450/µL (HR=2.45 [95%CI=1.20-5.03], p=0.014) and group 1 of cytokines (HR=1.055 [95%CI=1.004-1.109], p=0.034) remains independent prognostic factors; in the cohort B, poor Performance Status (HR=3.10 [95%CI=1.99-4.86], p<0.0001) and group 3 of cytokines (HR=1.09 [95%CI=1.01-1.17], p=0.020) were shown to be independent prognostic factors.

**Conclusions:** Combination of PS and biological covariates such as lymphocyte CD4+ count or cluster of cytokines is an effective strategy to predict survival of pts with MBC receiving first-line chemotherapy or subsequent lines. The validation of our immune-based prognostic score (combining cytokine levels and immune cell phenotypes) will be initiated in a prospective study.

**P4-09-11**

**Kinesin Family Member 2C (KIF2C) Is a New Surrogate Prognostic Marker in Breast Cancer (BC).**

*Abdel-Fatah TMA, Green AR, Lemenet C, Moseley P, Chan S, Ellis IO, Balls G. Nottingham University City Hospital NHS Trust, Nottingham, United Kingdom; Nottingham University, Nottingham, United Kingdom; Nottingham Trent University, Nottingham, United Kingdom*

**Introduction**

Gene expression microarrays, artificial neural network (ANN), tissue microarray and immunohistochemistry (IHC) techniques allow for the analysis of huge numbers of gene transcripts and their corresponding proteins and have been widely applied in predicting clinical outcome.

**Methods**

1. In this study, we analysed 48,000 gene transcripts of 171 unselected series of BC using ANN and pathways analysis to identify genes that can be used to predict clinical outcome of BC.

2. The clinic-pathological outcome of candidate genes were validated by using IHC in 4 independent primary BC data sets: a) a series of 379 consecutive high risk BC (NPI>3.4) who treated with surgery (S)+ radiotherapy (RT) and did not received neither endocrine (ET) nor chemo-therapies (CT), b) A series of 1650 consecutive cases of
BC who treated with S + RT and received adjuvant CMF and/or ET according to Nottingham prognostic index (NPI), menopausal and ER status, c) 250 locally advanced BC treated with anthracycline-based combination with or without Taxane followed by S + RT and d) 145 BC overexpressing HER-2 treated with S + RT followed by sequential adjuvant anthracine combination CT + trastuzumab.

**Results**

**Gene expression analysis**

ANN analysis revealed that KIF2C gene was the highest ranked gene that predicted clinical outcome and accurately differentiated between low and high grade BC based on a 10-fold external cross-validation analysis with an average classification accuracy of >98%. High KIF2C gene expression level was associated with shortest BC specific survival (BCSS), disease free (DFS) and distant metastasis free survivals (DM-FS); p<0.0001. In univariate analysis, high level of KIF2C gene expression was associated with large tumour size, higher lymph node stage, negative ER, positive p53 expression and HER2 overexpression. However in multivariate analysis, KIF2C gene expression level was only statistically associated with histological grade (p=0.0001) and mitosis (p<0.0001). Pathways analysis revealed that KIF2C is likely to play a significant role in cytokinesis, cell division and cell cycle regulations.

**Immunohistochemistry**

75% of BC showed overexpression of KIF2C protein. KIF2C protein overexpression was associated with unfavourable clinicopathological features including high grade, high mitotic index, basal like phenotype, triple negative phenotype, HER2 overexpression, TOP2A overexpression, p53 mutation, and loss of BRCA1 (adjusted p=0.0001).

In univariate analysis, KIF2C protein overexpression was associated with patient’s BCSS in both ER+/high and ER/-high risk patients (NPI > 3.4) who did not received ET (HR: 3.3, 95% CI: 1.2-9.3, p=0.02) and ER-/ high risk patients who did not received CT (HR: 3.2, 95% CI: 1.1-8.8, p=0.025).

In 1650 BC series, multivariate Cox regression model including validated prognostic factors, confirmed that KIF2C overexpression is an independent prognostic factor. KIF2C overexpression showed increase in the risk of death (HR: 1.5, 95% CI: 1.1-2.0, p=0.009), recurrence (HR: 1.4, 95% CI: 1.1-1.8, p=0.017) and DM (HR: 1.6, 95% CI: 1.2-2.3, p=0.005).

In conclusion, our findings provide a new insight to a better understanding of mammary carcinogenesis and that KIF2C is a promising molecular prognostic factor and a potential therapeutic target.

**P4-09-12**

**Clinical Validation of Immunohistochemical Signature Predictive of Patients’ 8 Year Outcome in Node Negative Breast Carcinomas**

Charpin C, Tavassoli F, Giuiano S, Secq V, Villeret J, Garcia S, Lavault M-N, Bonnier P, Birnbaum D, Iovanna J. INSERM U624 - Hopital Nord, Marseille, France; Yale University School of Medicine, New Haven; INSERM UMR 891, Marseille, France

**Background:** Immunohistochemical (IHC) signatures predictive of prognosis can be a cost effective alternative to genomic signature suitable in clinical practice for patients' management in early stages of breast carcinoma (BrCa) in clinical. IHC procedures are very easy to handle in pathology laboratories, since require very few amount of formalin fixed tissue samples since assessed on consecutive 4 µm thick sections of paraffin embedded tumors fragments validated by pathologists’ expertise. We recently reported (C Charpin et al Int J Cancer 2009) that standardized IHC assays using high throughput densitometry on digitized microscopic images allow to predict an adverse outcome of patients with BrCa, provided that identified the IHC predictive signatures can be validated in other patients’ cohorts. In this regard we have repeated our previously reported IHC procedures on 418 series of BrCa (Marseille University) on a second series including 303 BrCa diagnosed at Yale University.

**Material and Methods:** TMA(s) of two cohorts of patients with BrCa (418/Marseille University and 303 Yale University) were respectively investigated for immunohistochemical expression of 15 markers, including (i) those of the best signature predictive of patients outcome in N- patients in our previous studies and (ii) new markers reported in the literature as EMT cells and Stem cells. Monoclonal antibodies against HIFa, PI3, pAKT, pmTOR, moesin, P21, 4E-BP, p70S6K, Ker 5.6, pMAPKAPK-2, SHARP2, Claudin, ALDH, AF6, CD24, IHC was screened using standardized (Ventana Benchmark XT) on consecutive 4 µm thick sections of TMA(s) from both series. Quantitative measurements of immunoprecipitates were automatically assessed with TRIBVN device, and correlated to 8 year patients’ outcome. Logistic regression determined the best combination of markers to predict patients’ prognosis and results of the two cohorts were compared.

**Results:** In node negative BrCa the best predictive combination of markers signature was HIF-1a, PI3K, Claudin, AF6, pAKT independently of ER PR and HER-2 status. When results of logistic regression with these markers was compared very similar results were obtained with 92.34% (333/418) of well classified patients in the first set (Marseille University series) and 89.8% (158/176) in the second set from Yale University.

**Discussion:** The results suggest that the new optimal IHC signature predictive of prognosis identified in BrCa including HIF-1a, PI3K, Claudin, AF6 and pAKT is validated by this study with very similar results in two different cohorts of patients. This validation also suggests (1) that IHC signatures investigated in individual patients can be considered as suitable in clinical practice offering a cost effective convenient mean to predict patients’ outcome at diagnostic time (2) and to select those patients with poor prognosis, particularly in N- BrCa subset, requiring more aggressive adjuvant therapies, and to avoid useless expensive therapies and their side effects in N- patients with favourable prognosis.

**P4-09-13**

**External Validation of Adjuvant! Online Breast Cancer Prognosis Tool. Improvement Is Still Needed.**

**Introduction:** AdjuvantOnline is a web-based application designed to provide 10 years survival probability patients with breast cancer. Few validation studies have underlined some limitations, particularly an overestimation of the prognosis among certain subgroups of patients. Moreover, several predictors such as HER2 over expression status and proliferation markers have not been assessed in Adjuvant! original study. We provide the validation of AdjuvantOnline algorithm on two breast cancer datasets collected from two large European cancer centres, and we determined whether the accuracy of AdjuvantOnline is improved by others well known prognostic factors.

**Material and Methods:** The French data set is composed of 456 women with early breast cancer, treated at the Institut Curie between 1995 and 1996. The dutch data set is composed of 295 women less than 50 years treated at the Netherlands Cancer Institute between 1984
and 1995. Agreement between observation and Adjuvant! prediction was checked by testing that the calibration slope was equal to 1. Logistic models were performed to evaluate whether risk factors adds significant prognostic information, including AdjuvantOnline a priori information as an offset.

**Results:** Ten years survival status was known for 383 patients in the French data set and 247 patients in the Dutch data set. Adjuvant! prediction was globally well calibrated in the French data set (observed survival 86%, predicted survival 85%), but was overestimated in high grade, HER2 positive and Ki67 > 20% subgroups. HER2 status, Mitotic Index, Ki67 and treatment type were strongly associated with 10-year survival, even considering AdjuvantOnline a priori information. In the Dutch data set, the overall 10-year survival was underestimated by AdjuvantOnline (observed 66%, predicted 79%), particularly in patients less than 40 years old.

**Conclusion:** AdjuvantOnline needs to be updated to adjust overoptimistic results in young and high grade patients, and should consider candidates, such as Ki67, HER2 and Mitotic Index.

### P4-09-14

**Differential Expression of the Akt1 Isoform in Mammary Ductal Carcinoma.**

**Sanders AJ, Mansel RE, Jiang WG. Cardiff University School of Medicine, Cardiff, United Kingdom**

**Introduction:**

AKT1 is an oncogenic protein and controls numerous cellular processes in both normal and cancerous cells. There are three isoforms, Akt1 (PKBα), Akt2 (PKBβ) and Akt3 (PKBγ). Frequently, regulation of the Akt pathway is disrupted in cancerous cells and interest within the scientific community has focused on the use of this pathway in treating cancer. However, recent studies have also implicated that Akt1 may act to limit invasive migration of breast cancer cells suggesting the potential of this isoform to have both pro- and anti-tumorigenic roles. In the current study we examined the expression profile of Akt1 in a cohort of ductal carcinoma of the breast.

**Methods:**

Quantitative transcript analysis was used to assess the expression levels of Akt1 in a range of ductal carcinoma of the breast (n=85) and normal samples. Expression levels were used in conjunction with clinical and pathological data, as well as the clinical outcomes of the patients (median follow-up 120 months).

**Results:**

Expression of Akt1 levels in the mammary ductal carcinoma cohort demonstrated a lower level of transcript expression in the lower grade and stage cancers. Levels of Akt1 were found to be significantly lower in grade 1 ductal breast carcinomas compared to the combined higher grade 1 and 2 carcinomas (ductal carcinoma grade 1 median = 3.7 vs ductal carcinoma grade 2,3 median = 33.6, p = 0.01). In addition to this, median transcript levels of Akt1 were found to increase with increasing TNM stage of the ductal carcinoma (Median values of Akt1 in ductal carcinoma TNM 1 = 5.9, TNM 2 = 63.6, TNM 3 = 533 and TNM 4 = 13680). This enhanced expression of Akt1 in higher TNM stages, compared to TNM stage 1, was found to be significant in most cases (TNM1 vs TNM2, p = 0.03; TNM1 vs TNM3, p = 0.15; TNM1 vs TNM4, p = 0.03).

**Conclusion:**

Variable expression of Akt1 was seen throughout the mammary ductal carcinoma cohort and correlated with a number of prognostic factors. Akt1 transcript levels were found to be significantly reduced in the low grade 1 and TNM1 stages when compared to the higher grades and TNM stages. Our current data suggests that low levels of Akt1 may be associated with better clinical patient prognosis in mammary ductal carcinoma.

### P4-09-15

**Clinical and Pathological Predictors of Outcome among Patients with Triple Negative Breast Cancer.**

**Pearlstone DB, Gray M, Garofalo RM, Trapani M, Nyirenda T, Hazelwood VA. Hackensack University Medical Center, Hackensack, NJ; Stevens Institute of Technology, Hoboken, NJ; John Theurer Cancer Center, Hackensack, NJ**

**Background:** Triple negative (TN) breast cancer portends a poor prognosis, yet outcomes remain heterogeneous. Specific characteristics of individual TN patients that can predict outcome compared to non-triple negative (NTN) patients have yet to be well defined.

**Methods:** A prospective oncology database at Hackensack University Medical Center was queried for all patients with invasive breast cancer between 2000 and 2005. Patients with triple negative breast cancer were identified and compared to non-triple negative patients. Numerical values were compared by Mann-Whitney test; categorical values by Chi square/Fisher exact test. Log-rank test was used to compare outcome statistics, univariate and multivariate analyses were used to identify factors affecting relapse-free survival and overall survival. **Results:** A total of 2,216 patients were identified (TN: n=260; NTN: n=1956). There was no difference in race (white vs non-white; TN: 82.3% vs NTN: 87.3%) or family history of breast cancer (TN: 19.2% vs NTN: 16.8%). TN patients were significantly younger (median age; TN: 55.5 vs NTN 57.7; p < .05), had larger tumors (mean cm; TN: 3.1 vs NTN: 2.4; p < .05), had higher grade tumors (% grade 3; TN: 74.6 vs NTN: 26.1; p < .0001), had higher proliferation index (>20% nuclei stained for Ki-67; TN: 30.8% vs NTN: 6.7%; p < .0001), but were less likely to have lymph node metastases at presentation (TN: 35.7% vs NTN: 48.0%; p < .0001). Among node negative patients, overall survival (OS) and disease free survival (DFS) were not significantly different between TN and NTN. Among node positive patients, both OS and DFS were worse for TN patients compared to NTN patients (p < .0008).

**Conclusion:** Although TN patients have poor outcomes overall, among node negative patients, TN status does not affect overall nor disease free survival. Among node positive patients, however, TN status, nodal status and tumor size were all independently associated with DFS.

### P4-09-16

**Factors Affecting the Development of Axillary Lymph Node Metastases in T1a-T1b Breast Cancers.**

**Khair TA, Boolbol SK, Boachi-Adjei K, Klein P. Beth Israel Medical Center, Continuum Cancer Centers of New York, New York, NY**

**Background:** The presence of axillary nodal metastases is a poor prognostic indicator in patients with breast cancer. In the majority of patients, axillary nodal involvement correlates with tumor size and most commonly in tumors greater than 1 cm. Many series report an incidence of axillary nodal metastases in 3-37% of patients with tumors less than or equal to 2 cm. The presence of axillary nodal metastases will often change the stage of the cancer and role of it.
adjuvant systemic treatment; therefore, it is important to understand what features are associated with these small lymph node positive tumors. The purpose of this study is to identify characteristics of T1a and T1b breast cancers that present with axillary nodal metastasis.

Methods: A retrospective review of a prospective database identified 878 patients with T1a and T1b breast cancer. Pathologic features including tumor grade, hormone receptor status, lymphatic and vascular invasion, Her-2 neu status, and tumor histology were examined in patients with and without axillary nodal metastases. Pearson’s χ² test along with stepwise linear regression analysis were used to determine which factors were associated with the development of axillary nodal metastases.

Results: There were 289 T1a lesions and 589 T1b lesions studied. Four independent variables were found to be associated with axillary nodal metastases in T1a-T1b breast cancer. As illustrated in Table 1, a significant difference was seen in nodal positivity among patients with ER negative tumors compared to those with ER positive tumors (p = .0000). An increased incidence of nodal positivity was also observed among patients with LVI compared to those without LVI (p = .0000). A significant difference was observed in nodal positivity among patients with perineural invasion compared to those without (p = .0006). An increased incidence of nodal positivity was also observed among T1a and T1b tumors with a higher histologic grade (p = .0409, p = .0001). Of note, when comparing T1a to T1b breast cancers, there was no significant difference found among the identified exposure variables of interest.

Conclusion: In this series, the overall prevalence of nodal positivity in T1a and T1b breast cancer is 12%. An absence of a relationship between T1a and T1b cancers with nodal positivity was observed. However, the presence of nodal positivity showed a significant correlation with ER negativity, LVI, perineural invasion, and higher histologic grades.

P4-09-17

Leptin and Adiponectin Expression in Breast Cancer.

Jeong Y-J, Jeong H-Y, Bong J-G, Park S-H, Choi J-H, Park S-H, Choi J-H, Oh H-K. School of Pharmacy, Kyung Hee University, Seoul, Korea; College of Medicine, Catholic University of Daegu, Daegu, Korea; College of Pharmacy, Kyung Hee University, Seoul, Korea

Background: Several adipocytokines, such as leptin, resistin, and adiponectin, are associated with obesity and breast cancer. Multiple studies have indicated that adipocytokines may significantly influence the growth and proliferation of tumors. However, the relationship between adipocytokines and breast cancer invasiveness has not been investigated in human tissue. The aims of this study were to determine the expression of leptin, leptin receptor (ObR), adiponectin and adiponectin receptor (AdipoR) in human breast cancer, to evaluate their prognostic significance in the breast cancer.

Material and Methods: Specimens from 198 patients with primary breast cancer were enrolled, and representative paraffin tumor blocks were selected for constructing tissue microarrays (TMA). Immunohistochemical staining for leptin, ObR, adiponectin, and AdipoR was performed using TMA, and the clinicopathologic characteristics were evaluated from the patient’s medical records.

Results: Stage 0 breast cancer accounted for 41 cases, and 157 cases were invasive cancer. A univariate analysis showed that positive rates of leptin and ObR expression in the ductal carcinoma in situ (DCIS) group were significantly higher than those of the invasive cancer group (97.4% vs. 34.0%, p = 0.001; 74.4% vs. 29.8%, p = 0.001). However, positive rates of adiponectin and AdipoR expression in the invasive cancer group were significantly higher than those in the DCIS group (53.7% vs. 33.3%, p = 0.024; 59.9% vs. 26.3%, p = 0.001). High leptin expression was significantly associated with high Ki-67 expression (p = 0.016). High adiponectin expression was significantly correlated with smaller tumor size (p = 0.001). The disease-free survival (DFS) and overall survival (OS) rate at 5 years were 89.3% and 96.7%, respectively. No difference in DFS and OS was observed based on leptin, ObR, adiponectin, AdipoR expression.

Discussion: Previous studies, using serum of breast cancer patients or breast cancer cell line, revealed that leptin and ObR may affect processes related to cancer initiation and progression, and adiponectin has protective effect on tumor progression. However, the precise effects of leptin, ObR, adiponectin and AdipoR in breast cancer are still unclear. Our results suggest that losses of leptin and ObR expression could be associated with invasive cancer, whereas high adiponectin and AdipoR expression may be associated with breast cancer invasiveness.

P4-09-18

Australian Decision Impact Study: The Impact of Oncotype DX Recurrence Score (RS) on Adjuvant Treatment Decisions in Hormone Receptor Positive (HR+), Node Negative (N0) and Node Positive (N+) Early Stage Breast Cancer (ESBC) in the Multidisciplinary Clinic (MDC).

de Boer RH, Baker C, Speakman D, Mann B. Royal Melbourne Hospital, Melbourne, Victoria, Australia; Austin Hospital, Melbourne, Victoria, Australia; Peter MacCallum Cancer Institute, Melbourne, Victoria, Australia; Royal Melbourne and Royal Women’s Hospital, Melbourne, Victoria, Australia

Introduction: There has been increasing interest in more accurately defining the need for chemotherapy in patients with HR+ ESBC. Oncotype DX® has been shown to provide prognostic and predictive information beyond traditional histopathological factors. Prior clinical impact studies have focused on decisions made by individual practitioners. In Australia, the MDC has become the standard forum for determining treatment decisions. In this study, we have assessed how the RS influences adjuvant systemic treatment decisions in the MDC at 4 separate hospitals. Methods: Patients with unifocal HR+, HER2-ve ESBC, N0 and N+ (1-3 positive nodes, including micrometastases and isolated tumour cells) and no contraindication to adjuvant chemotherapy (CTx) or endocrine therapy (H) were eligible. A total of 150 patients will be entered. Systemic adjuvant treatment recommendations were made and recorded in the MDC, both before and after testing with Oncotype DX. The primary endpoint was the overall change in the treatment recommendation. Other endpoints included confidence in recommendations, assessment of impact of the RS, and treatment the patient actually received. Results: Currently, RS results on 84 patients are available. Patient age range is 33-82 years. There are 56 (67%) N0 pts and 28 (33%) N+. Overall, 37 (44%) women had low, 36 (43%) intermediate and 11 (13%) high RS. The RS changed the initial treatment recommendations in 20 (24%) patients. Of the 34 patients initially recommended CTx+H, there was a shift to H alone for 12 (35%), whilst of the 50 patients initially recommended H alone, 7 (16%) shifted to CTx+H. A shift in treatment recommendations was reported for 8/37 (22%) pts with low, 8/36 (22%) with intermediate and 4/11 (36%) with high RS.
13/56 (23%) of N0 pts had a change in recommendation, whilst 7/28 (25%) N+ pts changed (table 1). 5 patients have decided against the final MDC recommendations: 3 chose CTx+H after recommendation of H (RS of 13, 19 and 21 respectively), and 2 declined a CTx+H recommendation (RS of 19 and 25). Conclusion: Early results of our Australian study suggest an impact of Oncotype DX RS on adjuvant treatment decision making in the MDC setting. Updated results on the full 150 patients will be presented at the meeting.

PCNA+ Tumor Associated Macrophages Are Associated With M1 and M2 Gene Expression, and Confer Poor Prognosis in the Absence of Anti-Tumor Immune Environment.

Background

Tumor associated macrophages (TAMs) promote breast tumor progression through the production of angiogenic factors, stromal breakdown factors, and the suppression of adaptive immunity. TAMs are recruited from the circulation to the tumor site, and can undergo a spectrum of phenotypic changes, with two contrasting activation states described in the literature: the M1 anti-tumoral and M2 pro-tumoral phenotypes. We previously identified a population of PCNA+ TAMs associated with high grade, hormone receptor (HR) negative tumors with poor outcomes. We hypothesized that high PCNA+ TAMs would be associated with expression of M2 related genes.

Methods

We used immunohistochemistry to measure PCNA+ TAM levels (double positive for PCNA and CD68) in 135 invasive breast cancer cases from the I-SPY 1 Trial, a prospective neoadjuvant trial with serial core biopsies and gene array data. We developed gene-sets representing M1 related, M2 related, and anti-tumor immune response (represented by cytotoxic T cells and MHC Class II) genes based on literature review. We compared PCNA+ TAM levels, expression of these gene-sets, and outcomes.

Results

Higher than mean PCNA+ TAM counts were associated with increasing grade (p < 0.001), HR negativity (p < 0.001), and decreased recurrence free survival (RFS, p = 0.05). Among subjects who had a pathologic complete response (pCR), there was no difference in RFS between those with high versus low PCNA+ TAMs. Among subjects without pCR, those with high PCNA+ TAMs had significantly worse RFS than those with low PCNA+ TAMs (p = 0.0028). In the 95 subjects with both PCNA+ TAM results and gene expression arrays available, high PCNA+ TAM levels were associated with more M1 than M2 related genes. The gene-set representing anti-tumoral immune environment was not by itself associated with RFS. However, those subjects with both high PCNA+ TAMs and the absence of anti-tumoral immune response gene expression had significantly worse RFS than those with high PCNA+ TAMs but the presence of anti-tumoral immune related genes (p = 0.01).

Conclusions

High PCNA+ TAMs had different effects on outcomes depending on tumoral immune environment. Instead of being purely M2 macrophages, PCNA+ TAMs likely represent a heterogeneous mixture of TAMs with different polarization states. Additional markers are needed to distinguish anti-tumoral from pro-tumoral PCNA+ TAMs.

P4-09-20

Expression Profile of Interleukin 17B and the Receptor IL-17BR in Clinical Breast Cancer.

Sanders AJ, Mansel RE, Mason MD, Jiang WG. Cardiff University School of Medicine, Cardiff, United Kingdom

Introduction:

Interleukin 17B (IL-17B) is a member of the interleukin 17 cytokine family. Members of this family have been implicated in conditions such as autoimmune diseases and the inflammatory response. A number of studies have examined the role of IL17A in cancer progression and angiogenesis and shown a variety of functions, both pro- and anti-tumorigenic. Currently there is little data on IL-17B and the receptor IL-17BR and their involvement in cancer progression. The current study looks at the expression profile of IL-17B and IL-17BR in a clinical breast cancer cohort.

Methods:

The expression profile of IL-17B and IL-17BR was examined in a cohort of human normal breast and breast cancer specimens (normal, n = 34; tumour, n = 109). IL-17B and IL-17BR transcript expression in the samples was analysed using Q-PCR and compared to clinical and pathological data.

Results:

Both IL-17B and IL-17BR expression seemed to correlate with NPI staging. IL-17B levels were low in patients with NPI-1 or -2 cancers (median values 3.1 and 1.1 respectively), with highest levels of IL-17B being observed in the poorer prognosis NPI-3 group (median value 206.9; p = 0.07 NPI-1 vs NPI-3 and p = 0.01 NPI-3 vs NPI-2). Similar to this IL17B levels in TNM stage 1 cancers were significantly lower than those in higher TNM stages (TNM1 median value = 0.3 vs grouped TNM234 median value 10.3, p = 0.03). IL-17BR expression also tended to increase with NPI staging (IL-17BR median expression, NPI-1 = 0.0, NPI-2 = 0.04 and NPI-3 = 1.59; NPI-1 vs NPI-3 p = 0.07). Additionally, levels of IL-17BR were found to be significantly lower in background tissue compared to cancer tissue (median values 0.00 vs 0.01 respectively, p = 0.014).

Conclusion:

IL-17BR expression seems to be higher in tumour tissue compared to normal background tissue. Additionally, expression of IL-17B and IL-17BR both appear to be associated with higher NPI stage, particularly in the poor prognostic NPI-3 group. Expression of IL-17B seems to be elevated collectively in TNM stage 2, 3 and 4 compared to the better prognostic TNM1 stage. Together the data suggests that IL-17B and IL-17BR expression may be useful molecules to identify poorer prognostic breast cancers in patients.

P4-09-21

A Novel Prognostic Marker for Triple-Negative Breast Cancers.

Wallon UM, Sabol JL, Zembala-Palko V, Carp NZ, Ciocca RM, Wojcieszowski BS, Prendergast GC. Lankenau Institute for Medical Research, Wynnewood, PA; Lankenau Medical Center, Wynnewood, PA

BACKGROUND: Triple-negative breast cancers (TNBC) represent a highly aggressive form of this disease with few treatment options.
available. Currently, even the smallest node negative cancers are considered by many to warrant treatment with chemotherapy (CTX). While many recur early (within 2-3 years), there is a subset of long-term survivors illustrating the heterogeneity within this group. Here we report our ongoing effort to establish tissue inhibitor of metalloproteinase-4 (TIMP-4) as a prognostic marker in all early breast cancers a. While the canonical function of TIMPs is to inhibit tissue degradation, numerous reports have established that TIMPs exert tumor promoting activity. In our prospective study, we evaluated TIMP-4 as prognostic marker for TNBC and its role in disease progression.

METHODS: Specimens from our retrospective and prospective cohorts were assessed by immunohistochemical staining using standard techniques and a monoclonal antibody for TIMP-4b in accordance with the IRB approved protocol. Staining intensity was documented on a scale of 0-3. No data was released to the treating physicians at the time of collection. Outcome data from a total of 240 pts was obtained through tumor registry and clinician practices. Staining intensity was then correlated to outcome to calculate sensitivity and specificity of the marker. To determine the role of TIMP-4 in TNBC cell behavior we have performed microarray analyses. The effects of TIMP-4-induced signaling were tested using invasion and clonogenic survival assays under normal growth conditions and after exposure to gamma radiation.

RESULTS: Elevated TIMP-4 expression identified a high risk of relapse and short survival time with 75% sensitivity and 80% specificity. No discernable differences were noted between retrospective and prospective cohorts. Array analyses revealed activation of the PI3K/AKT pathway in the presence of TIMP-4. Furthermore, elevated TIMP-4 increased the invasive behavior of breast cancer cells in Matrigel™-coated invasion chambers and reduced sensitivity to gamma irradiation. These effects were reversible by addition of either a PI3K inhibitor or an anti-TIMP-4 antibody, suggesting their use as potential therapeutic strategies.

CONCLUSIONS: On the basis of these clinical data we suggest that TIMP-4 may offer a simple prognostic marker for TNBC patients at highest risk. The presence of TIMP-4 identifies a patient population likely to recur quickly despite standard CTX treatment. Our research suggests that targeted therapy of the PI3K/AKT pathway and/or a biological therapeutic approach directed against TIMP-4 may be of benefit in this subset of pts and should be explored. Therefore, TIMP-4 testing of TNBC patients could aid in the selection of a treatment regimen to improve survival outcome.

Dabbs DJ, Hicks D, Tubbs R, Bhargava R, Brafsky A. University of Pittsburgh Medical Center, Pittsburgh, PA; University of Rochester Medical Center, Rochester, NY; Cleveland Clinic, Cleveland, OH

Introduction

The oncotype dx (ODX) 21 gene recurrence score (RS), was intended to predict the 10 year risk of breast cancer recurrence for estrogen receptor positive, lymph node negative disease (NEJM 2004;351:2817-26). The proportions of patients that were reported as low, intermediate and high risk were 51%/22%, 27%. This population of patients was dominated by ductal carcinomas (DCA), with a paucity of classical lobular carcinomas (CLCA), which are ER-rich and low grade histology. To date, there is dearth of data regarding the relationship of the RS and CLCA, and the clinical relevance regarding the ODX RS in CLCA has not been studied.

Methods

As part of quality assurance review at three institutions, the ODX RS for all CLCA were reviewed in order to determine the perceived clinical relevance of the ODX RS compared to the proportions of RS reported (NEJM 2004;351:2817-26).

RESULTS

A total of 219 cases of ODX were performed on CLCA. The low/intermediate/high risk profile was 58%/40%/2%. Conclusions (1) The risk profile of ODX for CLCA is very different from the original DCA dominant population previously reported. (2) If the goal of ODX is to identify candidates for chemotherapy, then a high RS is a rare event for CLCA, and as such, the judgment to administer chemotherapy to an individual patient would most likely depend upon factors other than the ODX, because 98 percent of patients are combined low/intermediate risk RS.

P4-09-23
Monitoring Autophosphorylation of Mammalian Target of Rapamycin (mTOR) for Histoprognostic Grading of Invasive Breast Cancer: Impact on the Reclassification of Patients with Grade 2 Tumors Using the Nottingham Grading System.

Sauri-Nadal T, Del Barco S, Vazquez-Martin A, Olivareras-Ferraros C, Cafi S, Martin-Castillo B, Lopez-Bonet E, Menendez JA. Catalan Institute of Oncology, Girona, Catalonia, Spain; Dr Josep Trueta University Hospital, Girona, Catalonia, Spain

Histological grade is one of the strongest prognostic factors in operable breast carcinomas (BC). Although Grade 1 and Grade 3 are biologically and clinically distinct tumor entities that clearly separate low-risk from high-risk BC patients, 30-60% of BC are classified as histological Grade 2, which is associated with an intermediate risk of recurrence and is not informative for clinical decision making. Previous studies using a 97-gene measure of histological tumor grade (i.e. the Genomic Grade Index, GGI) have confirmed GGI’s ability to accurately reclassify Grade 2 patients into 2 BC groups with high versus low risks of recurrence. However, GGI’s applicability is still expensive, technically demanding and is not readily available in a routine clinical setting in most hospital laboratories. The prognostic abilities of BC gene expression signatures such as GGI are due mostly to the detection of proliferation activity. One of the strongest, yet simple and well-reproducible proliferation-associated prognostic factors is the mitotic activity index (MAI). Here, we have tested whether immunohistochemical assessment of MAI by assessing the autophosphorylation status of mammalian Target Of Rapamycin (mTOR) at Serine 2481 could significantly impact on the histopathological classification of Grade 2 BC when using the Nottingham Grading System. 1.) We validated the sensitivity of phospho-mTORSer2481 (PP-mTOR) labeling in detecting & counting mitotic figures and also its usefulness for histoprognostic grading in a series of 144 BC biopsies; 2.) We investigated the correlation between PP-mTOR MAI and the MAI determined by using an antibody selective for the Ser10-phosphorylated Histone H3 (PP-H3), a well-recognized mitosis-specific marker. PP-mTOR-labeled mitotic figures were easily seen and permitted a quick identification of the area of highest mitotic activity, even at low-power magnification. Our study showed a statistically significant correlation between the subjective mitotic counts obtained by using PP-mTOR labeling and those assessed by either standard H&E (r = 0.662) or staining with PP-H3 (r = 0.896). PP-mTOR MAI correlated also with tumor
Correlation of Aurora Family Member Expression with Clinical Breast Cancer Prognosis.

Annakesavan A, Sanders AJ, Harding KG, Jiang WG. School of Medicine, Cardiff University, Cardiff, Wales, United Kingdom

Introduction:
Aurora-A, Aurora-B and Aurora-C are a family of protein kinases which have been identified as key regulators of the mitotic cell division process. Members of this group have been linked with pro-tumorigenic effects and have been reported as being up-regulated in certain cancers. Our current study examines the expression profile of the Aurora-A, Aurora-B and Aurora-C members in a breast cancer cohort in relation to a number of predictive factors.

Materials and Methods:
The expression of Aurora-A, Aurora-B and Aurora-C was examined in a breast cancer cohort using quantitative real time PCR (normal samples n = 34, tumour samples n = 109) and immunohistochemistry (IHC). Expression of the aurora members was related to clinical parameters such as staging and Nottingham prognostic index (NPI).

Results:
Examination of Aurora-A levels in the breast cancer cohort revealed an association of Aurora-A expression with NPI grouping. High levels of Aurora-A levels were seen in NPI-1 and NPI-2 stages (NPI-1 median = 66.0, NPI-2 median = 64.3), with expression reducing significantly at the higher NPI-3 group (NPI-3 median = 20.3; p = 0.029 vs NPI-2 and p = 0.009 vs NPI-1 respectively). Additionally, Aurora-A levels were found to be significantly lower in grade 3 cancers compared to grade 1 (median grade 1 = 86.5 vs median grade 3 levels = 52.6, p = 0.04). In contrast to this, examination of Aurora-C levels in the cohort identified a relatively low level of Aurora-C in NPI-1 and NPI-2 group (median values NPI-1 = 88, NPI-2 = 34.4) compared to a substantial increase in Aurora-C expression in NPI-3 (median value = 1602, p = 0.05 vs NPI-1 and p = 0.06 vs NPI-2). Aurora-B expression levels did not exhibit any significant differences within the breast cancer cohort.

Conclusions:
Differential expression of Aurora-A, Aurora-B and Aurora-C were observed within the breast cancer cohort. Higher Aurora-A expression was associated with low NPI groups and grades and potentially with better patient prognosis whereas lower levels were seen in the poorer prognostic NPI-3 group and higher grades. An opposite trend was seen in Aurora-C where lower levels were associated with the NPI-1 and NPI-2 groups and significantly higher levels were seen in the NPI-3 group. Aurora-B levels appeared to have no predictive function. This data suggests that together Aurora-A and Aurora-C levels, within a patient may be useful for predicting patient outcome.
P4-09-26
Prognostic Significance of Tissue Inhibitor of Metalloproteinase-1 (TIMP-1) in Breast Cancer.
Dechaphunkul A, Phukaloun M, Kanjanapradit K, Graham K, Ghosh S, Santos C, Mackey JR. Cross Cancer Institute, University of Alberta, Edmonton, AB, Canada; Faculty of Medicine, Prince of Songkla University, Hat Yai, Songkhla, Thailand

Background: Despite advances of systemic treatment in breast cancer guided by hormonal status and HER2 amplification, new prognostic and predictive factors are still warranted to optimize treatments among these patients. Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), a physiologic inhibitor of Matrix Metalloproteinases (MMPs), can act in both pro- and anti-tumoral effects. The prognostic significance of TIMP-1 in breast cancer is still controversial. This study aims to determine the prognostic significance of TIMP-1 in breast cancer.

Material and Methods: One-hundred and seventy-six primary breast cancers from women with early stage disease treated with standard adjuvant therapy were analyzed by gene expression microarrays and immunohistochemistry for TIMP-1. Immunohistochemical analysis was independently reviewed by two pathologists.

Results: At the optimized cut-off point, patients with high TIMP-1 RNA levels had a significantly shorter time to relapse, with a hazard ratio (HR) of 1.6 (p = 0.039), but without significant differences in overall survival (HR 1.29, p = 0.37). Although cytoplasmic overexpression of TIMP-1 protein was not correlated with early relapse (HR 1.2, p = 0.35), high expression was associated with shorter overall survival (HR 1.73, p = 0.027). In multivariate analysis, when considering stage, histologic grade, hormonal and HER2 status, TIMP-1 RNA levels remained independently prognostic for early relapse (HR 1.68, p = 0.04).

Discussion: Elevated TIMP-1 RNA levels are independently prognostic for early recurrence, whereas protein overexpression of TIMP-1 is correlated with short overall survival in primary breast cancer.

P4-09-27
Can We Predict the Benefit of the 70-Gene Signature in the Choice of Adjuvant Systemic Treatment for ER Positive, HER2 Negative Tumors in Daily Practice? A Single Institution Experience.

Purpose: Studies have shown that the 70-gene signature (MammaPrint®) (MP) may outperform clinicopathological risk assessment and may predict the benefit from chemotherapy (CT) in patients (pts) with early-stage breast cancer. However, the need of fresh tissue and the high cost of the assay limit its use in daily clinical practice. We investigated whether 1) tumor clinicopathologic features can predict MP risk (high vs. low); 2) MP results could help to make decisions for the use of CT in pts with ER positive (ER+ve) breast cancer beyond recommendations of known international guidelines (NCCN, St. Gallen).

Patients and methods: Women with operable invasive breast cancer without evidence of distant disease undergoing surgery at the Breast Surgery Department were enrolled into the study. A 3 mm punch biopsy of the tumor was obtained from the specimen within the first hour after surgery. Samples were shipped to the laboratory in an RNA-stabilizing solution and were studied to ensure the presence of at least 30% of tumor cells and a customized microarray containing 70 genes was analyzed as described by the manufacturer.

Results: 124 consecutive pts were enrolled into the study; 106 tumor samples were adequate for the microarray. Median age was 53 yrs (range 28-83), mean tumor size was 2.3 cm (SD ±1.34), 52.4% pts had pN0, 55% of tumors had Ki-67 ≥20% and 36% were poorly differentiated. ER were detected in ≥50% of cells in 82% and <1% of cells in 15% of tumors, respectively; HER2 was positive in 18% of tumors.

As expected, poorly differentiated, ER and PgR negative, HER2 positive and highly proliferating tumors were more likely to be classified as high-MP. We then focused our analysis on ER and PgR+ve, HER2 negative tumors and assessed features correlated with MP results in this subgroup. Unexpectedly, 31/80 (39%) of these tumors were classified as high-MP vs. 49 (61%) low-MP. We found that tumor size (T1 vs. T2-T4), poor differentiation (G3 vs G1-2) and high proliferation (Ki-67 ≥20%) were significantly associated with a high-MP result. In an exploratory multivariate analysis tumor size and Ki-67 remained as independent predictors of high-MP result.

At last, when we compared MP risk with recommendations for AT from international guidelines we found that in the subgroup of candidates for endocrine therapy (ET) in whom the benefit from the addition of CT is undetermined, 25/68 pts (37%) were high-MP and 43 pts (63%) low-MP. When we considered recommendations for AT proposed by our multidisciplinary team according to international guidelines, 11/25 pts (44%) with high-MP received ET only and 14 pts (56%) CT + ET, while among 43 pts with low-MP only 9 received both CT and ET.

Conclusions: Our study shows that the 70-gene signature was feasible in the clinical setting, as 85% of tumor samples were adequate. A substantial proportion of ER/PgR+ve, HER2 negative tumors was classified as high-MP; within this subgroup, proliferation and tumor size independently predicted high-MP results. In 20 pts, MP risk would have resulted in discordant recommendations for AT compared to those based on standard clinicopathologic features.

P4-09-28
Comparison of Oncotype DX (ODX) and Mammostrat (MS) Risk Estimations and Correlations with Histologic Tumor Features in Low Grade, ER-Positive Invasive Breast Carcinoma (BC).
Acs G, Kilik J, Loftus L, Laronga C. Moffitt Cancer Center; Tampa, FL; Women’s Pathology Consultants, Ruffolo Hooper & Associates, Tampa, FL

Several molecular tests have been developed to estimate risk of distant recurrence (RDR) and help clinical decision-making regarding adjuvant chemotherapy in early stage BC. The ODX assay is a 21-gene expression profile mainly based on expression levels of genes related to hormone receptor / HER2 signaling and cell proliferation. MS is an immunohistochemistry-based assay measuring the expression of five markers thought to play a significant role in BC biology. Although both validated tests were shown to stratify patients into groups with low, intermediate and high RDR, the tests have not been compared head-to-head in the same cohort of patients and little data is available regarding their correlation with clinicopathologic tumor features.

We have previously shown that a proliferative, cellular stroma and inflammatory cells associated with tumor cells may account for unexpected intermediate/high risk estimations based on ODX in low grade BC. In this study we compared the clinicopathologic tumor features with risk estimations by ODX and MS in 106 low grade ER-positive BC. The histologic features of tumors were prospectively determined without knowledge of test results. The tumor stroma was evaluated for increased cellularity and presence of inflammatory cells. Double immunostain for pancytokeratin and
Ki67 was performed to assess cell proliferation in cancer vs stromal/inflammatory cells. Based on ODX and MS, among the 106 cases 68, 38 and 0, and 91, 14 and 1 tumors showed low, intermediate and high RDR, respectively. Assessment of the concurrence between the tests to predict low vs intermediate/high RDR showed a kappa value of 0.0541. There was no statistically significant correlation between ODX Recurrence Score (RS) and MS risk index values. We found no correlation between low vs intermediate/high risk estimation by either test and patient age, tumor size, nuclear atypia, mitotic rate, ER and HER2 expression levels. BC with intermediate/high RDR by ODX, but not by MS, showed significantly lower PR expression, increased stromal cellularity and presence of inflammatory cells. Double immunostains showed increased proliferation in stromal/inflammatory cells compared to cancer cells in cases showing intermediate/high RDR by ODX; no such association was seen with regards to MS risk estimations. The ratio of Ki67-positive stromal/inflammatory vs tumor cells >1 had an area under the curve of 0.8929 (p<0.0001) and 0.5026 (p=0.9823) to predict intermediate/high RDR based on ODX and MS, respectively. Cases showing intermediate/high RDR by ODX but low risk by MS were associated with increased stromal cellularity, presence of inflammatory cells and increased numbers of Ki-67 positive stromal/inflammatory cells, compared to cases showing low risk by both assays. Our results suggest that low grade ER-positive BC with increased stromal/inflammatory cell proliferation may show an apparent increased RDR as assessed by ODX, which uses RNA extracted from a mixture of tumor and stromal/inflammatory cells in the assay. MS, which examines cancer cells only (thus, not influenced by stromal and inflammatory cells), may provide a better estimation of likely tumor behavior in low grade BC.

P4-09-29
A Nomogram To Predict Prognosis in Node-Negative Breast Carcinoma.
Mazouni C, Spryatos F, Romain S, Fina F, Bonnier P, Ouaïk L, Martin P-M. APHM, Marseille, France; Institut Curie - Hôpital René Huguenin, Paris, France

Background: Currently, the usefulness of conventional markers for breast carcinoma is limited to assess individual outcome. A statistical model was developed to improve the prognostic accuracy using multiple conventional and emerging prognostic biomarkers.

Methods: A total of 305 node-negative breast carcinomas who underwent surgery (+/- radiotherapy) but no adjuvant treatment was selected. Putative prognosis factors including age, tumor size, ER, PR, SBR grading, urokinase plasminogen activator (uPA), plasminogen activator inhibitor type 1 (PAI-1) and thymidine kinase (TK) were evaluated. The developed model was internally validated using Harrell’s concordance index and calibrated. An external validation of the new model is warranted.

Results: Age (p<0.001), PR (p=0.02), and PAI-1(p<0.001) were included in the Cox regression model predicting overall survival at 5-years. Internal validation revealed a concordance index of 0.711 to 0.694 before and after calibration.

Conclusion: A nomogram can be used to predict probability survival curves for individual breast cancer patients and the effect of treatment options can be evaluated using these models.

P4-09-30
Relationship between DNA Ploidy, Biomarker Expression and Molecular Subtypes of Invasive Breast Cancer.
Sarode VR, Rahardja D, Morrison DH, Peng Y, Rao R, Euhus D. University of Texas Southwestern Medical Center, Dallas, TX

Background: DNA ploidy has been shown to have prognostic significance in patients with breast cancer. Studies in the past have mainly utilized flow cytometry (FCM) for measuring DNA ploidy. However FCM has several disadvantages, the instrument cannot distinguish benign from malignant cells and it cannot be performed on small tumor samples. The relationship between DNA ploidy and biomarker expression in breast cancer has not been well studied. Recently, gene expression analysis has demonstrated distinct subtypes of breast cancer. Expression of ER, PR and Her2 by IHC has been used as a surrogate tool for the molecular classification of breast cancer.

Aim: To determine the relationship between DNA ploidy, biomarkers (ER, PR, HER2, Ki67 and p53) expression and molecular subtypes of invasive breast cancer (IBC) using image analysis.

Design: DNA analysis was performed on Feulgen stained sections from the same tumor block used for biomarker analysis. DNA indices and ploidy were analyzed using the Autocyte Pathology Workstation (Tripath, Burlington, NC). Briefly, a total of 200-300 nuclei were collected and mean DNA index reported. DNA index was obtained by measuring the optical density of tumor cells in comparison with those of the non-neoplastic stromal cells in the sample using the latter as the diploid reference (value of 1.0). Tumors were classified as diploid (DNA indices of 0.90 to 1.1), aneuploid (DNA indices of <0.89 and > 1.1) and multiploid tumors; multiple indices. Patient’s age, tumor size, histologic grade, stage, biomarker status and breast cancer subtypes were correlated with ploidy status.

Results: Of the 248 cases of IBCA, 176 had aneuploid DNA and 72 diploid. Aneuploid tumors were predominantly grade 3, 72.1% versus 27.9% of diploid (p<0.0001). Tumor ploidy had no significant association with age (<40 years) versus older age (>50 years), p=0.118. The mean tumor size in aneuploid and diploid tumors was 4.2 cm and 3.2 cm respectively (p=0.009). Aneuploid tumors were frequently ER and PR negative compared to diploid (p<0.0001) with a mean ER level of 31.7% compared to 72.2% in diploid tumors (p<0.0001). The mean PR level was 17.2% in aneuploid versus 34.0% in diploid tumors (p=0.0009). The Ki67 index was 52.4% in aneuploid compared to 29.1% in diploid (p<0.0001). Tumor ploidy had no significant association with age (<40 years) versus older age (>50 years), p<0.0001. Tumor ploidy had no significant association with age (<40 years) versus older age (>50 years), p=0.118. The mean tumor size in aneuploid and diploid tumors was 4.2 cm and 3.2 cm respectively (p<0.0001). Aneuploid tumors were frequently ER and PR negative compared to diploid (p<0.0001) with a mean ER level of 31.7% compared to 72.2% in diploid tumors (p<0.0001). The mean PR level was 17.2% in aneuploid versus 34.0% in diploid tumors (p=0.0009). The Ki67 index was 52.4% in aneuploid compared to 29.1% in diploid (p<0.0001). The p53 expression was 30.3% in aneuploid versus 14.4% in diploid tumors. Aneuploid tumors were frequently of advanced T stage compared to diploid tumors (p=0.0048). There was no significant association with N stage (p=0.734). By multivariate analysis after adjusting for age, grade, T and N stage, ER (p=0.0021), PR (p=0.0003), HER2 overexpression (p=0.0028), Ki67 (p=0.0383), T stage (p=0.0172 and grade (<0.0001) were significantly associated with aneuploidy. Of breast cancer subtypes, Her2 (p=0.0001), triple negative (p<0.0001), luminal B subtype (p=0.006) were frequently aneuploid and luminal A was frequently diploid (p=0.051).

Conclusion: DNA ploidy measured by image analysis has significant association with biomarker expression. Increased DNA content is associated with poor prognostic features and aggressive subtypes of breast cancer.

The Prognostic Significance of Metaplastic Carcinoma of the Breast – A Comprehensive Comparison Study with Common Breast Cancers.  
Lai H-W, Kuo S-J, Chen D-R, Chen S-T. Changhua Christian Hospital, Changhua, Taiwan

**Purpose:** Metaplastic carcinoma of the breast (MCB) is a rare histological subtype of breast cancer with incidence less than 1%. Due to its rarity, the clinical characteristics and prognostic significance of MCB compared with other common breast cancer, such as infiltrating ductal carcinoma (IDC) and infiltrating lobular carcinoma (ILC) are not clear and controversial between different reports. We performed a multi-institutional cases collective comparison study to evaluate the clinical characteristics and prognostic status with IDC and ILC.

**Materials and methods:** Cases of MCB were enrolled from 4 medical centers in Taiwan. Forty-five MCB patients combined with 1777 IDC and 53 ILC patients from cancer registry database of Changhua Christian Hospital (CCH) comprised the current study. The patients’ demographic data, tumor characteristics and prognosis of MCB were analyzed and compared with IDC, and ILC. To further clarify the prognostic difference between MCB and IDC, a case control analysis was performed to minimize the effect of tumor size, lymph node status and other clinicopathological factors. The disease free survival (DFS) and overall survival (OS) between groups were compared.

**Results:** Compared with IDC, MCB was associated with older age, larger tumor size, lesser lymph node positive rate, higher distant metastasis, higher tumor grade, lower ER positive tumor, and higher triple negative breast cancer subtype (TNBC). Compared with IDC, MCB was associated with worse OS (p=0.049), but not different in DFS (p=0.132). To eliminate the influence of other prognostic factors, 135 cases controlled IDC with MCB. Both DFS and OS (p=0.132 and 0.289, respectively). To eliminate the influence of other prognostic factors, 135 cases controlled IDC with MCB. Both DFS and OS (p=0.132 and 0.289, respectively). To eliminate the influence of other prognostic factors, 135 cases controlled IDC with MCB. Both DFS and OS (p=0.132 and 0.289, respectively).

**Conclusion:** MCB was associated with poorer OS compared with IDC, and this poorer prognosis was related to tumor behavior rather than clinicopathologic factors.

Luminal Infiltrating Lobular Carcinoma of the Breast: Clinical and Prognostic Features.  

**Background:** Infiltrating lobular carcinoma (ILC) and infiltrating ductal carcinoma (IDC) are the two most common histologic types of invasive breast cancer. Previous studies have demonstrated distinctive clinical and biologic characteristics, however some features of ILC are yet uncertain like the relationship with the particular subtypes according to the gene expression profile. The purpose of our study is to analyze how the patients with ILC differ from IDC regarding of percentage of luminal subtype, the tumor factors, treatment and patterns of recurrence.

**Patients and Methods:** We assessed 1190 breast cancer patients treated at the Hospital Universitario 12 de Octubre between 1995 and 2006 categorized as having ILC or IDC pure types.

**Results:** One thousand one hundred ninety tumors were included, being ILC 223 patients (18%, 7%), IDC 967 patients (81%, 3%) and 200 patients (10%) were luminal HER2+. The current analysis is limited to the 990 patients classified as luminal HER2-.

**Conclusion:** Luminal HER2- Infiltrating lobular carcinoma carries distinct clinicopathological features. In our study, ILC had similar prognosis as IDC.
P4-09-35
Park S, Koo JS, Lee JS, Hwang H, Ko S, Kim SI, Park B-W, Yonsei University College of Medicine, Seoul, Korea

Background: The purpose was to investigate the implications of cyclooxygenase-2 (COX-2) and Ki-67 expression on the progression and prognosis of breast cancer.

Methods: COX-2 and Ki-67 levels were immunohistochemically determined using tissue microarrays of 1,028 breast tumors treated between November 1999 and August 2005. COX-2 and Ki-67 levels were compared by tumor progression and clinicopathological parameters were investigated in association with both markers status which was divided into 3 subgroups: COX-2(+)/Ki-67(+), COX-2(+)/Ki-67(-), COX-2(-)/Ki-67(any).

Results: COX-2 expression was significantly higher in intraductal carcinoma and progressively decreased in small T1 lesions and then in T2-T4 tumors, but Ki-67 was significantly expressed at high levels in T2-T4 lesions than in intraductal or T1 carcinomas. COX-2 expression was positively associated with favorable parameters such as older age at diagnosis, smaller size, well-differentiation, hormone receptor-positivity, and was inversely associated with Ki-67 expression. Among 816 invasive tumors, COX-2 expression alone was not related to outcomes. In combination with Ki-67 expression, however, COX-2(+)/Ki-67(-) tumors were significantly associated with favorable characteristics including HER2-negativity and demonstrated favorable outcomes. COX-2(+)/Ki-67(-) tumors showed unfavorable factors and the worst outcomes. COX-2(-)/Ki-67(+) subgroup presented intermediate prognosis. Statistical significance of COX-2 combined with Ki-67 was maintained in Cox’s models adjusting for clinicopathological parameters among not only whole population but also ER-positive subgroup.

Conclusions: Our study suggests that COX-2 is expressed in early phase of breast cancer development and is associated with favorable prognostic markers. But co-expression of high Ki-67 proliferative index could indicate an aggressive phenotypic change in COX-2 positive breast cancer. The mechanisms should be further investigated.

P4-10-01
Tumor Markers Predicting Recurrence Type after a Primary Ductal Carcinoma In Situ.
Zhou W, Johansson C, Jirström K, Ringberg A, Blomqvist C, Amini B-M, Fjällskog M-L, Wärnberg F. Uppsala University Hospital, Uppsala, Sweden; Malmö University Hospital, Malmö, Sweden; Lund University, Lund, Sweden; Helsinki University Central Hospital, Helsinki, Finland; Uppsala University, Uppsala, Sweden

Background: The risk for recurrence after a primary ductal carcinoma in situ (DCIS) is approximately 8% after ten years. If a recurrence occurs, the risk of the recurrence being invasive is approximately 50%. However, the knowledge of determinants for type of recurrence is limited. The purpose of this study was to investigate the predictable effect of specific biologic markers on the type recurrence after a primary DCIS.

Material and Methods: All women diagnosed with a primary DCIS between 1986 and 2004 in Uppsala and Västerås, Sweden were included (n=458). We also included all women from the SweDCIS Trial with a known recurrence (n=166). TMA blocks were constructed and immunohistochemistry (IHC) was used to evaluate the status of estrogen receptor (ER), HER2, epidermal growth factor receptor (EGFR/HER1), cytokeratin 5/6 (CK 5/6), forkhead box A1 (FOXA1), forkhead box C1 (FOXC1), Ki 67, CD 10 and transacting T-cell-specific transcription factor GATA-3 (GATA-3) in the primary DCIS tumors. Logistic regression was employed to calculate the difference of expression status of biological markers between groups. Odds ratios (ORs) and 95% confidence interval (CI) were calculated, with adjustment for age, free margins, surgical type and molecular subtype by IHC.

Results: Of the 624 patients, 358 without recurrence were grouped as controls. Of the 266 with recurrence, 130 developed an in situ recurrence, while the remaining 136 developed invasive recurrence. Mastectomy compared to breast conserving surgery (BCS) and free margins were associated with less recurrences (OR 0.07, 95% CI 0.03 – 0.15) and (OR 0.39, 95% CI 0.26 – 0.58). As compared with the most common molecular subtype Luminal A, the subtype Luminal B had statistically significant higher risk of recurrence (OR 2.01, 95% CI 1.12 – 3.59). Higher risk of all recurrences was also observed for FOXA1 (OR 3.16, 95% CI 1.48 – 4.74) and FOXC1 (OR 2.39, 95% CI 1.39 – 4.09). In the analyses of type of recurrence, ER-negative, HER2-positive and EGFR-positive tumors recurred more often as in situ (OR 2.34, 95% CI 1.17 – 4.71), (OR 2.08, 95% CI 1.11 – 3.88) and (OR 2.40, 95% CI 1.11 – 4.36). The molecular subtype HER2- was also associated with a lower risk of invasive recurrence (OR 0.27, 95% CI 0.11 – 0.67).

Conclusion: As expected, mastectomy and free margins were associated with a lower risk of recurrence. Molecular subtype Luminal B and tumor markers FOXA1 and FOXC1 had a higher risk of recurrence. Recurrences after molecular subtype HER2+, ER-negative and EGFR-positive DCIS were more often of the in situ type.

P4-10-02
A Meta-Analysis of the Association of Blood Levels of Vitamin-D and the Risk of Breast Cancer.
Amir E, Carlsson L, Seruga B, Ocana A, Goodwin PJ. Princess Margaret Hospital, Toronto, Canada; Institute of Oncology Ljubljana, Ljubljana, Slovenia; Albacete University Hospital, Albacete, Spain; Mount Sinai Hospital, Toronto, Canada

Background: A considerable body of literature has examined the association of vitamin-D with breast cancer risk and the potential role in its prevention. Geographic studies show higher incidence of breast cancer in patients residing at high latitudes. Other data linking vitamin-D deficiency to breast cancer risk are inconsistent.

Materials and Methods: A literature based meta-analysis was conducted. Odds ratios (OR) for breast cancer based on blood levels of 25-hydroxy or 1,25-hydroxy vitamin-D were computed and pooled. Analysis was conducted separately for studies where blood levels were taken before (group A) or after (group B) breast cancer diagnosis.

Results: Thirteen studies were identified. Nine studies were included in group A and 4 studies included in group B. For group A, there was no significant association between lower vitamin-D levels and breast cancer risk (pooled OR = 1.09, 95% confidence intervals 0.99-1.20, p=0.08). For group B, there was a highly significant association between lower vitamin-D levels and breast cancer (pooled OR = 2.81, 95% confidence intervals 1.70-4.65, p=0.001). The test for interaction between groups was highly significant (p<0.001). When all studies were pooled, the OR was 1.38 (95% confidence intervals 1.13-1.70, p=0.002).

Conclusion: When measured before breast cancer diagnosis, blood levels of vitamin-D are not associated with breast cancer risk. Breast tumors have been shown to differentially express vitamin-D hydroxylase. Therefore, any association of vitamin-D and breast cancer in studies measuring blood levels after breast cancer diagnosis may be confounded by reverse causation bias.
P4-10-03
Association between BMI, Physical Activity and Breast Cancer Histologic Types.
Nyante SJ, Dallal CM, Gierach GL, Sherman ME, Park Y, Hollenbeck AR, Brinton LA. National Cancer Institute, Rockville, MD; AARP, Washington, DC

Background: Previous research indicates that certain breast cancer risk factor associations vary by histologic tumor type. However, most studies have been too small to examine risk factors for uncommon histologic types. We examined the association between body mass index (BMI), physical activity, and the relative risk of breast cancer histologic types in a large prospective cohort study to determine whether associations for these risk factors varied by histology.

Methods: This analysis included women in the NIH-AARP Diet and Health Cohort Study who were 50 to 71 years old, postmenopausal and weight at baseline, and not previously diagnosed with cancer (N=190,348). The study cohort was established in 1995-1996 when participants completed a baseline questionnaire regarding health and nutritional information. BMI (kg/m²) was calculated from self-reported height and weight. Daily routine physical activity at work or home was derived from a question asking women what best described their daily routine at work, or throughout the day if they did not work at a job. Choices were mostly sitting with little walking, sitting with a fair amount of walking, mostly standing or walking, light lifting or climbing stairs/hills, or heavy work/carrying heavy loads. Cancer diagnosis and histology were obtained from state cancer registries. This analysis includes participant follow-up through December 31, 2006. After a median 11.2 years of follow-up, 7,631 invasive breast cancers were diagnosed: 5,278 ductal, 831 lobular, 640 mixed ductal-lobular, 214 mucinous, 132 tubular, and 536 other types. Multivariable-adjusted hazard ratios (HRs) and 95% confidence intervals (CIs) were estimated using Cox proportional hazards regression.

Results: Compared to women with a BMI of 18.5 to 24.9, obese women had increased risks of ductal (HR and 95% CI for BMI 30 to 34.9: 1.24, 1.14 - 1.36; BMI ≥ 35: 1.45, 1.30 - 1.62) and mucinous (HR and 95% CI for BMI 30 to 34.9: 1.58, 1.04 - 2.39; BMI ≥ 35: 1.93, 1.16 - 3.20) cancers. For both histologic types, the relative risk increased with increasing BMI (P-trend: ductal P<0.01; mucinous P<0.01). Women whose daily activity at work or home consisted of mostly standing or walking were at reduced risk of ductal and mixed ductal-lobular cancers compared with women who reported mostly sitting (HR and 95% CI for ductal: 0.86, 0.77 - 0.96; mixed-ductal lobular: 0.64, 0.48 - 0.86). Women who performed heavy work or carried heavy loads were also at a decreased risk of ductal and mixed ductal-lobular cancers compared with women reporting mostly sitting (HR and 95% CI for ductal: 0.68, 0.52-0.91; mixed ductal-lobular: 0.18, 0.04-0.72), though there were few mixed ductal-lobular cases who reported heavy activity.

Conclusions: High BMI was associated with increased risk of ductal and mucinous breast cancers. Women who spent their daily routine activity mostly standing or walking or doing heavy work had a reduced risk of ductal and mixed ductal-lobular cancers. These differences suggest that associations of BMI and physical activity vary by breast cancer histologic type in postmenopausal women and may have different roles in the etiology of these cancers.

P4-10-04
Automated Breast Cancer Risk Assessment: Identifying High Risk Women in the Primary Care Setting.
Ozanne E, Omer Z, Carlson K. University of California, San Francisco; Massachusetts General Hospital

Background: Despite the availability of risk assessment tools and risk-reducing interventions, high risk women are not routinely identified in clinical practice, and the few that are, rarely choose interventions – often due to misperception of risk. Identification of patients at risk needs to begin in the primary care setting, rather than the breast health specialty world. To accomplish this, we developed a web-based tool that provides automated risk assessment and personalized decision support designed for collaborative use between patients and clinicians in the primary care setting. We assessed the feasibility and efficacy of using this tool in a primary care clinic at an academic hospital to identify women at high risk.

Methods: Women aged 40 to 65 years of age were recruited from a schedule of patients attending annual physicals at a primary care clinic in an academic hospital. Patients with a history of breast cancer, genetic testing, or chemoprevention education were excluded. Information used to assess breast cancer risk was gathered from medical record review and phone interviews when necessary. Risk assessment was performed on all patients using four risk assessment models (Gail, Claus, BRCAPRO, and BCSC Density). Patients were randomized to view the decision aid either before their appointment or with their PCP during their appointment. Prior to each visit, providers received a risk report that summarized patient risk and recommended referrals. Outcomes were gathered from surveys administered to patients before and after appointments, and to providers after appointments.

Results: Over 4-months, 98 women were approached to reach the enrollment goal of 60 women (61%). 24/60 (40%) patients were identified to be high risk for breast cancer using standard high risk thresholds. 9/60 (15%) of patients fit criteria for referral to genetic counseling, while 15/60 (25%) fit the criteria for referral to a BC specialist. Out of the 24 patients who fit the referral criteria, 17 (71%) were referred to a high risk cliniculary by their PCPs. 9/17 (53%) patients followed through in scheduling the appointment within 4 months of the referral date. The PCPs’ perceptions of these patients’ risk was in line with the calculated risk for 21 (88%) of the patients. A discussion regarding breast cancer risk reduction occurred with 22/24 (92%) of these patients during the visit, while the PCPs chose to use the decision aid with only 13/24 (54%) of them. PCP chose to view the decision aid during the visit with more high risk patients than average risk patients (p=0.04). Use of the DA during the appointment did not alter provider satisfaction with visit. A majority of patients thought the DA was helpful in making a decision and would recommend it to women like them.

Conclusions: Performing personalized risk assessment and use of the decision aid in the primary care setting was feasible and acceptable. These results suggest risk assessment alone may be enough to encourage a discussion about breast cancer risk reduction for some providers. This method of risk assessment and decision support holds promise in the effort to reduce the incidence and burden of breast cancer.

**Improved Breast Cancer Risk Assessment in Biopsied Women Using the Polyfactorial Model Oncovue®.**

*Jupé ER, Pugh TW, Knowlton NS, DeFreese DC. InterGenetics Incorporated, Oklahoma City, OK; NSK Statistical Solutions, LLC, Choctaw, OK*

**Background:** Regardless of the result, women that have undergone a breast biopsy are considered at increased risk due to the clinical circumstances leading to the need for the procedure. Both the number and outcome of biopsy are considered in the widely used Breast Cancer Risk Assessment Tool (BCRAT) also known as the Gail model. Accurately estimating individualized risk of developing breast cancer is useful for early detection and cancer prevention. Although the BCRAT has been demonstrated to accurately estimate the number of breast cancers likely to emerge in a population of women seeking regular mammography screening, it does not produce accurate individualized risk estimates for patient counseling. We have simultaneously analyzed gene polymorphism and clinical factor data in breast cancer cases and matched controls to develop a polyfactorial risk model (OncoVue) to improve estimation of individual risk. In three independent patient populations, OncoVue has been shown to significantly outperform both the BCRAT and composite risk scores produced by combining GWAS SNP risks with the BCRAT. Here we have characterized the performance of OncoVue in stratifying risk in women that have had one or more breast biopsies.

**Materials and Methods:** Risk scores were analyzed for participants ranging in age from 35 to 89 for a subset of participants that had enrolled in a larger case-control study conducted in six distinct geographic regions of the United States. The current study focused on the analysis of participants that had reported one or more biopsies (cases prior to diagnosis/controls at time of enrollment) amounting to 1265 Caucasian women (537 cases and 728 controls) in a model building set and 303 women in an independent validation set (134 cases and 169 controls). DNAs were genotyped for 22 SNP variants and genotype information was combined with clinical risk factor information to calculate the risk scores for the individual participants. Clinical factor information was also used to calculate BCRAT risk scores. The performance of OncoVue was examined in comparison to the BCRAT alone.

**Results:** For both models, positive likelihood ratios (PLR) were calculated as the proportion of patients with breast cancer with an elevated lifetime risk estimate (≥20%) divided by the proportion of disease-free individuals with an elevated risk estimate. In both the model building and validation sets, OncoVue exhibited approximately a 2.0-fold improvement compared to the BCRAT in more accurately assigning elevated risk estimates to breast cancer cases. In these women that are already considered at increased risk because of a history of biopsy, the observed level of improved performance of OncoVue was similar to that in our previous overall studies.

**Conclusions:** The OncoVue polyfactorial risk model incorporating both genetics and clinical factors improves on individualized breast cancer risk estimation compared to the BCRAT which uses only clinical factors. The performance in biopsied women further supports the potential utility of OncoVue for directing prevention and screening decisions.

---

**Evaluation of BRCAPRO Risk Assessment Model in Patients with Ductal Carcinoma In Situ.**

*Muse KI, Elsayegh N, Gutierrez-Barrera AM, Kerber H, Valero V, Litton JK, Hortobagyi GN, Arun BK. UT MD Anderson Cancer Center, Houston, TX*

**Background:** The BRCAPRO model is used to predict a patient’s likelihood to possess a BRCA1 or BRCA2 gene mutation based upon personal and family history. Ductal carcinoma in situ (DCIS) is considered a non-invasive condition which can progress to an invasive breast cancer if left untreated. Currently, DCIS is not specifically accounted for in the BRCAPRO model, thereby causing DCIS to be weighted in the same manner as an invasive breast cancer diagnosis. Historically, a diagnosis of DCIS has been entered as having developed into an invasive breast cancer ten years later. However, there are no standard guidelines of how DCIS should be entered. We sought to determine if there were any differences in how DCIS was treated in the BRCAPRO model to predict the more effective method in calculating the BRCAPRO. Methods: Women with pure DCIS, who were referred for genetic counseling and underwent genetic testing, were included in the study. The likelihood of carrying a BRCA mutation was calculated using the BRCAPRO model (Version 5.1). Patient characteristics which were entered into the BRCAPRO model include: tumor markers (estrogen receptor-ER and progesterone receptor-PR), history of oophorectomy prior to diagnosis, family history of 1st and 2nd degree relatives with breast and ovarian cancer, race and Ashkenazi Jewish ancestry. Each patient’s BRCAPRO risk estimate was calculated and compared by entering DCIS at the presenting age of diagnosis and by adding 10 years to the age of diagnosis. Descriptive statistics and a student’s t-test were used to compare BRCAPRO estimates between the two groups. Results: Ninety-five patients with pure DCIS underwent genetic counseling and testing. The average age of DCIS diagnosis was 45 years (range 26-65). Of the 95 DCIS patients included in the study 21% (n=20) tested positive for a BRCA gene mutation (8 BRCA1 and 12 BRCA2), 77% (n=74) test negative and 0.01% (n=1) had a variant of uncertain significance. Overall, DCIS patients who tested positive for a BRCA mutation had a higher BRCAPRO (40%) than patients who tested negative (12%) when presenting age of diagnosis was assessed. When 10 years was added, the BRCAPRO estimate was still higher amongst BRCA positive patients (28%) than BRCA negative patients (8%). The mean BRCAPRO probability when DCIS was entered at presenting age of diagnosis was 18% (0.1-95.4) versus 12% (0.1-89.9) when calculated 10 years later. Conclusion: In our cohort there was no significant difference in BRCAPRO probability whether DCIS was entered at the presenting age of diagnosis or 10 years later (p=0.1). However, future studies are needed to determine the most effective method to incorporate DCIS into the BRCAPRO model in order to determine those individuals who may or may not be at increase risk to possess a BRCA gene mutation.
P4-10-07
Clinico-Pathological Features of Breast Cancer Patients with Primary Metastatic Disease Versus Localized Disease: A Multicenter Study.
Barinoff J, Hils R, Bender A, Gross J, Kurz C, Tauchert S, Mann E, Schwidde I, Ipsen B, Sawitzki K, Heitz F, Harter P, Traut A, du Bois A. Kliniken Essen Mitte, Essen, Germany; Dr.-Horst-Schmidt-Klinik, Wiesbaden, Germany; Asklepions Klinik, Lich, Germany; Sankt Gertrauden-Krankenhaus, Berlin-Wilmersdorf, Germany; Klinikum Esslingen, Esslingen am Neckar, Germany; CaritasKlinik St. Theresia, Saarbrücken, Germany; Universitätssklinikum Gießen und Marburg, Standort Marburg, Marburg, Germany; Klinikum Frankfurt Hôchst, Frankfurt am Main, Germany; Evangelisches Krankenhaus Wesel, Wesel, Germany

Objective: Approximately 6% of breast cancer patients present with primary metastatic disease (pmBC) at first diagnosis. Clinico-pathological differences to non-metastatic patients are undetermined.

Methods: Exploratory analysis of patients with pmBC treated in 8 breast cancer units between 1998 and 2010. Tumor characteristics of these patients were compared with non-metastatic breast cancer patients (BC) of one breast cancer center who had neither local-recurrence nor distant metastases during 30 months of follow-up after first diagnosis. Standard staging in patients with first recurrence nor distant metastases during 30 months of follow-up. These patients were compared with non-metastatic breast cancer patients of one breast cancer center who had neither local-recurrence nor distant metastases during 30 months of follow-up.

Results: 2,214 patients were included, 1,642 with BC and 572 with pmBC, respectively. Patients with pmBC were 7 years older (BC 58 years of age vs. pmBC 65 years; p=0.000) and were more likely to be postmenopausal (74% vs. 83%; p=0.000). Most common localizations of distant first metastases were bone (61.5%), liver (24%), lung (21%) and non-axillary lymph nodes (12%).

85 (15%) patients with pmBC were diagnosed in stage T1. Factors associated with pmBC in multivariate analysis for this group were positive lymph node status (OR 4.8; 95%CI 1.1-13.0; p=0.017) and grading 3 (OR 1.6; 95% CI 1.1-2.3; p=0.019) were reported as risk factors for this group. 90 (16%) and 200 (35%) patients were diagnosed with stages T3 and T4, respectively. In T3/4 tumors a positive lymph node status (OR 5.2; 95% CI 2.9-9.3; p=0.000) and grading 3 (OR 2.2; 95% CI 1.2-3.9; p=0.009) could be defined as significant risk factors for distant metastases.

Postmenopausal status was associated with primary metastases in stage T2; positive lymph node status (OR 4.8; 95%CI 1.1-13.0; p=0.017) and grading 3 (OR 1.6; 95% CI 1.1-2.3; p=0.019) were reported as risk factors for this group. 90 (16%) and 200 (35%) patients were diagnosed with stages T3 and T4, respectively. In T3/4 tumors a positive lymph node status (OR 5.2; 95% CI 2.9-9.3; p=0.000) and grading 3 (OR 2.2; 95% CI 1.2-3.9; p=0.009) could be defined as significant risk factors for distant metastases.

Conclusion: The clinico-pathological features of breast cancer patients with or without primary metastases differ. In all stages positive lymph node status and higher grading were associated with pmBC significantly. Lobular histology was reported as a risk factor for T1-2 compared to patients without metastases. This feature was not found for T3/4 pmBC. T1 pmBC were likely to be associated with luminal B phenotype. T3-4 pmBC have not been associated with any phenotype or hormone receptor constellation as risk factor for metastases. Tumor biology seems to play a minor role for risk of metastases in T3-4 stages compared to patients with T1-tumors. Findings from this analysis should be considered in the choice of staging methods, especially in stage T1.

P4-10-08
Risk Factor Profiles of Women with DCIS and Invasive Ductal Breast Cancers.
Schnabel F, Chun Kim J, Billig J, Cimeno A, Mehta P, Gudh A, Hochman T, Shapiro R, Hoots K, Siegel B, Axelrod D. NYU Cancer Institute, NYU Langone Medical Center, New York, NY; NYU Langone Medical Center, New York, NY

Background
There are well established risk factors for breast cancer, including elements of personal and family history. Ductal carcinoma in situ (DCIS) and invasive ductal carcinoma (IDC) have long been viewed as representing two points on the spectrum of one disease. There is limited and conflicting information in the literature regarding risk factor profiles for DCIS as compared with IDC. The purpose of this study was to investigate the relationship of established risk factors in a population of women newly diagnosed with pure DCIS and IDC.

Methods
The Breast Cancer Database at NYU Langone Medical Center was queried for women who were diagnosed with pure DCIS and IDC from 1/2010-3/2011. Variables of interest included: age, family history of breast cancer (FHBC), BRCA1/2 status, age at menarche and menopause, parity, age at first birth, breast feeding, body mass index (BMI), history of atypical hyperplasia or lobular carcinoma in situ (ADH, ALH, LCIS), stage, ER/PR status, and method of presentation. Wilcoxon non-parametric tests, Chi-Square tests, and Fisher’s Exact Tests were used to evaluate differences among DCIS and IDC patients.

Results
Of the 593 women identified in this study, 140 (24%) had pure DCIS and 453 (76%) had IDC. The median age at diagnosis was 59 years. There were 9 (1.5%) BRCA1/2 mutation carriers. Of these, 7 had IDC and 2 had DCIS. The majority of patients with IDC were stage I (67%) and ER/PR+ (73%). The majority of patients with DCIS were also ER/PR+ (71%). In our cohort, the majority of DCIS (83%) was mammographically detected versus 47% of IDC cases. There were no statistically significant differences in breast cancer risk factors between the two groups.

*Wilcoxon Non-Parametric Test, ^Pearson’s Chi-Square, ^^Fisher’s Exact Test

Conclusions
In contrast to some previously published work, the risk factor profile in our cohort was similar for patients with IDC and DCIS. In this population, the majority of cases of DCIS were detected mammographically, underscoring the importance of mammography in early detection of breast cancer. There is increasing interest in identifying a population of women with DCIS who might never progress to invasive disease. Our data suggests that this population...
is unlikely to be distinguished by its risk factor profile. Genetic and molecular characteristics are more likely to provide the criteria by which this subgroup of patients is identified.

P4-10-09
Hormone Replacement Therapy: A Benign Breast Disease’s Risk?

Background
Use of hormone replacement therapy (HRT) has been associated with increased risk of breast cancer. However, relations between use of HRT and benign breast lesions remain contradictory (1-3). Our goal was to investigate whether HRT and its duration use are associated with benign breast lesions.

Materials & Methods
From 2001 to 2007, 2708 patients with a non palpable breast lesion were referred to our breast care center. Radiological abnormalities were screened either by breast ultrasound mammography, or MRI. Of those, 1,329 patients had a biopsy in our Radiology Unit. We focus on the postmenopausal women (n=739). Clinical data including HRT use extent were reported. Patients with previous history of benign breast disease or malignancy were excluded.

Results
The analysis was performed on 739 patients. Biopsies yielded a benign result in 414 (56%) of them (fibroadenoma n=71, blunt duct adenosis n=94, fibrocystic disease n=92, epithelial hyperplasia n=56, others n=101), high risk lesions in 57 (8%) (atypical ductal hyperplasia n=28, atypical lobular hyperplasia n=19, lobular carcinoma in situ n=10) and malignancy in 268 (36%) (not studied here). For the 471 patients with benign or high risk breast lesion, the median age was 59 years, 80% had at least one pregnancy and 27% had a family history of breast cancer. Among these 471 patients, 47% of them had used an oral contraceptive and 53% of them a HRT, with a mean duration of use of 2 years.

The HRT use was not significantly associated with the type of benign or high risk breast disease. No association was observed either between breast disease and duration of HRT (less or more than 7 years). Older age was significantly correlated to atypia or carcinoma (median age at diagnosis: 59 y.o in benign lesions, 60 y.o in high risk lesions and 62 y.o in malign lesions, with significant difference) (p<0.0001).

Conclusion
In this study of postmenopausal women, HRT and its duration use were not associated with the type of benign or high risk breast lesion. Although a lack of statistical power may be invoked to explain the results, we are called to believe that the magnitude of an effect of HRT use is small, if ever it exists.

P4-10-10
Breast Cancer Risk Factors among Asian Versus Caucasian Women with BRCA1/2 Mutations.
de Bruin MA, Kwong A, Goldstein BA, Lipson JA, Ikeda DM, McPherson LA, Sharma B, Kardashian A, Schackmann EA, Kingham KE, Mills MA, West DW, Ford JM, Kurian AW. Stanford University School of Medicine, Stanford, CA; University of Hong Kong Li Ka Shing Faculty of Medicine, Hong Kong, China

Background: Prior research suggests that the prevalence and penetrance of BRCA1/2 mutations may be different in Asians compared with Caucasians. Such differences in penetrance could be related to genetic, as well as hormonal, reproductive and lifestyle factors.

Methods: Chinese and Caucasian BRCA1/2 mutation carriers were recruited from genetics clinics in Hong Kong and California. We compared personal and family history of cancer, as well as hormonal, reproductive and lifestyle exposures between racial groups. Breast density was estimated using BI-RADS breast composition categories on mammogram. We analyzed DNA samples for single-nucleotide polymorphisms (SNPs) that may modify BRCA-associated cancer risk, and compared the prevalence between groups. A multivariable analysis of potential modifiers of cancer risk is underway.

Results: Forty-two Chinese women from Hong Kong and forty-nine Caucasian women from California were enrolled. BRCA1 mutations were more common in Caucasian women (63% vs. 43%, P=0.05), while BRCA2 mutations were more common among Chinese women (57% vs. 33%, P=0.02). More Chinese women had a personal history of breast cancer (91% vs. 53%) and ovarian cancer (12% vs. 4%). In contrast, significantly more Caucasian women had a family history of breast and ovarian cancer. On average, Caucasian women had higher parity, breastfed more, had less dense breasts on mammogram, and more often underwent prophylactic oophorectomy, all of which are protective against breast cancer in the general population. However, Caucasian women also consumed more alcohol and had higher average BMI. Risk associated alleles in RAD51, MAP3K1 and TOX3/TNRC9 were more common in Chinese women; risk associated alleles in FGFR2 and RASSF1 were similar in frequency between groups. Results of the multivariable analysis are pending and will be presented.

Discussion: We found notable differences between Chinese and Caucasian women in the proportion of BRCA1 versus BRCA2 mutations, and in the distribution of hormonal, reproductive and lifestyle factors, and SNPs associated with breast cancer risk. Such variations in risk-modifying factors may contribute to differences in BRCA mutation penetrance. Enhanced understanding of racial differences in BRCA1/2 mutation epidemiology may inform targeted cancer screening and prevention strategies.
demonstrated that this marked increase is mostly due to an increase in the estrogen receptor (ER)-positive subtype. It is necessary to establish risk factors capable of predicting the risk of ER-positive breast cancer which will enable the efficient selection of candidates for preventive chemotherapy. We analyzed genetic factors, including 14 single nucleotide polymorphisms (SNPs), environmental risk factors (body-mass index (BMI), age at menarche, pregnancy, age at first birth, breastfeeding, family history of breast cancer, age at menopause, use of hormone replacement therapy, alcohol intake and smoking), serum hormones and growth factors (estradiol, testosterone, prolactin, insulin-like growth factor 1 (IGF1) and IGF binding protein 3 (IGFBP3)) and mammographic density in 913 women with breast cancer and 278 disease-free controls. To identify important risk factors, risk prediction models for ER-positive breast cancer in both pre- and postmenopausal women were created by logistic regression analysis. In premenopausal women, 1 SNP (CYP19A1-rs10046), age, pregnancy, breastfeeding, alcohol intake, serum levels of prolactin, testosterone and IGFBP3 were considered to be risk predictors. In postmenopausal women, 1 SNP (TP53-rs1042522), age, BMI, age at menopause, serum levels of testosterone and IGF1 were identified as risk predictors. Risk factors may differ between women of different menopausal status, and inclusion of common genetic variants and serum hormone measurements as well as environmental factors might improve risk assessment models. Further validation studies will clarify appropriate risk groups for preventive chemotherapy.

Bilateral Oophorectomy Is Associated with a Higher Prevalence of Arthritis and Lower Bone Mineral Density in Women 40 Years and Older.

McCarthy AM, Visvanathan K. Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD

**Background:** BRCA 1/2 mutation carriers are encouraged to have their ovaries removed by age 40 to reduce cancer risk and prolong survival. Given the recency of genetic testing, it will be some years before robust estimates are available of the long term adverse effects. In the meantime data from the general population can help inform women and providers about potential adverse effects so that preventive strategies can be implemented. Bone loss accelerates following natural menopause and oophorectomy before age 45 is a known risk factor for osteoporosis. However there is limited data quantifying the effects of bilateral oophorectomy on bone mineral density (BMD), an early sensitive marker of osteoporosis.

**Methods:** We evaluated the associations of oophorectomy with arthritis and BMD in NHANES III, a nationally representative survey conducted 1988-1994. For analysis we included women aged 40 years and older with no history of cancer who reported a bilateral oophorectomy or intact ovaries. Women were asked if a doctor told them they had arthritis. Femoral neck BMD was measured by dual energy x-ray (DXA). Osteoporosis was defined as BMD (g/cm^2) more than 2.5 standard deviations below the mean of white women aged 20-29 years. Survey weights were used to account for the complex survey design. Odds Ratios (OR) for arthritis and osteoporosis were estimated using logistic regression. Oophorectomy status was categorized into intact ovaries, oophorectomy <45 years, and oophorectomy ≥45 years. Multivariate models were adjusted for age at interview, race, income, smoking status, education, alcohol, and BMI. Analyses were repeated excluding women who reported using hormone replacement therapy (HRT).

**Results:** The sample size was 4039 for the arthritis analysis and 3660 for the BMD analysis. Women with oophorectomy were more likely to report arthritis than women with intact ovaries (45.4% vs. 32.1%; p<0.001). The prevalence was even higher in women with oophorectomy <45 years (47.7%). The age-standardized mean femoral neck BMD was lower for women reporting oophorectomy at <45 years than women with intact ovaries (0.711 vs. 0.743 g/cm^2; p=0.017). In multivariate models women with oophorectomy had greater odds of arthritis than women with intact ovaries, particularly among women with oophorectomy <45 years (OR=1.78 95% CI 1.31-2.42). The odds of arthritis were even greater after excluding HRT users (OR=1.99 95% CI 1.25-3.18). Similarly, women who had a prior oophorectomy had greater odds of osteoporosis than women with intact ovaries, particularly among women with oophorectomy <45 years (OR=1.78 95% CI 1.07-2.97). The odds were increased further after excluding HRT users (OR=2.92 95% CI 1.32-6.44).

**Conclusions:** The prevalence of arthritis and osteoporosis were significantly greater in women who reported bilateral oophorectomy. Results were most profound among women whose oophorectomy was performed before age 45 and among women who never used HRT. These results suggest that women who undergo oophorectomy for cancer prevention should be closely monitored for osteoporosis over the long term.

**P4-11-02**

Insulin-Like Growth Factor-1 (IGF-1), Insulin-Like Growth Factor Binding Protein-3 (IGFBP-3) and Lobule Type among Women in the Nurses' Health Study II (NHS II).

Collins LC, Rice MS, Shen D, Connolly JL, Schnitt SJ, Tamimi RM. Beth Israel Deaconess Medical Center and Harvard Medical School; Brigham and Women’s Hospital and Harvard School of Public Health, Boston

In a previous analysis of women enrolled in NHSII, we found that among women diagnosed with benign breast disease (BBD), those with predominant type 1/no type 3 lobules were at lower risk of subsequent breast cancer compared to women with other lobule types. Additionally, studies in animal models suggest that higher levels of IGF-1, a polypeptide hormone involved in the proliferation/differentiation of normal mammary epithelium, may inhibit involution of breast lobules. However, the interaction between IGF-1 levels and lobule types in determining breast cancer risk has not been previously evaluated. Therefore, we examined the association between IGF-1 levels and lobule type among women with BBD.

**Methods:** We conducted a cross-sectional study among 484 women in NHSII with biopsy-confirmed BBD between 1993-2001 who had blood samples available for determining levels of IGF-1 and IGFBP-3. A pathologist, blinded to exposure status, classified lobule type on biopsy slides according to the number of acini per lobule (type 1 = 12; type 2=50; type 3~80 acini). Lobule type was classified into (1) predominant type 1/no type 3 lobules or (2) other lobule types. Multivariate logistic models were used to assess the associations between plasma IGF-1, IGFBP-3, and IGF-1/IGFBP-3 levels with lobule type. Models were adjusted for age, IGF-1 batch and additional potential confounders in secondary analyses.

**Results:** In univariate analyses, older age at biopsy, higher body mass index, postmenopausal status, nulliparity, and lower IGF-1 levels were associated with predominant type 1/no type 3 lobules (p<0.05). In multivariate logistic models adjusting for age, higher IGF-1 levels were associated with a decreased risk of predominant type 1/no type 3 lobules (OR quartile 4 vs. quartile
1 = 0.35, 95% CI: 0.15-0.81). Greater IGF-1/IGFBP-3 ratio was also associated with a decreased risk of predominant type 1/no type 3 lobules (OR quartile 4 vs. quartile 1 = 0.24, 95% CI: 0.10-0.57).

IGF-1/IGFBP-3 Ratio and Lobule Type.

Model 1: Age and batch

Quartile 1 (30/91) Quartile 2 (20/101) Quartile 3 (19/102) Quartile 4 (9/112)

p-value

0.60 (0.30, 1.21) 0.59 (0.28, 1.19) 0.24 (0.10, 0.57) <0.01

Model 2: Model 1 + BMI, Menopausal Status, Histological categories

Quartile 1 (30/91) Quartile 2 (30/96) Quartile 3 (30/93) Quartile 4 (9/111)

p-value

0.74 (0.36, 1.55) 0.73 (0.33, 1.60) 0.34 (0.13, 0.86) 0.07

Model 3: Model 2 + parity, alcohol

Quartile 1 (30/91) Quartile 2 (30/96) Quartile 3 (30/93) Quartile 4 (9/111)

p-value

0.79 (0.38, 1.66) 0.79 (0.36, 1.75) 0.34 (0.13, 0.86) 0.06

Outcome is predominant type 1/no type 3 lobules (complete involution)

These associations persisted, though were slightly attenuated, in models adjusting for additional potential confounders. **Conclusion:** Higher IGF-1 levels and greater IGF-1/IGFBP-3 ratios are associated with a decreased risk of predominant type 1 lobules/no type 3 lobules among women with BBD in the NSHII. Whether this association contributes to the mechanism by which IGF-1 confers an elevated breast cancer risk requires further investigation.

**Prognosis of Pregnancy-Associated Breast Cancer: A Meta-Analysis Involving 39,415 Patients.**

Azim, Jr HA, Santoro L, Russell-Edu W, Pentheroudakis G, Pavlidis N, Peccatori FA. Institut Jules Bordet, Brussels, Belgium; European Institute of Oncology, Milan, Italy; University of Ioannina, Ioannina, Greece

**Background:** Pregnancy-associated breast cancer (PABC), defined as breast cancer diagnosed during pregnancy or one year after, is a relatively rare disease and hence considerable controversy exists regarding its prognosis compared to non-pregnancy-related breast cancer.

**Methods:** Two of the authors independently performed a literature search on MEDLINE and Cochrane Library with no date or language restrictions. Eligible studies were control-matched, population-based and hospital-based studies that have addressed the outcome of patients diagnosed during pregnancy or one-year afterwards. The control group was defined as patients diagnosed with breast cancer not related to pregnancy. The primary and secondary end-points were overall and disease-free survival respectively. Pooling of data was done using the random effect model. To control for potential differences between the two groups in systemic treatment and clinico-pathological features (e.g. tumor size, nodal status, ER, etc...) that could affect prognosis, we performed a sensitivity analysis by pooling the hazard ratios (HRs) of the adjusted multivariate models within each study. We also analyzed differences according to time of diagnosis (during pregnancy or post-partum), type of study and year of reporting the study. Finally, we communicated with the authors of the eligible studies to collect unpublished statistics relevant to our analysis to further refine our findings.

**Results:** 29 studies were included in this meta-analysis (2903 cases and 36,512 controls). Women diagnosed with PABC had a significantly higher risk of death compared to those diagnosed with non-pregnancy-related breast cancer (pooled hazard ratio (pHR): 1.47 [95% CI: 1.30-1.65]). A sensitivity analysis including 11 studies (1222 PABC cases, 19231 controls) adjusted for differences in tumor size, nodal status and systemic treatment showed the same result (pHR: 1.44 [95% CI: 1.17-1.77]). These findings were consistent in patients diagnosed either during pregnancy (pHR: 1.30 [95% CI: 1.01-1.67]) or in the post-partum period (pHR: 1.56 [95% CI: 1.08-2.26]) with no heterogeneity observed (p=0.43). Sensitivity analyses according to the type and year of study showed the same findings. Regarding the secondary end-point, only ten studies (531 cases, 1842 controls) provided sufficient information to estimate disease-free survival, and indeed PABC patients had a higher risk of relapse compared to breast cancer controls (pHR: 1.59 [95% CI: 1.23-2.07]). Collection of unpublished data is currently ongoing and further analyses will be presented at the meeting.

**Conclusion:** To the best of our knowledge, this is the largest analysis addressing the prognosis of PABC. Our results confirm that PABC is independently associated with a worse prognosis whether diagnosis is made during pregnancy or in the post-partum period. This underscores the possible impact of pregnancy on breast cancer biology. In this regard, we are currently interrogating potential biological differences between PABC patients and matched breast cancer controls at the gene expression level to elucidate the biology of this relatively rare, yet very challenging disease.

**P4-11-04**

**Risk of Primary (PBC) and Contralateral Breast Cancer (CBC) after Ovarian Cancer (OC) in BRCA1 and BRCA2 Mutation Carriers: Implications for Surveillance and Risk Reducing Mastectomy.**

**Background:** In view of the increased risk of developing breast (BC) cancer, BRCA mutation carriers are offered intensive surveillance or risk reducing mastectomy (RRM) and/or salpingo-oophorectomy (RRSO). It is insufficiently clear how to counsel mutation carriers who have been treated for OC, and it may be questioned whether RRM is indicated. It is possible that BC risk, both of primary (PBC) and contralateral BC (CBC), may be modified by the treatment given for OC mostly including surgery and platinum-based chemotherapy. Further, the BC risk has to be weighted against the risk of death after OC. So far, there are no data available on the PBC or CBC risk after OC in BRCA mutation carriers.

** Patients and Methods**

From the database of the institutional Family Cancer Clinic (FCC), we selected BRCA1-associated OC patients either without (n= 79, at risk of PBC) or with a history of unilateral BC (n=37, at risk of CBC). Controls were BRCA mutation carriers without OC, either without (n=351) or with a history of unilateral BC (n=294). Follow-up started at OC diagnosis, and for controls at date of first visit at the FCC or the 35th birthday. Exclusion criteria were: other malignancy besides epithelial OC or BC, inadequate follow-up data, bilateral breast cancer or mastectomy. Data analyses were performed using t- and chi-squared tests, and Kaplan-Meier survival method with death prior to BC as competing risk event.

**Results**

Only six OC patients (5.1%) did not receive chemotherapy as part of primary therapy for OC, five at risk of PBC and one at risk of CBC. Chemotherapy schedules were mainly platinum-based (92%). RRSO was performed in 45% of the controls. The risks of PBC at 2, 5, and 10 years in BRCA-associated OC patients were 3%, 6% and 11%, respectively, versus 6%, 16% and 28% in unaffected BRCA mutation carriers (p=0.03). The mortality...
rate at those time points in the OC group was 13%, 33% and 61%, respectively, versus 1%, 2% and 2% in unaffected mutation carriers (p<0.001). In patients with a history of unilateral BC, the risks of CBC at 2, 5, and 10 years in OC patients were 0%, 7% and 7%, respectively, versus 6%, 16% and 34% in the BC patients without OC (p=0.06). The mortality rate at similar time points was 19%, 34%, and 55%, respectively, in the OC group versus 4%, 11%, and 21% for the non-OC patients (p<0.001).

Conclusions
The risk of developing a PBC or CBC was much lower in BRCA mutation carriers with a history of OC than in mutation carriers without OC. Also, since the 10-year mortality rate after ovarian cancer was 55-60% and the risk of developing a PBC or CBC at the highest was 11% over the same time period, our data suggest that intensive breast cancer surveillance strategies for the BRCA-associated ovarian cancer group might be reconsidered, while risk reducing mastectomy is not indicated unless in specific cases requiring careful consideration in a multidisciplinary setting. Further studies in larger groups are warranted.

P4-11-05
Association between Bisphosphonate Use in Metastatic Breast Cancer (MBC) and Overall Survival.
Mathew A, Mathew IE, Rosenzweig MQ, Brufskey AM. University of Pittsburgh Medical Center; University of Pittsburgh Cancer Institute; Magee-Womens Hospital

Background: Pre-clinical studies on bisphosphonates in breast cancer have suggested an anti-tumor effect in addition to its bone protective role. However, randomized controlled trials of bisphosphonates versus placebo have found little evidence of increased overall survival (OS) in MBC. We conducted a retrospective single institution cohort study of MBC patients to evaluate the association between bisphosphonate use and overall survival.

Methods: Baseline demographic and tumor specific data were collected on newly diagnosed MBC patients between January 1998 and December 2009. Other variables included the number and sites of each metastasis, use of baseline neoadjuvant and adjuvant chemotherapy, and use of hormonal therapy. Bisphosphonate use was defined as present if it was administered for a period of at least 3 months in the metastatic setting. Overall survival was determined from the date of diagnosis of first metastatic disease. Survival analysis was performed using the Kaplan-Meier method and Cox proportional-hazards model.

Results: Data were available on 737 patients with MBC, of whom 434 died during a median follow-up of 2 years; median age was 50.3 years. 92% of patients were Caucasian; 32% were both ER and PR-negative; and 31% were HER2-positive. Over 67% of MBC patients had bone metastasis and nearly 80% received bisphosphonates. Multivariate analysis found an overall survival benefit for bisphosphonate use, with a hazard ratio of 0.63 (95% confidence interval: 0.48-0.84; p=0.002), when adjusted for variables with significant effect on survival on univariate analysis and other known prognostic variables. These variables include age, stage at diagnosis, race, hormone receptor status, HER2 status, and number of metastatic sites, presence of bone metastasis and the use of adjuvant therapy. The administration of adjuvant therapy did not yield a significant survival advantage in the analyses.

Conclusion: This retrospective cohort study provides evidence for an OS benefit with the use of bisphosphonates in MBC even after controlling for other significant prognostic factors.

P4-11-06
Uptake of Selective Estrogen Receptor Modulators and Other Breast Cancer Prevention Strategies among High-Risk Women Seen in a Breast Center.

Background: Selective estrogen receptor modulators (SERMs), tamoxifen and raloxifene, are FDA-approved for breast cancer (BC) risk reduction. However, uptake has been poor in the prevention setting, partly due to a lack of knowledge in the medical community about BC prevention and public misconceptions about the risks of SERMs. We assessed demographic and clinical factors that influence SERM uptake among high-risk women seen in an academic breast center, where specialized risk counseling is provided by a breast surgeon or medical oncologist.

Methods: Potential subjects included high-risk women seen for an initial consultation by Breast Surgery or Medical Oncology. Eligibility for SERM use included a 5-year Gail risk ≥1.67%, lobular carcinoma in situ (LCIS), BRCA mutation carrier, or estrogen receptor (ER)-positive and/or progesterone receptor (PR)-positive ductal carcinoma in situ (DCIS). Demographic and BC risk factor data was collected from self-administered questionnaires. Clinical data, including prior/current SERM use, was abstracted from medical chart review. Differences in distribution of risk factors, between women who ever took a SERM and those who did not, were examined using chi-square statistics or Fisher’s exact test. Multivariable logistic regression models were used to calculate odds ratios (OR) and 95% confidence intervals using SERM use as the dependent variable.

Results: Among 247 high-risk women enrolled between March 2007 and January 2011, median age 51 (17-82); White/Hispanic/Black/Asian (%): 55/32/7/6. 85% of women were undergoing annual mammography; 94% had a breast biopsy, 19% genetic testing, and 71% Medical Oncology referral. Among 181 (73%) women eligible for a SERM, Gail risk ≥1.67%/LCIS/DCIS/BRCA mutation (%): 35/22/39/3; 83 (46%) ever took a SERM, including 62 on tamoxifen and 21 on raloxifene. Early SERM discontinuation was only 7%. In multivariable analysis, significant predictors of SERM uptake included risk category (DCIS vs. Gail risk ≥1.67%/LCIS/BRCA mutation), higher income, higher body mass index (BMI), and referral to Medical Oncology. In terms of this high-risk population meeting American Cancer Society (ACS) behavioral guidelines for cancer prevention, 53% had a BMI <25 kg/m2, 44% consumed ≤1 alcoholic beverage per day, and 10% engaged in ≥4 hours of moderate physical activity per week; only 3.5% met all 3 recommendations.

Conclusions: Among high-risk women seen at a specialized breast center, application of clinical recommendations such as screening mammography, genetic testing, and SERM uptake were relatively high, suggesting that a comprehensive approach to the management of high-risk women is feasible. However, meeting ACS nutrition and physical activity guidelines for cancer prevention was limited, perhaps due to a lack of reimbursable staff to implement these guidelines. Breast cancer risk assessment and available interventions for prevention among high-risk women are underutilized in the U.S. Future studies should focus on the development and delivery of breast cancer prevention strategies.
P4-11-07

Background: Currently there are no real attempts internationally to tailor breast screening programmes to individual risk.

Methods: We have assessed the feasibility of collecting breast cancer risk information during routine mammographic screening in the National Health Service Breast Screening Programme (NHSBSP) in England, in order to consider, ultimately, adapting the screening interval to risk of breast cancer and introducing preventive strategies in women at high risk. The study Predicting Risk Of Cancer At Screening (PROCAS) aims to recruit 60,000 women over 3 years. Results: 26,000 women (June 8th 2011) have so far given consent to join the study. Thirty six percent of the first 20,000 women in nineteen screening sites in Manchester consented to enter the study and completed a risk factor questionnaire. The median 10 year breast cancer risk was 2.65%, with 926 (9.26%) of the first 10,000 women having a 10 year risk of ≥5% and 92 (0.92%) having a 10 year risk of ≥8% (Tyrer-Cuzick), IQR:1.35. 832 (8.32%) women had a mammographic density of 60% or greater (Visual Analogue Scale). We collected saliva samples from 1019 women for genetic analysis and will extend this to 18% of participants. Of those who agreed to participate in the study, 94% indicated that they wished to know their breast cancer risk. Women with a 10-year risk of ≥8%, and women with a 10-year risk of ≥5% and mammographic density ≥60% were invited to attend or be telephoned to be counselled. To date 138 have accepted with 135, so far, having received risk counselling. Nineteen percent of the high-risk women identified subsequently decided to enter a randomised breast cancer prevention study with either a dietary or drug intervention (IBIS2, anastrozole vs placebo). Results from the first 1,000 women who provided DNA samples suggest that the risk information from the 18 validated SNPs may enhance existing risk models. Conclusion: This study demonstrates that it is feasible to determine individual breast cancer risk and offer women appropriate risk-reducing interventions within the context of a population-based mammographic screening programme.

P4-11-08
Changes in the Distribution of Loco-Regional and Distant Breast Cancer Recurrences over the Last 20 Years: Implications for Patient Care and Future Research.

Bouganim N, Clemons M, Amir E. The Ottawa Hospital Cancer Center, Ottawa, ON, Canada; Princess Margaret Hospital, Toronto, ON, Canada

Introduction: Improvements in adjuvant therapy have led to a sustained fall in recurrences after early breast cancer. The differential reduction of both local-regional and systemic recurrences is poorly understood. This study aimed to explore changes in the distribution of loco-regional and distant recurrences in clinical trials reported over the last 20 years. We also aimed to determine the relative impact of adjuvant chemotherapy and endocrine therapy.

Methods: A MEDLINE search for adjuvant, Phase III randomized breast cancer clinical trials between January 1990 and March 2011 was performed. Neo-adjuvant, single agent biologics and studies that did not report the proportion of loco-regional and distant recurrences were excluded. Change in the frequency of recurrences was assessed as the non-parametric correlation between the number of loco-regional recurrences (as a proportion of all recurrences) and time. Studies were weighted by sample size. Pre-specified subgroup analyses were assessed using the interaction test and included type of surgery performed, radiotherapy use, menopausal status and type of systemic therapy delivered. Definition of local and distant recurrences differed between studies. For consistency, loco-regional recurrences were classified as recurrences limited to the ipsilateral breast, chest wall, axillary, supraclavicular and internal mammary lymph nodes. Any other recurrence was defined as distant, with the exception of contralateral breast cancer, that was excluded from this analysis.

Results: Fifty-three randomized clinical trials with a total of 86,598 patients were included in the analysis. Between 1990 and 2011, the proportion of loco-regional recurrences has decreased from approximately 50% to 10% (Spearman’s rho = -0.40, p<0.001).

Conclusion: Advances in treatment of early breast cancer have differentially reduced the proportion of loco-regional recurrences compared with distant recurrences. In recent trials, loco-regional recurrences account for less than 10-15% of all recurrences. These falling event rates may affect patient care, especially when deciding on treatments influencing loco-regional control. This change may also impact on the design of clinical trials assessing loco-regional therapy such as surgery and/or local radiation therapy.

P4-11-09
Polymorphisms Related to Steroid Hormone Concentrations in Nipple Aspirate Fluid (NAF).

Lee O, Chatterton RT, Shidfar A, Wang J, Scholten D, Khan SA. Northwestern University, Chicago, IL

Background: The steroid hormone concentrations in NAF are variable, and differ significantly from systemic levels. Single nucleotide polymorphisms (SNPs) in genes associated with the metabolism of estradiol (E2) to 4-hydroxyestradiol (CYP1B1) and a transporter of steroid sulfate uptake (SLCO2B1) may partially determine the steroid hormone level in NAF, and thereby contribute to breast cancer risk. We determined the relationship between SNPs of interest and the measured concentrations of sex steroids in NAF.

Methods: Blood samples of 263 women at high risk of breast cancer who produced NAF were extracted for gDNA, and 40 ng of gDNA was used to determine the presence of the selected SNPs or their wild type genes in all subjects by the Taqman Drug Metabolism panel. The concentrations of six steroid hormones, estradiol(E2), estrone (E1), progesterone (P4), testosterone (T), androstenedione (A4), and dehydroepiandrosterone (DHEA), from NAF were measured by immunoassay procedures after extraction and purification by High Pressure Liquid Chromatography. Comparisons of NAF steroid hormone concentrations were made for the polymorphism and wild type groups using the nonparametric Mann-Whitney tests (significance p < 0.05, two-tailed).
Results: 46% of the subjects carried the V432K polymorphism of CYP1B1 (rs1056836, C>G), and 45% of the subjects carried the S486F polymorphism of SLCO2B1 (rs2851069, C>T). All NAF hormone concentrations are represented as a median with a quartile range (25%, 75%). The NAF P4 levels of the V432K mutation carriers of CYP1B1 were significantly lower than those of subjects with the wild type alleles: 3.54 (1.62, 8.79) ng/mL and 7.65 (2.13, 27.77) ng/mL, respectively (p = 0.002). Those with the S486F polymorphism of SLCO2B1 had significantly higher E1 levels than the wild type subjects: 0.35 (0.14, 1.12) ng/mL and 0.25 (0.11, 0.59) ng/mL, respectively (p = 0.026) and significantly lower P4 levels: 3.77 (1.71, 11.53) ng/mL and 6.65 (2.34, 22.24) ng/mL, respectively (p = 0.021). In addition, we found that the women carrying both the V432K and S486F mutations had significantly lower P4 levels than the women carrying only the S486F mutation: 2.43 (1.45, 6.67) ng/mL and 6.94 (2.13, 26.64) ng/mL (p = 0.013). No associations were found between the other hormones and these polymorphisms.

Conclusions: The anticipated effects of CYP1B1 in increasing clearance of E2 and E1 were not observed. Instead, NAF E1 concentrations were significantly increased. In contrast, with the S486F polymorphism of SLCO2B1 the expected decrease in E1 and E2 in NAF was not observed; nor was the DHEA concentration decreased. These expectations were based on the reported lower activity of the S486F gene product. The decreased concentrations of NAF P4 associated with both polymorphisms are difficult to explain. Additional studies are required to understand the observed associations, but these findings raise the possibility that low P4 levels in NAF may be genetically determined, and suggest the hypothesis that this polymorphism may be related to a decreased risk of breast cancer.

P4-11-10
Perceptions, Knowledge and Satisfaction with Contralateral Prophylactic Mastectomy among Young Women with Breast Cancer.
Tracy MS, Meyer ME, Sepucha K, Gelber S, Hirshfield-Bartek J, Troyan S, Morrow M, Schapira L, Come S, Winer E, Partridge AE, Dana-Farber Cancer Institute, Boston, MA; Massachusetts General Hospital, Boston, MA; Memorial Sloan-Kettering Cancer Center, New York, NY; Beth Isreal Deaconess Medical Center, Boston, MA

Background: There has been an increasing prevalence of contralateral prophylactic mastectomy (CPM), particularly among younger women with breast cancer. There has been limited research evaluating patient preference, knowledge and decision-making regarding this issue. Methods: We surveyed women who had bilateral mastectomy who were enrolled in a multicenter, longitudinal cohort study of women diagnosed with breast cancer at age 40 and younger. The CPM survey included 23 items on decision making, knowledge, and satisfaction with CPM. Results: Of the 550 patients enrolled as of November 2010, 157 (28.5%) had bilateral mastectomy, of whom 124 completed the CPM survey (response rate 79%). Women with bilateral breast cancer (3% or bilateral prophylactic (1) indications for surgery were excluded. Median age at diagnosis was 37 years (range 26-40); 26 women (21%) reported having a genetic mutation (21 BRCA1 and 5 BRCA2). Excluding mutation carriers, women estimated that a median of 10 of 100 women (range 0-90) would develop contralateral breast cancer in the 5 years after unilateral breast cancer treatment and that 5 of 100 women (range 0-98) treated with CPM would develop contralateral breast cancer. Eighteen percent of all respondents believed that women who undergo bilateral mastectomy live longer. Women were asked the importance of potential reasons for undergoing CPM (see Table 1). Eighty-two percent of women were "extremely confident" in their decision to undergo CPM and 92% would "definitely" still choose CPM.

Table 1: Importance of reasons for choosing CPM

Conclusion: Young women with breast cancer have high rates of CPM. Many young women who have undergone CPM overestimate the risk of contralateral disease and the benefits of CPM, including believing that CPM will prevent metastasis and extend life. Interventions to counsel young women with early breast cancer to help them make optimal surgical treatment decisions are needed.

P4-11-11
Thyroid Disease Is Associated with Breast Cancer: A Meta-Analysis.
Hardefeldt PJ, Esliek GD, Edirimanne S. The University of Sydney, Sydney, NSW, Australia; Nepean Hospital, Penrith, NSW, Australia

Background: The controversial relationship between benign thyroid diseases and breast cancer has been investigated for over 50 years. Despite extensive population studies, the results as a whole have been inconsistent. The purpose of this study was to collate and analyse available data, calculating a pooled odds ratio of the risk of breast cancer in patients diagnosed with benign thyroid diseases.

Materials and Methods: Studies were obtained from a database search of MEDLINE, EMBASE, PubMed, Current Contents and Google Scholar with additional cross checking of reference lists. Inclusion criteria required a confirmed diagnosis of a benign thyroid disease, reporting of an odds ratio or data to calculate an odds ratio (and 95% confidence interval) and the use of an internal control group as the comparator. Collated data was assessed for heterogeneity and a pooled odds ratio calculated. From 276 citations identified in this search, a total of 28 studies were identified meeting our inclusion criteria. No language restrictions were used in the search or study selection. All data were analysed using a random effects model.

Results: There was significant evidence of an increased risk of breast cancer in patients with auto-immune thyroiditis, evident in a pooled odds ratio (OR) of 2.92 (95% CI: 2.13-4.01). No heterogeneity was present (I²=0, p=0.62) and there was no publication bias (p=0.15). In addition, the results supported an increased risk associated with the presence of anti-thyroid antibodies (OR 2.02, 95% CI: 1.63-2.50) and goitre (OR 2.19, 95% CI: 1.44-3.33). Moderate but non-significant heterogeneity was present in the analysis of goitre (I²=49.2, p=0.08). No heterogeneity was present in the analysis of antibody presence, moderate and non-significant heterogeneity was evident (I²=58.3, p=0.08) with no publication bias (p=0.07). Subgroup analysis of antibody presence revealed increased risk associated with both anti-TPO (OR 2.64, 95% CI: 1.82-3.83)
and anti-Tg antibodies (2.71, 95% CI: 1.58-4.69). No heterogeneity was present in the analysis of either subgroup evidenced in I² index of 29.3 (p=0.22) and 18.1 (p=0.30), respectively. Publication bias was not significant (p=0.53 and 0.17). Quantitative analysis of hypothyroidism and hyperthyroidism was not significant, evident in pooled odds ratios of 1.56 (95% CI: 0.78-3.12) and 1.56 (95% CI: 0.84-2.88), respectively. Heterogeneity was high in hypothyroidism (I²=80.9, p=0.001) yet minimal in hyperthyroidism (I²=0, p=0.75). Publication bias was not significant in either hypothyroidism (p=0.06) or hyperthyroidism (p=0.20).

Conclusion: While these results indicate a link between thyroid autoimmunity and breast cancer, further prospective studies are required to definitively prove causality.

### P4-11-12

**Molecular Phenotype of Breast Cancers in a Large Cohort of Young Women According to Time Interval Since Pregnancy.**

Collins LC, Gelber S, Marotti JD, Cole K, Kereakoglow S, Ruddy KJ, Brachtel EF, Schapira L, Come SE, Borges VF, Schedin PJ, Warner E, Winer E, Partridge A. Beth Israel Deaconess Medical Center, Boston; Harvard Medical School, Boston; Dana Farber Cancer Institute, Boston; Dartmouth-Hitchcock Medical Center, Lebanon, Hanover, NH; Brigham and Women’s Hospital, Boston; Massachusetts General Hospital, Boston; University of Colorado Cancer Center, CO; Sunnybrook Odette Cancer Centre, Toronto, ON, Canada

**Background:** The increase in breast cancer risk during pregnancy and post partum is well recognized. The cross-over to protective effect does not occur until many years later and varies with age at first birth. Recently, a genomic signature specific to the pregnant compared with the non-pregnant breast has been identified; this signature remains present in the postmenopausal parous breast. Given this, we investigated whether time interval since pregnancy affects the phenotype of breast cancers arising in young women compared with nulliparous women. Methods: We examined molecular phenotype, according to histologic grade and biomarker status, in relation to time since pregnancy in an ongoing prospective cohort study (n=355) of young women (≤40yrs) with breast cancer. Medical records were reviewed for tumor stage and receptor status. Parity was ascertained from questionnaires completed within 9 months of diagnosis. Tumor grade was determined by central pathology review. Using tumor grade and biomarker expression, cancers were categorized as luminal A (ER+ and/or PR+, HER2-, histologic grade 1 or 2); luminal B (ER+ and/or PR+, HER2+, or ER and/or PR+, HER2- and grade 3); HER2 type (ER-, PR-, HER2+); and triple negative (ER-, PR-, HER2- and grade 3); HER2 type (ER-, PR-, HER2+); and triple negative (ER-, PR-, HER2-). Results: The median age of the study population is 37 years (range 17-40). Overall, 80% of women had stage 1 or 2 disease; 67% of cancers were ER positive and 32% showed HER2 overexpression. The distribution of breast cancer molecular phenotypes by time interval since last pregnancy is shown in the table.

**In our large cohort of parous young women, we found no differences in the distribution of molecular phenotype according to time interval since pregnancy. However, nulliparous young women were more likely to develop luminal A cancers compared to parous women. (40% vs. 29%; unadjusted chi square p-value=0.03) and appeared less likely to develop HER2-type and triple negative cancers (7% vs. 13%, p-value=0.09 and 17% vs. 23%, p-value=0.22 respectively). There were no differences in the distribution of luminal B cancers. Conclusions: The distribution of molecular phenotypes is similar among parous young women regardless of the time interval since parturition. Nulliparous young women appear more likely to develop luminal A cancers compared to parous women. Whether the difference in molecular phenotypes of pregnancy-associated breast cancers vs. cancers arising in nulliparous women is due to the effects of genomic alteration remains to be investigated. Effects of a prior pregnancy appear consistent across a 5-year period, in keeping with the concept of genomic alterations identified in the normal pregnant breast and thereafter.**

### P4-11-13

**Influence of Two Years of Exemestane on Bone Mineral Density in Postmenopausal Women at Increased Risk of Developing Breast Cancer: a Companion Study to the NCIC CTG MAP3 Trial.**

Goss PE, Richardson H, Ingle JN, Chlebowski RT, Fabian CJ, Garber JE, Sarto GE, Hiltz A, Tu D, Cheung AM. Massachusetts General Hospital Cancer Center, Boston, MA; Queen’s University, Kingston, ON, Canada; Mayo Clinic, Rochester, MN; Los Angeles Biomedical Research Institute, Torrance, CA; University of Kansas Medical Center, Westwood, KS; Dana Farber Cancer Institute, Boston, MA; Center for Women’s Health and Health Research, Madison, WI; General Hospital, Toronto, ON, Canada

**Background:** Exemestane significantly reduced invasive and pre-invasive breast cancers in postmenopausal women at increased risk for breast cancer in the NCIC CTG MAP3 trial with no serious toxicities, including excess fractures or osteoporosis. **Purpose:** To provide additional information on the effect of exemestane on bone loss in women at high risk for breast cancer, within a subset of women participating on the NCIC CTG MAP3 trial. The primary hypothesis is that exemestane does not induce clinically significant bone loss in postmenopausal women at increased risk of developing breast cancer at 2 years. The primary objective of this companion study is to examine the effect of exemestane on lumbar spine and total hip BMD by DEXA at 2 years in women participating in the MAP3 trial.

**Methods:** The MAP.3B bone sub-study registered women from the main MAP.3 trial from May 2008 to March 2010. Eligible women had to have an acceptable quality BMD scan by DEXA taken within 12 months prior to randomization to MAP3. A BMD T-score >-2.0 SD (i.e. better than 2 standard deviations below the average peak BMD of a young adult woman) was established as the study population cutoff. A questionnaire including information on height, falls, fractures, lifestyle information including physical activity, tobacco and alcohol use was completed at baseline, 12 months, 24 months and at last visit. Fasting serum for bone biomarkers was collected at 12 months and total hip and L1-L4 (postero-anterior) spine BMD were measured 2 years after randomization on the same Lunar or Hologic scanner. The primary objective was to determine differences in hip and spine BMD at 2 years. Secondary outcomes include number of skeletal fractures and development of osteoporosis 2 years after randomization and changes in bone biomarkers at 1 year after randomization. For the analysis of the primary endpoints, the upper limit of a one-sided 95% confidence interval for the difference in mean percentage changes between placebo and exemestane will be calculated for the BMD by DEXA at each site. We will conclude that exemestane does not induce significant bone loss in postmenopausal women at increased risk of...
developing breast cancer at 2 years when the upper limit is less than 3% for both sites. Similar confidence interval approach will be used to analyze the secondary endpoints.

**Results:** Between May 2008 and March 2010, 238 postmenopausal women were recruited. Median age was 61.8 years, and the majority of women were Caucasian (91%), with approximately 20% of the participants reporting a recent fall (within past 12 months) and another 13% reporting a recent fracture prior to randomization. We will report results from the primary as well as the secondary endpoints at the SABCS meeting.

**P4-11-14**

**Number Needed To Treat (NNT) as a Measure of Incremental Drug Benefit: Denosumab vs. Zoledronic Acid for the Prevention of Skeletal Related Events (SREs) in Advanced Breast Cancer.**

**Dranitsaris G, Kaura S. Augmentium Pharma Consulting, Toronto, Canada; Novartis Pharmaceuticals, NJ**

**Background:** Intravenous zoledronic acid (ZOL) is the standard of care for the prevention of SREs in advanced breast cancer. However, monthly subcutaneous denosumab (Dmab) was recently approved in the US, as an alternative to ZOL based on the results of a large randomized trial which demonstrated a prolongation in median time to first SRE (HR = 0.82, p = 0.01) and a 5.8% (p = 0.01) absolute reduction in SREs in favour of Dmab over the 34 month study period. The challenge for clinicians and payers is how to reconcile the modest benefits of Dmab with the cost, which is approximately twice that of ZOL. NNT represents the number of patients that need to be treated with a new intervention in order to avoid one additional event, and is a widely accepted approach used to make sense of numerical results from clinical trials. In this analysis, the NNT approach was used to assess the incremental benefit of Dmab over ZOL for the prevention of SREs in advanced breast cancer.

**Methods:** The pivotal randomized trial for Dmab vs. ZOL in breast cancer (Stopeck, JCO 2010 & US PI 2010) was reviewed. As an alternative to ZOL, the NNT with Dmab to avoid any SRE at 12 and 34 months (trial end) was determined. NNT by type of SRE was also estimated. These consisted of pathologic fractures, radiation to bone, spinal cord compressions and surgery to bone. The calculated NNT represents the number of patients that need to be treated with a new intervention in order to avoid one additional event, and is a widely accepted approach used to make sense of numerical results from clinical trials. In this analysis, the NNT approach was used to assess the incremental benefit of Dmab over ZOL for the prevention of SREs in advanced breast cancer.

**Results:** To avoid a single SRE after 12 months of treatment of continuous therapy with Dmab, approximately 36 patients need to be treated. To avoid a single fracture and radiation to bone, approximately 39 and 27 patients need to be treated with Dmab over a 34 month period. Dmab was unable to offer any incremental benefit over ZOL in terms of avoiding spinal cord compressions or surgery to bone after 34 months of treatment.

**Discussion:** The NNT approach is a simple and effective method to express the findings in a clinically meaningful way. In this analysis, the incremental benefit of Dmab would only be realized when a minimum of 36 patients are treated for 12 months. For the more severe skeletal-related events, in terms of clinical and economic burden to patients and society, such as spinal cord compression and surgery to bone, Dmab did not offer any incremental benefit over ZOL in terms of SRE avoidance. This marginal incremental benefit needs to be considered alongside the high cost of Dmab.

**P4-11-15**

**Increased Propability of Triple Negative Breast Cancer (TNBC) in Premenopausal Patients after Exogenous Hormonal Intake (EHI).**

**Pistamaltzian NF, Tzavara C, Papadimitriou C, Gyftaki R, Tryfonopoulou D, Papanoulous C, Tsoukalas N, Koumakis G, Demiri S, Koutopoulou N, Misitiz Y, Apostolikas N, Efremidis A. Agios Savvas Cancer Hospital of Athens, Athens, Greece; University of Athens, Athens, Greece**

**Purpose:** HRT is a known risk factor for breast cancer (BC) among post-menopausal women. Our knowledge in relation to EHI (estrogens and/or progesteron) and BC among pre-menopausal women is scarce. We have studied whether previous EHI influences BC phenotype, clinical and pathologic characteristics and correlation with other known BC risk factors.

**Patients and methods:** A prospective analysis (data recorded upon patients first presentation) of an electronic database at a tertiary cancer centre was performed. Patients’ demographics, risk factors for BC (smoking, alcohol use, obesity, family history), clinical profile, EHI parameters (duration, cause) and the tumors’ histopathology (type, grade,ER/PgR and HER2 by IHC and FISH) were analyzed.

Premenopausal patients without an EHI history consisted control group.

**Results:** Out of 938 patients treated for BC between 2006 and 2010, 333(35,5%) were premenopausal and 131(39%) of them reported any use of hormones. Median age was identical (43 years,range:20-57) among premenopausal patients with and without EHI history. Mean duration of use was 28 months (range:1-180). Causes of EHI were contraception (35%), pregnancy(17%), menstrual abnormalities(17%) and medically assisted fertilization(17%). Smoking, alcohol use and obesity didn’t differ among two groups. Family history for BC was more common (31, 3% vs. 22,8%, p=0,08)among women with EHI. No correlation was found during duration of use and the time of cancer diagnosis, while the mean time from the cessation of hormones to cancer diagnosis was 13 years(range:1-32). Only 18% of breast cancers were diagnosed within the first 5 years after exogenous hormones cessation.

TNBC was found to be significantly increased among premenopausal women with a history for EHI (23,6% vs. 13,4%, p=0,016). This increase was independent of the existence of positive family history for BC (p=0,61). EHI conferred a twofold increase in the risk for a TNBC (OR=1,99 p=0,019). No other clinical or histopathologic parameter showed any difference among the two groups.

**Conclusion:** Prior use of exogenous hormones, for any cause and irrespective of the coexistence of other risk factors and family history, increases the probability of a triple negative breast cancer diagnosis by twofold. Whether this represents a trend of a changing epidemiology in the types of BC in prior hormone users vs. non-users, poses an extremely challenging hypothesis to be verified in large epidemiologic studies - given the young age and the treating difficulties of this patient population.

**Noninferiority (NI) Phase III Trials in Advanced Breast Cancer (ABC) over 12 Years.**

**Saad ED, Militao MS. Dendrix Research, Sao Paulo, Brazil**

**Background:** NI trials have gained increasing importance in oncology. The contemporary practice regarding the design features
and the results of NI trials have not been formally assessed in ABC.

**Results:** We retrieved 93 reports, 12 of which (13%; 95% CI, 7% – 22%) had a NI primary hypothesis. Of note, there were no equivalence (i.e., two-sided question) studies. There was no significant trend in the proportion of NI trials in the two 6-year periods compared (17% vs 9%; P=0.36). The median (range) sample sizes for NI and superiority trials were 404 (160-1354) and 326 (118-907) patients, respectively (P=0.32). NI trials enrolled exclusively first-line patients more frequently than superiority trials (83% vs 51%; P=0.06). The primary endpoint for NI trials was response rate (RR) and progression-free survival/time to tumor progression in 8 and 4 cases, respectively. Despite their nominally higher number of patients, NI trials were more likely than superiority trials to have RR as their primary endpoints (67% vs 32%; P=0.03). The NI margin was reported in all trials, but justified by authors in only one case. Among trials with RR as primary endpoint, the NI margin was 15% in six cases and 25% in two. In trials with progression-free survival/time to tumor progression as primary endpoints, the lower limit of the confidence interval for the hazard ratio to demonstrate NI was always 0.8. Of 12 NI trials, 9 were positive (i.e., proved NI).

**Conclusion:** NI trials represent 13% of contemporary phase III trials on ABC. Most such trials achieve their primary endpoint. At present, NI margins seem to be chosen on historical basis rather than on statistical reasoning, and such choice could bear implications on trial positivity.

**Mammographic Surveillance in Atypical Hyperplasia of the Breast and Subsequent Development of Cancer: A Need for Long Term Follow Up.**

Koron R, Sridharan U, Mitchell G, Holcombe C. Royal Liverpool and Broadgreen University Hospital Trust, Liverpool, Merseyside, United Kingdom

**Introduction**

Atypical hyperplasia of the breast is a known risk factor for breast cancer. Despite this risk there are no published guidelines on a recommended follow up regime for these patients.

**Methods**

A retrospective study was carried out on 1920 core biopsy results within a major screening breast unit from 2001 to 2005. Patients who had a final diagnosis of Atypical Ductal Hyperplasia (ADH), Atypical Lobular Hyperplasia (ALH) and Lobular Carcinoma in Situ (LCIS) were included.

Information was extracted from multidisciplinary team meeting records, departmental data bases, pathology and radiology reports. Details of follow up and subsequent cancer diagnosis were noted.

**Results**

83 patients were diagnosed with ALH, ADH or LCIS from a core biopsy. The mean age was 54 years (range 40-85 years). Seventy six (91.6%) of these patients went on to have an excision biopsy. Sixty four (77.1%) women have received long term mammographic follow up ranging from 5 to 9 years to date. Nineteen patients did not receive mammographic surveillance. Of this group 2 patients with LCIS had bilateral risk reducing mastectomies and 2 patients died shortly after diagnosis with no evidence of breast cancer. Eight patients developed breast cancer 3 to 8 years after their initial diagnosis. Of these, four patients developed cancer in the same breast that atypia had been diagnosed in previously, and four in the contra lateral breast.

**Conclusion**

12.5% of patients in the follow up group developed breast cancer within 8 years of diagnosis of atypical hyperplasia. A review of the literature suggests that in view of the increased risk of subsequent breast cancer in this group of women long term follow up is required. On the basis of these findings we recommend that all patients diagnosed with ALH, ADH or LCIS should be entered into an 18 monthly mammogram surveillance programme for 15 years.

**Healthcare Resource Utilization among Breast Cancer Patients with Bone Metastases and Skeletal-Related Events: A Population-Based Cohort Study in Denmark (1997 - 2009).**

Yong M, Christiansen CF, Gammelager H, Sverke C, Chia V, Atchison C, Fryzek J. Amgen Inc, Thousand Oaks, CA; Aarhus University Hospital, Aarhus, Denmark; Exponent, Alexandria, VA

**Background:** The healthcare resource utilization (HRU) of breast cancer patients who develop bone metastases and skeletal-related events (SREs) has not been well-characterized. Our objective was to describe the HRU associated with SREs in a large population-based cohort of Danish breast cancer patients with bone metastases and one or more SRE.

**Methods:** We identified women diagnosed with incident breast cancer from January 1, 1997 through December 31, 2006 using the Danish Cancer Registry. We followed this cohort of patients for development of subsequent bone metastases and SREs identified through the Danish National Registry of Patients through December 31, 2009. SREs were defined as pathologic fracture, spinal cord compression, and radiation or surgery to bone. Among patients with only one SRE, the HRU period, composed of all HRU occurring within a 90-day period after the SRE and within a two-week diagnostic period prior to the SRE, was assessed. For patients with multiple SREs (each one separated by less than 90 days), the HRU period, composed of all HRU occurring within a two-week diagnostic period prior to the first SRE up until 90 days after the last SRE, was described. Patients may have had multiple HRU periods if SREs were separated by more than 90 days. The HRU summarized included number of inpatient hospitalizations, length of hospitalization stay, outpatient physician visits, emergency room visits, and procedures.

**Results:** We identified 1,148 patients with bone metastases and SREs among 38,485 breast cancer patients. The mean age at breast cancer diagnosis for those who developed bone metastases and SREs was 59 years (SD, 13 years) and the majority (72%) of patients had multiple SREs during the first HRU period. Approximately 20% to 30% of patients with single and multiple SREs, respectively, died within the first HRU period. Overall, length of hospitalization was longest for patients with spinal cord compression followed by patients with pathologic fracture. In general, patients with multiple SREs had higher HRU compared to those with a single SRE in the first HRU period, particularly in length of hospitalization stay.

**Conclusion:** SREs secondary to bone metastases are serious events. In Denmark, high HRU was observed in all patients with SREs, but especially in those with multiple SREs, where increased lengths of hospitalization were observed.
P4-11-20
Background: Obesity, post-diagnosis weight gain, and presence of metabolic syndrome in breast cancer are reported to adversely affect survival among breast cancer survivors. Most of the studies on weight gain and metabolic syndrome in breast cancer are from Western countries and few information is available on Asian population. We designed this prospective observational study to characterize weight and metabolic changes during adjuvant treatment in women with early breast cancer and to identify factors associated with occurrence of metabolic syndrome, focusing on dietary pattern.
Methods: Patients aged 18-75 who underwent curative surgery with stage I-III invasive breast cancer were enrolled from 2008 to 2010. We measured glucose (FBS), hemoglobin A1c (HbA1c), total cholesterol (TC), HDL cholesterol, and triglyceride (TG) level in fasting serum samples before starting adjuvant therapy, at 6 months and 12 months after enrollment. Body weight, body mass index (BMI), body fat mass, and percent body fat at baseline, 6 months, and 12 months were also measured. Dietary intake was assessed using valid semi-quantitative food frequency questionnaire (FFQ).
Results: Total of 63 patients were enrolled. Median age of the enrolled patients was 48 (range, 25-68), with premenopausal/postmenopausal 40 (63.5%)/23 (36.5%). Fifty (82.0%) and 10 (16.4%) received adjuvant chemotherapy followed by hormone therapy and hormone therapy alone. Hormone receptor positive (ER+/PR+) and HER2 positive cancer accounted for 52 (83.9%) and 7 (12.1%). Mean FBS, HbA1c, TC, HDL, and TG level was 99.9 mg/dL (range, 83-159), 5.59 mg/dL (range, 4.8-7.5), 197.4 mg/dL (125-298), 51.9 mg/dL (range, 30-90), and 119.7 mg/dL (42-371). Mean height, weight, and BMI was 158 cm (range, 149-169), 61.7 kg (range, 46.2-96.0), and 24.7 kg/m² (range, 18.7-35.7), respectively. According to the WHO and NIH guidelines for Asian, normal (BMI 18.5-22.9), overweight (BMI 23-24.9), and obesity (BMI≥25) was 18 (28.6%), 13 (20.6%), and 32 (50.8%), respectively. Number of patients with metabolic syndrome was 18 (34%). Mean BMI (26.1 vs 24.0, p=0.021) and TG (180.6 vs 92.0, p=0.001) was higher, HDL cholesterol was lower (42.2 vs 57.3, p<0.001) in patients with metabolic syndrome. Composition of daily calorie intake consisted of 13.5% (range 10.7-21.8) of protein, 6.7% (range, 3.3-22.1) of fat, and 70.1% (range, 28.1-79.5) of carbohydrate. The presence of metabolic syndrome was associated with a higher carbohydrate intake (carbohydrate intake per ideal body weight>6.0) (p=0.071). The TG level of patients who ingested high carbohydrate was significantly higher (143.8 vs 102.9, p=0.023). The HDL level of patients who took high fat diet (>20% of total calorie) was lower (45.3 vs 53.5, p=0.045).
Conclusion: In our cohort of Korean breast cancer patients, 34% had metabolic syndrome at baseline. Those patients with metabolic syndrome consumed higher proportion of carbohydrate, which resulted in significantly higher level of TG. Our data suggest that composition of calorie intake is different in Asian population compared to Western countries, warranting for reappraisal on the recommendation on life style modification and diet.

P4-11-21
A Retrospective Analysis of Women at Increased Lifetime Risk for Breast Cancer: Referral Patterns to Subspecialty Providers, Recommendations and Outcomes.
Background: Inheritance of an abnormal BRCA 1/2 gene, a family history of breast cancer (BrCa), or a personal history of lobular carcinoma in situ (LCIS), atypical hyperplasia, or chest wall radiation can significantly increase an individual’s lifetime risk for developing BrCa. In 2007, the American Cancer Society (ACS) released updated guidelines for screening in women with a lifetime risk of BrCa ≥20-25%. These guidelines added MRI screening to annual mammography. The objective of our analysis is to characterize patients referred after the release of the 2007 ACS guidelines to subspecialty providers specifically for evaluation of BrCa risk and analyze subsequent screening and risk reduction recommendations in the cohort of patients (pts) with a predicted increased lifetime risk for BrCa.
Methods: Pts seen at a single center (University of Wisconsin [UW]) between 1/2007-3/2011 by medical, surgical and/or gynecology-oncology for an increased lifetime risk of BrCa were identified by billing codes or evaluation in the UW Breast Cancer Prevention, Assessment and Tailored Health Screening (PATHS) Clinic. Pts with a personal history of BrCa prior to 1/2007 are excluded. Patients with a known genetic predisposition to BrCa, family history of breast cancer, or a personal history of LCIS, atypical hyperplasia or chest wall radiation are included in this analysis. All charts will be evaluated for documentation of the individual’s lifetime risk of BrCa and method used for risk-assessment, recommended and performed screening tests, concordance with ACS screening guidelines, patient adherence to initial and subsequent screening recommendations, and uptake of risk reduction strategies. Call-back rates for additional or follow-up imaging and/or biopsy following BrCa screening and characteristics of all new BrCa diagnoses will be collected.
Results: 240 eligible pts were seen during the study period. 15% of pts referred had a known genetic predisposition to BrCa. Most pts (75%) were referred for a family history of BrCa. The majority of these pts had a predicted lifetime risk of BrCa in excess of 20%, with less than 10% of patients being referred having a lifetime risk <20%. The remaining pts were referred for a personal history of LCIS, atypical hyperplasia or previous radiation to the chest wall. Results including subspecialty provider BrCa risk assessment, screening and risk reduction recommendations, patient uptake and adherence, outcomes of screening and characteristics of diagnosed BrCa cases will be presented.
Conclusion: Pts with a predicted increased lifetime risk for BrCa are often evaluated by oncology subspecialty providers. The primary factor related to referral is family history of BrCa. The majority of patients referred to a subspecialty provider have a calculated lifetime risk for BrCa in excess of 20%. This study evaluates provider assessment of BrCa risk and subsequent recommendations for screening and discussion of risk reduction strategies.
P4-11-22
Familial History of Cancer among Breast Cancer Women under 36 yr. in Rio de Janeiro, Brazil.
Koifman S, Ortega GPJ, Koifman RJ. National School of Public Health, Oswaldo Cruz Foundation (FIOCRUZ), Rio de Janeiro, RJ, Brazil

Background. Antecedents of familial history of cancer (FHC) have been reported as an important feature observed among young women with breast cancer (BC). Objective. To explore the distribution of FHC in a sample of young women with BC in Brazil. Methods. Antecedents of FHC were obtained by a face to face interview carried out with 224 BC cases 20-35 yr., and 246 age-frequency matched controls, enrolled in a hospital-based case control study carried out among 1996-2006 in Rio de Janeiro, Brazil. Unconditional logistic regression was performed and BC odds ratios adjusted for age and education (adj. OR) were obtained according to FHC characteristics (parenthood degree, age of diagnosis and amount of relatives with cancer). Results. BC antecedents among 1st degree relatives was 5.4% among BC cases and 1.2% of controls (p=0.01). The adj. OR for BC among 1st degree relatives was 4.3, 95% CI 1.2-15.8. Comparatively to families without BC antecedents, an adj. OR =2.4, 95% CI 1.4-4.1 was observed for those with 1 reported BC case, and an adj. OR = 3.7, 95% CI 1.0-14.0 for those with 2 or more BC cases (p trend =0.0002). A similar trend was verified according to all other cancer sites (p-trend < 0.0001). The reported median age of BC diagnosis in the 1st generation (proband grand-mothers) was 76 yr., being 45 yr. at the 2nd generation (proband mothers) , and 38,4 yr. at the 3rd (proband sisters). A similar trend along generations was also verified for other cancer sites among case relatives, respectively, 69 yr., 58 yr. , and 45 yr. The mean age of diagnosis among the cases offspring was 6.7 yr. (standard deviation, SD = 0.6) and 12.0 yr. (SD = 1.4) among the controls descents (p< 0.01). Brain cancer reported among case relatives was 6.0 fold higher than among control relatives (3.7 fold higher for ovarian cancer, and 3.2 higher for skin cancer). Discussion. The observed results reveal that cancer risks among relatives of young women with BC are either higher for BC or other selected cancer sites. The observed decline along successive generations on the age at diagnosis of BC and other tumors is suggestive of recent genetic-environmental interaction in the studied sample of young women with BC in Brazil.

P4-12-01
The Breast-Activity and Healthy Eating after Diagnosis (B-AHEAD) Study – A Randomised Comparison of Weight Control Programmes during Adjuvant Treatment.
Harvie M, Pegington M, Bunded N, Campbell A, Wolstenholme J, Adams J, Speed S, Morris J, Howell A. University Hospital of South Manchester, Manchester; United Kingdom; University of Dundee, United Kingdom; University of Oxford, United Kingdom; University of Manchester; United Kingdom; University Hospital of South Manchester; United Kingdom

Background: Excess weight at diagnosis and weight gain during treatment are linked to increased mortality from breast cancer. Since 60% of breast cancer patients are overweight at diagnosis and 75% gain weight during treatment, weight control should improve outcome but the optimal intervention is unknown.

Aim: To compare 3 programmes for weight control after surgery for primary breast cancer.

Methods: We have recruited a randomised trial of 2 diet and exercise weight control interventions 1. a community based supervised group programme, 2. a mail and phone programme compared to standard written advice (control). We are comparing the relative effects of the 3 programmes on body weight and composition (by dual energy x-ray absorptiometry), cardiovascular risk parameters (lipids, blood pressure), a marker of breast cancer prognosis (insulin resistance), fitness and quality of life over the first year after diagnosis.

In total 409 women have been randomised (45% of eligible women) and 21 women have left the trial (5.1%). 357 have completed the 6 month assessments, all are due to complete the trial in December 2011.

Results: Weight and body fat results at 6 months indicate that the low cost mail and phone programme is equal to the supervised programme and both are significantly superior to written advice, but not in patients receiving chemotherapy.

The high uptake and adherence to the trial shows interest and motivation of a significant number of cancer patients to make positive changes to lifestyle at the time of diagnosis.

The final trial results will be presented at the December meeting.

This abstract presents independent research commissioned by the National Institute for Health Research under the Research for Patient Benefit programme. The views expressed here are those of the authors and not necessarily those of the funding organisations.

P4-12-02
Sereika SM, Dunbar-Jacob JM, Ryan CM, Adam B, Bender CM. University of Pittsburgh, Pittsburgh, PA; University of Pittsburgh Medical Center, Pittsburgh, PA

Background: Women with breast cancer experience deterioration in cognitive function with adjuvant therapy. Little is known about whether declines in cognitive function are associated with nonadherence to oral hormonal therapy over time. We investigated anastrozole adherence over time and its association with cognitive function over the first 12 months of therapy in women with breast cancer.

Methods: Using a prospective cohort design, 169 women with early stage breast cancer were monitored for 12 months 1) continuously for their adherence to anastrozole using electronic event monitoring and 2) objectively for cognitive function via a neuropsychological battery every 6 months for the first 12 months of hormonal therapy. Adherence data were summarized monthly as the percentage of prescribed doses taken and the timing of doses taken as the percentage of days with correct intake and the percentage of doses with correct timing. Six cognitive factors, derived via exploratory factor analysis applied to the neuropsychological battery, were used for analysis. Data were analyzed using descriptive and longitudinal methods.

Results: Participants were white (n=166, 98.2%), well-educated population. The views expressed here are those of the authors and not necessarily those of the funding organisations.
(Mean=15.1 years; SD=2.9, range=10-26) and on average 61.1 years of age (SD=5.9, range=46-75). Most had stage 1 breast cancer (n=123, 72.8%) and were prescribed anastrozole either alone (n=110, 65.1%) or immediately after chemotherapy (n=59, 34.9%). Initial levels of adherence were fairly high based on number of (Mean=89.1, SD=27.1, range=0-111.1) and timing of doses taken (Days with correct intake: Mean=86.4, SD=26.8, range=0-100; Doses with correct timing: Mean=83.6, SD=29.8, range=0-100); however, adherence decreased over the first 12 months of therapy (p<0.05) in terms of the number of and timing of doses taken and regardless of chemotherapy use. Specifically, we found a linear decrease for the percentage of prescribed doses taken (linear: t=-2.97, p=0.0035); however, nonlinear declines were observed for both the percentage of days with correct intake (linear: t=-3.33, p=0.0011; quadratic: t=2.10, p=0.0371) and the percentage of doses taken at the correct time (linear: t=-3.38, p=0.0009; quadratic: t=2.28, p=0.0242), suggesting a slowing of the rate of decline in adherence related timing of doses for months 9 through 12. We found that a decrease in executive functioning was related to lower percentages of prescribed doses taken (p=0.06) and doses taken at the correct time (p=0.06) from pretreatment to 6 months post-anastrozole initiation and even greater evidence (p<0.05) from pretreatment to 12 months post-anastrozole initiation. From 7 to 12 months post-anastrozole initiation, we found that a decrease in visual learning and memory was related to lower percentages of prescribed doses taken (p=0.04), days with correct intake (p=0.04), and doses taken at the correct time (p=0.03), while a decrease in attention was related to a lower percentage of days with correct intake (p=0.04).

Conclusions: These results suggest that breast cancer survivors who experience deterioration in cognitive function tend to have lower adherence. Efforts should be made to develop interventions to compensate for declines in cognitive function and to improve anastrozole adherence.

P4-12-03
Post-Diagnosis Weight Gain in Breast Cancer Survivors: When Should We Intervene?
Bradshaw PT, Cleveland RJ, Stevens J, Rosamond W, Abrahamson PH, Feitlbaum SL, Neugut AI, Gammon MD. University of North Carolina at Chapel Hill, Chapel Hill, NC; Mount Sinai School of Medicine, New York, NY; Columbia University, New York, NY

Significance. Weight gain after breast cancer diagnosis is common and has been linked to poor prognosis. Studies of the etiology and longitudinal pattern of post-diagnosis weight gain are limited, yet are critical to developing effective prevention strategies to enhance survival. Approach. We investigated the longitudinal pattern and determinants of post-diagnosis weight gain among 1,436 breast cancer survivors. The population-based cohort included women newly diagnosed with a first primary in situ or invasive breast cancer. Participants were randomized 1:1 to the WLI or educational control (EC) arm, with mean weight loss of 6.1% of body weight vs. 0.6% to loss of funding. The WLI arm lost significantly more weight than EC arm, with mean weight loss of 6.1% of body weight vs. 0.6% were more likely to gain weight during the first year after diagnosis [difference in mean yearly increase: BMI 25.0-29.9 vs. 18.5-24.9 (95% confidence interval): 1.93 kg/year (0.50, 3.37); BMI >=30.0 vs. 18.5-24.9: 0.47 kg/year (0.24, 0.71)] and after the first year [5.17 kg/year (3.68, 6.66) and 0.93 kg/year (0.58, 1.28), respectively], with the effect greater during the first year (p-interaction: <0.001). A pre-diagnosis weight gain of more than 10% since age 20 was also associated with post-diagnosis weight gain during year 1, difference in mean yearly increase compared to maintenance within 3% age 20 weight: 2.32 kg/year (0.59, 4.05); after year 1: 0.53 kg/ year (0.17, 0.89)] with the effect again stronger during the first year (p-interaction: 0.02). Modest associations, which varied only slightly with time, included: increases in post-diagnosis weight gain with chemotheraphy, tumor characteristics indicative of poor prognosis, and a previous diagnosis of hypertension, blood clots, or diabetes; and decreases with increasing recreational physical activity and a history of myocardial infarction.

Conclusions. Greater pre-diagnosis BMI and pre-diagnosis adult weight gain are strongly related to post-diagnosis weight gain among breast cancer survivors. The rate of post-diagnosis weight gain appears to be faster during the first year than after, suggesting that interventions to prevent post-diagnosis weight gain may be most important during the first year after diagnosis, especially among women who with BMI >= 25.0 1 year prior to diagnosis.

Impact of the Lifestyle Intervention Study in Adjuvant Treatment of Early Breast Cancer (LISA) Weight Loss Intervention upon Physical Activity.
Ligibel JA, Segal R, Pond G, Dion M-J, Pritchard KI, Levine M, Goodwin PJ. Dana-Farber Cancer Institute, Boston, MA; University of Ottawa, Ottawa, ON; McMaster University, Hamilton, ON; University of Toronto, Toronto, ON

Observational evidence shows a relationship between obesity and poor prognosis in breast cancer (BC). Physical activity (PA) is an important component of weight loss and maintenance, but most large-scale interventions in BC patients have produced only modest improvements in activity. We sought to evaluate changes in PA in women participating in LISA, a randomized trial coordinated by the Ontario Clinical Oncology Group which was designed to examine the impact of a telephone-based weight loss intervention (WLI) upon disease free survival in BC patients.

Methods:
Participants were randomized 1:1 to the WLI or educational control (EC) group. Eligibility included diagnosis of Stage I-III BC, BMI ≥24 kg/m², and treatment with letrozole. The WLI, based on the Diabetes Prevention Program, focused on weight reduction through calorie restriction and increased physical activity. Delivery involved 19 calls, mailings and a participant manual. The PA goal was 150 minutes/week. PA was measured using the International Physical Activity Questionnaire (Short Form) at baseline, 6, 12, and 18 months. Changes in time (minutes/week) spent sitting and engaging in moderate, vigorous, and walking activities were compared between groups.

Results
338 women were randomized to WLI (n=171) or EC (n=167) from 20 centers in Canada and the USA. The study was discontinued due to loss of funding. The WLI arm lost significantly more weight than EC arm, with mean weight loss of 6.1% of body weight vs. 0.6%
at 12 months (p<0.001). Activity data are presented in Table 1. At baseline, participants were inactive; median vigorous activity was zero minutes/week and median time spent sitting was more than 35 hours/week. WLI participants reported significantly higher participation in vigorous, moderate and walking activities, and lower levels of sedentary behavior, compared to controls at 6 and 12 months. Higher levels of PA were significantly associated with increased weight loss at all time periods. Factors associated with increases in activity included higher baseline BMI (p=0.014), lower baseline activity (p<0.001) and assignment to the WLI arm (p=0.02). Women assigned to WLI increased their PA during the intervention period (p=0.017) even after adjusting for other significant baseline factors.

Conclusion
Participants in the LISA WLI reported significantly higher levels of PA compared with controls. Activity increased most in women who were heavier and less active at baseline. Further study of this WLI as a potential means to improve BC outcomes is warranted.

P4-12-06
Risk Factors for Relative Weight Gain >10% in Breast Cancer Survivors: Findings from the SU.VI.MAX Cohort.
Zelek L, Czernichow S, Galan P, Hercberg S. Assistance Publique Hôpitaux de Paris, CHU Avicenne, Bobigny, France; INSERM U1125 INRA/CNAM/Université Paris 13, Bobigny, France
Purpose: Since extreme weight gain (EWG, defined as weight gain >10% of baseline body weight) raises risk for recurrence among breast cancer survivors (Caan et al. ACR 2011) we undertook this study to identify risk factors for EWG after breast cancer. Methods: We screened the database of the SU.VI.MAX trial (13017 pts randomized between low-dose antioxidants and placebo, Arch Int Med 2004) to retrieve women with confirmed breast cancer occurring after inclusion, and post-cancer follow-up. The following data were collected at inclusion and during the study: anthropometric measurements, physical activity, tobacco and alcohol consumption, level of instruction and socio-economic status, current medications. Unlike other breast cancer survivor studies, data have been collected prospectively before breast cancer diagnosis. Data management and data analysis were performed using SAS software 9.1.3. We also screened questionnaires and medical reports to collect data that were not recorded in the study database: type of adjuvant therapy (chemo- and hormone therapy), use of vitamins and dietary supplements, concomitant medications (such as antidepressants, lipid lowering agents, thyroid hormones or anti-thyroid drugs), previous use of HRT, and whether patients were following a diet plan after breast cancer or not.

Results: We identified 176 pts with breast cancer included since 1994 in the SU.VI.MAX 8-year Cohort Study. Among them, 25% (n=44) had weight gain >10% of baseline. The only variable significantly correlated with EWG was age at breast cancer diagnosis. Other differences, in particular level of physical activity or anthropometric measurements, did not reach statistical significance.

No significant differences were seen between patients with EWG and others regarding the use of adjuvant chemotherapy (34 v 28%), aromatase inhibitors (18 v 22%), or tamoxifen (25 v 21%), previous HRT use (44 v 50%) or concomitant drugs including thyroid hormones (20 v 17%). A minority of patients was following a diet (16 v 17%) but consumption of vitamins or dietary supplements was slightly higher in patients without EWG (35 v 50%).

Discussion: Weight gain after breast cancer is a well-known phenomenon affecting at various levels half of breast cancer survivors. Most recent studies suggest that patients with EWG could have an increased recurrence rate. Risk factors for weight gain are still matter of debate but the role of adjuvant chemotherapy is widely admitted. Our results however indicate that adjuvant therapy does not seem to be a major risk factor for EWG. Furthermore, lifestyle and diet do not seem to markedly affect the risk of EWG. The only significant difference observed in our study is age at diagnosis, suggesting that treatment-induced amenorrhea could play a role in some patients. Although identification of women at risk remains difficult, thus precluding a large proportion of this population from tertiary prevention, younger women seem to deserve particular attention.

P4-12-07
Outcomes of a Behavioral Weight Control Intervention among Rural Breast Cancer Survivors.
Befort CA, Klemp JR, Austin HL, Krigel S, Sullivan DK, Schmitz KH, Perri MG, Fabian CJ. University of Kansas Medical Center; University of Pennsylvania; University of Florida
Background: Obese breast cancer survivors have 1.5 to 2.5 fold increased risk of recurrence and death compared to their normal weight counterparts. Rural women, who comprise over 20% of the U.S. population of women, have significantly higher obesity rates as well as breast cancer treatment-related disparities. Thus, weight control intervention is a key strategy for secondary breast cancer prevention in this population. However, access can be challenging in the rural setting. Using conference call technology to deliver group-based intervention is well-suited for rural breast cancer survivors because it is easily accessible and provides real-time peer support. The purpose of this one-arm treatment study was to examine the impact of a 6-month group phone-based behavioral weight control intervention on anthropomorphic, diet, physical activity, and psychosocial quality of life outcomes.

Methods: Eligible participants were post-menopausal breast cancer survivors (Stage I-IIIC, 3 months to 10 years since surgery, radiation, or chemotherapy, < 75 years of age, BMI 27-45 kg/m²) who resided in a rural area. The weight control intervention included a reduced calorie diet with 2 prepackaged meals and ≥ 5 fruit and vegetables servings daily, home-based physical activity gradually increased to 225 min/week of moderate intensity exercise, weekly self-monitoring logs, and weekly 60-minute group phone sessions that addressed...
behavorial modification and breast cancer survivorship topics. Group size ranged from 9 to 13 women. Measures included anthropometrics, two 24-hour dietary recall interviews, and questionnaires measuring physical activity, fatigue, depression, body image and sexuality, and self-efficacy for diet and physical activity behavior change.

Results: Participants (n = 34) were 58.9 ± 7.8 years-old, 3.1 ± 1.6 years out from treatment, had a baseline BMI of 33.7 ± 4.4 kg/m², and 63% were on anti-hormone therapy. Average sessions attendance among all participants, including 3 non-completers, was 90%. Ninety-one percent of participants (n = 31) attended > 75% of intervention sessions and completed post-treatment data collection visits. At 6 months, significant changes were observed for weight (−12.5 ± 5.8 kg, 13.9% of baseline weight), waist circumference (−9.4 ± 6.3 cm), daily energy intake (−349 ± 550 kcal/day), fruits and vegetables (+3.7 ± 4.3 servings/day), percent kcal from fat (−12.6 ± 8.6%), and physical activity (+1235 ± 832 kcal/week; all p's < .001). Significant improvements were also seen for Body Image subscales (Strength and Health, Social Barriers, Appearance and Sexuality), Depression, and Self-Efficacy for diet and physical activity behaviors (all p's < .05).

Discussion: The intervention produced significant improvements in weight, diet, physical activity, and quality of life outcomes that compare favorably to the literature. The group phone-based treatment delivery approach appears feasible and effective for weight control intervention among obese rural breast cancer survivors.

P4-12-08
Five Year Preliminary Outcomes of a Prospective Surveillance Model To Reduce Upper Extremity Morbidity Related to Breast Cancer Treatment.

Stout NL, Pfalzer L, Levy E, McGarvey C, Gerber L, Springer B, Soballe P. National Naval Medical Center; University of Michigan-Flint; National Institutes of Health; CLM Consulting; George Mason University; Office of the Surgeon General; Naval Hospital San Diego

Background: Early detection and management of physical impairments after breast cancer treatment contribute to successful functional outcomes and improved quality of life throughout disease treatment and survivorship. Assessment of upper extremity (UE) morbidity including; shoulder dysfunction, scarring, pain, fatigue and lymphedema should be conducted through a prospective surveillance model of care to promote early identification of impairments and provide intervention while functional limitations are minimal, thereby preventing long term loss of function. This report highlights 5-year findings related to physical function in patients participating in a prospective surveillance model of care.

Methods: A prospective, observational study enrolled women with breast cancer at the point of disease diagnosis (n=196) and measured UE morbidity, impairments and functional disability over a 5 year period. Patient demographics, cancer characteristics, measures of UE strength, range of motion (ROM) and limb volume were taken pre-operatively and repeated at 1, 3, 6, 9, 12 and 60 months post-operatively. Subjective assessment of physical activity, health status and quality of life were assessed by questionnaire at 12 and 60 months. 166 subjects completed visits at 1 year and 95 completed visits at 5 years. All subjects received education regarding exercise, risk reduction and advice on return to activity. If physical impairments were detected during the study, immediate physical therapy intervention was initiated to alleviate the impairment.

Results: The incidence of objective UE impairments at five years after treatment was 9% with loss of shoulder ROM, 25% with subclinical lymphedema (defined as ≥ 3% change in limb volume from baseline), 5.6% with advanced lymphedema (Stage I or II) and 27.8% with clinically significant fatigue (defined as ≥ 3 on a visual analog scale). Subjectively 8.4% reported feeling moderately or severely disabled with their affected arm, 11.1% reported moderate to severe difficulty carrying heavy objects, 4.2% reported moderate to severe limitations with heavy household chores.

Discussion: This is the first prospective cohort study in the United States to specifically monitor physical and functional outcomes to 5-years post breast cancer treatment. The prospective surveillance model of care, conducted by the physical therapist, enabled early detection and treatment of breast cancer treatment–related impairments resulting in improved long-term function. Long-term incidence of UE morbidity after breast cancer treatment has been documented in the literature as high as 40-60% with lymphedema and up to 60% with fatigue. This study clearly demonstrates the potential for substantial reduction in UE dysfunction related to breast cancer treatment when using an early identification and intervention model. Morbidity such as pain, reduced range of motion, decreased strength and sub-clinical lymphedema were detected early and managed through the prospective model. These results strongly suggest that prospective surveillance monitoring for functional impairments is an optimal construct to assure long-term function in women after breast cancer treatment.

A Prospective Study of Physical Activity Patterns and Changes in Breast Cancer Patients during Active Breast Cancer Treatment.

Kim I-R, Choi E-K, Nam S-J, Lee J, Lee S-K, Yang J, Noh DY, Han W, Cho J. Samsung Comprehensive Cancer Center, Samsung Medical Center; Sungkyunkwan University School of Medicine, Seoul, Korea; SurgerySamsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea; Konkuk University Medical Center, Konkuk University School of Medicine, Seoul, Korea; Seoul National University Hospital, Seoul National University School of Medicine, Seoul, Korea; Johns Hopkins Bloomberg School of Public Health, Baltimore; Behavior and Society, Johns Hopkins Bloomberg School of Public Health, Baltimore

Purpose

Physical activity (PA) has been shown to benefit cancer patients’ physical functioning, emotional well-being, and symptom management. Moderate PA may reduce the side effects of breast cancer treatment and improve quality of life, but most of the studies have been conducted after active treatment was completed and there is little data on patterns of PA during active treatment. This study aims to evaluate patterns and changes in physical activity among breast cancer patients during active treatment.

Patients and Methods

We recruited 411 women with non-metastatic breast cancer between July 2010 and Dec 2010 from two major cancer hospitals in Seoul, Korea. Trained researchers interviewed participants at enrollment (before surgery), and at 2 weeks, 3 months, and 6 months post surgery. Intensity and duration of PA were assessed using the Minnesota Leisure Time Physical Activity Questionnaire, and energy expenditure (the average calories spent per day) was calculated as metabolic equivalents (METs). Quality of life (EORTC), fatigue (BFI), socio-demographic and clinical characteristics were also assessed. After excluding 15 patients with recurrence during follow-up and 65 patients were lost to follow-up, the final sample size was 331 patients (80.5%).
Results
The mean (SD) age and BMI of study participants were 46.4 years and 23.3kg/m² (SD 3.35). 87.3% of women had lumpectomy, and 70.6% and 85.9% had adjuvant chemotherapy and radiotherapy respectively. Breast cancer patients were most likely to spend their energy in lifestyle (walking and driving) and leisure (shopping, reading, and watching TV) activities but spent little energy in sport activities (Table).

Conclusion
PA declined after the surgery and gradually recovered at 3 and 6 months post surgery but it did not return to the baseline level. Breast cancer patients may need encouragement and support to perform more intensive physical activities during active treatment.

*Acknowledgement: The research was accomplished by the support from AMOREPACIFIC and Korea Breast Cancer Foundation.

P4-12-11
Myelodysplastic Syndrome Post Primary Breast Cancer Treatment: Cases from a Community Cancer Center: 1990-2010.
Kaplan HG, Malmgren JA, Atwood MK. Swedish Cancer Institute, Seattle, WA; HealthStat Consulting, Inc., Seattle, WA

Background: Myelodysplastic syndrome (MDS) has not been well documented or described post breast cancer (BC) treatment.

Methods: A cohort of all breast cancer patients from 1989 to 2010 at our institution were followed for incidence of blood disorders of any type by our registry system and by linkage to the Surveillance, Epidemiology and End Results (SEER) registry for our area. All cases of post breast cancer leukemia were reviewed for incidence of MDS from a cohort of 9846 cases diagnosed between 1990 and 2010. Coding of cases was assigned by the SEER registry using ICD-0 codes for type of leukemia from pathology reports. 20 cases of MDS were identified and confirmed using SEER coding for MDS and death certificate review if applicable. Variables of interest included age, race, treatment received, recurrence and treatment for recurrence, time interval from breast cancer diagnosis to leukemia diagnosis and time from leukemia diagnosis to follow up or death. Cytogenetic studies were available on 5 of the 20 patients.

Results: Mean age of the patients was 56 years, range 33-79, with 65% < age 65. 90% of the patients were white and 10% Asian. TNM BC stage distribution was stage I=0, stage II=8, and stage III=2. MDS was diagnosed at a median time post BC diagnosis of 65 months, range 8-205 months including 5 patients treated for recurrence and median 47 months, range 8-205 months excluding patients with recurrence. Nine patients had initial chemotherapy treatment, two without initial adjuvant therapy received chemotherapy for recurrence, and 9 received radiation only. Eight of eleven patients who received chemotherapy were treated with doxorubicin. All eleven received cyclophosphamide. Five of the 20 cases had MDS, not otherwise specified (NOS) (9989), 4 cases had MDSaAML, 3 MDS treatment related (9987), 3 refractory anemia (RA) (9980), 3 refractory anemia with excess blasts (RAEB) (9983), 1 RA with sideroblasts (9982), and 1 MDS with 5q deletion. Three of the five patients with cytogenetics available had chromosome 7 abnormalities and one had 11q21.23.

Eleven of the 20 patients (55%) died of MDS or MDSaAML with a mean survival of 17 months, range 0.5-72 months. Six patients were alive at follow up with mean survival 56 months, range 43-89. Two of the surviving patients had stem cell transplants. The remaining three patients died of other causes with mean survival 66 months, range 7-109 months. Mean survival of all patients was 36.26 months, range 53-109 months with a significant difference in survival time between the patients that died of MDS, those alive at follow up and those that died of other causes (F statistic 6.56, p=.008).

Discussion: MDS is a significant complication of breast cancer treatment with radiation and/or chemotherapy with a high rate of associated mortality.

P4-12-12
Patient-, Illness-, and/or Treatment-Related Baseline Predictors of Nonadherence to Oral Hormonal Therapy.
Wickersham KE, Sereika SM, Bender CM. University of Pittsburgh, Pittsburgh, PA

Background: Nonadherence to oral hormonal therapy is problematic for women with breast cancer. Patient-, illness-, and treatment-related factors have been associated with nonadherence, but with inconsistent findings. Therefore, our aim was to explore predictors of nonadherence to hormonal therapy for women with early stage breast cancer from the baseline assessment (pre-hormonal therapy) to 6 months post-treatment.

Methods: A secondary analysis was performed to explore potential patient-, illness-, and treatment-related predictors of nonadherence for 198 women enrolled in either: 1) The Anastrozole Use in Menopausal Women Study (AIM Study, n=162), or, 2) Predictors of Adherence to Hormonal Therapy in Breast Cancer (ONS Study, n=36). Nonadherence was defined as the percentage of prescribed administrations of hormonal therapy that were not taken during the first 6 months of therapy as measured using an electronic Drug Exposure Monitor (eDEM) (AARDEX, Ltd.). Chi-square tests of independence and Mann-Whitney U tests were performed to determine whether data from the two studies could be pooled. Descriptive statistics were performed to characterize the sample. Multiple linear regression analyses were performed to identify the best model in two stages: 1) univariate relationships between each candidate predictor variable and the outcome variable (6-month nonadherence) were assessed using a cut-off of p=.20; and, 2) candidate predictors meeting the criteria were retained for further exploration in model-building multiple linear regression analyses (stepwise and backward) to determine the predictors of 6-month nonadherence summary scores. Candidate predictors were retained in the model if they remained associated at p<.10 in the multiple regression analysis.

Results: Women were 98.3% Caucasian with a mean age 59.1 years (SD 7.5) and mean number of years of education of 15.0 (SD 2.9). Overall mean nonadherence was 11.6% (13.2% AIM Study, 4.6% ONS Study). Chi-square and Mann-Whitney U tests demonstrated that the two samples could be pooled, given the data were similar on key variables (number of years of education, depression, anxiety, fatigue, symptoms, and nonadherence). Both stepwise and backward elimination modeling algorithms demonstrated evidence of 3 significantly significant variables associated with nonadherence; however, the backward elimination model best represented the sample (R²= .106, adjusted R²= .086, s=.28490). Women who worked (p=.082), whose primary occupation was clerical or administrative (p=.029), had DCIS tumor type (p=.017), or who had higher gastrointestinal (GI) symptoms scores (p=.013) were associated with nonadherence. The potential for interactions between primary occupation, DCIS tumor type, and higher GI symptoms was explored and was not significant. In addition, while all tumor types were...
examined as candidate predictors, participants with DCIS also had another tumor to be eligible for the parent studies.

Conclusions: Our study offers insight into potential predictors of nonadherence for women participating in one of two cohort studies. The findings suggest additional examinations of nonadherence concerning work and symptom burden and their relationship to nonadherence are indicated.

P4-12-13
A Multi-Center Randomized Controlled Double Blind Trial Assessing the Effect of Acupuncture in Reducing Musculoskeletal Symptoms in Breast Cancer Patients Taking Aromatase Inhibitors: First Interim Analysis.

Background: Aromatase inhibitors (AIs) are recommended as first-line adjuvant hormonal therapy in postmenopausal women with hormone-receptor–positive breast cancer, as monotherapy or sequential therapy after tamoxifen. AI-associated musculoskeletal symptoms (AIMSS) occur in approximately 50% of women receiving AIs and in some may result in discontinuation of treatment. Symptom management is essential to ensure that breast cancer patients receive the full recommended duration of AI therapy. We conducted a randomized, placebo-controlled trial to evaluate the effect of acupuncture on AIMSS and report the first interim analysis.

Method: Postmenopausal women with early stage breast cancer, experiencing AIMSS, who had not had acupuncture in the year prior to the study, were eligible. Patients were randomized to 8 weekly acupuncture or sham acupuncture. Health assessment questionnaire disability index (HAQ-DI) ranging 0-3.0) and pain visual analog scale (VAS ranging 0-100) were used to assess clinical musculoskeletal disorder severity at weeks 0, 4, 8, and 12 or 24. Change in HAQ-DI (ΔHAQ-DI) and VAS scores (ΔVAS) from baseline were compared between patients receiving acupuncture versus sham acupuncture using exact Wilcoxon rank sum test. Serum samples were collected for measurements of estrogens and beta endorphin concentrations and cytokine profile before and after the intervention to evaluate the etiology of AIMSS and the mechanism of acupuncture in treating AIMSS.

Results: Between May 2008 and June 2011, 48 patients were enrolled, 2 patients were not evaluable due to noncompliance to treatment and lost to follow up, 10 were still receiving treatment and therefore not evaluable. Thirty-six were evaluable, and were equally distributed between the real and sham acupuncture groups. Baseline characteristics were balanced between the two groups with regard to age, race, and body mass index (BMI) with the exception that baseline mean HAQ-DI was higher in the acupuncture group (0.9 vs 0.55, p = 0.04). White/Black/Asian: 26/7/3. Median (range): age: 61 (45-82); BMI (kg/m²): 31 (22.9-59.6). At week 8, both groups showed a wide range of ΔHAQ-DI (ΔHAQ-DI = HAQ-DI week8 - HAQ-DI baseline): from -1.38 to 0.5 in the acupuncture group versus from -1 to 0.12 in sham acupuncture group. There was no statistically significant difference in mean ΔHAQ-DI between the real and sham acupuncture groups (-0.33 vs -0.33, p=0.87). Eleven patients in each group (61%) reported decreased HAQ-DI scores, which correlated with improved function. There was no difference in mean ΔVAS between the real and sham acupuncture groups (-9.27 vs -13.82, p=0.67). No significant side effects were reported. Changes in other time points and in serum biomarkers will be presented at the meeting.

Conclusions: The majority of breast cancer patients experiencing AIMSS who participated in our study reported a reduced HAQ-DI score both from acupuncture and sham acupuncture. We did not observe significant differences between responses to real versus sham acupuncture after 8 weekly treatments. The study remains open to accrual to reach 50 evaluable patients.

P4-12-14
Pilot Study Utilizing Fluorine-18 Fluorodeoxyglucose (F-18 FDG) Positron Emission Tomography–Computed Tomography Scan (PET-CT Scan) To Investigate Brain Metabolic Changes during Treatment in Women with Breast Cancer.

BACKGROUND: Approximately 25% of the patients undergoing chemotherapy develop cognitive changes. Similarly, significant neurocognitive changes in verbal memory and executive functioning have been reported in patients undergoing endocrine therapy. Though extensively studied, specific changes in the brain associated with cognitive dysfunction are still not clear. We performed an IRB-approved retrospective pilot study utilizing brain images from standard PET-CT scans in patients being treated for breast cancer. Comparison was made between patients initial and follow-up scans to look for metabolic changes.

MATERIALS AND METHODS: Thirty nine patients with a diagnosis of breast cancer were identified from radiology database of West Virginia University Hospitals, who underwent at least two PET-CT scans during their treatment for breast cancer from 2004-2009. Patients with brain metastasis were excluded. NeuroMIM® software analysis program was used to compare a comprehensive database of physiologic brain anatomy and metabolism with F-18 FDG perfusion brain images from the patients. Comparison was made in sixty-three defined brain regions. For each patient, two scans at approximately twelve month intervals were analyzed. The data sets from initial scans were compared with the follow up.

RESULTS: A total of 37 patients received cytotoxic chemotherapy, 2 patients received only endocrine therapy. Data analysis using the signed-rank test shows that the collective Z-score values change between the initial and follow up scans. When data analysis is applied to the individual brain regions, the Lingual Gyrus (p=0.012) and the Angular Gyrus (p=0.056) show statistically significant and near significant decreases in brain metabolism respectively. These regions are attributed with language, mathematics and cognition. Several additional regions such as the fusiform gyrus and the primary visual cortex show p-values between 0.05 and 0.10, which indicate “trending”. These regions may demonstrate statistically significant decrease in metabolism if the sample size is increased.

DISCUSSION: The Lingual and the Angular Gyrus show a statistically significant and near significant decrease in glucose metabolism respectively, in patients receiving treatment for breast cancer. Limitations of this study include lack of baseline brain imaging and its clinical correlation with cognitive function. Based upon these preliminary findings prospective studies are being planned.

**Cancer Survivor Care: An Evaluation of a Group Visit Model of Care for Breast Cancer Survivors at Duke Cancer Center.**

*Trotter KJ, Schneider S. Duke University Medical Center; Durham, NC; Duke University, Durham, NC*

**Background:** The number of cancer survivors is growing, currently with about 2.5 million breast cancer survivors. (ACS, 2010). The Institute of Medicine report on survivor care stressed care coordination along with attention to survivor concerns as key issues in improving follow-up care. Group visits have been shown to improve access, health outcomes and health care utilization rates, as well as self-management skills.

**Purpose:** This prospective program evaluation measured patients opinions about participation in a group visit clinic.

**Methods:** A new model of breast cancer survivor care was designed and piloted at Duke Cancer Center. Breast cancer survivors who were three years post diagnosis attended the clinic together in groups of six. An interdisciplinary group visit format in the initial part of the appointment provided surveillance, education and support, as well as formation of an individualized survivorship care plan to be shared with the primary care provider. The first hour included review of their personal care plan and a 45-minute facilitated discussion. Afterwards, individual visits with the nurse practitioner, and dietitian, physical therapist or social worker occurred.

A 22-item questionnaire designed to ascertain opinions regarding logistics and the style and function of care delivered is being administered to participants. The evaluation tool was approved by a panel of experts; pilot tested and has a reading level of 7.8. Data collection will be complete July 1, 2011. 103 surveys have been collected with a 91% response rate. Preliminary analysis shows high satisfaction with the group visit format. What participants liked most about the program was sharing with other survivors. 86% of participants indicate that they will share the survivorship care plan with their PCP. Only 10% responded that they were not sure they needed this type of follow up now and expressed that it would be more helpful immediately after finishing treatment. Final data will be presented. Barriers and facilitators to implementing this type of care model will be presented.

**Conclusions:** The group visit model applied to a breast cancer survivor clinic appears feasible and highly satisfactory to participants.

**Implications for practice:** Group visits can be considered one option for survivor care.

**P4-13-01**

**Pain Severity and Analgesic Use Associated with Skeletal-Related Events in Patients with Advanced Breast Cancer and Bone Metastases.**

*Fallowfield L, Cleeland CS, Body J-J, Stopeck A, von Moos R, Patrick DL, Clemons M, Tonkin K, Masuda N, Lipton A, De Boer R, Salvagni S, Tosello Oliveira C, Ying W, Braun A, Cong Z. Cancer Research UK, University of Sussex, Brighton, UK; University of Arizona, Arizona Cancer Center, Tucson, AZ; University Libre de Bruxelles, Brussels, Belgium; University of Texas, M.D. Anderson Cancer Center, Houston, TX; CHU Brugmann, Université Libre de Bruxelles, Brussels, Belgium; University of Arizona, Arizona Cancer Center; Tuscon, AZ; University of Washington, Seattle, WA; The Ottawa Hospital Cancer Centre, Ottawa, ON, Canada; Cross Cancer Institute, Edmonton, AB, Canada; Osaka National Hospital, Osaka, Japan; Penn State Milton S. Hershey Medical Center, Hershey, PA; Royal Melbourne Hospital, Melbourne, Australia; Azienda Ospedaliera di Parma, Parma, Italy; Instituto Brasileiro de Controle do Cancer-IBCC, Sao Paulo, Brazil; Amgen Inc., Thousand Oaks, CA*

**Background:** Skeletal-related events (SREs), which include pathologic fracture (PF), radiation to bone (RB), surgery to bone (SB), and spinal cord compression (SCC), occur frequently in patients with bone metastases and can lead to debilitating clinical consequences such as functional impairment and bone pain. Denosumab (XGEVA®) is a fully human monoclonal antibody against RANKL, shown to be superior to zoledronic acid (ZA; Zometa®) for the prevention of SREs in patients with solid tumors. Denosumab also delayed the onset of moderate or severe pain compared with ZA. The pain severity and analgesic use associated with each type of SRE were assessed in patients with advanced breast cancer and bone metastases.

**Methods:** Eligible patients received denosumab 120 mg SC or ZA 4 mg (adjusted for renal function) IV every 4 weeks in a randomized, multinational, double-blind, double-dummy trial. Patient-reported pain was assessed with the Brief Pain Inventory (BPI; 0 no pain to 10 severe pain) at baseline (BL) and at each monthly visit. Opioid and non-opioid analgesic use was recorded and scored using the Analgesic Quantification Algorithm (AQA; 0 no analgesic use to 7 > 600mg oral morphine equivalent/day). Data from the two treatment arms were pooled for this analysis. Pain and analgesic use were evaluated from 6 months prior to and 6 months after the first on-study SRE for each patient. The comparator group included patients without an SRE and was centered at the median time from randomization to first SRE by SRE type, with corresponding 12 month assessments. The proportion of patients with moderate/severe pain (BPI worst pain score > 4) and proportion of patients shifting from no/low analgesic use (AQA ≤ 2) at baseline to strong opioid use (AQA ≥ 3) were reported by month and by SRE type, and are summarized by mean relative change (%) across the time period.

**Results:** In total, 687 patients with first on-study SRE occurrences (PF=450, RB=201, SCC=16, SB=20) were analyzed. A similar proportion of patients with and without a PF had moderate/severe pain, but a higher proportion of patients with a PF shifted from no/low analgesic use to strong opioid use (mean relative increase 80%). Starting 3 months prior to the event, more patients with RB than those without had moderate/severe pain (27% mean relative increase) and shifted from no/low analgesic use to strong opioid use (mean relative increase 269%). Similar pain and analgesic use patterns were noted for patients with SCC (mean relative increase in pain: 63%; in AQA shift: 913%). More patients with SB than those without had moderate/severe pain in the 6 months leading on to SB (mean relative increase 51%). The difference was attenuated after SB, but during this time a much higher proportion of patients with SB shifted from no/mild opioid use to strong opioid use (mean relative increase 22%).
Discussion: SREs are associated with increased pain severity and analgesic use in patients with advanced breast cancer and bone metastasis. Patterns of pain severity and analgesic use differed by SRE type. Effective treatments to prevent SREs can decrease pain and the need for treatment with opioid analgesics.

**P4-13-02**

**Hospice Utilization and End of Life Care in Metastatic Breast Cancer Patients at a Comprehensive Cancer Center.**

O’Connor TL, Ngamphaiboon N, Morris J, Callinan NK, Milch RA, Kerr CH, Watroba N, Edge SB. Roswell Park Cancer Institute, Buffalo, NY; The Buffalo Center for Hospice and Palliative Care, Cheektowaga, NY

Background: Metastatic breast cancer patients have many options for therapy and may be at risk for late or absent hospice referrals. Previous studies suggest that late referrals to palliative care make meaningful improvements in symptoms and quality of life difficult to achieve. We examined hospice utilization, status of patients on hospice admission, and quality of care documentation in patients treated for metastatic breast cancer at Roswell Park Cancer Institute (RPCI) from 1999-2010.

Methods: Analysis of breast cancer cases through the RPCI database identified 182 cases with deaths resulting from breast cancer eligible for services through The Buffalo Center for Hospice and Palliative Care (HB) (residence in Erie County, NY). Cases were cross-matched to the HB database for information on hospice utilization and outcome, and patient symptoms/status on admission to hospice. Date of last chemotherapy, opiate use, anxiolytic use, documentation of advance directive and palliative care discussion, and place of death were collected through chart abstraction.

Results: 182 patients eligible for HB services expired from breast cancer during the study period. 122 (67%) utilized hospice services; 60 (33%) did not. 117 patients received chemotherapy as their last treatment for metastatic breast cancer; patients referred to hospice received their last dose of chemotherapy a median of 31 days (14.1-47.9) prior to death; non-hospice patients 16 days (0-44.1) p=0.071. Patients subsequently admitted to hospice were significantly more likely to have a discussion of advance directives by their oncology team (30% vs. 5% p<0.001) and were more likely to die at home (56% vs. 8%, p<0.001). Only 7% of the 60 patients who died without a hospice referral had a documented discussion of palliative care as a therapeutic option by the oncology team (p<0.001) versus 100% of patients referred to hospice. 79% of breast cancer patients not admitted to hospice died in an acute care setting. Prior to hospice admission or death, 38% (69) patients had documentation of long-acting opiate use; 72% (131) were prescribed a short acting opiate, while 29% (52) patients were prescribed an anxiolytic. Median length of stay (LOS) was 17 days; 14% of patients died within 3 days of admission. Patient status on hospice admission is reported in Table 1.

| Status on HB admission (n=122) |

| Palliative care          | 79 (65%)
| documentation missing    | 43 (35%)
| Pain Score               | 0-1 (15%)
| 2-5 (30%)
| 6-10 (21%)
| missing                  | 14
| Palliative Performance Score (PPS) |
| 10-20                    | 15 (11%)
| 30-40                    | 63 (50%)
| 50-60                    | 32 (26%)
| missing                  | 19
| 8/10 dependent children  | 1 (0.8%)
| 0                        | 76 (62%)
| 1                        | 16 (13%)
| 2                        | 5 (5%)
| 3                        | 8 (6.6%)
| missing                  | 17
| Palliative care          | 79 (65%)
| documentation missing    | 43 (35%)
| Pain Score               | 0-1 (15%)
| 2-5 (30%)
| 6-10 (21%)
| missing                  | 14

Conclusion: Despite the recognition of the importance of high-quality end of life care, including end of life decision-making, advance directives, pain and symptom management, and hospice care, 33% of metastatic breast cancer patients at our institution died without hospice referral. Those patients referred to HB were significantly more likely to have an advance directive discussion, and to die at home. However, patients referred to HB had a median LOS of 17 days, and poor PPS. Efforts to enhance discussion of palliative care earlier in the treatment of MBC are critical to improved patient care.

**P4-13-03**

**Retrospective Analysis of Palonosetron Compared with Older 5-HT3 Receptor Antagonists (Ondansetron, Dolasetron, and Granisetron) in Preventing Anthracycline-Induced Nausea and Vomiting in Breast Cancer Patients from Four Phase 3 Trials.**

Rugo HS, Schwartzberg L, Morrow GR, Barbour SY, Ballinari G, Thorn MD, Cox D. UCSF Helen Diller Family Comprehensive Cancer Center; West Clinic; University of Rochester, School of Medicine and Dentistry; Duke University Medical Center; Helsinn Healthcare SA; Statistical Resources, Inc; Eisai, Inc.

In patients with breast cancer, the risk of developing chemotherapy-induced nausea and vomiting (CINV) is particularly high due to the common use of highly emetogenic chemotherapy coupled with pt-related risk factors including female gender and young age. Despite prophylactic antiemetics, controlling CINV is difficult in this high risk population, particularly in the delayed phase following CT. Palonosetron, a potent 5-HT3 receptor antagonist (RA) with a distinctly different pharmacokinetic and receptor binding profile, has demonstrated improved CINV protection compared to older 5-HT3 RAs in phase 3 and 4 clinical trials in a variety of settings and tumor types.

We conducted a retrospective subset analysis of pts with breast cancer, the majority of whom (89%) received anthracycline combination chemotherapy (doxorubicin+epirubicin+cylophosphamide, AC/EC) from four phase 3, randomized, double-blind, parallel group studies to assess the comparative effectiveness and safety of single IV doses of palonosetron (0.25 or 0.75 mg) versus older 5HT3-RAs (ondansetron 32 mg, dolasetron 100 mg, and granisetron 3 mg) in preventing CINV in pts receiving this highly emetogenic chemotherapy. The primary efficacy evaluation was for complete response (CR), defined as the proportion of patients with no emetic episodes & no use of rescue medication during 0-24hrs (acute), >24-120hrs (delayed), & 0-120hrs (overall) using a logistic regression model. A comparative descriptive safety assessment was also performed.

A total of 1197 patients with breast cancer were included in this analysis (palonosetron n=714; older 5HT3-RAs n=483). Higher CR
rates were seen for palonosetron vs. older 5HT3-RAs during the acute (63.4% vs 59.4%, p= 0.08), delayed (59.2% vs. 44.9%, p=0.0001) and overall (50.7% vs.38.5%, p<0.0001) phases. Rates for CR were similarly higher for palonosetron-treated patients in the large subgroup of patients receiving AC/EC based chemotherapy. Consistent improvements associated with palonosetron were seen for secondary endpoints of complete control (CR + no more than mild nausea), no emesis, and severity of nausea. The adverse event (AE) profile for palonosetron was similar to older 5HT3-RAs, with headache and constipation being the most commonly reported treatment-related AEs with similar incidences for all 5-HT3 RAs. This retrospective analysis of patients with breast cancer, including a large subgroup receiving anthracycline-based highly emetogenic chemotherapy, demonstrated significantly improved CINV prevention with palonosetron compared to older 5HT3-RAs, particularly in the delayed phase. Safety was comparable. This data has important implications for current CINV prevention guidelines.

### P4-14-01

**Weight-Adjusted Change of Unilateral Arm Volumes for Quantification of Lymphedema after Bilateral Breast Surgery.**

Miller CL, Specht MC, Ancukiewicz M, Skalny MN, O’Toole J, Taghian AG. Massachusetts General Hospital, Boston, MA

**Background:** Accurate quantification of breast cancer-related lymphedema (BCRL) is important for early detection and successful management. Arm volume changes after unilateral breast surgery can be calculated through relative volume change (RVC) of the affected arm using the contralateral arm as a control (Ancukiewicz et al Int J Radiat Oncol Biol Phys 79(5):1436-43 2011). However there currently exists no accurate method for quantifying arm volume changes in patients after bilateral breast surgery. As the number of women undergoing bilateral mastectomies continues to increase, it is critical to develop a method to quantify arm volume changes in this population for detection of lymphedema. Our aim was to develop a weight-adjusted formula for unilateral arm volume changes independent of the contralateral arm for application in the setting of bilateral breast surgery.

**Materials and Methods:** We analyzed longitudinal measurements of arm volumes in 141 unilaterally affected patients undergoing screening for BCRL with a perometer at our institution (71 with left affected and 70 with right affected arms). Each patient had a baseline measurement prior to surgery and at least one post-surgical measurement. Median time of follow-up was 27.5 months and median standard deviation of longitudinal weight changes within patients during follow-up was 3%.

**Results:** Unilateral arm volume changes of the unaffected arm were correlated with weight changes at the last follow-up point (Kendall’s tau=.58 and P<.0001). Estimates of slope and intercept for median regression line between percent weight change and percent arm volume change in the unaffected arm for application in the setting of bilateral breast surgery.

**Discussion:** Unilateral arm volume changes can be quantified by adjusting for weight changes. We propose the weight-adjusted change (WAC) formula to calculate unilateral arm volume changes for detection and monitoring of BCRL in patients who undergo bilateral breast surgery. The validity of such a formula needs to be assessed in conjunction with clinically reported lymphedema.
was a transient increase in LE. However, overall, we speculate that the higher risk for LE after 1 year is because of lack of use of the non-dominant affected arm. It is use of the upper limb which is likely the critical issue in this first year. Exercise was preventative while it was being undertaken; we question whether women maintained the level of exercise once the intervention concluded.

Akknowledgement: Cancer Council NSW; NBCF Australia

P4-14-03
Support Groups in Breast Cancer: An Evidence Based Assessment of 1606 Patients with Concerning Topics for Support Group Discussion and Presentation.
Gralla RJ, Morse KD, Rittenberg CN, Petersen JA, Rosen LM, Lesser M. Hofstra North Shore - LIJ School of Medicine, New York, NY; Nexcura, Seattle, WA; Feinstein Institute for Medical Research, Manhasset, NY

Background: Cancer support groups are conducted at most cancer centers. Although there is increasing demand among patients and families for support groups, little data exist outlining which topics patients and caregivers consider as most important for support group discussion and presentation. We conducted a large web-based anonymous survey to determine preferences of patients and caregivers for cancer support groups, including 1606 individuals with breast cancer and 3723 with other malignancies.

Methods: The established patient base of NexCura®, a web-based information resource, was used to survey registered patients and caregivers in this on-line assessment. Participants ranked 26 topics on a 5-point Likert scale which evaluated the importance of each item. Demographic characteristics, clinical factors, and support group content preferences were assessed.

Results: There were 4402 respondents to the invitation to participate, and 3723 patients and caregivers elected to participate (85%). Characteristics included for all 3723 patients: 70% women, mean age 58 (range 20-89). For the 1606 patients with breast cancer, 99.8% were women, the mean age was 56 (range 27-88); 53% were free of cancer. For the whole group, the four most common cancers were breast 45%, prostate 15%, lung 6%, and colorectal 5%. 90% of participants were women, the mean age was 58 (range 20-89). For the 1606 patients with breast cancer, 99.8% were women, the mean age was 56 (range 27-88); 53% were free of cancer.

Topics similarly to the general cancer population; however, topics dealing with fatigue and stress management were somewhat more highly ranked by those with breast cancer. 3) Physical, psychological, and communication issues were the most highly ranked issues by breast cancer patients and families. 4) These results should guide the content of support groups to meet the needs of patients and caregivers.

Conclusions: 1) This is the largest survey of patients and caregivers concerning support groups for patients with breast cancer and for a general cancer population. 2) Patients with breast cancer ranked most topics similarly to the general cancer population; however, topics dealing with fatigue and stress management were somewhat more highly ranked by those with breast cancer. 3) Physical, psychological, and communication issues were the most highly ranked issues by breast cancer patients and families. 4) These results should guide the content of support groups to meet the needs of patients and caregivers.

P4-14-04
Parent D, Rallet A, Jovenin N, Yazbek G, Cure H, Rey J-B. Institut Jean Godinot, Reims, France

Background
Few data are available in the literature regarding chemotherapy dosage adjustment in obese patients. Docetaxel is a lipophilic substance, highly bound to albumin; obesity might result in an accumulation of docetaxel and may lead to a higher rate of toxicity. The objective of this study was to assess the tolerance to docetaxel in obese and non obese patients, according to their body mass index (BMI).

Methods
A retrospective study was carried out. Patients were divided according to their BMI, considering a limit of 30 kg/m². All patients received docetaxel (100 mg/m²) as a part of adjuvant chemotherapy for breast carcinoma. Toxicity of docetaxel such as neutropenia, hand-foot syndrome, mucositis, and neuropathy were assessed in both groups. Patients receiving concomitant therapies leading to similar adverse events were excluded (e.g. cyclophosphamide, 5-FU, ...). The included patients received docetaxel alone or in association with trastuzumab or bevacizumab. Qualitative data analysis was performed using Fisher’s exact test. Quantitative data were studied using the Student test.

Results
Among the 49 patients, 18 (37%) presented with a BMI > 30 kg/m². The median age was 53 years-old in the group BMI > 30 and 55 years-old in the group BMI < 30 (p = 0.9383). The median dose intensity delivery was 91% (74-100%) in the group BMI> 30 and 97.7% (75-100%) in the group BMI < 30 (p = 0.06). The median value for albumin was 75 g/L (59-86 g/L) in the BMI > 30 and 71 g/L (56-79 g/L) in the BMI < 30 (p = 0.122). Toxicity in both groups was as follows:

Table 1 - Docetaxel toxicity according to patients’ BMI

<table>
<thead>
<tr>
<th>Neutropenia - n (%)</th>

</tr>
<tr>
<td>All toxicities - n (%)</td>
<td>11 (61.1%)</td>
<td>7 (22.6%)</td>
<td>0.013*</td>
</tr>
</tbody>
</table>

No neuropathy was observed in both groups.

Conclusions
Obese patients (BMI > 30 kg/m²) presented with more toxicities (p = 0.013). Hypoalbuminemia did not represent a risk factor for toxicity in this study as patients had normal albumin levels. Obesity is a risk factor for toxicity in patients treated with docetaxel. Dosage calculation according to body surface area is not suitable for these patients. Toxicity in the group BMI < 30 seems to demonstrate greater susceptibility to the molecule for these patients.

Further studies will try to identify the different mechanisms of toxicity of docetaxel involved obese patients, including the interaction between docetaxel and fats. Measures have also to be taken to obtain a favorable effectiveness/toxicity balance in obese patients.
**P4-14-05**

Chemotherapy-Induced Alopecia, Body Image and Psychological Distress in Women with Breast Cancer: A Prospective Study.

Choi E-K, Kim J-R, Nam S-J, Lee J, Yang J, Lee S-K, Noh D-Y, Han W, Cho J. Samsung Comprehensive Cancer Center, Samsung Medical Center, Sungkyunkwan University School of Medicine; Johns Hopkins Bloomberg School of Public Health; Samsung Medical Center, Sungkyunkwan University School of Medicine; Konkuk University Medical Center, Konkuk University School of Medicine; Seoul National University Hospital, Seoul National University School of Medicine

**Purpose:** While chemotherapy-induced alopecia (CIA) is known to be associated with lower quality of life, the longitudinal effect of alopecia on body image and distress in unknown. This study examined the effect of CIA on body image and psychological distress during active breast cancer treatment.

**Patients and Methods:** Between July and Dec 2010, we recruited patients with non-metastatic breast cancer who were expected to receive adjuvant chemotherapy (N=411) from two cancer hospitals in Seoul, Korea. After excluding 15 patients with recurrence and 65 patients lost to follow-up, the present analysis is based on 331 patients (80.5%). Participants completed questionnaires on body image, quality of life, alopecia distress at enrollment (before surgery), before chemotherapy (2 weeks post surgery), during chemotherapy (3 months post surgery), and after chemotherapy (6 months post surgery). Body image and quality of life were assessed by the EORTC QoL Questionnaire BR23. Alopecia distress was assessed by the Alopecia Distress Scale, which evaluated distress in 4 domains: physical, emotional, daily activity, and relationship.

**Results:** The mean age of the participants was 46.4 (SD 7.91) year. 44.9% and 37.6% of them had stage I and II breast cancer, respectively. 83.0% of the patients had lumpectomy, and 70.6% and 85.9% had chemotherapy and radiotherapy, respectively. Patients who experienced alopecia had a significantly more negative body image and higher distress compared to those who did not experience alopecia. Body image rapidly decreased at 3 months post surgery coinciding with alopecia, and its effects lasted until 6 months post surgery. Moreover, there was a highly statistically significant association between more negative body image and higher alopecia distress after adjusting for other socio-demographic and clinical characteristics. The patterns and changes in body image and distress comparing patients with and without alopecia are reported in Table 1.

**Discussion:** Health professionals need to develop clinical pathways and education programs to help women with breast cancer manage alopecia distress and negative body image during active treatment.

**P4-15-01**

High Prevalence of Prospective Memory (PM) Impairment in Early Breast Cancer (EBC) Survivors within 1 Year of Adjuvant Chemotherapy Completion: Novel Findings Concerning Post Chemotherapy Cognitive Effects.

Paquet L, Verma S, Collins B, Song X, Wheatley-Price P, Hopkins S, Segal R, Dent S, Mirsky D, Goel R, Young V, Clemons M, Keller O, Chinneck A, Young R, Bedard M. Carleton University, Ottawa, ON, Canada; The Ottawa Hospital Cancer Centre; Ottawa, ON, Canada; The Ottawa Hospital, Ottawa, ON, Canada

**Background** Numerous studies have demonstrated that EBC survivors report more memory problems than healthy controls. However, evidence of impairment on objective tests of memory remains inconclusive. Past research has focussed exclusively on retrospective memory (remembering information from the past when asked to do so), but the complaints of EBC patients appear better described as “prospective memory” failures defined as forgetting to carry out in the future previously formed intentions. The effective performance of many day-to-day activities relies on PM and its impairment has negative consequences in everyday life. Despite its high ecological relevance, no study has evaluated PM functioning in EBC survivors. Consequently, we assessed the prevalence of PM impairment among EBC survivors in the year following completion of chemotherapy.

**Methods** We undertook a cross sectional quantitative case-control study aiming to recruit 80 patients from the Ottawa Hospital Regional Cancer Centre and 80 matched healthy controls from the community. Patients were within 1 year of having completed a first course of chemotherapy. A standardized test of prospective memory (Memory for Intention Screening Test) was administered to both groups. Following the International Cognition and Cancer Task Force recommendation (2008), impairment was defined as a score that fell one standard deviation below the mean performance of the control group. Standardized measures of depression (CESD), anxiety (STAI) and fatigue (Fact-F) were also completed.

**Results** Data are available on 36 patients and 18 controls. Age was well balanced between the groups (case-control mean age 54y vs. 51y, respectively, p=0.204). Overall PM impairment was observed in 41% of the participants. More importantly, the rate of PM impairment was significantly higher in the EBC group than controls (53% vs 17%; p < 0.005; odds ratio = 5.588; 95% CI=1.376 to 22.7). Multivariate logistic regression showed that PM performance was unaffected by age (p=0.459), depression (p=0.358), anxiety (p=0.512) or fatigue (p=0.595).

**Conclusions** These preliminary findings provide further support for the hypothesis that breast cancer treatment can impair cognitive processes and yield new and important insights into the type of memory problems experienced by EBC survivors. They suggest that a significant proportion of patients exhibit deficits in PM, an aspect of memory involved in effective daily functioning. Our results also suggest that emotional distress and fatigue do not contribute to PM functioning. Further studies in this area should be directed at understanding the severity and duration of PM impairment. Acknowledging and studying this vexing problem in EBC survivors will aid in developing appropriate rehabilitation strategies.
P4-15-02
Clinical and Epidemiological Correlates of Elevated Distress Thermometer Scores in Breast Cancer Patients.

Powers K, Pappas L, Buchmann L, Anderson L, Gauhcy L, Rich A, Agarwal J. University of Utah, Salt Lake City, UT; Huntsman Cancer Institute, Salt Lake City, UT

Objectives: Distress is prevalent in breast cancer patients and can be detrimental to quality of life, performance status, treatment adherence, and satisfaction with medical care. The National Comprehensive Cancer Network (NCCN) developed the Distress Thermometer (DT) as a quick and efficient self-assessment tool for screening distress in cancer patients. While surveys estimate that between 20-40% of patients with cancer have significant levels of distress, fewer than 10% are identified and treated. Given time and monetary constraints, it is important to refine screening criteria to identify patients with elevated risk for distress. In this study, we identify clinical and epidemiological factors that are associated with an increased likelihood of elevated DT scores (≥4 and ≥7) in breast cancer patients.

Methods: We assessed 229 consecutive female patients with the DT at their initial consultation for breast cancer at the Huntsman Cancer Hospital between September 2007 and December 2008. The DT screening tool measures a global level of distress using a visual analogue scale from 0-10 in the shape of a thermometer, with zero identified as “No Distress” and ten labeled as “Extreme Distress.” The DT screening tool also includes a checklist of common emotional, family, physical, practical, and spiritual concerns with instructions for the patient to indicate which of those concerns contributed to the distress they experienced within the past week. We chose a score ≥4 as our cutoff for a positive screen for “distress” and a score ≥7 as our cutoff for a positive screen for “extreme distress/depression” based on previous studies. Variables included in the analyses were: age, employment status, race/ethnicity, personal history of depression, family history of breast cancer, marital status, estrogen and progesterone receptor status, stage of cancer, time since diagnosis, and recurrence. Descriptive statistics and logistic regression models were used to determine associations between DT and patient data.

Results: Emotional and physical concerns were associated with scores ≥4 and scores ≥7. Spiritual concerns were significantly associated with patients reporting scores ≥7. Patients who were non-Caucasian, unemployed, had a prior history of depression, who presented for recurrent disease, or who had been recently diagnosed had a higher likelihood of scores ≥4 and scores ≥7.

Conclusions: The likelihood of scoring ≥4 and ≥7 on the DT screening tool is highest during the first 30 days after receiving a breast cancer diagnosis. Four groups of patients should be targeted for aggressive screening: patients with a prior diagnosis of depression, patients presenting with recurrent disease, unemployed patients, and non-Caucasian patients. Interventions should address physical, emotional and spiritual concerns.

P4-15-03
Patient-Provider Communication and Patient Informational Needs for Breast Reconstruction Post-Mastectomy: Results from a National Survey.

For many women, the complexity of processing and learning about their breast cancer diagnosis is further complicated by decisions to be made about breast reconstruction post-mastectomy. Existing studies suggest that these women are provided with information about breast reconstruction options of differing depth, breadth, and quality, but little is known about how this information is received by the patient as well as the value of this information. Guided by Social Cognitive Theory, the Cancer Support Community (CSC) conducted a national survey in an effort to better understand patients’ information-seeking experiences, patient-provider communication, and knowledge about breast reconstruction. 840 U.S. women with breast cancer (762 eligible for breast reconstruction who were then eligible to answer survey questions pertaining to their experiences) participated in the survey online or by paper-and-pencil at CSC affiliate sites in 2010. In addition to demographics, information about their diagnosis, treatment, and experience with reconstruction, women rated their experience with receiving breast reconstruction information from their healthcare professionals as well as their experience searching for and receiving information about options and realistic expectations for breast reconstruction.

Survey participants came from 46 states, were primarily Caucasian (85%), and the mean age at diagnosis was 48.9 years old. Most women reported that either a plastic surgeon (73.3%) or a breast surgeon (64.0%) had spoken to them about reconstruction, followed by oncologist (34.2%) and surgical oncologist (24.8%). Of women whose healthcare team had spoken with them about reconstruction, 57.1% reported that reconstruction was first discussed at diagnosis. Women reported that this information was somewhat (35.1%) or extremely (55.5%) useful, though they sought additional information elsewhere. Aside from their health care team, most women (60%) sought information about reconstruction from other women with breast cancer and half sought information from the Internet. Participants reported that they would have liked to have had more information prior to reconstruction about a variety of topics, including: how they would look after reconstruction (34.8% endorsing), how they would feel after reconstruction (35.5%), and information about their future breast health (25.9%). Open-ended responses suggest many patients experience gaps in information with regard to establishing realistic expectations about the procedures and outcomes, providing comprehensive information at various stages throughout the process, and across various treatment options.

Though many participants reported satisfaction with how information about reconstruction was provided to them and the quality and scope of this information, responses suggest that there is work to be done with regard to establishing realistic expectations about the procedures and outcomes, providing comprehensive information at various stages throughout the process, and across various treatment options.

P4-16-01
Proteomic Analysis of Patient Plasma Identifies Parathyroid Hormone Related Protein (PThrP12-48) as a Potential Biomarker of Breast Cancer Bone Metastasis.

Washam CL, Byrum SD, Leitzel K, Suhail AM, Lipton A, Suva LJ, Winthrop P. Rockefeller Cancer Institute, University of Arkansas for Medical Sciences, Little Rock, AR; Penn State Hershey Cancer Institute, Penn State Hershey Medical Center, Hershey, PA; Lebanon V4 Medical Center, Lebanon, PA

Background: Bone metastasis is a devastating and often incurable phase of breast cancer progression that significantly compromises patient morbidity and mortality. Despite the well-characterized issues associated with tumor progression, there is currently no reliable method to detect or predict which patients have or are at increased risk for developing bone metastasis. In this study a validated plasma-based proteomic profile for the diagnosis of breast cancer bone metastasis...
was developed and a highly discriminatory protein component of the profile identified as a novel fragment of parathyroid hormone related protein (PTHrP).

Materials and Methods: Plasma samples were collected from a total of 110 breast cancer patients. The training set consisted of 38 breast cancer patients with clinical evidence of bone metastasis and 38 with no evidence of a bone metastasis from time of diagnosis to clinical outcome. The independent validation cohort consisted of 34 breast cancer patients with an unknown bone metastasis classification. The training set was analyzed using surface enhanced laser desorption time-of-flight mass spectrometry (SELDI-TOF MS) and 13 discriminatory protein peaks that contributed to a homogeneous partitioning of the training set (n = 76) in multiple statistical, bioinformatics, and machine learning modeling scenarios were identified and used to construct a RandomForest classifier for the detection of breast cancer bone metastasis (sensitivity: 100%, specificity: 100%).

Results: The diagnostic profile identified was then independently confirmed in a blinded fashion using the validation cohort (sensitivity: 97%; specificity: 82%). Importantly, the most discriminatory protein peak (m/z 4260.92 Da) in the plasma of bone metastasis patients was subsequently identified using specific immunodepletion, trypic peptide mapping and peptide sequencing as a unique proteolytic PTHrP fragment, PTHrP(12-48). Ongoing studies are determining the biogenesis and biological activity of this unique PTHrP peptide.

Discussion: Our discovery of PTHrP(12-48) as a novel plasma biomarker of breast cancer bone metastasis validates our plasma proteomic approach and provides the first direct evidence for the existence of a circulating PTHrP biomarker in breast cancer patient plasma that is associated with bone metastasis.

P4-16-02
Problems with Identifying Bone Metastasis-Specific Genes without Considering Biological Differences between ER-Positive and ER-Negative Breast Cancers.
Hayashi N, Iwamoto T, Qi Y, Niikura N, Santarpia L, Nakamura S, Horiobagyi GN, Puszta I, Symmans F, Ueno NT. The University of Texas MD Anderson Cancer Center; Houston, TX; The University of Texas MD Anderson Cancer Center; Houston, TX; Hospital of Prato and Instituto Toscano Tumori, Prato, Italy; Showa University School of Medicine, Tokyo, Japan

Background: Bone metastasis-specific genes in breast cancer have been reported without considering the significant differences in ER status between bone and non-bone metastases. The aims of this study were to validate genes that had been reported as bone metastasis-specific genes using our data set and to identify bone metastasis-specific genes on the basis of biological differences between ER-positive and ER-negative breast cancers.

Patients and Methods: We used Affymetrix GeneChip arrays to analyze tumor samples obtained from 365 primary invasive breast cancer patients who underwent surgery from 1999 to 2008. We excluded patients with HER2-positive breast cancer (normalized HER2 mRNA expression [probe set 216836_s_at] > 12.54). We classified the samples into 3 cohorts according to first metastatic site: bone, non-bone, or no metastasis. Differential expression of genes between bone and non-bone cohorts that were differentially expressed was identified using the Cox proportional hazards model, and gene sets were assessed using gene-set analysis.

Results: Of the 365 patients, 34 (9.3%) were included in the bone cohort and 32 (8.8%) in the non-bone cohort. Two hundred fourteen (58.6%) had ER-positive and 151 (41.4%) had ER-negative breast cancer. First, we performed gene-set analysis using 5 gene sets that had been reported to be associated with bone metastasis. One gene set, which had been detected using an ER-negative breast cancer cell line, was validated as predicting bone metastasis in ER-positive breast cancer. None of the 5 gene sets predicted bone metastasis in ER-negative breast cancer. We then determined the levels of individual genes associated with bone metastasis by ER status using all 16,712 probe sets filtered by average gene expression level. When we analyzed all patients without any stratification by ER status, as in previous studies, 592 probe sets were significantly overexpressed in the bone cohort compared with the non-bone cohort, with a false discovery rate of ≤0.05. However, when we analyzed ER-positive and ER-negative breast cancers separately, no genes were found with significant differences between bone and non-bone cohorts. Finally, we used 2,246 functionally annotated gene sets assembled from Gene Ontology to examine possible biological differences between bone and non-bone cohorts. In the bone cohort, 151 and 125 gene sets were significantly overexpressed in ER-positive and ER-negative breast cancers, respectively (P ≤ 0.05). Ppathways related to Cellular growth and proliferation, intracellular and second-messenger signaling were overexpressed in ER-positive breast cancer, whereas pathways related to nuclear receptor and cytokine signaling were overexpressed in ER-negative breast cancer. Most bone-metastasis-related pathways were different in ER-positive and ER-negative breast cancers (91.4% and 89.6% of the gene sets, respectively).

Discussion: No genes were found that can predict bone metastasis. ER-positive and ER-negative breast cancers have different biological potentials for bone metastasis. Therefore, we need to assess the prediction model of bone metastasis based on the biological features for each ER status separately.

P4-16-03
Proof of the Anti-Tumour Effect of Zoledronic Acid (ZA) in Naive Bone-Only Metastatic and Locally Advanced Breast Cancer: Results from the Biological Window Therapy.
Foroni C, Andreis D, Maldotti M, Cappelletti MR, Generali DG. Istituti Ospitalieri di Cremona, Cremona, Italy

Background: Pre-clinical studies have demonstrated an anti-tumour activity of ZA in several cancers. However, the clinical evidence of the ZA anti-tumour effect is still uncertain. Our study aimed to prove that ZA has anti-tumour activity administered alone as a biological window of 14 days therapy on naïve bone-only metastatic and locally advanced breast cancer.

Material and Methods: 27 patients with locally advanced breast cancer (Group 1) and 12 patients at their first relapse with bone metastasis only (Group 2) received 4 mg single dose of ZA before starting with any treatment. In Group 1, Ki67 expression was evaluated in tumour specimens obtained before and after ZA administration (basal, day 14). In Group 2, circulating tumour cells (CTCs) were evaluated at baseline, 48 hrs and day 14. In Group 1 and 2, the apoptosis and necrosis of tumour cells were tested on blood samples by M30 and M65 ELISA assay respectively. Parallel, the anti-antitumor activity administered alone as a biological window of 14 days therapy on naïve bone-only metastatic and locally advanced breast cancer.

Results: A significant reduction of CTC number after 48 hrs (median, 16 to 7; p=0.045), followed by a tendency to increase on
day 14 (p=0.093). The M30/M65 analysis performed on paired blood samples in Group 2 showed after 14 days a significant increase in M65 (median, 97 to 112 U/L; p=0.018), more accentuated than the concomitant increase in M30 (p=0.308). In MDA-MB-231 bearing mice, ZA treatment caused a significant inhibition of tumor growth. Conclusions: These results are the first prospective clinical data showing a direct anti-tumour effect (either on the tumour or on CTCs) of ZA, confirming the in vitro data. By directly affecting the proliferation, ZA could have an anti-tumour effect via induction of necrosis, suggesting its possible use in combination with conventional oncologic treatments of breast cancer.

**P4-16-04**

**An Open-Label, Phase IIa, Non-Randomized Study of Radium-223 in Breast Cancer Patients with Bone Dominant Disease No Longer Considered Suitable for Endocrine Therapy.**

Coleman R, Flamen P, Naume B, Jerusalem G, Garcia C, Piccart M, O’Bryan-Tear CG, Aksnes A-K. Weston Park Hospital, Sheffield, United Kingdom; Institut Jules Bordet, Brussels, Belgium; Oslo University Hospital, Oslo, Norway; CHU Sart Tilman, B35, Liege, Belgium; Algea ASA, Oslo, Norway; Bayer Healthcare Pharmaceuticals, Montville, NJ

**Background:** Radium-223 (Alpharadin™) is a 1st-in-class alpha-pharmaceutical. It targets bone metastases (mets) with high-energy alpha-radiation of extremely short range that spares bone marrow. These characteristics generate highly localized radiation zones that may inhibit tumor progression and induce pain relief. Radium-223 has a profound effect on markers of bone metabolism and has shown a survival advantage over standard of care in pts with castration-resistant prostate cancer. The study’s main objective was to investigate whether multiple IV injections (inj) of radium-223 have any clinically relevant effect on bone markers in metastatic breast cancer (MBC) pts with bone dominant disease (BDD). **Methods:** Study included MBC pts with BDD who had progressed (based on imaging or other clinically relevant information) on endocrine therapy and were no longer considered suitable for endocrine therapy. In this open-label, multicenter, single-arm, phase IIa study (EudraCT #2009-012189-30), 23 pts were scheduled to receive 4 IV inj of radium-223 50 kBq/kg every 4 wk. Bone markers were assessed at baseline, prior to every treatment, and thereafter at each follow-up visit. Primary efficacy endpoint was change in urine levels of NTX (uNTX) and bALP at 16 wk. Functional imaging with FDG-PET was performed in 20 pts at baseline and wk 8 and 16. Symptomatic response was assessed using validated questionnaires. **Results:** Histologic types were ductal carcinoma (n=12), lobular carcinoma (n=7), and others (n=2). Median interval from diagnosis of breast cancer to 1st relapse was 3 (1, 11) years. All except 1 pt received endocrine therapies, and adjuvant chemotherapy was given to approximately 60%. 21/23 pts were treated concurrently with bisphosphonates. 15 of 23 pts received all 4 inj of radium-223; 4/23 received 3 inj; and 4/23 received 2 inj. Pts who received ≤4 inj had disease progression (bone and visceral mets [n=3], visceral mets [n=3]) or withdrawn consent (n=1) and were not eligible to continue radium-223. One pt died before 4th inj due to atrial fibrillation. Median age was 58 (41, 83) years. Median uNTX levels were reduced by 20% (from 36 to 29 nmolBCE/mmol creatinine; \(P=0.03\)) and 5% (from 23 to 22 nmolBCE/mmol creatinine; \(P=NS\)) at wk 8 and 16 respectively; 12/23 and 9/13 pts (for whom data were available) had a decrease in uNTX at wk 8 and 16 respectively. Median bALP levels were reduced by 33% (from 22.1 to 12.1 ng/mL; \(P=0.0001\)) at wk 8 and 33% (from 22.1 to 10.4 ng/mL; \(P=0.04\)) at wk 16. Bone-ALP levels were reduced in 20/22 pts at wk 8 and in 10/12 pts (for whom data were available) at wk 16. Radium-223 was found to be safe and well tolerated. 3 pts had serious AEs, none related to study drug; 1 of them died due to disease progression. Functional imaging results, additional bone marker data, and pt-reported outcomes are being analyzed. **Conclusions:** Radium-223 consistently reduced uNTX and bALP during the 16-wk treatment period, results observed in addition to bisphosphonate use. Results show radium-223 targets the areas of increased bone metabolism caused by bone mets. Radium-223 found to be safe and well tolerated, confirming highly tolerable SE profile seen in other studies.

**P4-16-05**

**A Randomized Phase 2 Study of a Loading Dose of Ibandronate in Patients with Bone Metastases from Breast Cancer.**

Ritchie DM, Bray C, Canney P. Beatson West of Scotland Cancer Centre, Glasgow, United Kingdom

Bisphosphonates have proven efficacy in reducing skeletal complications in metastatic breast cancer. Potent third generation bisphosphonates are more effective but the dose limiting toxicity is usually renal. Ibandronate is a 3rd generation bisphosphonate available in oral and intravenous form which offers many clinical advantages in ease of administration and lack of renal toxicity. A dose-response effect has been observed between 2mg and 6 mg IV doses and there is a single study suggesting that higher dosing (4 mg IV daily for 3 days) is tolerable and effective. A steady state of oral ibandronate is achieved at 8 days with oral administration but time to response is not known. In trials so far, IV ibandronate 6mg appears safe. Due to lack of renal toxicity there is potential for further escalation of IV ibandronate. The objective of this study was to establish if an IV loading dose can improve efficacy and time to biochemical response compared to oral standard therapy and to assess the safety of a higher IV dose of ibandronate.

**Methods and Patients:** This was an open randomised phase II study conducted on patients with bone metastases from breast cancer comparing IV ibandronate 12 mg on day 1 followed by oral ibandronate 50 mgs daily (Arm A) with standard oral therapy of 50 mgs daily from day 1 (Arm B). The primary study end-point was the percentage reduction in serum CTX from baseline by day 5 on study, secondary end-points were the percentage reduction of bone turnover markers including serum CTX from baseline end of week 8 and percentage reduction in urine NTX from baseline to day 5 on study and baseline to end of week 1-8. Bone pain was recorded by Brief Pain Inventory. Patients had metastatic breast cancer with proven bone metastases, no previous treatment with bisphosphonates or other bone directed therapy within 6 months and no change in systemic therapy within a 3 months preceding trial therapy. Sample size of 22 patients in each arm was calculated to give a 90% chance of detecting a 20% difference in average percentage reduction between the IV and oral arms.

**Results:** Seventeen patients were randomised to each study arm. A more rapid change in bone turnover markers was demonstrated in patients receiving the 12 mg loading dose of ibandronate. There was a 15.8% greater reduction of serum CTX in Arm A compared with Arm B. The primary study endpoint was the percentage reduction in serum CTX from baseline by day 5 on study, secondary end-points were the percentage reduction of bone turnover markers including serum CTX from baseline end of week 8 and percentage reduction in urine NTX from baseline to day 5 on study and baseline to end of week 1-8. Bone pain was recorded by Brief Pain Inventory. Patients had metastatic breast cancer with proven bone metastases, no previous treatment with bisphosphonates or other bone directed therapy within 6 months and no change in systemic therapy within a 3 months preceding trial therapy. Sample size of 22 patients in each arm was calculated to give a 90% chance of detecting a 20% difference in average percentage reduction between the IV and oral arms.

**Results:** Seventeen patients were randomised to each study arm. A more rapid change in bone turnover markers was demonstrated in patients receiving the 12 mg loading dose of ibandronate. There was a 15.8% greater reduction of serum CTX in Arm A compared with Arm B. The primary study endpoint was the percentage reduction in serum CTX from baseline by day 5 on study, secondary end-points were the percentage reduction of bone turnover markers including serum CTX from baseline end of week 8 and percentage reduction in urine NTX from baseline to day 5 on study and baseline to end of week 1-8. Bone pain was recorded by Brief Pain Inventory. Patients had metastatic breast cancer with proven bone metastases, no previous treatment with bisphosphonates or other bone directed therapy within 6 months and no change in systemic therapy within a 3 months preceding trial therapy. Sample size of 22 patients in each arm was calculated to give a 90% chance of detecting a 20% difference in average percentage reduction between the IV and oral arms.

**Results:** Seventeen patients were randomised to each study arm. A more rapid change in bone turnover markers was demonstrated in patients receiving the 12 mg loading dose of ibandronate. There was a 15.8% greater reduction of serum CTX in Arm A compared with Arm B. The primary study endpoint was the percentage reduction in serum CTX from baseline by day 5 on study, secondary end-points were the percentage reduction of bone turnover markers including serum CTX from baseline end of week 8 and percentage reduction in urine NTX from baseline to day 5 on study and baseline to end of week 1-8. Bone pain was recorded by Brief Pain Inventory. Patients had metastatic breast cancer with proven bone metastases, no previous treatment with bisphosphonates or other bone directed therapy within 6 months and no change in systemic therapy within a 3 months preceding trial therapy. Sample size of 22 patients in each arm was calculated to give a 90% chance of detecting a 20% difference in average percentage reduction between the IV and oral arms.
12 mg of IV ibandronate and no evidence of additional renal toxicity. Conclusion: A 12 mg dose of IV ibandronate can be safely administered without additional renal toxicity. A rapid reduction in bone turnover markers is demonstrated within 5 days of IV loading dose of ibandronate. Potential exists for dose escalation of ibandronate. The clinical benefit of a more rapid reduction in bone turnover markers is unknown.

P4-16-06
Expression Patterns of Receptor Activator of Nuclear Factor-κB (RANK) and Src in a Series of Primary Breast Tumors (BT) and Bone Metastases (BM) in Patients (pts) with Metastatic Breast Cancer (MBC).
Gcapal A, Comen E, Redana S, Evangelista L, Giri DD, Zhang XH, Patil S, Akram M, Norton L, Hudis CA, Fornier MN. Memorial Sloan-Kettering Cancer Center, New York, NY; Sloan-Kettering Institute, New York, NY; Piemontese per l’Oncologia - Institute for Cancer Research and Treatment, Candiolo, Italy; Istituto Oncologico Veneto (HOV - IRCCS), Padua, Italy

Background: BM develops in 65-70% of pts with MBC. RANK and its ligand (RANK-L) can be critical in the development and progression of BM. Src overexpression and deregulation occurs in many solid tumors but it has not been fully characterized although an association between Src activity defined by a gene expression signature and BM particularly in ER+ pts has been described. (Zhang XH et al. Cancer Cell. 2009) Our goal was to elucidate the relationship between Src and RANK expression in BT and BM in relation to estrogen-/progesterone-receptor (ER/PR)/HER2 status of BT and BM. Scoring: 0=negative, 1+=weak, 2+=intermediate, 3+=strong and the percent of positive tumor cells; RANK+ = 2-3+, > 1% of cells; Src+ = 1-3+; > 1% of cells. Associations between RANK/Src expression and tumor histology (invasive ductal carcinoma (IDC) vs invasive lobular carcinoma (ILC)).

Methods: Immunohistochemistry (IHC) for RANK (R&D Systems clone 80707) and Src (Cell Applications Inc. Phospho Tyr-416) protein expression was performed on archived paraffin embedded BT and BM. Scoring: 0=negative, 1+=weak, 2+=intermediate, 3+=strong and the percent of positive tumor cells; RANK+ = 2-3+, > 1% of cells; Src+ = 1-3+; > 1% of cells. Associations between RANK/Src expression and tumor characteristics were assessed using the chi-square test or McNemar’s test for pairs, as appropriate.

Results: From the MSKCC database, using an IRB-approved waiver of consent, we identified 54 pts with MBC who underwent surgical biopsy of a metastatic bone lesion at our center between 2005-2010, and had tissue available for further testing. 17 corresponding BT samples were identified. At the time of diagnosis, 43 (79.5%) primary tumors were ER or PR (+); 6 (11%) were HER2+; 41 (76%) were invasive ductal carcinoma. 87% of BM expressed RANK and 44% expressed Src. (Table 1) No significant correlation between RANK or Src expression in BM and ER/PR/HER2 status of BT was observed. A significant correlation between RANK expression and BT histology was observed, (p=0.0016): 93% of IDC were RANK (+), in comparison to 50% of invasive lobular carcinomas. RANK expression was not significantly different between primary tumor and metastatic bone samples (p=0.06). There was a borderline significant difference in Src expression between primary and metastatic site (p=0.06).

Conclusions: In our cohort, no correlation between RANK or Src by IHC and ER/PR/HER2 was identified but RANK expression was more common in IDC than ILC. Fidelity was high for RANK between primary and metastatic lesions while Src expression may possibly vary.

P4-16-07
Mitchell ME, Taylor A, Lowe KA, Langeberg W, Alexander D, Kelsh M, Body J-J. Exponent; Amgen; CHU Brugmann

Background: Bone metastases are common in breast cancer patients and an important cause of morbidity and mortality. This review provides the first systematic and quantitative summary of the proportion of breast cancer patients with bone metastasis and their survival, presented by stage at diagnosis and length of follow-up.

Materials and methods: A literature review was conducted using PubMed to identify full-text studies published in English 1999-2009. Studies were included if they had ≥100 adult patients with Stage I-IV breast cancer and were generalizable to the overall breast cancer population. The design and intent of included studies varied, including clinical trials of bone-targeted therapies and observational studies of cancer patients evaluating staging techniques, biomarkers, and other factors. To improve homogeneity, studies were grouped by stage at diagnosis, whether follow-up for bone metastases occurred, and the clinical point at which the proportion of patients with bone metastasis was estimated (e.g., at initial staging). Studies reporting survival were only included in quantitative summaries if survival was measured from the date of bone metastasis diagnosis. With regard to clinical trials of bisphosphonates, only proportion and survival data from the placebo group were utilized since the goal was to describe bone metastasis among patients untreated with bone-targeted therapy. Meta-analytic techniques were applied to (1) proportion data using random effects models to calculate weighted averages, and (2) survival data using an average of reported median survivals. Various sensitivity analyses were also conducted.

Results: Nineteen studies were included in our quantitative summary of proportion data. At initial staging of breast cancer, 7% (N=2; 95% confidence interval [CI]=5-9%) of all patients had bone metastases and 69% (N=2; 95% CI=47-85%) of Stage IV patients had bone metastases. Among breast cancer patients followed from the diagnosis of Stage I-III breast cancer, 10% (N=6; 95% CI=6-15%) had bone metastases after a median follow-up <10 years, compared to 24% (N=3; 95% CI=19-31%) after a median follow-up ≥10 years. Twelve studies were included in our quantitative summary of survival data.
Survival was longer among patients with metastases solely in bone (N=7; average median=30 months), compared to patients with bone metastases and metastases at other sites (N=5; 23 months) and patients with metastases only at sites other than bone (N=3; 9 months).

**Discussion:** Significant heterogeneity across studies was observed, reflecting the variability in study populations, locations, and other factors. Despite this and other limitations (e.g., few studies in some categories), this represents the first analysis of the literature to quantify the prevalence and survival of bone metastasis in breast cancer. Our results indicated that bone is a site of metastasis among more than 50% of Stage IV patients at diagnosis of breast cancer. Median survival among breast cancer patients with metastases located solely in the bone is at least six months longer compared to those with metastases at multiple sites (including bone) and sites other than bone.

**P4-16-08**

**Pilot Randomized Trial of De-escalated (q12 Weekly) Versus Standard (q3-4 Weekly) Intravenous Bisphosphonates in Women with Low-Risk Bone Metastases from Breast Cancer.**

Amir E, Freedman O, Carlsson L, Usmani T, Lee E, Dranitsaris G, Clemmons M. Princess Margaret Hospital and The University of Toronto, Canada; The Ottawa Hospital Cancer Centre and The University of Ottawa, Canada

**Background:** Bone-targeted agent such as bisphosphonates (BPs) can reduce skeletal complications from bone metastases but have no effect on either disease progression or survival. Despite substantial variability in the frequency and severity of skeletal complications, patients are empirically treated with BPs at the same dose and schedule irrespective of their individual risk.

**Materials and Methods:** A pilot, randomized, non-inferiority trial was conducted. Patients with low-risk bone metastases (serum C-telopeptide [CTx] <600ng/L after at least 3 cycles of monthly IV BP) were assigned to pamidronate 90mg IV either every 3-4 weeks (control) or every 12 weeks (de-escalated). Data on serum CTx and bone alkaline phosphatase (BAP), pain scores (brief pain inventory [BPI] and functional assessment of cancer therapy-bone pain [FACT-BP]) were collected at 12 weekly intervals for 48 weeks.

**Results:** Fifty-four patients were approached, 44 provided consent and 38 were eligible for randomization. Median age was 55 (range 29-77) and mean baseline CTx was 319ng/L (range 10-526). Thirty-five participants (92%) completed the trial, 2 withdrew consent and one participant died. Fourteen control group participants (73.7%) and 13 experimental group participants (68.4%) maintained CTx in the low risk range (test for two proportions p=0.64). All patients not maintaining CTx in the low risk range showed evidence of both visceral and bone progression. Compared to the control group, there was a trend towards increasing CTx with time in the experimental group (p=0.10). There was no significant difference in BAP (p=0.37), BPI (p=0.21) or FACT-BP scores (p=0.59) between the two groups. Over the 48 week follow-up, two skeletal events were observed in each group.

**Conclusions:** Randomized trials of de-escalated BP therapy in women with low-risk bone metastases are feasible. Twelve-weekly pamidronate appears non-inferior to 3-4 weekly treatment. Larger trials are required to assess whether: 1) increasing CTx levels with de-escalated therapy will lead to higher rates of skeletal complications and 2) whether BP should be given every 3-4 weeks in patients with progressive visceral and bone disease.

**P4-16-09**

**Health Resource Utilization (HRU) Associated with Skeletal-Related Events (SREs) in Advanced Breast Cancer Patients with Bone Metastases: Results from a Prospective Multinational Observational Study.**

Läffner D, Lorusso V, Duran I, Hechmati G, Garzon-Rodriguez C, Aschroft J, Bahl A, Ghelani P, Wei R, Thomas E, Hoefeler H. Universitätsmedizin Berlin, Berlin, Germany; Oncology Institute ASL, Lecce, Italy; Centro Integral Oncologico Clara Campal (CIOCC), Madrid, Spain; Ament (Europe) GmbH, Zug, Switzerland; Instituto Catalán Oncología ICO-IDIBELL, Barcelona, Spain; Pinderfields General Hospital, Wakefield, United Kingdom; University Hospitals Bristol, Bristol, United Kingdom; Ovatech Solutions, London, United Kingdom; Amgen Inc., So. San Francisco, CA; Forschungszentrum Ruhr, Witten, Germany

**Background:** Patients with advanced breast cancer and bone metastases suffer from skeletal complications (SREs), defined as spinal cord compression [SCC], surgery to bone [SB], pathologic fracture [PF] or radiation to bone [RB]). Planning future resource requirements and estimating the value of new treatment options requires prospective data on the health resource burden. However, there is a lack of these data in the literature.

**Materials and Methods:** Patients had bone metastases secondary to advanced breast cancer and were eligible to be included in the study if they had: at least one SRE within 90 days prior to enrolment; life expectancy >6 months; ECOG ≤2. HRU (number and length of inpatient hospitalizations, outpatient visits, emergency room visits, number of procedures, etc) associated with SREs was collected retrospectively for 90 days prior to enrolment and prospectively for up to 18-21 months. Attribution of HRU to each SRE was determined independently by the investigators. This pooled European analysis includes data for breast cancer patients from centers in Germany, Italy, Spain and UK.

**Results:** A total of 223 eligible patients with breast cancer and bone metastases were enrolled from the four countries. A total of 118 of 457 SREs (25.8%) were associated with inpatient stays with a mean duration of 18.2 (SD=15.7) days per inpatient stay (for the total 125 stays; a single SRE could contribute multiple hospitalizations). The length of inpatient stays varied by facility (i.e., oncology, radiation, surgical) and SRE type. The most common SRE requiring hospitalization was SB (42 of 54 events [77.8%]) with 45 inpatient stays requiring an average length of stay of 15.1 (SD=16.8) days. The least common SRE requiring hospitalization, RB (27 of 279 events [9.7%]), was still associated with 23 inpatient stays with an average of 16.7 (SD=12.4) days per inpatient stay. A total of 342 SREs (74.8%) required an outpatient visit and 159 (34.8%) required >5 visits. As expected, RB was associated with the highest number of outpatient visits (239 of 279 [85.7%] SREs). SB and PF were associated with fewer outpatient visits with 23 of 54 (42.6%) of 54 SREs and 66 of 105 (62.9%) SREs requiring a visit, respectively. 22 of 457 (4.8%) SREs were associated with an emergency room visit.

**Discussion:** SREs can lead to lengthy hospitalizations and numerous outpatient visits. Neither pain requiring opioid use nor changes in cancer therapy to treat bone pain were reported as SREs, although they may have led to additional inpatient and outpatient visits. Thus, HRU estimated in this study likely underestimates overall HRU associated with SREs in advanced breast cancer patients. Relatively low utilization of emergency room visits reported here may be due to emergency care provided directly by the specialist oncology unit or the patient visiting...
P4-17-01
Trastuzumab Does Not Increase the Incidence of Central Nervous System (CNS) Relapses in HER2-Positive Early Breast Cancer: The HERA Trial Experience.

Pestalozzi B, Holmes E, Metzger O, de Azambuja E, Hogge L, Scullion M, Gelber R, Piccart-Gebhart M, Cameron D. HERA Study Team

Background: Retrospective studies of HER2-positive metastatic breast cancer (BC) showed an incidence of CNS metastases of 21% to 34%. We investigated the incidence and clinical aspects of CNS relapse (CNS-R) in patients (pts) enrolled in the HERA trial, a prospectively randomized adjuvant trial in node + or high-risk node - HER2-positive early BC pts.

Methods: 3401 pts were randomized into the 1-year trastuzumab (1yT) and the observation (obs) arms of HERA (Piccart-Gebhart et al, 2005, Gianni et al, 2011). The cumulative incidences of first disease-free survival (DFS) events in the CNS vs other sites were estimated using competing risk analysis. The database of the main study had a clinical cut-off date of 9th June 2008. To obtain additional information regarding CNS-R (including occurrence of CNS-R after first DFS event), a specific CNS-directed questionnaire was sent to investigators of pts who were deceased as of July 2009. Information collected included the date of CNS-R, whether it was symptomatic, the type of CNS-R (brain metastases (BM) or meningeal carcinomatosis (MC)), methods of diagnosis, and treatments at the time of CNS-R.

Results: 1yT significantly reduced the risk of other DFS events (p=0.000017, Gray’s test), but not of CNS-R (p=0.55) as first event (see table). During the first year of follow up, CNS-R accounted for 15 (14.9%) of the 101 first DFS events in the 1yT arm and 15 (7.7%) of the 194 first DFS events in the obs arm. The analysis of baseline patient and tumor characteristics associated with CNS-R as first event confirmed known risk factors such as young age (<35y), T3 tumor, ≥ 4 + LN, ER neg, and G3.

Based on the survey data, CNS-R was symptomatic in 189 pts (87.1%) with no differences between arms. BM were present in 211 pts (97.2%), absent in 5 (2.3%), and missing information in 1 (0.5%). MC was diagnosed in 25 pts (11.5%), absent in 187 (86.2%), missing information in 5 (2.3%). Frequencies for BM and MC were very similar in both arms.

Conclusion: This retrospective analysis of a prospective large study shows more than 50% incidence of clinically diagnosed CNS-R in HER2-positive BC pts who have died. CNS-R was symptomatic in most pts. CNS-R at any time was less frequent in the 1yT arm (88 vs 129). There is no evidence that adjuvant trastuzumab increases the incidence of CNS-R.

P4-17-02
Whole-Brain Radiation Therapy Plus Concomitant Temozolomide for the Treatment of Brain Metastases from Breast Cancer: A Randomized Prospective Multicenter Phase II Study.

BACKGROUND: A previously published study of temozolomide (TMZ) concurrent with whole-brain radiation therapy (WBRT) reported significant improvement in response rates and a nonsignificant trend toward improved overall survival compared with WBRT alone in patients with brain metastases in different type of tumors. A prospective randomized phase II trial of concurrent WBRT and TMZ versus WBRT alone was conducted to assess whether the concurrent use of WBRT-TMZ resulted in measurable radiological response differences at 6 weeks after the treatment in homogeneous population of breast cancer (BC) patients.

PATIENTS AND METHODS: In this intent-to-treat study, patients with metastatic breast cancer to the brain and not suitable for surgery or radio-surgery were enrolled in a randomized prospective multicenter phase II study between February 2008 and December 2010. Patients received temozolomide 75 mg/m²/2day (days 1-15) concurrently with WBRT 30 Gy/10 fractions. Patients were stratified by type and metastatic sites. The (MRI) response at 6 weeks was the main criteria; response was defined as complete (CR) or partial response (PR). Initial and follow-up MRI were realized on a 1.5T unit (Siemens) by axial SE-T1 WIs and FLAIR WIs with GdDTPA injection, EG-3DT1 WIs after GdDTPA. Five target lesions (over 10 mm greatest diameter) were measured in their 3 dimensions. Non measurable lesions were noticed. The treatment tolerance and clinical responses were also evaluated. The study was designed according to a modified Fleming two-stage plan based on response hypotheses of 30% (H0) versus 50% (H1). Twenty or more responses among 50 subjects were needed to declare the treatment effective, with risk errors alpha 9% and beta 7%.

RESULTS: One hundred metastatic breast cancer patients were enrolled in the study, as following: 49 in WBRT-TMZ and 51 in WBRT groups. The median age was 55 years [range, 29-79]. The median follow-up was 12 weeks [range, 1-94]. There were 15/49 (31%) partial responses (PR) in WBRT-TMZ and 18/51 (35%) PR in WBRT group. No complete responses were observed. The symptoms relief was obtained in 27/49 and 31/51 pts, respectively. The treatment tolerance was acceptable in both groups.

CONCLUSION: The benefit of adding TMZ to WBRT was not confirmed at 6 weeks. The tolerance was good in both groups. Longer follow-up is needed to evaluate the combination of TMZ with WBRT in terms of progression free survival.
**P4-17-03**
Incidence Rate of Asymptomatic Brain Metastases in Patients with HER2+ Metastatic Breast Cancer Screened for EGF111438/CEREBEL Study.
Pivot X, Hackmann J, Manikhias A, Moore Y, Parikh R, Kohli D, Joshi A, Akton G, Coleman R. University Hospital of Besancon; Marien-Hospital; St Petersburg City Clinical Oncology Dispensary; GlaxoSmithKline, Collegeville, PA; GlaxoSmithKline, Uxbridge, United Kingdom; Weston Park Hospital

**BACKGROUND**
Brain metastases constitute a major clinical concern occurring in 28-43% of women treated for HER2+ metastatic breast cancer (MBC). The initial diagnosis of Central Nervous System (CNS) lesion is commonly based upon development of neurological symptoms. Data to address incidence of CNS lesions in asymptomatic patients are rare and not generally reported. EGF111438/CEREBEL study requires systematic screening for brain metastases by brain MRI and the ineligible patients due to detection of asymptomatic brain metastases are reported here.

**METHODS**
The patients screened for CEREBEL have consented to a multi-centre, open-label Phase III study in subjects with HER2+ metastatic breast cancer who received prior treatment with anthracyclines or taxanes and trastuzumab in the adjuvant or metastatic setting. Eligible subjects must not have any history of CNS metastases (including leptomeningeal involvement) or have evidence of benign or malignant brain tumours and/or clinical evidence of spinal cord metastases at baseline. In order to confirm this, subjects must have negative brain MRI at baseline as confirmed by independent review (IR). All MRI scans of the brain had to be acquired with gadolinium contrast agent (T1 only) and 3mm slice thickness without gaps. The primary endpoint of CEREBEL is the incidence of CNS lesions as first site of relapse. A total of 650 subjects (325 per group) are expected to be randomized in the study who were clinically thought to be free of brain lesions actually had brain metastases verified by brain MRI. We therefore conclude that screening for occult brain metastases by MRI is important for trials with defined CNS endpoints.

**RESULTS**
The study is currently recruiting with 322 patients enrolled as of 15.06.2011. At this date, the total number of patients screened were 492 and 170 of these patients were screen failures. There are 15 patients in screening. The percentage of screen failures due to asymptomatic brain metastases assessed by investigators was 13.5% (23/170). The overall incidence of clinically asymptomatic brain metastases assessed by investigators for this study is 4.7% (23/492).

**CONCLUSIONS**
Around 5% of all screened patients (14% of screen failures) in this study who were clinically thought to be free of brain lesions actually had brain metastases verified by brain MRI. We therefore conclude that screening for occult brain metastases by MRI is important for trials with defined CNS endpoints.

**P4-17-04**
Pharmacokinetic Disposition of PEGylated Liposomal Doxorubicin Compared with Non-Liposomal Doxorubicin in an Intracranial Breast Cancer Murine Model.
Anders CK, Adamo B, Walsh MD, Karginova O, Darr D, Deal AM, Santos C, Bash R, Hanna SK, Carey LA, Miller CR, Sharpless N, Zamboni WC. University of North Carolina at Chapel Hill (UNC), Chapel Hill, NC; UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC; Lineberger Comprehensive Cancer Center, Chapel Hill, NC; University of Messina, Messina, Italy

**Background:** Breast cancer brain metastases are an increasingly common consequence of advanced breast cancer associated with poor prognosis and survival. Systemic therapies capable of crossing the blood brain barrier to control both intra- and extracranial disease are few. Nanoparticle agents, such as liposomes, achieve a higher concentration and prolonged exposure in solid tumors. Liposomal formulations of anti-cancer agents have also been shown in preclinical and clinical studies to enhance delivery to tumors within the brain. We compared the pharmacokinetic (PK) disposition of PEGylated liposomal doxorubicin (Doxil®; PLD) with non-liposomal doxorubicin (NLD) in an intracranial breast cancer model.

**Methods:** Athymic (nu/nu) mice (~8wks) were inoculated with MDA-MB-231-BR (brain subclone) cells expressing luciferase (2×10^6 cells/ injection) in 5% methylcellulose (5µL) into the right caudate nucleus. On day 18, tumor-bearing mice via bioluminescence imaging were administered PLD or NLD at 6 mg/kg IV x 1 via tail vein. Mice (n=3) were sacrificed at 6 and 24h for PLD and NLD; and 72h for PLD. Plasma and intracranial tumor were processed to measure sum total doxorubicin via high-performance liquid chromatography (HPLC, lower limit of quantification=10 ng/mL). T-tests were used to compare means between treatment groups.

**Results:** Treatment with PLD resulted in higher plasma sum total doxorubicin concentrations compared with NLD (Table). PLD was detected at 72h in plasma. There were higher intracranial tumor sum total doxorubicin concentrations at 6 and 24h for PLD compared with NLD; NLD was below limit of quantification (BLQ) at both time points. Consistent with the plasma PK of PLD, intracranial tumor total doxorubicin concentrations for PLD remained elevated at 72h.

**Conclusions:** Liposomal formulations of anti-cancer agents represent a promising treatment strategy to treat aggressive breast cancer brain metastases due to extended circulation time in plasma and higher exposure in intracranial tumor compared with small molecule counterparts. In this proof-of-concept preclinical study, PLD exhibits both higher and prolonged plasma and intracranial tumor exposure compared with NLD. The mechanism of higher intracranial tumor exposure with liposomal agents is unknown, however may be due to prolonged exposure in plasma, diffusion of encapsulated and/or released drug across the blood brain barrier, or enhanced permeation and retention effect in tumors. The improved PK profile and tumor distribution of PLD compared with NLD in this intracranial BC model are hypothesized to translate to improved efficacy and toxicity profiles over that of non-liposomal formulations and may represent a promising treatment strategy for a disease with limited treatment options.

**P4-17-05**
Brain Metastasis Free Survival (BMFS) Differs between Breast Cancer Subtypes.
Bartsch R, Berghoff A, Bago-Horvat Z, DeVries C, Dubsky P, Pluschnig U, Rudas M, Rottenfusser A, Fitzal F, Dieckmann K, Mader RM, Grant M, Zielinski CC, Steger GG. Medical University of Vienna, Vienna, Austria

**BACKGROUND**
Brain metastases (BM) are frequently diagnosed in patients (pts) with Her2-positive metastatic breast cancer (BC); a rising incidence was also reported in triple-negative disease. We hypothesized that pts with triple-negative or Her2-positive tumours had shorter BMFS as compared to other BC subtypes.
Therefore, we aimed to compare BMFS in pts with Her2-positive, estrogen receptor (ER) positive and triple-negative BC treated at the Medical University of Vienna from 1999-2009. In Her2-positive tumours, we further investigated the influence of ER co-expression on BMFS, as Her2-positive / ER-positive tumours were reported to express less aggressive biological properties.

**METHODS**

BMFS was defined as primary study endpoint and measured as the interval from diagnosis of metastatic BC until diagnosis of BM. A total of 168 pts were identified from a breast cancer database. 34 pts were excluded from this analysis as brain was the first site of disease progression; hence complete datasets from 134 pts were available (69 Her2-positive; 33 triple-negative; 32 ER-positive).

Her2 status was analyzed by immunohistochemistry (IHC) and reanalyzed by FISH if a score of 2+ was gained. ER was analyzed by IHC; ER negative tumours were defined by a cut-off value of <10% positively stained tumour cells. BMFS was estimated with the Kaplan-Meier product limit method and compared with the log-rank test; factors significantly associated with BMFS in the univariate analysis were included into a Cox proportional hazard model.

**RESULTS**

Median BMFS in triple-negative pts was 14 months (m) (95% CI 12.17-15.83), as compared to 25 m (95% CI 13.37-36.62) in Her2-positive (p=0.001) and 35 m (95% CI 19.79-50.22) in ER-positive pts (p<0.001), respectively. In Her2-positive pts, prior trastuzumab treatment for metastatic disease prolonged median BMFS (29 vs. 11 m; p=0.001); BMFS was further improved by trastuzumab in multiple lines (p=0.045) and co-positivity for ER and Her2 (30 vs. 15 m; p<0.001). ER-expression (HR 2.03; 95%CI 1.22-3.36; p<0.05) and prior trastuzumab (HR 2.72; 95%CI 1.20-6.17; p=0.017) remained independent predictors of longer BMFS in the Cox regression model. In ER-positive, triple-negative as well as Her2-positive pts, no correlation was found between BMFS and factors such as grading, histological subtype, stage IV disease at primary diagnosis, disease-free interval <24 months from primary treatment to diagnosis of metastatic disease, presence of visceral metastases, presence of lung metastases, and prior capcitabine exposure.

**CONCLUSIONS**

BMFS in triple-negative disease is significantly shorter as compared to Her2-positive or ER-positive tumours, mirroring the aggressiveness of this breast cancer subtype. Probably due to improved systemic disease control, trastuzumab significantly prolonged BMFS in Her2-positive pts. Longer BMFS in ER/Her2 co-positive disease reflects a less aggressive subtype of Her2-positive breast cancer which is less likely to benefit from strategies of BM screening or prevention.

**P4-17-06**

**Prognostic Role of Triple Negative Subtype in Breast Cancer Patients with Brain Metastases.**

Matthew A, Mathew IE, Rosenzweig MQ, Brufsky AM. University of Pittsburgh Medical Center; University of Pittsburgh Cancer Institute; Magee-Womens Hospital

**Background:** Metastatic breast cancer (MBC) patients with brain metastases (BM) have a poorer prognosis compared to patients with metastases to sites such as bone or other visceral organs. The role of breast cancer subtypes such as triple negative (TN) status and its relationship with other known prognostic factors have not been well delineated in the context of metastatic disease to the brain. We conducted a retrospective single institution cohort study of MBC patients with BM to evaluate the association between TN subtype and overall survival from the diagnosis of BM.

**Methods:** Baseline demographic and tumor specific data including ER, PR and HER2 status were collected on newly diagnosed MBC patients between January 1998 and December 2009. Overall survival was determined from the date of diagnosis of BM. Survival analyses were performed using the Kaplan-Meier method and Cox proportional-hazards model.

**Results:** Data were available on 186 MBC patients with BM, of whom 156 died during a median follow-up of 10.2 months from the diagnosis of BM; median age was 47.9 years. 91% of patients were Caucasian; 25.3% had triple negative disease. Median survival from the period of diagnosis of BM in patients with triple negative disease was 7 months (Interquartile range, IQR: 3-13) as compared to 11 months (IQR: 5-22) in patients who were HER2-positive or ER/PR-positive. Multivariate analysis found a higher risk of death after BM for TN disease subtype, with a hazard ratio for death of 2.89 (95% confidence interval: 1.89-4.44; p<0.001), when adjusted for variables such as age and stage at initial diagnosis of breast cancer, race, the number of metastatic sites, and the use of metastatic chemotherapy. The administration of metastatic chemotherapy had a significant survival benefit in the analyses, with a hazard ratio for death of 0.52 (95% CI: 0.27-0.99; p=0.048).

**Conclusion:** This retrospective cohort study in MBC patients with BM provides evidence for a greater risk of death in those with TN disease as compared to HER2-positive or ER/PR-positive subtypes even after adjusting for other prognostic factors.

**P4-17-07**

**The Shifting Landscape of Metastatic Breast Cancer to the CNS.**

Quigley MR, Fukai O, Chew B, Bhatia S, Karlovits S. Allegheny General Hospital, Pittsburgh, PA

**Introduction:** Improved survival following the diagnosis of breast cancer, in conjunction with new therapies and diagnostics has potentially altered the characteristics and course of patients presenting with CNS involvement.

**Methods:** Review of clinical and radiographic records of women presenting to a tertiary medical center with the new diagnosis of CNS metastatic disease from breast cancer. This was a retrospective review from patients identities obtained from two prospective databases. Results: There were 88 women analyzed who were treated over the period 1/2003-2/2010, average age 56.9. At the time of initial presentation of CNS disease, 68% of patients had multiple brain metastases, 17% had a solitary metastasis and 15% had only leptomeningeal disease (LMD). The median survival for all patients from the time of diagnosis of breast disease was 50.0 months, and 9.7 months from diagnosis of CNS involvement. The only factor related to overall survival was estrogen receptor positive (ER+) pathology (57.6 vs. 38.2 months, p=0.02 log-rank); those related to survival post CNS diagnosis were presentation with LMD (p=0.004, HR=3.1, Cox regression) and triple negative hormonal/HER2 status (p=0.02, HR=2.3, Cox regression). Patients with either had a median survival of 3.1 months (no patients in common). Of the 75 patients who initially presented with metastatic brain lesions, 20 (26%) subsequently developed LMD in the course of their disease (median 10.4 months), following which survival was grim (1.8 months median). Of note was that HER2+ status was protective in regard to late development of LMD (14.7 vs. 42.3%, p=0.03, Chi-square). Symptoms of LMD were most commonly lower extremity weakness (14/33), followed by cranial nerve deficits (11/33).
Conclusion: Treatment of patients with metastatic brain disease from breast cancer should be tailored to the patient’s hormonal status (as it markedly effects survival) and practitioners must be vigilant for the development of LMD, especially as it often presents with non-descript complaints such as back pain.

**P4-17-08**

Is Cranial Magnetic Resonance Imaging (MRI) Necessary for Staging of Asymptomatic HER2-Positive Breast Cancer Patients?

**Kaplan MA, Inal A, Kucukoner M, Urakci Z, Isikdogan A.** Dicle University, Diyarbakir, Turkey

**Background:** Breast cancer one of the most common tumors of the adults. Approximately 20% to 25% of all breast cancers are HER2-positive. It can be assumed that up to 30% of HER2-positive metastatic breast cancer (MBC) patients may experience brain metastasis during the course of their disease. The aim of this study is to investigate whether cranial MRI is necessary for staging in asymptomatic HER2-positive breast cancer patients.

**Material and methods:** HER2-positive breast cancer patients without symptoms of brain metastasis included in the study. Cranial MRI was added to the staging procedures. Subgroup analysis was performed to determine risk factors for developing brain metastasis.

**Results:** Seventy-five patients included in the study. Of whom, 71 were women (94.7%). Median age was 42.5 (22-76). Ten of the 75 patients (13.3%) had brain metastasis. The distribution rate of brain metastasis according to breast cancer stage at diagnosis was: 0% for stage I, 9.1% for stage 2, 4.3% for stage 3 and 28.6% for stage 4 (p = 0.027). There was no association between presence of brain metastasis and the site of metastasis, estrogen and progesterone receptor positivity, grade, histological subgroup, menopausal status and gender.

**Discussion:** Brain metastasis is an important problem for breast cancer patients. Treatment strategies may vary in the presence of brain metastasis. In our study we found brain metastasis nearly one quarter of patients with metastatic HER2-positive breast cancer. Cranial MRI imaging can be performed routinely in patient with metastatic HER2-positive breast cancer patients.

**P4-17-09**

Comparative Performances of Prognostic Indexes for Breast Cancer Patients Presenting with Brain Metastases.

**Braccinti A-L, Azria D, Thecasus S, Ferrero J-M, Romieu G, Jacot W. CRLC Val d’Aurelle Paul Lamarque, Montpellier; France; Antoine Lacassagne Cancer Center, Nice, France**

**Introduction:** Incidence of brain metastases (BM) from breast cancer has increased over the past decade, especially for HER2(+) tumours. Several scores and prognosis systems have been developed in the brain metastases (BM) setting in order to help physicians tailor treatment options depending on patient prognosis and to stratify patients enrolled in clinical studies. The aim of our study was to compare the clinical relevance of the major classifications and existing prognostic scores in a population of breast cancer patients affected by BM.

**Methods and Materials:** In this retrospective study conducted in Montpellier and Nice Cancer Centres, we retrospectively reviewed the clinical and biological data of 250 patients diagnosed with breast cancer BM between 1995 and 2010. Prognostic value and accuracy of recursive partitioning analysis (RPA), graded prognostic assessment (GPA), basic score for brain metastases (BS-BM) and a clinico-biological score (BS) developed in phase I study and validated in the BM setting were compared.

**Results:** Median age at BM diagnosis was 55 years-old. Most patients (74%) had good performance status (0-1). Brain was the first metastatic site in one third of patients (33.6%). In 12.4% of cases, no extracerebral metastases were detected at BM diagnosis. Among the 250 patients’ tumors, 43.6% overexpressed HER2 receptor and 25.6% were triple negative (negative estrogen receptor, progesterone receptor and HER2 status). After a median follow up of 4.5 years, median overall survival from BM diagnosis was 8.9 months (CI 95%, 6.9-10.3 months). The four scores were able to discriminate patients according to their survival. Chi2 tests showed a correlation between the different scoring systems. In multivariate analysis, the elimination model identified RPA (p = 0.031; hazard ratio, 0.77; 95% confidence interval, 0.64-0.91) and BS (p = 0.043; hazard ratio, 0.5; 95% confidence interval, 0.31-0.80) as the only two independent predictors of survival. RPA was the most accurate score in order to identify patients with high life expectancy, while RPA and BS were the most accurate scores to classify patients with short life expectancy.

**Conclusions:** In a general unslected population of breast cancer affected by BM, RPA seems to be the most useful score. Integration of biological parameters in addition of existing clinico-radiological scores is promising in order to improve the prognostic determination accuracy.

Insights into Mechanisms Involved in the Accumulation of Nanovectors within the Breast Cancer Brain Metastasis.

**Yokoi K, Xuewu L, Alexander JF, Fidler IJ, Mauro F, Biana G. The Methodist Hospital Research Institute, Houston, TX; M D Anderson Cancer Center, Houston, TX**

Systemic chemotherapy for brain metastasis of breast cancer (BMBC) is considered to be inefficient. It is widely accepted in the literature that blood-brain-barrier (BBB) is responsible for clinical failures with the conventional chemotherapy. We hypothesized that nanovectors, therapeutic carriers with submicron dimensions, can be delivered to the brain tissue through a different pathway than molecular therapeutics. The objective of this study was to examine the accumulation of various intravenously injected nanovectors into the brain metastasis of breast and other cancers loci and to explore possible mechanisms involved.

Both human (MDAMB231) and mouse (4T1) breast cancer brain metastasis were evaluated. We also tested lung (3LL) and colon (CT26) originated cancers. Orthotopic brain tumors were produced either by intracarotid injection or stereotactic brain injection of cancer cells. When the animals became moribund, they were injected intravenously with one of the following nanovectors including fluorescently labeled PEGylated (100nm) and non-PEGylated (100nm, 250nm, 500nm) liposomes, disc-shape silicon particles (600, 1000nm in diameter). The accumulation of the nanovectors was compared to an unencapsulated fluorescent molecule. The accumulation of the nanovectors in the brain tumor tissue was evaluated through live animal imaging (IVIS) and immunohistochemical analysis. Immunohistochemical staining of endothelial cells and basal membrane markers was performed to determine the integrity of the tumor associated vasculature and the co-localization of the fluorescent nanovectors/molecules with tumor associated vasculature.

Interestingly, we have found that brain metastasis of different tumors (originated form breast, lung and colon cancers) possess dissimilar accumulation profiles for intravenously administered nanovectors. For example when comparing various tumor origins, 4T1 breast cancer originated brain tumors enabled the highest accumulation of the nanovectors as compared to CT26 and 3LL. On the other hand,
free molecule accumulated into the 4T1 brain metastasis model to a much lower extend than in nanovector. Finally, the observed brain distribution of nanovecortors corresponded well with impairment in vascular endothelium and basal membrane integrity shown in immunohistochemical analysis.

The results of our study point toward a possibility to treat specific patients with impaired BBB function with nanovector encapsulated chemotherapeutics based on the fact that their transport, accumulation and retention in the brain tissue are governed by different biological mechanisms, such as Enhanced Permeation and Retention (EPR) effect. These studies indicate that it is possible to cross the blood brain barrier, thus giving hope to patients with brain metastasis.

Central Nervous System Involvement and Clinical Outcome, Review of 135 Patients, 9-Year Follow Up.
Watanabe J, Ogiya A, Tadokoro Y, Tanaka K, Takahashi K, Uematsu T, Mitsuya K. Shizuoka Cancer Center, Shizuoka, Japan; Shizuoka Cancer Center

Background: Breast cancer infiltrates into central nervous system (CNS) with the incidence of 10-20%. It is commonly accepted CNS screening does not contribute to maintain patients’ survival in metastatic breast cancer (MBC). We review our MBC cases with CNS involvement with the aim of searching prognostic factors and evaluating benefits derived from early detection of CNS lesion. Patients and Methods: From October 2002 to January 2011, 473 MBC patients treated at our hospital were reviewed and assessed. CNS lesion was found in 133 of 473 (28.5%) mostly by magnetic resonance imaging. Receptor statuses in patients with CNS disease were as follows; Estrogen receptor-positive 52.4%, HER2-positive 41.1% and triple-negative 12.7%. Asymptomatic patient at the diagnosis of CNS metastasis, in other words, CNS screening performed case, was 57.8%. Liver metastasis prior to CNS involvement was observed in 51.2% of patients.

Results: Within our 9-year follow-up, 122 patients received irradiation or operation, and 118 died. While major cause of death was lung or liver failure, 23.7% was considered as CNS death. Median overall survival from the diagnosis of primary breast cancer, survival from the MBC development and survival from CNS involvement were 1951, 1027 and 321 days respectively. Patients having HER2-disease showed superior survival after detection of CNS disease than HER2-negative patients. (median 514.0 vs 220.0 days, p=0.001) Asymptomatic patients, excluding underwent best supportive care (BSC), could not receive any survival benefit from early detection of CNS lesion. Liver metastasis prior to CNS involvement did not affect patients’ survival. Nineteen patients (14.1%), 17 of them were asymptomatic, received stereotactic irradiation as an initial treatment for CNS lesion, and showed superior survival after CNS event than patients received whole brain irradiation, surgery or BSC (median 670.0 vs 287.0 days, p=0.01).

Conclusion: Our review disclosed superior survival of HER2-disease with CNS metastasis. Early detection of CNS metastasis is only beneficial to patients when stereotactic irradiation will be suited for.

Analysis of Predictive and Prognostic Factors for Metastatic Breast Cancer Patients with Brain Metastasis Treated by Whole Brain Radiotherapy.
Park IH, Lee KS, Shin KH, Ro J. National Cancer Center, Goyang, Korea

Background
We addressed the progression free survival of brain metastasis (PFS_BM) in metastatic breast cancer (MBC) patients treated by whole brain radiotherapy (WBRT) for brain metastasis (BM). In addition, we investigated predictive and prognostic factors for the PFS_BM and OS_BM.

Patients and methods
A total of 212 patients with BM, treated by WBRT at the National Cancer Center between January 2000 and December 2010 were reviewed. The PFS_BM was defined as the time interval from the date of start of WBRT to the date of a progression of metastatic lesions in the brain or death or last follow-up.

Results
The median age of patients was 45 years (range, 22-72 years) and the median time to brain metastasis was 12.7 months (range, 0.0-72.8 months).

LD-long diameter of all patients, 50 (23.6%) patients were hormone receptor (HR) positive and 104 (49.1%) HER2 positive. Six patients received a surgery or a focal radiotherapy for metastatic lesions prior to WBRT. Seventy one (33.4%) patients had well controlled extracranial systemic disease (CR+PR+SD) when brain metastasis was diagnosed. The median survival after BM (OS_BM) was 5.4 months (95% CI, 4.4-6.4 months) and approximately 14.6% of patients died mainly of progressive brain metastasis. The PFS_BM was significantly affected by poor performance status (PS ≥3) (P<0.001), uncontrolled systemic disease status (P=0.029), disease free interval (DFI) < 2 years (P=0.011), no chemotherapy after BM (P<0.001), and HER2 positivity (P=0.002). Of those, poor PS, no chemotherapy after BM, and uncontrolled systemic disease status were remained important factors on a multivariate analysis. In terms of OS_BM, poor PS...
(P<0.001), older age (P=0.005), number of systemic metastatic sites >3 (P<0.001), uncontrolled systemic disease status (P<0.001), disease free interval (DFI) < 2 years (P=0.014), no chemotherapy after BM (P<0.001), and visceral involvement (P=0.009) were significant factors. Of those, poor PS (P<0.001), uncontrolled systemic disease status (P<0.001), and no chemotherapy after BM (P=0.001) were important factors for shorter OS_BM when adjusted with other factors.

Conclusions
Uncontrolled extracranial systemic disease status, no chemotherapy after BM, and poor PS were significant factors for shorter PFS_BM and overall survival after brain metastasis.

P4-18-01
Prognostic Role of Tumor and Stromal p16/INK4A in Ductal Carcinoma In Situ (DCIS).

Linke SP, Bremer TM, Wärnberg F, Zhou W, Goldstein L, Jirström K, Amini R-M. Prelude Corporation, Laguna Hills, CA; Uppsala University Hospital, Uppsala, Sweden; PhenoPath Laboratories, Seattle, WA; Lund University, Lund, Sweden

Background: DCIS is a pre-invasive breast disease diagnosed in ∼50,000 women/year in the US. The standard treatment recommendation is for mastectomy or breast-conserving surgery plus radiotherapy (BCS+RT). However, only ∼10% of BCS patients avoid recurrence due to RT, and RT provides little or no survival benefit. Thus, it is important to stratify patients by risk to help tailor treatment to maximize benefit and minimize unnecessary adverse effects and costs.

Material and Methods: Tissue microarrays that included tumor cores from all women diagnosed with pure DCIS between 1986 and 2004 in Uppland and Västmanland, Sweden (n=458) were stained and scored for p16/INK4A (clone E6H4) using immunohistochemistry (IHC). Semi-quantitative manual scoring was done separately in the tumor epithelial cells and peri-tumoral carcinoma-associated fibroblasts (CAFs). Based on previous reports, thresholds to define low and high risk groups with 10-year recurrence rates of 38% and 7%, respectively, were censored if they had contralateral breast or other cancers as the first event.

Results: Patients were stratified into low and high risk groups using a multivariate model incorporating tumor p16, stromal p16, HER2, and margin status. Patients treated with BCS only (n=67) had a baseline 10-year recurrence rate of 31%. The model identified high and low risk groups with 10-year recurrence rates of 38% and 7%, respectively (hazard ratio=7.1, p=0.009). Similar results were achieved when BCS and BCS+RT patients were combined (n=130). Interestingly, all six recurrence events in the set of patients who received full mastectomies (n=43) were in the model high risk group.

Discussion: Previous studies have shown mixed results when p16 was used as a single marker. Our results suggest a prognostic interaction between tumor and stromal p16, as well as HER2, that will form the basis of a more comprehensive multi-marker IHC-based prognostic panel to assess risk of recurrence in DCIS patients.

P4-18-02
Sentinel Node Biopsy in Extensive Ductal Carcinoma In Situ (DCIS) Diagnosed by Vacuum-Assisted Macrobiopsy (VAMB) and Treated by Mastectomy: Results of the French Prospective Trial CINNAMOME.

Background: Lymph node evaluation in the management of DCIS has been completely abandoned as a result of the documented low incidence of nodal metastases (<2%) and the significant morbidity of lymph node dissection. However, the risk of occult invasive disease exists when the initial diagnosis is performed by vacuum-assisted micro biopsy (VAMB). Invasive disease is usually discovered during the histological analyses following mastectomy. Therefore, the only option for patients is complete axillary lymph node dissection (ALND). The aim of this study was to evaluate the number of ALND that can be avoided by using the sentinel lymph node (SLN) procedure to identify patients with invasive disease but no SLN involvement.

Trial design: Patients with extensive microlcalifications on mammography and DCIS diagnosed by VAMB treated by mastectomy were included in the study. The SLN procedure was performed and intraoperative evaluation on frozen sections was carried out. If the SLN was positive an ALND was performed during the same intervention. If the SLN procedure failed or was negative an ALND was not performed. Radiography of the mastectomy specimen was performed to assist the pathologist in confirming the DCIS diagnosis, to evaluate the size and to determine concordance rates between initial VAMB diagnosis and histological analyses. Results: Fourteen French cancer centers took part in this protocol over 2 years (May 2008-December 2010). 228 patients were enrolled, including 197 DCIS on VAMB. The SLN was identified in 193 cases (98%) but one case was not documented at histology leaving 192 valid cases for analysis.

Distribution of SLN results and histological lesions found on mastectomy specimens in the series

</tr>
</tbody>
</table>

ALND was not performed for non-invasive disease and negative SLN (n=114) and invasive or micro-invasive disease and negative SLN (n=51). This meant that ALND was avoided for 67.1% of the patients with invasive disease (51/76, 95% CI[56.5-77.7]), or 26.6% of patients overall (95%CI [20.3-32.8]), whereas these patients would have previously received ALND without the use of the SLN procedure. We observed 39.6% (76/192) of discordance between VAMB results and definitive results from histology analysis after mastectomy across all patients.

Conclusions: SLN is a useful procedure for patients with DCIS diagnosed by VAMB treated by mastectomy and presenting extensive microlcalifications on mammography. For patients for whom microinvasive or invasive carcinoma is later identified on the mastectomy specimen, the use of this procedure makes it possible to spare over a quarter of them from ALND and the associated morbidity. Biological analyses are currently underway to determine predictive factors of invasive disease associated with DCIS.
P4-18-03
Basal-Like Phenotype of BRCA Associated Ductal Carcinoma In-Situ.
Kristjansdottir K, Laprise J, Scalia-Wilbur J, Simon R, Steinhoff M, Legare R. Women and Infants Hospital of RI, Providence, RI.

Background: Molecular profiling has identified different subtypes of invasive carcinoma. The basal-like tumors represent a subgroup that is known for aggressive behavior. The NCCN guidelines recommend genetic testing for patients with triple negative breast cancer as over 80% of breast cancers in BRCA1 mutation carriers are triple negative tumors, and 70% of those fulfill criteria for basal-like tumors. Ductal carcinoma in-situ (DCIS) is thought to represent a non-obligate precursor to invasive breast cancer. Little is known about basal-like precursor lesions and their association with germline BRCA mutations. The aims of this study were to characterize the immunohistochemical phenotype of BRCA associated DCIS and evaluate the clinical importance of such lesions.

Material and Methods: We identified 32 cases of DCIS from 28 women with a known BRCA1/2 mutation, from our genetics database. Tumor samples were reviewed to identify areas of DCIS for staining. Five micron sections were stained on the Dako Autostainer with antibodies to estrogen receptor (ER), progesterone receptor (PR), human epidermal growth factor receptor 2 (HER-2), epidermal growth factor receptor (EGFR), and CK 5/6.

Results: 44% of the DCIS tumors were from BRCA1 mutation carriers and 56% from BRCA2 mutation carriers. 53% of the samples were triple negative (staining negative for ER, PR, HER-2) and 69% of the triple negative tumors were basal-like tumors (staining positive for either EGFR or CK5/6). The basal-like DCIS specimens were all high grade, and they all came from BRCA1 positive patients. 71% of BRCA1 positive DCIS had basal-like features.

Conclusions: DCIS in BRCA1 mutation carriers shows basal-like features that are in line with historical control for invasive carcinomas in the same group, suggesting that DCIS is a precursor lesion for BRCA1 positive cancer. Although further investigation is needed, our data suggest that patients with basal-like DCIS should be offered genetic testing.

P4-18-04
Hypofractionated Radiotherapy for Breast Ductal Carcinoma In Situ.
Hathout L, Fortin B, Vulpe H, Hijal T, Bahig H, Dubé P, Yassa M. Hôpital Maisonneuve-Rosemont, Centre Affilié à l’Université de Montréal, Montreal, QC, Canada; McGill University Health Centre, The Montreal General Hospital, Montreal, QC, Canada.

Background: Conventional radiotherapy at a dose of 50 Gy in 25 fractions after breast conservative surgery is the standard treatment for ductal carcinoma in situ of the breast (DCIS). Hypofractionation is an interesting alternative for the treatment of breast cancer, providing a less intense treatment scheme for the patient. While the hypofractionated regimen of 42.5 Gy in 16 fractions has been shown to be equivalent to 50 Gy in 25 in infiltrating ductal carcinoma, few studies and no prospective study have reported results using hypofractionation in DCIS.

Materials and Methods: In this multicenter collaborative effort, we retrospectively reviewed the records of women with a diagnosis of DCIS at two Canadian institutions, treated with conservative surgery followed by hypofractionated radiotherapy (42.5 Gy in 16 fractions) to the whole breast. Tumor, patient and treatment factors were collected. Local control was evaluated using the Kaplan Meier method. Curves were compared using log rank.

Results: Between 2003 to 2008, 292 patients with DCIS underwent conservative surgery followed by hypofractionated radiation in 16 fractions for a total dose of 42.5 Gy. Treatment delivery was similar at both institutions. Mean age at diagnosis was 59 years, with 70% of women being postmenopausal. Nuclear grade was 1-2 in 65% of patients while 28% had grade 3 tumors. Complete surgical excision with negative margins was achieved in 92% of patients. Radiotherapy boost was given to 92 patients (31.5%) at the discretion of the radiation oncologist. After a mean follow up of 3.35 years (range 1-8 years), 10 patients (3.4%) had ipsilateral local relapse resulting in a disease-free survival (DFS) of 96% at 4 years. The histology at recurrence was DCIS for 8 patients; infiltrative disease for one patient and one patient had an unknown histology at recurrence. Age was statistically associated with local relapse (DFS 89% for patients under 50 years old vs 97% for those older than 50, p=0.027). Grade was also a significant prognostic factor (DFS 98% for grade 1-2 vs 91% for grade 3, p = 0.015). Finally, administration of boost did not have an impact on local control (DFS boost 98% vs 95% for no boost, p=0.44).

Discussion: Hypofractionated radiotherapy (42.5 Gy in 16 fractions) provides excellent local control for patients with DCIS undergoing breast conservative surgery. This regimen is more convenient to both patient and physician since it is less time consuming. Further work needs to be done to determine if this regimen is as effective as conventional radiotherapy in younger women (age less than 50) and those with grade 3 tumors.

P4-18-05
Ductal Carcinoma In Situ with Microinvasion: Clinical and Pathological Characteristics, Treatments and Outcomes.

Background: Ductal carcinoma in situ with microinvasion (DCSIM) is a rising rare entity. Because of that and its controversial pathological definition, there is a lack of clear recommendations for treatment. The purpose of this study was to describe the clinical and pathological characteristics, treatments and outcomes of our single institutional experience.

Patients and methods: Individual clinical and pathological data were collected from 63 women, diagnosed and treated for DCISM at the Claudius Regaud Cancer Hospital between January 2000 and April 2010. All available histological material (45 patients) was reviewed by an expert pathologist.

Results: The median age was 56 years (range 34-83). Seven patients (11.5%) had a personal history of DCIS, 27 patients (42%) had a familial history of breast cancer. Fourteen patients (22%) had a clinical sign at the diagnosis. Fifty one patients were mammographically detected (81%). All the patients underwent surgery, mastectomy for 17 patients (27.4%) and conservative surgery for 45 (72.6%). Secondary surgery of the breast was required for 21 patients (46.6%) after conservative surgery, enlarging surgery (N=13) or mastectomy (N=8). Surgical axillary lymph node evaluation was performed on 52 patients (82.5%), axillary dissection alone for 10 patients, sentinel node biopsy alone for 37 patients and the 2 methods for 5 patients. The median size of the DCIS was 16mm (6-90mm) with 37/60 (61.7%) grade III Van Nuys classification. The most histological subtype was comedo carcinoma (68%). Concerning the 45 reviewed biopsies, the size of the microinvasive component was ≤ 1mm for 38 lesions and between 1 and 2 mm for 7 lesions. Hormonal receptor status was positive for 29 (64.4%), 27 (64.3%) for estrogen receptors and 20 (44.4%) for progesterone receptors. HER 2 status was performed.
for 34 patients, among 12 (35%) of them were found overexpressed on the microinvasive component. Lymph node invasion was found among 2 of the 52 patients (3.8%) who underwent axillary lymph node evaluation. Radiation therapy was delivered to all the patients after conservative surgery (n=37) (50 Gy with a 10 Gy boost for 22 of them) and 2 after mastectomy (chest wall irradiation (50 Gy)). Adjunct hormonotherapy was delivered on 11 patients (18%). With a median follow-up of 36.4 months (95% CI=[27.7-44.16]), 62 patients are alive at the last follow-up and 58/63 free of disease (2 relapses and 3 second cancers). The 3 year disease free survival rate was 91.1 (95% CI=[78.1;96.6]). During follow-up, two local relapses occurred on patients treated by mastectomy. One of them had local invasive relapse at 43 months and she is still NED after 90 months. The second patient who had local invasive carcinoma with axillary node invasion at 32 months treated by conservative surgery, axillary dissection, radiotherapy and chemotheraphy, had metastasis at 51 months and passed away after 70 months. Conclusion: Mammographic screening programmes increase the rate of small diagnosed tumours, specially DCISM. Despite a priori good prognostic outcome, 2 axillary node involvements and 2 delayed relapses were observed. So, this kind of presentation deserves better evaluation of relapse risk factors to determine adapted adjuvant therapies.

P4-18-06 Relationship between Pathological Features, Her2 Protein Expression, and HER2 and CEP17 Copy Numbers in DCIS.

Lambein K, Van Bockstal M, Praet M, Denys H, Braens G, Nuiys A, Cocquyt V, Pauwels P, Van Den Broecke R, Libbrecht L. Ghent University Hospital, Ghent, Belgium; Ghent University, Ghent, Belgium

Background Previous studies in which HER2 status in ductal carcinoma in situ (DCIS) was evaluated yielded conflicting results. The reported prevalences of HER2 overexpression and amplification vary remarkably. These discrepancies might partly be due to differences in assessment methods, i.e. FISH or immunohistochemistry (IHC) and usage of tissue microarrays or whole mount slides. To further investigate this issue, we performed both FISH and IHC for HER2, evaluated HER2 and CEP17 copy numbers and correlated these data with histopathological findings.

Methods
61 DCIS cases were studied, of which 55 pure DCIS and 6 DCIS with micro-invasion. Pathological features were evaluated and included: architecture, nuclear atypia, necrosis, calcifications, stromal inflammation, stromal morphology, extent of lesion, margin width, Van Nuys Prognostic Index and Pinder classification. Her2 IHC and HER2 dual probe FISH analysis were performed and scored according to ASCO/CAP guidelines. HER2/CEP17 ratio and HER2 and CEP17 copy numbers were separately analysed. IHC for estrogen and progesterone receptor (ER and PR) was also performed. Whole mount slides were used for all analyses.

Results
15 cases (25%) were scored negative (1+), 10 cases (16%) equivocal (2+) and 36 cases (59%) positive (3+) using Her2 IHC. According to FISH analysis, 34 of 60 cases (57%) showed HER2 amplification; there was insufficient tissue for FISH analysis in one case. The amplification status of the DCIS lesions correlated with the IHC score (p<0.001). 30 of all 34 amplified cases were assigned a 3+ IHC score, and remarkably, all these cases showed HER2 clusters on FISH analysis (88%). Amplified lesions showed more frequently nuclear atypia grade 3 (p=0.0335), extensive comedonecrosis (p=0.002) and stromal inflammation (p=0.003). HER2 amplification correlated with the presence of micro-invasion (p=0.0218%). There was no correlation with hormone receptor status or other pathological variables. In the amplified group, high-grade nuclear atypia was associated with a higher mean HER2 copy number (p=0.0026) and HER2/CEP17 ratio (p=0.0356), while this was not the case in the non-amplified group. CEP17 copy numbers did not correlate with nuclear atypia.

Conclusions
The correlation between HER2 amplification and adverse pathological features, including micro-invasion and the association in amplified DCIS between HER2 copy number and high-grade nuclear atypia, underscore that HER2 is a driver of DCIS aggressiveness and possibly of recurrence in the form of non-invasive cancer. However, the prevalence of HER2 overexpression, amplification and cluster formation was much higher than in invasive carcinoma, suggesting that HER2 might play a less important role in transition from DCIS to frankly invasive cancer. Further studies should evaluate non-invasive and invasive recurrence of resected DCIS separately.

P4-19-01 Male Breast Cancer According to Tumor Subtype and Race: A California Cancer Registry (CCR)-Population Based Study.

Chavez-MacGregor M, Clarke CA, Lichtensztajn DY, Hortobagyi GN, Giordano SH. The University of Texas, MD Anderson Cancer Center; Cancer Prevention Institute of California

Background: Breast cancer in men is a rare disease and accounts for 0.6% of all breast cancer cases. Prior reports suggest that male breast cancer typically has a ductal histology and is more likely than cancers of the female breast to express estrogen and progesterone receptors (ER and PR). To our knowledge, there are no population-based estimates of the rates of Her-2 positive breast cancer or of the distribution of breast cancer subtypes in male patients. The categorization of breast cancers according to tumor subtype has important implications in the prognosis and in the management of breast cancer patients. We explored the tumor subtype distribution by race/ethnicity in the large, ethnically diverse population of California.

Methods: Retrospective study using the CCR. Participants included all male breast cancer patients diagnosed with invasive breast cancer between 2005-2009 with known ER, PR and Her2neu status. Among the patients with hormone receptor positive (HR+) tumors, survival analysis using Kaplan-Meier method was used. Differences in probability of survival between groups were compared using log-rank test.

Results: Six-hundred and seven patients were included. Median age at diagnosis was 68 years. Ductal histology was present in 84.7% (n=514) of the cases, 51.6% (n=313) of all the tumors were classified as grade II. Four hundred and ninety four (81.4%) patients had HR+ tumors, defined as ER+ and/or PR+ and Her2neu negative. Ninety (14.8%) had Her2neu positive, and 23 (3.8%) had triple receptor negative tumors (TN). The majority of patients were white (71%), 11% were Hispanic, 7.6% black and 10.4% were Asian/Pacific Islander/other. The breast cancer tumor subtype varied significantly across races/ethnicities (p<0.0001). Among non-Hispanic Whites, 82.6% had HR+, 14.6% had Her-2+, and 2.8% had TN breast cancer. For Blacks and Hispanics the distributions were 73.9% HR+, 17.4% Her-2+, 8.7% TN and 77.6%, 16.4%, 6.0% respectively. Among HR+ patients, blacks and Hispanics were less likely to have PR+ tumors compared to whites. The rate of ER+PR- was 6.3% among whites, 19.6% among blacks and 16.4% among Hispanics (p<0.001).
survival analysis among HR+ patients showed significant differences according to race (p=0.018) and stage (p=0.001), with Black patients and patients with higher stage disease having poorer outcomes. **Conclusions:** In this large cohort of male breast cancer patients, the distribution of tumor subtype was different than what has been reported in females. Among males, differences in tumor subtype exist among different racial/ethnic groups. Blacks were more likely to have triple receptor negative tumors and more likely to have ER+/PR- tumors than white patients. Among HR+ patients, blacks experience the worse survival.

**P4-19-02**

A Population-Based Study of Contemporary Systemic Therapy for Male Breast Cancer.

Purpose: To describe the contemporary utilization, effectiveness and tolerability of tamoxifen, aromatase inhibitors, and trastuzumab in the treatment of early and advanced male breast cancer at a population level in British Columbia.

Patients and Methods: Records of 158 consecutive referred cases of invasive male breast cancer diagnosed from January 2000 to March 2010 were analyzed in a population-based cancer program with respect to patient and tumour characteristics, usage of endocrine agents, toxicity and medication adherence, trastuzumab usage and outcome. This group was compared to a population-based random sample of 1000 contemporary female breast cancer patients for prognostic and demographic factors. Survival outcomes were also compared to a cohort of women, matched 2:1 on prognostic and treatment factors.

Results: Pathology was most commonly infiltrating ductal carcinoma (94.3%) and estrogen-receptor positive (98.7%). Males were older (median 69.5 years) compared to women (median 60 years). Stage distribution was I (25.3%), II (43.0%), III (24.7%) and IV (7.0%), reflecting more advanced presentation compared to female cases I (43.9%), II (37.9%), III (12.5%) and IV (5.3%). Tamoxifen was prescribed as adjuvant therapy to 109 patients, and as palliative therapy to 11. Fourteen (11.7%) patients discontinued tamoxifen due to toxicity. Aromatase inhibitors were prescribed as adjuvant therapy for 16 patients and as palliative therapy for 24; these were discontinued due to toxicity in 5 patients (12.5%). Five of 9 patients known to over-express Her2 were treated with adjuvant chemotherapy with trastuzumab. Overall survival, breast cancer-specific survival and progression-free survival at 5 years were 72.4%, 85.5% and 79.7%, respectively. There was no statistical difference in outcomes compared to the matched female cases.

Conclusions: In this large population-based study of contemporary systemic therapy for male breast cancer, outcomes appear to be similar to those of women with the same diagnosis. Side effect profiles, tolerance, adherence and outcomes after tamoxifen, aromatase inhibitors and trastuzumab appear to be similar in men compared to that described in the literature for women.

Physical and Psychological Sequelae of Breast Cancer in Men.

Ruddy KJ, Giobbie-Hurder A, Giordano SH, Goldfarb S, Kereaklogou S, Winer EP, Partridge AH. Dana-Farber Cancer Institute, Boston, MA; M.D. Anderson Cancer Center, Houston, TX; Memorial Sloan Kettering Cancer Center, New York, NY

Introduction: Little is known about the physical and emotional health of men with breast cancer. Information is also lacking regarding whether their informational and supportive care needs are being met regarding fertility and genetic concerns.

Methods: In an online pilot study recruiting participants through three websites focused on male breast cancer, www.outoftheshadowofpink.com, www.malebreastcancer.org, and www.malebreastcancer.ca, we surveyed men with breast cancer about their attitudes, symptoms, experiences, and health perceptions. We measured anxiety and depression using the Hospitalized Anxiety and Depression Scale (HADS), health-related quality of life (QOL) using Functional Assessment of Cancer Therapy-Breast (FACT-B), and hormonal and sexual symptoms using the Expanded Prostate Cancer Index Composite (EPIC) Hormonal and Sexual Scales. We assessed select toxicities from therapy and history of genetic and fertility counseling.

Results: Forty-two men responded to this online survey at least in part.

Conclusions: Men with breast cancer experience substantial symptoms in follow-up. Sexual functioning, in particular, may be impaired (in men without cancer, mean EPIC Sexual Score is 61.4 with SD 23.6). Hormonal symptoms are also prevalent (in men without cancer, mean EPIC Hormonal Score is 91.7 with SD 9.7). We plan to use data from this pilot study to inform a larger study and develop targeted interventions to improve sexual functioning and reduce symptoms in male breast cancer survivors.
P4-19-04
Evaluation of Histopathological Parameters in Male Breast Cancer Reveals Differences Compared with Female Breast Cancer.
Nilsson C, Johansson I, Ahlin C, Thorstenson S, Bergkvist L, Amin R-M, Holmgqvist M, Hedenfalk I, Fjällskog M-L. Central Hospital of Västerås, Västerås, Sweden; Uppsala University, Uppsala, Sweden; Lund University, Lund, Sweden; Orebro University Hospital, Orebro, Sweden; Linköping University Hospital, Linköping, Sweden; Uppsala, Sweden

Purpose: To characterize male breast cancer (MBC) by evaluating established histopathological parameters and their prognostic value.

Methods: 197 male patients with invasive breast cancer and available paraffin-embedded tumor tissue were retrospectively assessed. Patient files were reviewed for clinicopathological data. Tumors were re-evaluated for histologic grading on conventional sections. Immunohistochemical (IHC) stainings for estrogen receptor (ER), progesterone receptor (PgR), human epidermal growth factor receptor 2 (HER2), silver-enhanced in situ hybridization (SISH), Ki-67, CK5/6 and epidermal growth factor receptor (EGFR) were performed on tissue micro arrays. Data on vital status and cause of death were retrieved from the Cause of Death Registry. Cox proportional regression models were used for uni- and multivariate analyses.

Results: ER and PgR positivity was demonstrated in 93 and 78% of patients, respectively. Nottingham histologic grade III was seen in 41% and HER2 positivity in 11% of all patients. Defining molecular phenotypes using IHC markers revealed luminal (ER+ and/or PgR+, and HER2-) in 83%, luminal/HER2+ (ER+ and/or PgR+, and HER2+) in 11%, basal-like (ER-, PgR-, HER2-EGFR+ and/or CK5/6 +) in 1%, but no cases of HER2-like or unclassified. Node-positivity (HR 4.6; 95% CI 1.9-11.4), tumor size > 20 mm (HR 2.3; 95% CI 1.1-5.0) and ER-negativity (HR 4.6; 95% CI 1.1-14.2) were significant risk factors for breast cancer death. Grade, HER2 status, Ki-67, age did not demonstrate independent prognostic information. No difference in breast cancer deaths was demonstrated between luminal and luminal/HER2.

Conclusion: Male breast cancer tumors seem to be of grade III more often than female breast cancer, whereas HER2 expression appears equally common. In our study, the most important predictors for breast cancer death in male breast cancer were lymph nodes, tumor size and ER status. The most common molecular phenotype was luminal.

P4-19-06
Ghrelin Expression Is Associated with Favorable Outcome in Male Breast Cancer.
Grönberg M, Nilsson C, Johansson I, Hedenfalk I, Janson ET, Fjällskog M-L. Dept. of Medical Sciences, Section of Endocrine Oncology, Uppsala, Sweden; Dept. of Oncology, Radiology and Clinical Immunology, Uppsala, Sweden; Dept. of Oncology, Clinical Sciences, Lund, Sweden; Center for Clinical Research, Västerås, Sweden

Background: Expression of the peptide hormones ghrelin and obestatin has previously been demonstrated in normal breast as well as in breast cancer. Interestingly, ghrelin expression has been shown to be associated with longer survival in female patients suffering from invasive breast cancer. However, the clinical implications of the expression of these peptides in male breast cancer are unclear. The aim of this study was to further investigate the role and potential clinical value of these peptides in male breast cancer.

Methods: A tissue microarray containing male breast cancer specimens from 197 patients was immunostained with antibodies directed towards the peptides. The expression of the peptides was evaluated and correlated to previously known prognostic factors in breast cancer and to the outcome. Cox regression analysis was used to assess whether these markers may predict survival of male breast cancer patients.

Results: Immunoreactivity for ghrelin and obestatin was observed in 81% and 87% of the cases, respectively. No strong correlations were found between ghrelin or obestatin expression and other known prognostic factors. Only ghrelin expression was significantly correlated to breast cancer-specific survival (HR=0.37-0.39, p=0.01-0.03) in both uni- and multivariate analyses. Reproducibility between the two readers was good to very good for both stainings with kappa values of 0.65-0.89.

Conclusions: Male breast cancer patients with tumors expressing ghrelin had 3 times lower risk for breast cancer death than those lacking ghrelin expression. Ghrelin expression is easily assessable with good reproducibility using immunohistochemistry. Further studies are needed to establish the clinical significance of ghrelin as a biomarker in breast cancer.
P4-20-01
Multicentric Phase II PACS 09/Beverly1 Trial: First Efficacy and Safety Results of Neoadjuvant Chemotherapy Combined with Bevacizumab in HER2-Negative Patients with Non-Metastatic Inflammatory Breast Cancer.

Viens P, Petit T, Dalenc F, Pierga JY, Delozier T, Romieu G, Bonnetere J, Ferrero J-M, Kerbrat P, Mouret-Reynier M-A, Bachelot T, Soulie P, Lerebourg F, Eymard J-C, Dehloeb M, Lortholary A, Hardy-Bessard A-C, Boher J-M, Asselan B, Charafe-Jauffret E, Lemontier J, Martin A-L, Andre F, Institut Pauli Calmettes, Marseille, France; Centre Paul Strauss, Strasbourg, France; Institut Claudius Regaud, Toulouse, France; Institut Curie, Paris, France; Centre François Baclesse, Caen, France; Centre Val d’Aurelle, Montpellier, France; Centre Oscar Lambret, Lille, France; Centre Antoine Lacassagne, Nice, France; Centre Eugène Marquis, Rennes, France; Centre Jean Perrin, Clermont-Ferrand, France; Centre Leon Berard, Lyon, France; Centre Paul Papin, Angers, France; Institut Curie, Saint Cloud, France; Institut Jean Godinot, Reims, France; Centre Alexix Vautrin, Nancy, France; Centre Catherine de Sienne, Nantes, France; Clinique Armoricaine, Saint Brieuc, France; R&D Unicancer, Paris, France; Institut Gustave Roussy, Villejuiff, France

Background: Inflammatory breast cancer (IBC) is a relatively rare form of breast cancer. Because this disease exhibits angiogenic properties, bevacizumab (BEV) may improve the efficacy of neoadjuvant chemotherapy (CT) in IBC.

Methods: Pts with HER2-negative IBC (IHC 0 or 1+ or FISH/CISH-, T4d, any N) were included to receive 4 cycles of FEC100 + BEV 15 mg/kg, d1 q3w, followed by 4 cycles of Docetaxel 100 mg/m2 + BEV 15 mg/kg q3w. Complete surgery was performed 4–6 weeks after the last dose of CT, followed by radiotherapy and endocrine therapy for receptor positive (HR+) pts. BEV was re-introduced as adjuvant therapy for 10 cycles, giving a total of 18 cycles of BEV. The primary endpoint of the PACS09/Beverly1 trial was to evaluate the pathologic complete response (pCR; Sataloff classification) rate in HER2-negative non-metastatic IBC patients.

Results: Between Jan 2009 and Sep 2010, 101 pts were included (100 pts were evaluable). Main baseline characteristics were: median age 49 years; postmenopausal status, 39 pts; SBR 2, 32 pts SBR3 61 pts, both HR-negative, 55 pts. 85 pts completed neoadjuvant therapy according to the protocol, 90 pts underwent complete mastectomy, 4 had a breast-conservative surgery. After neoadjuvant treatment, investigator-assessed pCR rate was 27% (18%-36%, CI 95%). Interestingly, a significantly greater proportion of pCR rate was observed in the HR-negative group compared to HR-positive group (38 vs 13% respectively; p=0.007). Results from central review of pCR are currently in progress. Main Grade 3,4 toxicities were: neutropenia (61 pts), febrile neutropenia (36 pts), mucitis (23 pts) Neither gr3/4 HTA nor cardiac failure or proteinuria was reported. There were no treatment-related deaths.

Conclusions: These data suggest that the use of BEV with neoadjuvant CT is active in HER2-negative IBC (pCR rate 27%), with an acceptable safety profile. Interestingly, the HR-negative subgroup is significantly more responsive than the HR-positive subgroup.

P4-20-02
Inflammatory Breast Cancer (IBC) in the National Comprehensive Cancer Network (NCCN): The Disease, the Recurrence Pattern and the Outcome.

Lubbe W, Li T, Hughes M, Ottesen R, Cristofanilli M, Weeks J, Wong Y-N, Fox Chase Cancer Center, Philadelphia, PA; Dana-Farber Cancer Institute, Boston, MA; City of Hope Cancer Center, Duarte, CA

Background: Inflammatory breast cancer (IBC) is a unique clinicopathologic entity that is characterized by rapid progression and aggressive behavior from the onset. The clinical presentation consists of erythema, rapid enlargement of the breast, skin ridging, and a characteristic peau d’orange appearance of the skin secondary to dermal lymphatic tumor involvement. Because of its uncommon presentation leading to frequent misdiagnosis, most reports are from small single institution series which describe a predictable pattern of recurrence in spite of appropriate multidisciplinary treatments. We sought to confirm these observations using the large multi-institutional National Comprehensive Cancer Network (NCCN) outcomes database.

Methods: Patients (pts) with newly diagnosed IBC treated between 1999 and 2009 at 12 participating NCCN institutions were identified. The clinical diagnoses of IBC was based on the AJCC definition and staged as clinical T4d, N0-3, M0-1. The baseline pathological characteristics included histological type, estrogen receptor (ER), progesterone-receptor (PR), and HER-2/neu status. Pts were classified as receiving multimodality therapy if they received two of the following three treatments: surgery (lumpectomy or mastectomy), perioperative (neoadjuvant or adjuvant) systemic therapy, or perioperative radiation therapy.

Results: We identified a cohort of 673 pts with newly diagnosed IBC with a median follow-up of 28.9 months. Of which 195 (29%) had metastatic disease at presentation. The median age at presentation was 52.6 years. Caucasians were 79.4% of the cohort, African American 9.7%, and 11.0% other ethnic groups. Invasive ductal type comprised 84% of histologies. Biomarker assessment revealed ER+ (44.7%), PR+ (34.3%), and Her2/neu+ (33.4%). LVI was documented in 53.3%. Of stage III patients, 75.7% pts received perioperative radiation, 82% received perioperative systemic therapy and 70.7% underwent surgery. All three modalities were received by 64.4% of women. Of the stage III pts, 203 recurred. The most frequent sites of recurrence for were CNS (20.2%), bone (17.2%), chest wall (13.8%), lung (12.3%), liver (11.3%), distant (7.4%) and regional lymph nodes (6.9%). With a median of 30 and 20 months of follow-up for stage III & IV respectively, the median survival was 66 months (95% CI 54-107) for stage III pts and 26 months (95% CI 22-33) for stage IV. Among the 82% of stage III pts who received multimodality therapy, the 5 year and 10 year OS of 62% and 47%.

Discussion: This is a large retrospective multiinstitutional study that confirms the aggressive clinical features, recurrence patterns and adverse prognosis of IBC described in previous single institution series. Even with aggressive multimodal therapy, the long term survival of IBC shorter is than non-IBC. Future investigations are needed to address the aggressive biology of IBC to improve diagnosis and therapy.
P4-20-03

T-Cell Cytokine Production Related to Progression of Breast Cancer Patients.

Cohen EN, Gao H, Lee B-N, Giordano A, Tin S, Anfossi S, Parker CA, Cristofanilli M, Valero V, Alvarez RH, Hortobagyi GN, Woodward WA, Ueno NT, Reuben JM. The University of Texas MD Anderson Cancer Center, Houston, TX; Fox Chase Cancer Center, Philadelphia, PA; The University of Texas Graduate School of Biomedical Sciences at Houston, TX

**Background:** Impaired immunosurveillance and immune dysregulation contribute to the pathogenesis and progression of breast cancer (BC). Upon activation, T cells synthesize inflammatory cytokines such as TNF-α that can promote or inhibit tumor growth. We therefore investigated T-cell cytokine syntheses as a predictor of disease progression.

**Methods:** We recruited 115 BC patients [25 with locally advanced breast cancer (LABC), 21 with metastatic breast cancer (MBC), and 44 with metastatic IBC (mIBC)] and 31 healthy donors (HD) for this ongoing study. The tumor phenotype consisted of 69 hormone receptor (HR) positive (including 26 patients with HER2 positive disease), 16 HR negative but HER2+, 30 triple negative BC (TNBC). To evaluate T cell function, peripheral blood mononuclear cells from patients and HD were stimulated overnight with immobilized anti-CD3 and soluble anti-CD28 antibodies and assessed for the percentage of T cells that synthesized cytokines by multi-parameter flow cytometry. The associations of T cell cytokine production profile with patient progression free survival (PFS) were analyzed by Kaplan Meier Test.

**Results:** The median follow-up (FU) of 113 evaluable patients was 14.1 months with a median time to relapse of 10.5 months; 54 patients had stable disease (SD) and 59 patients had progression of disease (PD). In the entire cohort, on univariate analysis, metastasis, BC, stage, and previous treatment predicted for worse PFS (p<0.05). In non-metastatic patients (LABC+IBC), absolute count of anti-CD3 activated CD8+ T cells producing IL-17 was significantly higher in the SD patients compared with patient with PD (p=0.038), but it did not predict PFS (p=0.073). Similarly in metastatic patients, anti-CD3 activated CD4+ T cells producing TNF-α were significantly higher in patients with SD (p=0.025) and were predictive of longer PFS (p=0.033). Considering all patients with IBC (IBC + mIBC), although patients with PD had significantly fewer (percent and absolute number) anti-CD3 activated T cells capable of producing cytokines, this immune impairment was mostly related to metastasis and previous treatment. However, the percentage of anti-CD3 activated CD8+ T cells producing TNF-α was an independent positive prognostic indicator of PFS (p=0.002).

**Conclusion:** Higher than average cytokine syntheses by anti-CD3 activated T cells are significantly associated with longer PFS. These data are consistent with the hypothesis that an adaptive immune response can control disease progression.

P4-20-04

Cytokine Synthesis by Activated Dendritic Cells in Relation to Disease Progression in Inflammatory Breast Cancer (IBC).

Gao H, Cohen EN, Lee B-N, Giordano A, Tin S, Anfossi S, Parker CA, Cristofanilli M, Valero V, Alvarez RH, Hortobagyi GN, Woodward WA, Ueno NT, Reuben JM. The University of Texas MD Anderson Cancer Center, Houston, TX; Fox Chase Cancer Center, Philadelphia, PA

**Background:** Deficiencies in innate and adaptive immune responses by plasmacytoid dendritic cells (pDC) and myeloid DC (mDC) have been linked to poor clinical outcome in breast cancer (BC) (Treilleux, Clin Cancer Res, 2004, PMID 15569976). pDC produce IFN-α and pro-inflammatory cytokines that regulate innate and adaptive immunity in breast cancer. mDC present in blood and secondary lymphoid organs secrete IL-12 and induce inflammatory cytokine production by T cells. Therefore, we studied DC activity in the peripheral blood and assessed their function with clinical outcome in breast cancer patients.

**Methods:** We recruited 115 BC patients [25 with locally advanced non-IBC (LABC), 25 with IBC, 21 with metastatic breast cancer (MBC), and 44 with metastatic IBC (mIBC)] and 31 healthy donors (HD) for this study. Peripheral blood pDC and mDC were activated through toll-like receptor (TLR)-7 to assess IFN-α and IL-10 production whereas mDC were activated through TLR-8 to assess production of IL-12 and TNF-α by multi-parameter flow cytometry. Associations between cytokine production by TLR-activated pDC and mDC with progression free survival (PFS) and overall survival (OS) of patients were analyzed by Kaplan Meier Test.

**Results:** The median follow-up (FU) of 113 evaluable patients was 14.1 months with a median time to progression of 10.5 months; 54 patients had stable disease (SD) and 59 had progression of disease (PD). Metastasis, previous treatments, and IBC contributed to shorter PFS and OS. Compared to HD, BC patients had significantly fewer total DC (p=0.008), mDC (p=0.008), and pDC (p=0.003) per µL. In general, the number of TLR-7-activated pDC per µL that produced IFN-α (p=0.023) or IL-10 (p=0.027) and the number of TLR-8-activated mDC per µL that produced IL-12 (p=0.001) and TNF-α (p=0.008) were significantly lower in BC patients than in HD. However, patients with DC that produced these cytokines above the median levels of HD had shorter PFS or OS. In BC patients, higher numbers of TLR-8-activated mDC that produced TNF-α (p=0.025) or IL-12 (p=0.003) predicted shorter OS. In mIBC patients, a higher number of TLR-7-activated pDC producing IFN-α (p=0.024) or IL-10 (p=0.034) predicted shorter PFS.

**Conclusion:** BC patients had significantly fewer pDC and mDC in peripheral blood than HD. BC patients with above average numbers of TLR-activated DC capable of producing proinflammatory cytokines had a significantly shorter PFS or OS. Disease progression in IBC is related to an increased number of activated dendritic cells producing inflammatory cytokines.

P4-20-05

Inflammatory Breast Cancer: Comparison of Epidemiology, Biology, and Prognosis between Japan and the United States, a Hospital-Based Study.

Yamauchi H, Natori A, Hayashi N, Soejima K, Takahashi O, Fukui T, Nakamura S, Cristofanilli M, Ueno N. St. Luke's International Hospital, Chuo-ku, Tokyo, Japan; Showa University, Shinagawa-ku, Tokyo, Japan; Fox Chase Cancer Center, Philadelphia, PA; The University of Texas M.D. Anderson Cancer Center, Houston, TX

**Background:** Inflammatory breast cancer (IBC) is a challenging disease characterized by low incidence, rapid progression, and poor survival. The epidemiology of IBC has been slow to emerge, given that the rarity of IBC makes large prospective clinical trials difficult. Compared to non-IBC, well-established features of IBC include a younger age of onset and lower frequency of hormone receptor positivity. Higher body mass index (BMI) is a purported risk factor. Previous reports also suggest that IBC is associated with more racial disparities, including incidence and age at diagnosis. The epidemiology of IBC in East Asia, however, has not been investigated. We performed a comparative study of IBC in Japan...
versus the United States to determine its epidemiologic and clinical features and to evaluate the differences in epidemiologic factors between the two countries.

Patients and Method: Patients who visited St. Luke’s International hospital (SLIH) in Tokyo, Japan and The University of Texas MD Anderson Cancer Center (MDA) in Texas, USA between 2003 and 2009 were identified. Epidemiological and biological data were collected from electronic medical records. Patient and tumor characteristics were tabulated and stratified by hospital. Kaplan-Meier curves were created for survival estimates and log-rank test was used for cross-group comparisons. Cox proportional-hazard analysis was used to identify a subset of significant prognostic variables that related to overall survival.

Result: 34 patients at SLIH and 531 patients at MDA were identified. Mean age at diagnosis was 52 years old (range, 32-81, SD, 10.8) and 50 years old (range, 22-87, SD, 11.6), respectively (P=0.476). Mean BMI was 22.9 kg/m² (range, 17.3-30.5, SD 3.3 ) and 31.0 kg/m² (range, 13.6-88.9, SD, 7.8) respectively (P<0.01). Clinical Staging was not significantly different; Stage IIIB 38.2%, Stage IIIC 26.5%, and Stage IV 32.4% at SLIH versus 48.6%, 23.7%, and 27.3% at MDA (P= 0.167). Estrogen receptor (ER) and progesterone receptor (PR) negative cases were, respectively, 50.0% and 64.7% at SLIH and 50.5% and 64.2% at MDA (ER, P= 0.935; PR, P=0.908). Her-2 over-expression cases were 38.2% at SLIH and 28.6% at MDA (P=0.174). A significant difference in nuclear grade was seen between SLIH and MDA: 20.6% at SLIH were Grade 3 versus 68.7% at MDA (P<0.01). Median overall survival at SLIH was 3.6 years versus 2.3 years at MDA (P=0.570). No prognostic factors were associated with overall survival.

Conclusion: Though IBC at SLIH differed significantly from IBC at MDA by several epidemiologic and biologic factors, there was no significant difference in survival. To define the epidemiological, prognostic, and risk factors of IBC in Japan, as well as in the world, further studies are needed.

P5-01-01
Identification, Validation and Assessment of Transcriptional Relevance of a PDGFR-Activation Signature in (Inflammatory) Breast Cancer.
Van Laere SJ, Van Golen KL, Joglekar M, Ueno NT, Finetti P, Van Dam PA, Viens P, Birnbaum D, Bertucci F, Vermeulen PB, Dirix LY. Oncology Center - GH Sint-Augustinus, Wilrijk, Antwerp, Belgium; University of Delaware, Newark, DE; The University of Texas MD Anderson Cancer Center, Houston, TX; Institut Paoli-Calmettes (IPC), Marseille, France; World IBC Consortium; Contributed Equally

Introduction. Breast cancer can be divided into several subgroups characterized by unique patterns of pathway activation. Platelet-derived growth factor receptor (PDGFR) signalling has not yet been included in this classification scheme, although it has been reported to be a potential target for therapy. In this study, we have constructed a PDGFR-activation signature and investigated its relevance in breast cancer.

Materials and Methods. Sixteen PDGFR-modulated genes were identified by intersecting two published PDGFR-modulated gene lists. The resulting gene signature was applied onto a publicly available gene expression data set of GIST (GSE17743) using principle component analysis. The segregation of PDGFR- and KIT-mutated GIST samples was investigated using permutation analysis and classification sensitivity and specificity were assessed. Using the regression coefficients from the first principal component, a PDGFR-activation score was constructed and applied onto a second data set in order to validate the score (GSE1923). Finally, the score was applied onto a gene expression data set of 389 breast cancer samples, including 137 samples from patients with IBC.

Results. Sixteen PDGFR-modulated genes (NR4A1, EGR3, JUNB, IER3, TIEG, JUN, BCL3, MYC, NR4A3, PLAU, MCL1, DUSP1, DUSP5, DUSP6, SGK, GADD45A) were able to discriminate PDGFR-mutated GIST samples from KIT-mutated GIST samples with a sensitivity of 75% and a specificity of 85%. Application of the PDGFR-activation score onto a data set of control and PDGF-treated glioblastoma cells showed a significant increase in the PDGFR-activation score in the treated condition (P=0.0302). Application of the PDGFR-signature onto our series of IBC and nIBC samples demonstrated a significant and molecular subtype-independent increase in PDGFR-activation in IBC (P=0.0015; FDR=3%). In addition, in our series of nIBC samples only, PDGFR-activation was associated with decreased DMFS and RFS (P<0.0038 and P=0.0137 respectively). In fact, PDGFR-activation was an independent prognosticator in a multivariate model incorporating the molecular subtypes.

Discussion. We identified a gene signature composed of 16 genes able to predict PDGFR-activation in tissue samples by gene expression analysis. PDGFR-activation is significantly increased in samples from patients with IBC, an aggressive form of locally advanced breast cancer. In addition, in nIBC, PDGFR-activation is associated with DMFS and RFS, independently of the molecular subtypes suggesting that PDGFR-activation might add another level of clinically relevant heterogeneity in breast cancer.

P5-01-02
Wnt5a Is a Prognostic Biomarker in Estrogen Receptor-Positive Premenopausal Breast Cancer.
Sand-Dejmek JT, Ehrnstrom R, Andersson T, Ryden L. Clinical Sciences, Skåne University Hospital, Lund University, Malmö, Sweden; Laboratory Medicine, Skåne University Hospital, Lund University, Malmö, Sweden

Background: Wnt proteins belong to a family of secreted growth factors, which are involved in a wide range of cellular processes. Wnt signaling can be broadly divided into two categories; the canonical, β-catenin-dependent pathway and the non-canonical β-catenin-independent pathway. Wnt5a is a non-canonical signaling member of the Wnt family. Studies in two smaller cohorts of breast cancer revealed that loss of Wnt5a was associated with early relapse, metastatic disease and poor survival. Moreover, reconstitution of Wnt5a signalling decreased the migratory capacity and invasiveness of cultured breast cancer cells and administration of a Wnt5a-mimicking peptide was proven to inhibit metastases in a mouse model.

Material and methods: Premenopausal women (n=564) were included in a controlled randomised trial and allocated to tamoxifen for two years versus no adjuvant treatment. A tumour tissue microarrays was constructed and 390/500 samples were evaluable for Wnt5a protein expression by immunohistochemistry. Only cases with at least 2 evaluable cores were included. Wnt5a levels were determined semiquantitatively (scores 0-3). Clinical and pathological data such as patient age, histological subtype, pT stage, tumor size, pN stage, ER, PR, Ki67 and HER2 status were available. The endpoint was 10 year recurrence-free survival.

Results: Wnt5a protein expression was lost in 158/390 of the analyzed tumors and more common in younger (<45 yrs) women (p=0.032). Furthermore, loss of Wnt5a was significantly associated with ER and PR negativity (p=0.019 and p= 0.033, respectively). Loss of
Wnt5a was significantly correlated to poor survival in the whole cohort, \( p=0.02 \). When analyzing the data according to breast cancer subtype, we found that Wnt5a was a strong independent prognostic factor in ER+ breast cancer \( p=0.009 \), but not in ER- breast cancer \( p=0.8 \). This was true both in the adjuvantly treated and untreated cohorts, verifying that Wnt5a is a true prognostic factor and not a predictor of response to therapy.

**Discussion**: While associated with a better short-time prognosis than ER negative tumors, a subset of ER positive breast cancer patients are known to experience tumor recurrences >5 years after primary treatment and hence have a dismal prognosis. Those patients need to be identified and their tumors targeted with more aggressive treatment regimens. We have identified and validated Wnt5a as a prognostic biomarker in ER positive breast cancer in premenopausal women. Wnt5a signalling could potentially be reconstituted by administration of a Wnt5a-mimicking peptide, shown to inhibit metastases in mice, thereby offering ER positive premenopausal patients a targeted adjuvant therapy that potentially could lower their risk of metastatic disease.

**Correlation between Aromatase Expression in Metastatic and Primary Breast Cancer.**
Ribeiro JM, Luis IV, Correia I, Casimiro S, Fernandes A, Quintela A, Mestan J, Ramos M, Costa L. Hospital de Santa Maria, Lisbon, Portugal; University of Lisbon, Lisbon; Hospital de Santa Maria, Lisbon; Novartis Pharma

Background: Estrogens are the major mitogenic factor in hormone dependent breast cancer. In postmenopausal women, estrogen production results mainly from extra-glandular conversion of androstenedione to estrone. This conversion is catalyzed by the enzyme aromatase (Aro). It is known that an higher expression and activity of the enzyme Aro is present in primary breast carcinoma compared with normal breast tissue. These data may indicate that tumors have the ability to produce their own estrogen. However, it is not known whether this process can occur at the level of metastasis. This study aims to determine the expression of aromatase in metastatic breast cancer and to analyze its correlation with expression at primary tumor and response to aromatase inhibitors (AI).

Material and Methods: We selected 41 patients with metastatic breast cancer, followed in the Department of Medical Oncology since 1995, undergoing surgery or biopsy of a metastatic lesion in the course of the disease (24 liver metastases; 10 bone metastases; 6 lung metastases; 1 lymph node metastases). For all these patients a detailed clinical chart review regarding clinical information (including treatment and tumor status) was obtained. Samples (formalin fixed and paraffin embedded) were analyzed for aromatase expression by immunohistochemistry (IHC), using the anti-aromatase monoclonal antibody # 677 (Novartis). Slides were scored considering the proportion of immunoreactive cells and intensity of the staining, and evaluating separately the epithelial and stromal component. The Fisher and log-rank test were used to determine the correlation between Aro expression in metastatic tissue and response to AI.

Results: Aromatase was expressed in 51% (21/41) of the samples (13 liver metastases; 8 bone metastases). The average combined score was 130 (10 - 320). The average score was higher in the epithelial component versus the stromal component (123 vs. 17.5). There was a strong expression of Aro in bone metastases (average combined score: 176) compared with other sites. There was no correlation between Aro expression and estrogen receptors expression. In 15 patients, it was also possible to evaluate the expression of Aro in the primary tumor. Aro was expressed in four cases (36%), with an average combined score of 52.5. The Aro expression between the primary tumor and metastasis was concordant in nine cases.

Thirty-four patients received AI to treat metastatic disease. The median time to progression (TTP) with AI in the entire population was 17.8 months. In the group of patients with Aro expression in metastasis, the median TTP in AI was 19.5 months, significantly higher than that obtained in the group without detectable Aro expression: 6.5 months (\( p = 0.045 \)). The overall survival in the group with Aro expression was 125 months and the 77 months in patients without Aro expression (\( p = 0.54 \)).

Conclusions: Aromatase is expressed by metastatic tumor cells from breast cancer, with a positive and statistically significant correlation between its expression in the metastasis and the clinical benefit to IA. Its expression was higher in bone metastases compared with other sites of metastasis although this difference was not, in our study, statistically significant.
standard IHC also showed a similar trend (median H score 100, 150 and 120, respectively) with a significant increase in the normal vs. DCIS comparison (p=0.0090). FOX3 lymphocyte count had a positive correlation with FOX3 epithelial intensity in the normal and invasive components (Spearman ρ=0.4343, p=0.0130 for normal and Spearman ρ=0.5456, p=0.0012 for IDC). FOX3 lymphocyte fraction and FOX3 epithelial intensity did not vary significantly with size of invasive tumor, nodal status, or stage of disease.

Discussion: FOX3 is expressed both by tumor infiltrating T lymphocytes as well as tumor epithelium. The significant increase in FOX3 T regulatory lymphocytes and FOX3 epithelial expression from normal to invasive cancer suggests a role of FOX3 in breast carcinogenesis and progression. The significant correlation of FOX3-T regulatory lymphocytes and FOX3 epithelial expression in the normal and invasive components suggests expression of one may influence the other early in the breast cancer progression pathway.

P5-01-05
Activating Mutations in PIK3CA or AKT1 in the I-SPY 1 Trial (CALGB 150007/150012; ACRIN 6657).
Boudreau A, Yau C, Petrelli L, Stemke-Hale K, Mills GB, Gray JW, Wolf DM, van ’t Veer LJ. The I-SPY 1 TRIAL Investigators, Esserman LJ. University of California, San Francisco; University of Texas MD Anderson Cancer Center; Oregon Health & Science University

Background: Mutations in the catalytic domain of phosphatidylinositol 3-kinase (PIK3CA) are among the most frequently observed activating mutations in breast cancer. We used the I SPY 1 TRIAL, a group of biologically and clinically high risk patients molecularly profiled and treated with neoadjuvant chemotherapy, to determine the frequency of mutations and their relationship to pathologic complete response (pCR) and outcomes, within the entire cohort and within subtypes defined by growth and hormone receptor (HR) expression.

Methods: Patients enrolled in the I-SPY 1 TRIAL had a tumor size ≥3.0cm and were administered a doxorubicin-containing regimen, followed by a taxane, prior to surgery. Sequenom single nucleotide polymorphism (SNP) profiling was performed on breast tumor genomic DNA isolated from a subset of patients (n=152). A total of 149 SNPs covering 16 genes (including PIK3CA and AKT1/2/3) were analyzed. Mutations were tested for association with estrogen receptor (ER), progesterone receptor (PgR), and HER2 status, as well as pCR, using Fisher’s exact test; associations between mutations and recurrence-free survival (RFS) were measured by log-rank tests. pCR was defined as no invasive tumor present in either the breast or axillary lymph nodes following neoadjuvant treatment.

Results: Of 149 mutations profiled in the cohort, 13 of the SNPs were observed. PIK3CA mutations were the most frequently observed in the panel (15.1%), followed by AKT1(E17K; 2.7%), CTNNB1(D32; 1.4%), NRAS(Q61; 0.7%), and FGFR2(N549; 0.7%). Mutations in PIK3CA or AKT1 were associated with ER-positivity (p=0.0047) and PgR-positivity (p=0.044). Within receptor subtypes, the frequencies of PIK3CA/AKT1 mutations were also significantly different (HR+HER2+: 27%; HR+HER2-: 14%); HR-HER2+: 0% (0/36), p<0.0008). Unlike previous reports (Loi et al, PNAS 2010), no significant association between PIK3CA/AKT1 mutation status and RFS was observed when we restricted our analysis to the adjuvant endocrine treated subset of the HR+HER2- patients (n=49; log rank p = 0.369). In contrast, and similar to cell line reports (Juntilla et al, Cancer Cell 2009), PIK3CA mutations appears to associate with worse RFS within the small subset of trastuzumab treated HER2+ patients (n=22, 13 HR-HER2+; 9 HR+HER2-; log rank p=0.001), suggesting mutations may influence response. Similar analyses of a larger cohort are planned to confirm these observations.

Conclusions: Within the I-SPY 1 TRIAL cohort, PIK3CA and AKT1 mutations are much more frequent in the HR+ and HER2 subsets but are not predictive of response to therapy or outcome except potentially within the HER2+ subset. The potential link observed between activating PIK3CA/AKT mutations and trastuzumab resistance merits further investigation, as it may provide a clinical rationale for testing PIK3CA mutation status in HER2+ patients and investigating combination therapies targeting this pathway, particularly in the HER2-+HR+ subset which have an elevated risk for recurrence despite pCR and trastuzumab therapy.
2) a trend towards worse outcome with higher TYMS expression in a) the overall population (TTP-HR 1.23, 95% CI 0.93 to 1.64, p=0.148), b) in ER+ patients (TTP-HR 1.46, 95% CI 0.97 to 2.19, p=0.07) as well as in c) HER2- patients (TTP-HR 1.17, 95% CI 0.85 to 1.61, p=0.343), 3) a statistically significant association between higher TYMP expression and longer PFS, but not TTP in ER+ and HER2- patients (table).

Discussion: Our ASCO 2011 analysis showed that high TYMS GCN is predictive of poor outcome in ER+ and HER2- patients, consistent with the fact it is the target of C. Here, we show that 1) expression of TYMS is significantly correlated with GCN 2) higher TYMS expression demonstrates the same trend towards poor outcome in ER+ and HER2- patients as in FISH, 3) higher TYMP expression is significantly associated with longer PFS in ER+ and HER2- patients, consistent with its C activating role. Differential sensitivity between FISH and DASL might be explained by the fact that DASL is performed in a pool of RNA coming from many cellular types, whereas FISH is scored selectively in tumor cells. These findings suggest that TYMS and TYMP GCN and expression can be useful predictive markers of C sensitivity in human breast cancer.

Identification of SORBS2 as a Candidate Marker To Predict Metastatic Relapse in Breast Cancer.

Background: Elucidation of promising cancer biomarkers from gene expression data can provide important insight into the relationship between signaling networks and cancer. SORBS2, sorbin and SH3 domain containing 2, is a multi-adapter protein involved in signal transduction associated to the cytoskeleton and was reported to be strongly repressed in pancreatic and cervical cancers.

Methods: With the purpose of identifying genes involved in metastatic process, we compared gene expression profiling of 19 invasive ovarian cancers and 24 borderline tumors. Prognostic value of the selected genes was then tested in a gene expression array database that includes 1659 patients with early breast cancer (Gyorffy B et al. 2010). Upon isolation of SORBS2 as a predictor, its involvement in cell migration and tumor progression was investigated in vitro. Small interfering RNA targeting SORBS2 was used to downregulate its expression in T47D and Hela, two cell lines overexpressing SORBS2. Functional effect of siRNA-induced knockdown of SORBS2 on cell viability was determined by WST-1 assay and Trypan Blue exclusion test. Effect of siRNA-induced knockdown of SORBS2 on cell viability was performed in a pool of RNA coming from many cellular types, whereas FISH is scored selectively in tumor cells. These findings suggest that TYMS and TYMP GCN and expression can be useful predictive markers of C sensitivity in human breast cancer.

in demographic characteristics, but the systemic endocrine profiles of Y and NY populations have not been studied, and may affect the generalizability of findings in studies of NAF.

Methods: A subset of participants from an ongoing case-control study was included (120 cases, 120 controls). Cases are women presenting to the Lynn Sage Breast Center with newly diagnosed unilateral breast cancer, and controls are women presenting to the Lynn Sage Mammography Center who do not have cancer. NAF collection was attempted on all consented subjects; those yielding ≥2 uL NAF were designated as Y and those yielding <2 uL NAF were NY (120 Ys, 120 NYs). Menopausal status, age, race, menstrual cycle phase, mammographic density, and serum hormone levels were also collected. Differences between Y and NY groups were tested using a t-test for age, \( \chi^2 \) for race, and Wilcoxon Sum Rank Test for serum hormone levels. Mammographic density was quantitated using digital or digitized images and the CUMULUS software. Linear regression was used to test the relationship between a logged serum hormone values and if a patient yielded adjusting for phase of menstrual cycle in premenopausal women.

Results: Mean ages of Ys and NYs were not different 51.0 and 52.6, respectively (p=0.11). The distribution of Ys by race (Caucasian, African American, other), was not different (\( \chi^2 \) p=0.58). Median serum prolactin concentrations were higher in Ys than NYs for both pre- (7.0 and 2.5 ng/ml) and post-menopausal (5.6 and 2.4 ng/ml) women, respectively (both p<0.01). Median serum estradiol was lower in yielding premenopausal patients only (pre- 90.5 and 64.3 pg/ml p=0.02; post- p=0.59). Stratifying the premenopausal women further into cases and controls, the difference only held for cases and not for controls (p=0.02, p=0.033). In the premenopausal patients the regression models suggested that these relationships for estradiol and prolactin remain even after adjusting for phase of the menstrual cycle. No differences in Ys versus NYs were found for progesterone, follicle stimulating hormone, or sex hormone binding globulin. Mammographic density was not different for Ys as compared to NYs for pre- (22% and 20%, p=0.83), but was marginally lower for post-menopausal Ys versus NYs (11% and 15% density; p=0.07). Following stratification of the postmenopausal women into cases and controls, the cases who yielded had significantly lower than NYs (11% and 19% density, p=0.03), but the control Ys and NYs were not different (10% and 11% density, p=0.65).

Conclusion: Pre- and post-menopausal women who yield NAF display increased serum prolactin levels, whereas decreased estradiol levels were observed in premenopausal NAF Ys. These findings suggest that NAF yield has systemic endocrine determinants, with implications for biomarker research on NAF samples. Further characterization of Y and NY women is important, along with standardization of methods of NAF collection, since NAF yield varies widely between studies.

P5-01-10

A Potential New Marker for, and Facilitator of, Hormone Independence.

Monaco ME, Wu X, Lee P. NYU School of Medicine, New York, NY; VA NY Harbor Healthcare System, New York, NY

Triple negative breast cancers (TNBC) are generally more aggressive and have a worse prognosis than cancers that express estrogen (ER), progesterone (PGR) and/or human epidermal growth factor receptor 2 (HER2). Recent data suggests that another hormone receptor, that for androgen (AR) may be relevant in terms of further stratifying TNBC, with quadruple negative breast cancer (QNBC) having a worse prognosis than TNBC. In addition, TNBC vary with respect to prognosis and sensitivity to specific treatments, and foreknowledge of treatment outcomes has been the goal of numerous studies designed to generate predictive gene signatures. Development of these signatures involves the use of algorithms that can potentially exclude important biomarkers that may appear to be too weakly expressed to make the cut-off. We report here that the lipid metabolic enzyme, long-chain fatty acyl-CoA synthetase 4 (ACSL4) falls into this category of a heretofore-unrecognized biomarker for aggressive breast cancer. We have previously reported that ACSL4 expression is negatively correlated with the expression of ER and AR in both breast cancer cell lines and tumor samples. We now report a positive correlation between ACSL4 mRNA expression and QNBC status. In two separate studies involving a total of 71 separate breast cancer cell lines, values for ACSL4 expression derived from microarray data indicated increased expression in QNBC cell lines, p=3.75E-08 and p=4.59E-08, when compared with cell lines expressing one or more receptor biomarkers. An analysis of data derived from 178 tumor samples indicated a similar correlation, p=2.2E-03. ACSL4 expression was also correlated with molecular subtype. When breast cancer cell lines were classified by subtype, 24 of 26 luminal cell lines were negative for ACSL4 expression, 8 of 8 claudin-low cell lines were positive for ACSL4 expression, as were 12 of 17 basal-like cell lines. Three basal-like cell lines expressed both ACSL4 and HER2. Upon further examination, these lines were demonstrated to express relatively low levels of other markers that have been suggested to correlate with HER2 sensitivity (ESR1, XBPI, FASN, ERBB3), as well as to express relatively high levels of markers correlated with HER2 resistance (CD44, CAV2).

In order to determine the relationship between ACSL4 expression and estrogen independence, ACSL4-negative MCF-7 cells were inducibly transfected with ACSL4 cDNA. Induction of ACSL4 resulted in abrogation of the proliferation response to estrogen, accompanied by a reduction in expression of ER, AR and PGR. In addition, induced cells were less sensitive to treatment with tamoxifen, etoposide and triacsin C. Information derived from RAF-1-transfected MCF-7 microarray data suggest that ACSL4 expression can be regulated by RAF-1. To further explore this notion, QNBC cells, MDA-MB-231, which express high levels of ACSL4, were treated with siRNA for RAF-1 and ACSL4 levels monitored by RT-PCR and immunoblot. The fall in levels of expression of RAF-1 was accompanied by a similar decrease in expression of ACSL4. Reduction of ACSL4, however, had no effect on RAF-1 expression. In summary, these data demonstrate a possible role for ACSL4 as a biomarker for prognosis and treatment outcome, as well as a facilitator of hormone resistance.

P5-01-11

Small Node-Negative (T1b-cN0) Invasive Hormone Receptor (HR)-Positive Breast Cancers: Is There a Population Which Might Have Benefit from Adjuvant Chemotherapy?

Park YH, Cho EY, Lee JE, Nam SJ, Yang JH, Ahn JS, Im Y-H. Samsung Medical Center

Background: It has been widely accepted that small and node-negative breast cancers have an excellent prognosis and do not generally have clinical benefit from adjuvant chemotherapy. Recently, the role of adjuvant chemotherapy for small node negative breast cancers has been justified in some high-risk patients, which include HER2-positive and triple negative breast cancers. However, the question has been raised as to whether there are some patients who might have benefit from adjuvant chemotherapy in small node-negative HR-positive breast cancers. According to the current 2011 NCCN guideline, 21-gene RT-PCR assay can be considered for tumor
size of more than 0.5 cm in HR-positive, HER2-negative cancers. In cases of high recurrence score (≥ 31), adjuvant chemotherapy in addition to endocrine therapy is recommended as category 2B. Because gene array cannot routinely be used in clinical practice and has not been validated in prospective randomized trials and the usefulness of it still needs to be defined, it would be better if there were valuable markers to determine risk for relapse in this setting. We hypothesized that there could be a population who might have clinical benefit from adjuvant chemotherapy in this small node-negative HR-positive tumors.

**Patients and Methods:** We retrospectively analyzed the clinicopathologic characteristics and outcomes of 538 postoperative HR-positive (ER-positive and/or PgR-positive) T1b-cN0 breast cancer patients between 2004 and 2007 at the Samsung Medical Center. We performed Cox regression multivariate analysis for relapse using variables from univariate analysis by log-rank test for relapse.

**Results:** The median age at diagnosis was 46 years (range, 22-79). During the median 60.5 months of follow-up, the 5-year recurrence rate was 5.2%. Anthracycline-based adjuvant chemotherapy was administered to 44.8% of the patients. Adjuvant endocrine and radiation treatment were administered to 94.6% and 63.7% of the patients. There were significant differences according to histologic grade (HG), Ki67 index, and age of less than 35 years in univariate analyses regarding RFS (p=0.003, p=0.0001, and p=0.003, respectively by log-rank test). There was no significant difference according to tumor size of subcentimeter (<1 cm) (p=0.826). In Cox regression multivariate analysis, high Ki67 index and young age of less than 35 years were identified as independent risk factors for relapse (p<0.0001 for Ki67 index and 0.015 for young age). The high risk patients (n=24, 4.5%) who have high Ki67 index (more than 75%, +) or young age of less than 35 and more than 50% of Ki67 index showed better RFS with statistical significance for anthracycline-containing adjuvant chemotherapy (p=0.029).

**Conclusion:** A patients’ population may exist who have clinical benefit from adjuvant chemotherapy in T1b-cN0 HR-positive breast cancer patients. Ki67 index and age are useful as valuable surrogate markers to predict recurrence and to have benefit from adjuvant chemotherapy in this population.

**P5-01-12**

Identification of an ATM Activation Subtype in PTEN Mutant Breast Tumours.

**Background**

PTEN is frequently lost in cancer cells through genetic mutation or epigenetic silencing. Loss of PTEN function has been widely reported to cause up-regulation of the PI3K/AKT signalling pathway resulting in increased cell growth, proliferation and survival. More recently it has been reported that PTEN null cells demonstrate genomic instability through increased ROS and oxidative stress induced DNA damage. The aim of this study was to identify a biomarker for PTEN status in human breast cancers.

**Materials and Methods**

A metagene representing ATM activation was generated from public cell line data of AT fibroblasts treated with gamma-irradiation. This was used to perform hierarchical clustering analysis of a public DNA microarray profiling dataset with known PTEN IHC status. The metagene was validated in PTEN wildtype and null breast cancer cell lines.

**Results**

We found that PTEN null cells have elevated levels of ROS and furthermore activation of the DNA damage signalling kinase, ATM. In agreement with this, the ATM metagene signature correlated with PTEN mutation in breast cancer tumours. Scoring of PTEN wildtype and null breast cancer cell lines using the metagene correlated with ATM activation and sensitivity to inhibition of ATM. Furthermore we show that inhibition of ATM caused DNA damage, cell cycle arrest and apoptosis in PTEN deficient cells suggesting a novel therapeutic strategy.

**Conclusion**

These observations suggest that ATM may represent a therapeutic target in PTEN deficient tumours and furthermore ATM activation may also be an important biomarker of PTEN mutation or loss in breast cancer.

High Levels of Nuclear Heat Shock Factor 1 (HSF1) Are Associated with Poor Prognosis in Breast Cancer: Results from the Nurses’ Health Study.

Santagata S, Hu R, Lin NU, Mendillo ML, Collins LC, Hankinson SE, Schnitt SJ, Whitesell L, Lindquist S, Tamimi RM, Ince TA, Brigham and Women’s Hospital, Boston, MA; Harvard School of Public Health, Boston, MA; Dana Farber Cancer Center, Boston, MA; Whitehead Institute for Biomedical Sciences, Cambridge, MA; Beth Israel Deaconess Medical Center, Boston, MA; University of Miami Miller School of Medicine, Miami, FL

**Purpose:** Heat shock factor 1 (HSF1) is the master transcriptional regulator of the cellular response to heat and a wide variety of other stressors. We previously reported that HSF1 promotes the survival and proliferation of malignant cells. At this time, however, the clinical and prognostic significance of HSF1 in cancer is unknown.

**Patients and methods:** Breast cancer samples from 1,841 participants in the Nurses’ Health Study (NHS) were scored for levels of nuclear HSF1. Associations of HSF1 status with clinical parameters and survival outcomes were investigated by Kaplan-Meier analysis and Cox proportional hazard models. The associations were further delineated by Kaplan-Meier analysis using publicly available mRNA expression data.

**Results:** Nuclear HSF1 levels were elevated in ~80% of in situ and invasive breast carcinomas. In invasive carcinomas, HSF1 expression was associated with high histologic grade, larger tumor size, and nodal involvement at diagnosis (P<0.0001). Overall, in multivariate analysis, high-HSF1 levels were associated with increased breast cancer-specific mortality (HR, 1.62; 95% CI, 1.21-2.17). This association was seen in the ER-positive population (HR, 2.10; 95% CI, 1.25-2.47), even in early-stage lymph node negative cases (HR, 1.98; 95% CI, 1.17-3.33). In public expression profiling data, high-HSF1 mRNA levels were also associated with an increase in ER-positive breast cancer-specific mortality.

**Conclusions:** Increased HSF1 is associated with reduced survival in breast cancer. The findings indicate that HSF1 should be evaluated prospectively as an independent prognostic indicator in ER-positive breast cancer and that HSF1 may provide a useful therapeutic target.
P5-01-14
Phosphoproteomic Analysis of TIMP-1 Overexpressing MCF-7 Human Breast Cancer Cells Reveals Increased Expression and Phosphorylation of Topoisomerase Proteins.
Fogh L, Helmut O, Munk S, Jensen NF, Brünner N, Stenvang J, Lademann U, Olsen JV. Faculty of Life Sciences, University of Copenhagen, Copenhagen, Denmark; Faculty of Health Science, Copenhagen University, Copenhagen, Denmark

Background: Tissue inhibitor of metalloproteinase 1 (TIMP-1) is a protein with a potential biological role in drug resistance. Lack of TIMP-1 protein either alone (Willemoe et al., Eur J Cancer 2009) or in combination with Topoisomerase 2A gene aberrations has been shown to associate with increased benefit from adjuvant treatment with a Topoisomerase 2 inhibitor (epirubicin containing combination chemotherapy) while this association was not observed in patients treated with a non-Topoisomerase 2 inhibitor combination chemotherapy (Ejlsretsen et al., JCO 2010).

Aim: To further investigate the molecular mechanisms underlying the association between TIMP-1 and epirubicin sensitivity by quantitative phosphoproteomics.

Methods: MCF-7 human breast cancer cells were transfected with pcDNA3.1(Hyg)-TIMP-1. Among 11 single cell clones, two TIMP-1 low expressing and two TIMP-1 high expressing clones were selected. The clones were labeled by SILAC (stable isotope labeling with amino acids in cell culture). Lysates were digested with trypsin and fractionated with SCX followed by subsequent enrichment of phosphopeptides by TiO2-based chromatography and desalting by C18 purification. Total peptides and phosphopeptides were analyzed by tandem mass spectrometry and quantified as described (JV Olsen et al., Science Signaling 2010). Selected proteins were confirmed on Western blots. The sensitivity of the four TIMP-1 cell clones was analyzed by treatment of the cells with the following drugs: The Topoisomerase 2 inhibitor epirubicin (an anthracycline). The Topoisomerase 1 inhibitor SN-38 (the active metabolite of irinotecan, a camptothecin analogue) and the combination of these. A specific Topoisomerase 2B inhibitor (XK 469, a quinoxaline analogue and the DNA crosslinker cisplatin. All experiments were determined with an endpoint MTT assay.

Results: The quantitative proteomic analyses confirmed the differences in TIMP-1 levels among the four clones. Several proteins were consistently found to be upregulated and/or had changed phosphorylation levels in the TIMP-1 high cells in two biological replicates. Of particular interest was the observation that the phosphorylation status and protein levels of Topoisomerase-1, -2A and -2B were increased in TIMP-1 high expressing cells compared to TIMP-1 low expressing cells. When the four clones were treated with specific Topoisomerase inhibitors, the TIMP-1 high expressing cells exhibited significantly more resistance to all three inhibitors compared to TIMP-1 low expressing cells. When cells were treated with a combination of SN-38 and epirubicin, we observed an additive but not a synergistic effect. At last, cells were treated with cisplatin with no different effect on TIMP-1 high and low expressing cells.

Conclusion and perspectives: The observed upregulation of both protein and phosphorylation levels of Topoisomerasers in TIMP-1 high cells may be part of the mechanism by which TIMP-1 confers resistance to treatment with Topoisomerase inhibitors in primary breast cancer. Further work will include pathway analyses and hypothesis testing in clinical material.

P5-01-15
The Functional Role of the Estrogen-Regulated Gene GREB1: Characterization of a Novel GREB1 Knockout Mouse Model.
Hnatsyzn HJ, Rodriguez C, Herbert L, Olson R, Lippman ME. University of Miami, Miami, FL

Background: Gene regulated in breast cancer 1 (GREB1) was initially discovered in breast cancers as an estrogen-regulated gene that mediates estrogen-stimulated cell proliferation and is a candidate clinical marker for response to endocrine therapy. However, little is known of the functional role of GREB1 protein in normal breast tissue or breast cancers.

Methods: To address this unknown role, our laboratory designed and created a novel Greb1 Knockout Mouse model (C57/bl MEL Greb1 KO). This constitutive model results in the loss of Greb1 mRNA and protein expression in cells where expression of Cre recombinase promotes the cleavage of exon 1 and intron 1 of the gene encoding Greb1. ROSA26 Cre C57/bl MEL Greb1 KO mice heterozygous for the floxed Greb1 allele were crossed to generate experimental litters. Initial experiments were designed to evaluate if the complete loss of Greb1 expression in offspring homozygous for the floxed Greb1 allele was lethal during gestation. Experimental litters were tail clipped and genotyped using gDNA and genotype-specific PCR.

Results: Offspring homozygous for the floxed Greb1 allele were identified in expected Mendelian ratios with wild type and heterozygous siblings. Loss of Greb1 expression was confirmed using RT-PCR, in situ hybridization and immunoblotting. Loss of both Greb1 alleles was not observed to be lethal during gestation for either male or female pups. Preliminary gross observation of these homozygous KO mice revealed no overt anatomical differences, however, they were 25-30% smaller than their heterozygous and wild-type siblings. Breeding experiments are underway to determine the fertility of crossbred Greb1 homozygous KO mice. Imaging experiments and necropsy with histochemical analysis of tissues will reveal any alteration in architecture and function. These findings will be summarized in this presentation.

Discussion: As GREB1 has been identified as an estrogen-regulated gene involved in breast cancer cell proliferation and a potential target for new therapeutic strategies, it is important to understand the contribution of GREB1 to the differentiation, development and function of normal tissues as well as in breast cancers. Characterization of this novel Greb1 KO mouse model will provide answers to these functional questions surrounding GREB1.

P5-01-16
The Detection of Circulating CK19 mRNA-Positive Cells in the Blood and the Mitotic Index of the Primary Tumor Have Independent Prognostic Value in Early Breast Cancer.
Tryfonidis K, Perraki M, Apostolaki S, Kafousi M, Agelaki S, Georgoulas V, Stathopoulos EN, Mavrooudis D. University General Hospital of Heraklion, Heraklion, Crete, Greece; School of Medicine, University of Crete, Heraklion, Crete, Greece

Background: Previous studies have shown that the molecular detection of CK-19 mRNA in peripheral blood and the mitotic index of primary tumor have prognostic value in early breast cancer. The aim of the present study was to assess the association between these variables. Patients and Methods: The primary tumors of 223 operable breast cancer patients (92 premenopausal and 131 postmenopausal) were evaluated for the mitotic activity index (MAI) classified either as <5/10, 6-10/10 and >10/10 or <10/10 and >10/10 mitoses/hpf using a standardized protocol as previously reported (Baak JP et al, Breast Cancer Res Treat 2009, 115:241-254). Peripheral blood was also
collected before the start and after the end of adjuvant chemotherapy for detection of CK-19 mRNA-positive cells by RT-PCR as previously described (Stathopoulou et al., Clin Cancer Res 2003, 9:5145–5151). Results: After a median follow-up of 118 months, 75 (33.6%) patients have experienced disease relapse and 56 (25.1%) have died of breast cancer. MAI was strongly associated with disease-free survival (DFS) and overall survival (OS) (p < 0.001 for both DFS and OS). Detection of CK19 mRNA-positive cells in the peripheral blood before but not after adjuvant chemotherapy was marginally associated with worse DFS (p = 0.055) and OS (p = 0.059). There was no correlation between MAI and CK19 mRNA detection before chemotherapy. Cox regression analysis revealed that both MAI and CK19 mRNA-positive cell detection before adjuvant chemotherapy were independent variables associated with decreased DFS (p < 0.001 and p = 0.038, respectively) and OS (p < 0.001 and p = 0.029, respectively). The interaction test showed no significant association between MAI and detection of CK19 mRNA-positive cells. Conclusion: MAI of the primary tumor and detection CK-19 mRNA-positive cells in the blood before the start of adjuvant chemotherapy in women with early breast cancer are two independent prognostic factors associated with clinical outcome.

P5-01-17
HER2 Amplification in Primary Tumor: A Potential Marker for Presence of Circulating Tumor Cells in Inflammatory Breast Cancer Patients?
Bhattacharyya A, Krishnamurthy S, Lodhi A, Hall C, Anderson A, Jackson S, Ueno N, Bedrosian I, Kuerer H, Lucci A. University of Texas MD Anderson Cancer Center, Houston, TX

Background: Inflammatory breast cancer (IBC) is a rare but aggressive form of invasive breast cancer accounting for 3-6% of all cases and have higher rates of distant recurrence. Circulating tumor cells (CTCs) are known to predict outcome in metastatic breast cancer (BC) patients, but little is known about their prognostic significance in non-metastatic BC. We hypothesized that CTCs can be identified in patients with IBCs and may correlate with primary tumor characteristics. Methods: All patients had blood samples collected at the time of primary surgery. CTCs (per 7.5 ml blood) were detected using the Cell Search™ system (Veridex) and were defined as nucleated cells lacking CD45 but expressing cytokeratins (CK) 8, 18, or 19. The presence of ≥1 epithelial cells meeting morphologic criteria for malignancy was considered a positive result. Statistical analyses employed Chi square and Fisher’s exact tests using STATA software. Results: We prospectively evaluated 41 IBC patients enrolled in an IRB approved protocol undergoing surgery for stage I-III breast cancer. Median follow-up was 30 months. Mean age was 52 years. Thirty five patients (94%) had positive lymph nodes (LNs) at presentation, 30 (75%) had high-grade tumors and 20 (53%) had lymphovascular invasion. Eleven patients (28%) were ER positive, 11 (27%) were PR positive and 18 (44%) were HER2 positive. IBCs were more likely to be high grade (P < 0.0001), ER negative (P < 0.0001), PR negative (P < 0.0001), HER2 positive (P < 0.0001), High Ki-67 (P = 0.005) and had a BMI of more than 25 kg/m2 (P = 0.04). Twelve (27%) patients were CTC positive. CTCs were more likely be found in HER2 positive (8/18; 44%) vs. HER2 negative primary tumors (3/20; 15%) [OR = 4.53; 95% C.I. = 1.02-19.52; P = 0.04]. We found no statistically significant correlations between primary tumor characteristics (ER, PR, LNs, high grade) and presence of CTCs. Conclusions: About a quarter of IBC patients had CTCs at the time of primary surgery. In these patients HER2 overexpression predicted the presence of CTCs. Studies with longer follow-ups is needed to determine if CTCs predicted survival.

P5-01-18
Identification of Pax6 as a Human Breast-Cancer-Testis Antigen.
Yang M, Wang Y. The First Hospital of Jilin University, Changchun, Jilin, China; Jilin University, Changchun, Jilin, China

Background:
Cancer-testis antigens (CTAs) are specifically expressed in the normal testis and various types of cancer cells, but not or expressed with very low level in the other normal tissues. CTAs are considered to be promising targets for immunotherapy. Little is known on CTAs which specifically expressed in breast cancer. Studies show that the transcriptional activation by CpG island hypomethylation is believed to be an important mechanism of their increased expression.

Objective:
To find CTAs which specifically expressed in breast cancer; prove the increase of its expression in human breast cancer, and explore the possibility for it to be developed as target for the immunodiagnosis and immunotherapy of breast cancer.

Methods and results
Genomic DNAs were isolated from testis tissue, breast cancer and normal breast tissues respectively. To perform CpG island microarray assays, genomic DNAs were prepared from 15 paired breast cancer biopsies and their normal controls. After obtaining sequence information for those clones from the CpG island database, they were then used to search for surrounding genes in the gene banks. We found several testis specific genes, such as, Pax6, NDRG3 and Synaptophysin. Since the last two genes had been extended investigated, they were not the subjects of this study. The Pax6 Gene Was Activated in Established Primary Breast Cancer Cell Lines. First, we examined Pax6 gene expression levels in a breast cancer cell line panel that included Hs578T, MDA-231, MDA-436, MDA-468, T47D, MCF7 and MCF7/Adr, by performing RT-PCR where b-actin served as control. In addition, the RNAs obtained from normal breast and testis tissues were used as negative and positive controls. We found that Pax6 was re-expressed in MDA-436, MDA-468, T47D, and MCF7/Adr. To further test the Pax6 gene’s behavior in primary breast cancer cells, we isolated breast cancer epithelial cells from the effusions of 8 patients (E4, E5, K151, K259, K473, K573, K596 and K605), cRNAs were prepared from those cells and the normal human breast cell line (HNBEC) for RT-PCR assays, where cRNAs of paired MCF7 cells and b-actin served as controls. Results showed that Pax6 was expressed in K259, K573, K596 and K605 cells to various degrees. Pax6 was re-expressed in a majority of Breast Cancer Biopsies. To test if Pax6 was also expressed in breast cancer tissues, IHC assays were carried out using 19 patients’ biopsies where human testes served as positive controls. We found that the Pax6 protein existed mainly in the cytoplasm of breast cancer cells, but was not detectable in normal breast tissue sections.

Conclusion
CpG islands of Pax6 promoter region were hypomethylated in human breast cancer. The mRNA level of Pax6 in human breast cancer was significantly increased contrast to normal breast tissue, contrast to all other analyzed normal tissues, suggesting Pax6 is a CTA for breast cancer and might be applied as molecular target in immunotherapy against human breast cancer.
P5-01-19
Endothelin-1 Expression in Breast Cancer Tissue, Surrounding Stroma, Correlation with Tumor Microvessel Density and Clinical Outcome.
Tamkus D, Wiese D, Sikorskii A, Chivu S, Peddi P, Chitneni S. Michigan State University (MSU); McLaren Regional Medical Center (MRMC)

Background: Endothelin-1 (ET-1) is a peptide which regulates normal biological processes such as vascular tone. In addition, endothelin signaling pathway is dysregulated in pathophysiological conditions such as cancer and fibrosis. It has been shown that endothelin-1 is expressed in breast cancer tissue but little is known with regard to ET-1 expression in surrounding tumor stroma. In the present study, we investigated ET-1 expression in breast tumor cells, surrounding stroma, association with tumor microvessel density (MVD) and impact on clinical outcome.

Materials and Methods: We conducted a retrospective, multicenter study. Patients from 3 medical centers with histologically documented stage I-III invasive breast cancer were included in the study. Paraffin embedded formalin fixed breast cancer tissue and surrounding stroma were evaluated for ET-1 and CD34 (marker for MVD) by IHC. ET-1 cytoplasmic expression was scored as positive (3+ by IHC) or negative (0, 1+, 2+). Stained vessels by CD34 were counted in five consecutive fields at 40 x magnification and their mean was recorded. Demographics, clinical data and recurrence free interval (RFI) in months were available for statistical analysis.

Results: The study included 92 patients with average age of 55 years at diagnosis. Median follow up of patients at the time of analysis was 72 months. Total of 29 patients experienced disease progression (17 locoregional and 12 distant). Tumor ET-1 expression positively correlated with earlier stage: odds ratio (OR) = 22 for stage I and OR=20 for stage II as compared with stage III. Positive ET-1 staining in tumor was detected in 72.8 % of cases, while ET-1 positive expression in stroma was detected only in 6.5% of cases. Interestingly, all ET-1 stroma positive tumors were estrogen receptor (ER) positive. The means of CD34 were not different according to ET-1 expression either in the tumor or stroma. Triple negative breast cancer tumors exhibited higher MVD (p=0.0177). In the logistic regression model relating ET-1 expression in tumor to clinical variables, ET-1 positive tumors showed a trend for the association with higher relapse rate (p=0.058). Multivariate analysis suggested that there was no significant difference in the recurrence free interval (RFI) between the ET-1 positive and ET-1 negative groups (long-rank test p-value = 0.71). Survival analysis identified stage as a significant predictor of RFI in the Cox proportional hazard model that included ET-1 expression and other clinical variables.

Conclusions: The significant predictor for ET-1 expression in the tumor was early stage. High tumor ET-1 expression was more common in patients who experienced breast cancer recurrence. No association was found between ET-1 expression and MVD, and between ET-1 expression and time to recurrence. Further studies with larger sample size are needed to better delineate a role of ET-1 as prognostic biomarker in early stage breast cancer.

P5-02-01
ErbB4 Ectodomain as a Biomarker and a Potential Therapeutic Target for Breast Cancer.
Hollmen M, Liu P, Wilders H, Reinvali I, Vandorpe T, Smeets A, Deraedt K, Yahlberg T, Joensuu H, Leahy D, Schoffski P, Elenius K. University of Turku, Turku, Finland; Johns Hopkins University School of Medicine, Turku, Finland; University Hospitals Leuven, Belgium; University of Turku, Finland; Helsinki University Hospital, Helsinki, Finland

ErbB4 function is controversial in breast cancer and influenced by alternative splicing of the ERBB4 gene. Here we evaluated the cleavable ErbB4 JM-a isoform as a potential drug target and biomarker. To address ErbB4 cleavage in breast cancer tissues in vivo, extracellular and intracellular cleavage products of ErbB4 were assessed by ELISA and immunohistochemistry using matched serum and tissue samples from a series of 243 breast cancer patients. Elevated serum ectodomain level (≥40 ng/mL) and nuclear immunoreactivity were present in 21% and 52% of the patients, respectively. An elevated serum ErbB4 ectodomain concentration was not associated with tumor nuclear immunoreactivity, but was significantly associated with the premenopausal status at diagnosis (P = 0.04). Estradiol also enhanced ErbB4 cleavage and ErbB4 cleaving enzyme activity in vitro, supporting a role for estrogen signaling in regulation of ErbB4 cleavage. Selective targeting of the cleavable ErbB4 JM-a in human breast cancer cells with an ErbB4 isoform-specific mAb 1479 inhibited ErbB4 cleavage and reduced tumor formation in a mouse xenograft model. Consistent with blocking of ErbB4 cleavage, mutagenesis studies and the 3.4 Å X-ray crystal structure of a complex of the ErbB4 extracellular region and the 1479 Fab localized the binding site of mAb 1479 on ErbB4 to a region on subdomain IV encompassing JM-a-specific residues. These data demonstrate that ErbB4 is cleaved in a subset of breast cancer patients, and suggest that the mechanisms by which mAb 1479 suppresses breast cancer cell growth involves inhibition of ErbB4 cleavage. Serum ErbB4 ectodomain concentration could be used as a biomarker to monitor the activity of compounds, such as mAb 1479, that target ErbB4 cleavage.

P5-02-02
Divergent Effects of Zoledronate and Denosumab on Cellular Interactions between Osteoblasts and Breast Cancer Cells.
Kaiser T, Teufel I, Wallwieder D, Klein G, Fehm T. Medical University Hospital of Tuebingen, Tuebingen, Germany; Center for Medical Research, University of Tuebingen, Tuebingen, Germany

Background: The development of bone metastases is a multistep process that involves interactions between tumor cells and normal host components of the bone marrow microenvironment. Emerging evidence suggests that the interplay of breast cancer cells with both RANKL-expressing osteoblasts, key mediators of osteoclastogenesis, and osteoblast-derived extracellular matrix structures is critical to the metastatic process. This relationship may contribute to the tumor cells’ colonization of bone, invasive behavior, and eventual tumor progression. Zoledronate, a nitrogen-containing bisphosphonate has demonstrated inhibitory effects on tumor cell adhesion and migration. Denosumab, a fully humanized monoclonal antibody against receptor activator of nuclear factor-κB ligand (RANKL), might also exhibit inhibitory effects on breast cancer cell adhesion and migration by neutralizing RANKL. However, despite their clinical importance, the mechanisms of zoledronate and denosumab in crosstalk between breast cancer cells and osteoblasts still remain poorly characterized.
Material and Methods: To investigate the influence of zoledronate and denosumab on osteoblast-breast cancer cell interactions, cell adhesion and migration assays using different breast cancer cell lines (MCF7, MDA-MB-231, and SKBR3) were performed.

Results: Cell-matrix adhesion assays revealed a strong attachment of breast cancer cells to several extracellular matrix components expressed by osteoblasts. The subsequent incubation of attached cells with 100 µM zoledronate for 72 h resulted in a prominent reduction of tumor cells’ binding to collagen type I, fibronectin, defined laminin isoforms and tenasin-C, whereas incubation with 10 µg/ml denosumab did not affect the adhesive behavior of breast cancer cells. In addition, cell-cell adhesion analyses indicated that zoledronate was able to decrease the attachment of breast cancer cells to osteoblasts. Furthermore, migration studies using the scratch assay and the transwell migration technique clearly showed that the conditioned media of osteoblasts (primary osteoblasts as well as the osteoblastic cell line CAL72) strongly enhanced the migration of the breast cancer cell line MDA-MB-231 compared to the conditioned media of osteoclast-like cells, stromal cells and control medium, suggesting that exclusively osteoblasts release factors that significantly increase tumor cell migration. Interestingly, exposure to zoledronate inhibited osteoblast-induced tumor cell migration in a concentration-dependent manner. In contrast, denosumab (0.1 – 50 µg/ml) had no inhibitory effect on the migration of MDA-MB-231 cells in scratch analysis. However, this agent was found to cause a reduction in the number of migrated cells when 10 µg/ml were used in transwell assays.

Discussion: Our data clearly demonstrate that breast cancer cells interact with osteoblasts and osteoblast-secreted extracellular matrix proteins. The osteoblast-induced breast cancer cell abilities, including tumor cell adhesion and migration, were strongly affected by zoledronate, but not by denosumab. The influence by zoledronate on these interactions provides further insights into the antiresorptive effect of this substance on bone metastasis.

P5-02-03
Lipid Raft Disruption by Docosahexaenoic Acid Induces Apoptosis in Transformed Human Mammary Luminal Epithelial Cells Harboring HER-2 Overexpression.
Ravacci GR, Tharcisio Junior T, Logullo AF, Torrinhas RS, Brentani MM, Waisberg DL. Medical School, University of São Paulo, São Paulo, Brazil; UNIFESP University, São Paulo, Brazil

Background, In HER-2 overexpressing breast cells, HER-2 receptors exist on the cell surface as monomers, homodimers and heterodimers with EGFR and HER-3. For signal activation and transduction to occur, the HER-2 receptors must be located in lipid rafts. Therefore, HER-2 overexpression must be accompanied by increased lipid rafts on the cell membrane to ensure constant signal transmission. Methods, To test this hypothesis, we used HB4a – untransformed human mammary epithelial cell strain – and HB4aC5.2 cells – HB4a cells co-transfected with ErbB-pJ5E.c-2 (normal full length human HER-2 cDNA). We analyzed the lipid rafts, cholesterol and fatty acids from cell membrane by confocal microscopy and gas chromatography. The proteins associated to HER-2 activity and lipid rafts formation, such as Akt, ERK ½ and FASN were analyzed by western blotting. To evaluate the lipid rafts importance for HER-2 signaling, we treated cells with docosahexaenoic acid (DHA) to disrupt the lipid rafts. Thereby, all analysis was repeated and cells death and apoptosis were analyzed by flow cytometry. Values were obtained by the mean and standard deviation of five independent experiments and developed in triplicate, by using one-way analysis of a variance (ANOVA) test, followed by Bonferroni post-test, to identify significant (p<0.05) differences between cell lines and results with different concentrations of DHA treatment. Results, HB4aC5.2 cells have five copies of pJ5E.c-ErbB-2 inserted into their genome and express approximately 900 times more HER-2 than HB4a cells. HER-2 overexpression in HB4aC5.2 cells was accompanied by increased lipid rafts in cell membranes, hyperactivation of downstream Akt and ERK1/2 proteins, and rate of cell growth increase as compared to the HB4a strain. In addition, HER-2 overexpression was associated to increased activation of FASN, a key enzyme involved in cellular lipogenesis. The final product of FASN activation, palmitate, is used to synthesize saturated phospholipids, necessary to form lipid rafts. Treatment of HB4aC5.2 cells with DHA, an omega-3 fatty acid, disrupted the lipid rafts by its increased incorporation into the cell membrane; inhibited HER-2 activation by decreasing Akt, ERK1/2, and FASN proteins; and induced apoptosis. The same treatment maintained the structure of HB4a cell lipid rafts, accompanied by a low percentage of DHA-induced apoptosis. Conclusion, Although little is yet known about lipid rafts, our data support the theory that disturbances these micro-domains may represent a useful tool in controlling cell signaling triggered by HER-2 receptors and contribute to a better understanding of the role of this receptor in HER-2 positive breast cancer.

P5-02-04
Disruption of Endothelial Cells Barrier Integrity by Invasive Breast Cancer Cells.
Haidari M, Zhang W, Chen Z, Mortazavi A, Dixon R. Texas Heart Institute, Houston, TX; The University of Texas Health Science Center at Houston, Houston, TX

Despite its critical role in cancer metastasis the molecular mechanisms regulating breast cancer cells transendothelial migration are poorly understood, but clearly depend on the invasive capacity of tumor cells and their ability to breach the endothelial cell barrier. Vascular endothelial-cadherin (VE-cadherin) is found specifically in the endothelial cell adherens junction and has been implicated in playing a fundamental role in controlling the transport across the endothelial barrier. Tyrosine phosphorylation of VE-cadherin has been implicated in the disruption of endothelial cells adherens junctions and diapedesis of metastatic cancer cells. We tested this hypothesis that interaction of breast cancer cells with endothelial cells initiates the signal transductions that disrupt the endothelium barrier integrity. Our studies demonstrated that the attachment of MDA-MB-231 human breast cancer cells to Human Umbilical Vein Endothelial Cells (HUVECs) leads to tyrosine phosphorylation of VE-cadherin and the formation of gaps between endothelial cells. These were accompanied by activation of two tyrosine kinases, Src and proline rich tyrosine kinase (Pyk-2). In addition, immunoprecipitation studies indicated that the endothelial cells adherens junction structure was disrupted through MDA-MB-231-induced dissociation of VE-cadherin and β-catenin complex. Activation of RhoA and HRas by over expression of constitutively active forms of the genes leads to tyrosine phosphorylation of VE-cadherin and Pyk-2 in HUVECs. Over expression of dominant negative forms of RhoA, HRas, Raf and ERK2 but not Rac1 and Cdc42 attenuated breast cancer cell-induced tyrosine phosphorylation of VE-cadherin and Pyk-2 in HUVECs. Indicating that breast cancer cell-induced VE-cadherin tyrosine phosphorylation and disruption of adherens junction in endothelial cells is mediated by RhoA and Hras/Raf/MEK/ERK signaling cascade. Understanding the precise molecular mechanisms...
that facilitate breast cancer cells transendothelial migration could develop novel therapeutic strategies targeting cancer cell metastasis by improving the protective role of endothelial cells.

**P5-02-05**

Suetsugu A, Digman M, Gratton E, Moriwaki H, Saij S, Bouvet M, Hoffman RM. AntiCancer Inc., San Diego, CA; University of California San Diego, San Diego, CA; Gifu University Graduate School of Medicine, Gifu, Japan; University of California Irvine, Irvine, CA

Background: Paxillin is involved in the assembly of focal adhesions. We wish to visualize paxillin behavior in breast cancer cells in vivo, as well as in vitro.

Materials and Methods: Dual-photon confocal microscopy was used to image paxillin behavior by linking it to GFP. MDA-MB-231 human breast cancer cells expressing paxillin-GFP were imaged in vitro and in vivo adhering and trafficking in blood vessels in mice. 10° paxillin-GFP expressing breast cancer cells were injected in the epigastric cranialis vein.

Results: In vitro, round breast cancer cells had greater paxillin movement than stretched cancer cells as seen by fluorescence imaging. Paxillin-GFP breast cancer cells in the epigastric cranialis vein were initially rounded and had GFP-expressing protrusions. At later timepoints, many paxillin-GFP-expressing breast cancer cells stretched. The breast cancer cells then extravesated and subsequently grew around the outer surface of the blood vessel after one week. Two weeks after injection, paxillin-GFP expressing breast cancer cells were imaged migrating along the vessel wall. Most of the paxillin-GFP expressing breast cancer cells were stretched and were not mobile. With anti-VEGF treatment, paxillin was observed in round structures within the cells rather than stretched structures and paxillin movement within the cell was arrested.

Discussion: These results demonstrate that breast cancer cells brightly expressing paxillin-GFP and two-photon confocal microscopy can allow the visualization of the behavior of paxillin within breast cancer cells during adhesion and migration along the walls of blood vessels, as well as during anti-angiogenesis therapy.

**P5-03-01**

Cytoplasmic Cyclin E and P-CDK2 Expression in Triple Negative Breast Carcinomas Measured by Immunohistochemistry Correlates with Poor Outcome.

Biernacka A, Karakas C, Wingate H, Bondy M, Sahin A, Hunt K, Khandan K. MD Anderson Cancer Center, Houston, TX

Background: Triple negative breast carcinomas (TNBCs) are aggressive malignancies that lack effective therapeutic targets but express low molecular isoforms of cyclin E (LMW-E). These LMW-E, generated primarily from NH2-terminal elastase cleavage of full length cyclin E (EL), preferentially accumulate in the cytoplasm of cancer cells. Using a transgenic mouse model system, our laboratory has recently shown that cyclin-dependent kinase 2 (CDK2) is required for LMW-E-mediated mammary tumorigenesis. These results lead us to hypothesize that immunohistochemical cytoplasmic detection of LMW-E and phospho-CDK2 in TNBC provides a valuable screening tool for those patients most likely to have a poor prognosis who could then be treated with anti-CDK2 therapy currently clinically available.

Material and Methods: Tissue micro-arrays from 168 TNBC patients were IHC stained for cyclin E and p-CDK2. Cyclin E staining intensity and percentage of positivity were evaluated both in the nucleus and cytoplasm of cancer cells and four different phenotypes of cyclin E were distinguished with respect to predominant nuclear or cytoplasmic localization of staining: cyclin E negative, predominantly nuclear, both nuclear and cytoplasmic and predominantly cytoplasmic. p-CDK2 IHC was achieved using an antibody, which recognizes phospho-threonine 160 on CDK2. Immunoreactive scores were determined by multiplying the intensity with the extent of staining of nuclei and cytoplasm. We sought correlations between different cyclin E and p-CDK2 expression patterns and disease-free survival (DFS).

Results: Cytoplasmic cyclin E accumulation on IHC of TNBCs correlated with poor outcome. Within the median follow up of 7.3 years tumors with both nuclear and cytoplasmic cyclin E expression demonstrated higher recurrence rate compared to entirely negative for cyclin E (p=0.0117). In contrast patients with exclusively nuclear cyclin E showed only a trend toward decreased DFS compared to patients with cyclin E negative tumors (p=0.0896). Furthermore we identified the new phenotype of cyclin E immunoreactivity, which is characterized by negative nucleus and positive cytoplasmic staining. This phenotype was the most significantly associated with poor DFS compared to cyclin E negative phenotype (p=0.0026) and as the only one distinguished at high risk of early recurrence among TNBC patient without axillary nodes involvement (p=0.0105). The expression of p-CDK2 was significantly higher in this phenotype than the cytoplasmic cyclin E negative tumors. High p-CDK2 tumors were also correlated to worse DFS then p-CDK2 low tumors (P=0.019).

Lastly, our analyses revealed that tumors positive for both cytoplasmic cyclin E and p-CDK2 had higher recurrence rate compared to negative for both or positive for one of them (p=0.003).

Discussion: Cytoplasmic cyclin E may help to predict recurrence, especially in early stage, node negative TNBCs. We present a new concept in assessing cyclin E expression. Poor outcome due to TNBCs overexpressing LMW-E provide a rationale to investigate the treatment strategies that could specifically target high LMW-E tumors. These patients could particularly benefit from treatment with CDK2 inhibitors.

Aurora A Is Closely Linked to an Aggressive Phenotype of Breast Cancer.

Yamamoto Y, Ishuski M, Murakami K, Iwase H. Kumamoto University, Graduate School of Medical Sciences, Kumamoto, Japan

(Purpose) Aurora A, a mitotic serine/threonine kinase, is involved in important process of mitotic progression. The aim of this study is to clarify characteristics of breast cancer with Aurora A expression. (Methods) We examined, by immunohistochemical analysis, the expression of Aurora A in primary invasive breast cancer. We also investigated the correlation between expression of Aurora A and clinicopathological and biological factors. In addition, we studied the prognostic value of Aurora A in breast cancer.

(Results) In 215 cases of invasive cancer examined, Aurora A was mainly identified in tumor nuclei. Aurora A expression was detected in 67 (31.2%) cases. Expression of Aurora A was correlated with tumor size (p=0.002), lymph node metastasis (p=0.002), tumor stage (p=0.04) and histological grade (p=0.0031). Aurora A expression was also associated with hormone receptor negativity (p=0.0001), and increased levels of HER2 (p=0.0028), Ki67 (p=0.0001), HIF-1alpha (p=0.0001), VEGF (p=0.007), COX-2 (p=0.002) and p53 (p=0.0001). Patients who had increased Aurora A levels in their tumor showed shorter disease-free survival (DFS) (p<0.0001) and overall survival.
(OS) (p=0.0002) than those lacking Aurora A in univariate analysis. However, in multivariate analysis of DFS and OS, Aurora A was not identified an independent prognostic factor.

(Conclusion) Aurora A expression was significantly correlated with tumor burden, poorly differentiation, negativity of hormone receptors, tumor cell proliferation, and tumor angiogenesis. These findings suggest that Aurora A was closely related with an aggressive phenotype in breast cancer.

P5-03-03
Identification of New Substrates for Breast Tumor Specific Low-Molecular-Weight Cyclin E Cyclin-Dependent-Kinase 2.
Akli S, Duong M, Keyomarsi K, M. D. Anderson Cancer Center; University of Texas, Houston, TX

Background: Cyclin E overexpression occurs in 25% of breast cancer tumors and is linked to poor prognosis. In tumor cells full length cyclin E (FL-E) is processed by an elastase-like protease into low-molecular weight isoforms (LMW-E) that are biochemically hyperactive. When overexpressed in breast cancer cells, LMW-E induced genomic instability and resistance to p21, p27, and antiestrogens. LMW-E are tumor specific and are associated with the aggressive triple negative breast cancer (TNBC). Transgenic mice overexpressing LMW-E had increased incidence of mammary tumors and distant metastasis when compared to FL-E. Furthermore, when the role of CDK2 in LMW-E mediated mammary tumorigenesis was interrogated by crossing LMW-E transgenic mice with CDK2 knock out mice, we found that the mice are protected against mammary tumor formation. Additionally, treatment of LMW-E transgenic mice with roscovitine (a CDK2 inhibitor) delays mammary tumor formation. These results indicate that kinase inhibition may have therapeutic activity in LMW-E overexpressing tumors as shown in this preclinical model. These results lead us to hypothesize that the biological and biochemical differences between FL-E and LMW-E may be due to the phosphorylation of a distinct set of substrates when complexes with CDK2. Our goal is to identify distinct LMW-E/CDK2 substrates on a proteome-wide scale that could serve as novel therapeutic targets for the treatment of the aggressive LMW-E expressing TNBC.

Material and Methods: We used two different approaches to identify LMW-E/CDK2 substrates. 1) We generated an analog sensitive CDK2 kinase, (F80A or F80G)-CDK2 to specifically radiolabel its substrates in cell extracts followed by their identification by mass spectroscopy. 2) We incubated ProtoArrayMicroarrays spotted with 3000 GST-tagged human protein on high density glass slides either with recombinant active FL-E/CDK2 or LMW-E/CDK2.

Results: In the first approach, we expressed and purified wild-type CDK2 in complex with FL-E or LMW-E and CDK2 (F80A) and CDK2 (F80G) from insect cells. Although all 3 CDK2 kinases can use ATP to phosphorylate GST-Rb protein, only the F80G mutant can use PE-ATP-p-S. In the second approach, we incubated incubated protein arrays either with recombinant active FL-E/CDK2 or LMW-E/CDK2 at a concentration of 50 nM. Our first screen identified a total of 122 potential substrates to both FL-E/CDK2 or LMW-E/CDK2 kinase complexes. We only identified 1 protein that is phosphorylated by FL-E/CDK2 significantly more than by LMW-E/CDK2 as compared to the 32 potential substrates specific to LMW-E/CDK2 suggesting that by losing the N-terminal portion, the LMW-E/CDK2 kinase complex is able to specifically interact and phosphorylate novel proteins.

Discussion: The identification of new physiological LMW-E/CDK2 substrates will lead to the development of novel targets for therapeutics and the identification of the biological function for the treatment of the aggressive LMW-E expressing TNBC.

P5-04-01
BP1, a Homeotic Transcription Factor, Indirectly Upregulates ER-alpha in ER Positive Cell Lines.
Berg PE, Avate S, Kirolikar SP. The George Washington University, Washington, DC

Background: BP1 is a member of the homeobox gene family of transcription factors. Our recent studies have shown that BP1 may play a role in breast cancer cell survival, aggressiveness and metastasis. BP1 protein (pBP1) is expressed in 80% of invasive ductal breast tumors, including in 57% of ER positive and 89% of ER negative tumors. BP1 overexpression results in a more aggressive phenotype in breast cancer cells and larger tumors in women with
breast cancer. We also observed the presence of mammary tumors in mice without estrogen supplementation after injection of MCF7 cells overexpressing BP1 compared with unsupplemented mice receiving MCF7 cells containing an empty vector. Our goal was to determine the pathway by which BP1 might cause this decrease in estrogen dependence of MCF7 cells. ER-alpha is a nuclear hormone receptor activated by estradiol and is a major target of anti-estrogen therapy. It is tightly regulated at the genomic and the non-genomic levels. Increased stability of ER-alpha is one mechanism by which cells can become ER-alpha independent. One way of altering ER-alpha stability is via p300 and BRCA1 since p300 acetylates and stabilizes ER-alpha, while BRCA1 destabilizes ER-alpha. We have previously shown that BP1 transcriptionally down-regulates BRCA1, suggesting that pBP1 may participate in this pathway.

Materials and methods: Protein levels of BRCA1, p300, pS2, pBP1 and ER-alpha were determined by Western Blot analysis. RNA levels were measured by real-time PCR. A ChIP assay was performed to confirm binding of pBP1 to the EP300 gene and binding of ER-alpha to BP1. MCF7 parental cell lines were treated with 10nM E2 to induce the expression of pBP1. Experiments involving effects of siBP1 on p300 expression are underway.

Results: Our data demonstrate that MCF7 ER+ cells engineered to overexpress BP1 exhibit increased ER-alpha protein, increased p300 and decreased BRCA1 protein as compared with control cells containing an empty vector and grown under the same conditions. Increased ER-alpha levels correlated with increased pS2 expression, a known downstream target of ER, demonstrating that there is more functional ER-alpha protein in cells overexpressing BP1. ChIP assays showed that pBP1 binds in the first intron of EP300-Histone acetyltransferase (p300). ChIP assays also showed that ER-alpha binds to an estrogen response element (ERE) upstream of the BP1 gene. MCF7 parental cell lines, when serum starved and treated with E2, showed increased BP1 expression compared with cells grown in charcoal stripped serum. Thus, BP1 may increase the stability of ER-alpha by decreasing BRCA1 and increasing p300.

Conclusions: pBP1 binds and transcriptionally activates p300, leading to increased ER-alpha stability, while also partially repressing BRCA1. Moreover, ER-alpha, via a feed-forward mechanism, binds to the BP1 gene and increases its expression.

TNBL: An Integrated Knowledge Space of Triple-Negative and Basal-Like Breast Cancers.
Zhu J. OmicsHealth LLC, Morris Plains, NJ

Background: To facilitate drug discovery and development in triple-negative (TNBC) and basal-like (BLBC) breast cancers, an integrated knowledge space was developed through standardizing and linking information reported in scientific publications. The tool was designed to 1) track and consolidate knowledge around TNBC and BLBC; 2) centralize computational resources on molecular profiles, disease models, drug effects and clinical outcomes; 3) establish a computational platform to facilitate identification of drug targets and biomarkers; 4) enable hypothesis generation for novel uses of pre-existing compounds including new indications and combinations. Technology and robust visualization capability, it offers integrated and exchange knowledge efficiently. Through its powerful semantic information from all possible sources in a computable format.

Discussion: The number of research papers on TNBC and BLBC are rapidly growing with 30-50% increase annually. TNBL provides a platform for the research community to standardize scientific findings and exchange knowledge efficiently. Through its powerful semantic technology and robust visualization capability, it offers integrated and comprehensive views of TNBC and BLBC which are not possible in the scope of any single research paper. In addition, it facilitates high quality hypothesis generation through consolidating up-to-date information from all possible sources in a computable format.

Personalized Cancer Treatment Selection Using Computational Signaling Pathway Models.
Verhaegh W, Hatzis P, Clevers H, van de Stolpe A. Philips Research, Eindhoven, Netherlands; Hubrecht Institute, Utrecht, Netherlands

Introduction: In clinical oncology, with breast cancer in the front line, - cancer genome sequencing is entering clinical diagnostics; - novel drugs target signaling pathways that drive tumor growth; - metastasized cancer is expected to change into a chronic disease, requiring therapy response monitoring and repeated personalized choice of targeted therapy. Hence, there is a need to clinically interpret available genomic data in order to diagnose which signaling pathway is driving tumor growth in a patient, including the causative mutation, such that appropriate targeted drugs can be chosen. Currently available pathway analysis tools and databases are not suitable for this.

Companion diagnostics: To address the above need, we are developing computational models of signaling pathways, which can be used as companion diagnostic tools to translate genomic data into meaningful clinical information to enable selection of targeted drugs. The aim is to develop such models for the 10 to 20 most relevant oncogenic pathways, and use them to predict which one is most likely to drive tumor growth in an individual patient, including the probable underlying genomic defect.

A model of the Wnt pathway: As a proof of concept, we have built a computational model of the Wnt pathway, which is active in colon...
adenoma and a main player in colon cancer, but also relevant in breast cancer. Our first generation model of the Wnt pathway covers its transcriptional program, for which we carefully selected a list of Wnt target genes. We have modeled this pathway by a Bayesian network, which interprets the expression levels of the target genes (from Affymetrix U133Plus2.0 arrays), and infers a probability that the Wnt pathway is active in a certain patient tumor sample. The parameters of the model are partly derived from literature and partly fitted on experimental data.

**Results:** We first fitted a model on data from six pairs of Wnt knock-down experiments on colon cancer cell line LS174T, and tested it on a public set of 32 normal colon samples plus 32 colon adenomas from patients (GSE8671). This model perfectly predicted no Wnt activity in the normal samples and an active Wnt pathway in the adenomas. Next, we fitted the model on these 64 patient samples, and tested it on a set of 145 normal colon and colon cancer samples from patients (GSE20916). The model again predicted no Wnt activity in all 44 normal samples, and an active Wnt pathway in all cancer samples, except for four of the 36 samples from surgically removed colon carcinomas, which most likely are the most heterogeneous.

Thirdly, we took the latter model, trained on colon samples, and tested it on three breast cancer data sets, one with 51 breast cancer cell lines (GSE12777) and two sets of breast cancer samples from patients (GSE12276, n = 204; GSE21653, n = 266). Also on this different tissue type, our model correctly predicted Wnt activity for the few breast cancer cell lines that are known to have an active Wnt pathway. For the two patient studies, a significantly higher number of samples of the basal subtype were predicted to have an active Wnt pathway compared to the other subtypes (Fisher’s exact test: p = 0.021 for GSE12276; p = 2.7e-5 for GSE21653), in line with increasing evidence for Wnt activation in the basal subtype.

**P5-05-01**

**Vitamin D Status in Newly Diagnosed Breast Cancer Patients Inversely Correlates with Tumor Size and Moderately Correlates with Outcome.**

**Aims:** To study the impact of Vitamin D (VitD) status and genetic variability in key VitD regulatory genes on patient and breast tumor characteristics, and on breast cancer related outcome.

**Methods:** We examined serum 25-hydroxyvitamin D$_3$ (25OHD) levels in a cohort of 1800 early breast cancer patients treated in Leuven between 2003 and 2010. Serum was collected at diagnosis for all patients; germline DNA from peripheral blood was also available for the majority of them. Serum 25OHD was measured by radioimmunoassay, and single nucleotide polymorphisms (SNP’s) were assessed by Sequenom. Statistical analysis was done by multivariable regression models including age, BMI and season and by a Cox proportional hazard model for analysis of disease-specific survival and disease-free interval.

**Results:** Lower 25OHD serum levels were significantly correlated with larger tumor size (0.4 ng/ml decrease in 25OHD per 1 cm increment in tumor size, p=0.0063) but not with lymph node invasion, estrogen receptor and HER2 status, or tumor grade. Serum 25OHD level was significantly affected by genotypes of rs10741657 and rs1993116 (25-hydroxylase; CYP2R1) and of rs222040, rs7041 and rs4588 (D-binding protein; DBP), yet its observed association with tumor size did not differ between distinct genotypes. Although not statistically significant, patients with higher 25OHD levels tended to have slightly improved survival. Also, a significant increase in relapse risk became apparent after 3 years for patients with 25OHD<30 ng/ml.

**Conclusion:** Vitamin D Level in breast cancer patients inversely correlates with tumor size and moderately correlates with outcome.

**Phenotypic Plasticity in the Normal Breast.**

Sauder CAM, Koziel JE, Choi M, Fox MJ, Badve S, Blosser RJ, Mathieson T, Rufenardt CA, Henry JE, Storniolo AMV, Herbert B-S, Clare SE. Indiana University School of Medicine, Indianapolis, IN; Susan G. Komen for the Cure® Tissue Bank at the IU Simon Cancer Center, Indianapolis, IN; The Catherine Peachy Fund, Inc., Warsaw, IN

Background: The cell of origin of metaplastic carcinoma of the breast (MCB) is an enigma. MCB comprises less than 4% of all breast cancers, and is a member of the subtype of breast cancer referred to as Triple Negative Breast Cancer (TNBC). It is aggressive with a prognosis worse than that for invasive ductal carcinoma NOS (not otherwise specified), as well as other TNBCs. Identification of the histogenesis of MCB is likely to provide clues to its oncogenesis. Differentiation along non-epithelial lineages is also observed in benign lesions of the breast. Adenomyoepitheliomas, thought to arise from myoepithelial cells, have been observed to contain areas of cartilaginous, sebaceous, squamous, and osseous differentiation.

**Methods:** Healthy woman volunteers from central Indiana were invited to donate breast tissue to the Susan G. Komen for the Cure® Tissue Bank at the IU Simon Cancer Center. Starting from the 10 gauge tissue cores, 28 normal mammary epithelial (HME) and 33 normal stromal (HMS) cell lines were established using an organoid isolation method after digestion with enzymes for 24 hours. The HME cell lines were characterized by immunohistochemistry (IHC). Ploidy was determined by karyotype and Interphase FISH mapping with centromere probes for Chromosomes X and 17. Cellular morphology was observed both on two-dimensional and in three-dimensional culture systems. The HME cell lines were subjected to FACS analysis using multiple antibodies including CD24, CD44, Muc1, CD49f, and EpCAM.

**Results:** 96.9% of early passage cells are diploid. The HME cells express vimentin, CK 5/6, p63, CD 10, CK 18, and HER-1 when tested on a set of 145 normal colon and colon cancer samples from patients (GSE8671). This model perfectly predicted no Wnt activity on a public set of 32 normal colon samples plus 32 colon adenomas from patients (GSE20916). The model again predicted no Wnt activity in all 44 normal samples, and an active Wnt pathway in all cancer samples, except for four of the 36 samples from surgically removed colon carcinomas, which most likely are the most heterogeneous.

Thirdly, we took the latter model, trained on colon samples, and tested it on three breast cancer data sets, one with 51 breast cancer cell lines (GSE12777) and two sets of breast cancer samples from patients (GSE12276, n = 204; GSE21653, n = 266). Also on this different tissue type, our model correctly predicted Wnt activity for the few breast cancer cell lines that are known to have an active Wnt pathway. For the two patient studies, a significantly higher number of samples of the basal subtype were predicted to have an active Wnt pathway compared to the other subtypes (Fisher’s exact test: p = 0.021 for GSE12276; p = 2.7e-5 for GSE21653), in line with increasing evidence for Wnt activation in the basal subtype.
Conclusions: Phenotypic plasticity is common to all the HME cell lines characterized to date. Differentiation into cells of mesodermal and ectodermal origin, CD49+/EpCAM- by FACS, and the presence of multiple nucleoli suggest that the isolated cells are a multipotent/ stem cell residing in the normal adult breast. These cells, through a series of yet to be elucidated events, may be the cells of origin of MCB.

P5-05-03
The Effect of Breastfeeding on Molecular Characteristics of Invasive Breast Cancer.
Ellsworth RE, Valente AL, Kane JL, Shriver CD. Henry M. Jackson Foundation, Windber, PA; Windber Research Institute, Windber, PA; Walter Reed Army Medical Center, Washington, DC

INTRODUCTION: Breastfeeding has been associated with an overall decreased risk of developing breast cancer and the protective effect of breastfeeding has been associated with decreased risk of triple negative and estrogen-responsive breast cancer. Although the mechanism by which breastfeeding provides a protective effect is not well-defined, physical changes in the mammary epithelium reflecting maximal differentiation, may be involved.

METHODS: The database of the Clinical Breast Care Project was queried to identify all patients born between 1946 and 1964 (“baby boomers”) with invasive breast cancer who had given birth to at least one living child. Clinicopathologic characteristics were compared between patients who breastfed for at least six cumulative months and those who never breastfed using chi-square and Fisher’s exact tests. RNA was isolated after laser-microdissection of 24 pairs of breastfeeding and non-breastfeeding tumors matched by stage, subtype and grade. Gene expression data was generated using HG U133A 2.0 microarrays and analyzed using the Partek Genomics Suite using a FDR<0.05, 2-fold expression difference to define significance.

RESULTS: Of the 1,008 parous women with invasive breast cancer in the database, 325 (33%) breastfed at least 6 months, 165 (16%) breastfed less than 6 months, and 518 (51%) never breastfed. Women who breastfed ≥6 months were not included in additional analyses. Age at menarche and first birth and number of children did not differ between groups; age at diagnosis was significantly (P<0.0001) lower (54.5 years) in women who breastfed compared to those who did not (61.0 years). No differences were detected between patients who breastfed and those who did not for ethnicity or for any tumor characteristics, including tumor stage, grade or size, hormone, HER2 or lymph node status, or subtype. At the molecular level, however, 21 probes representing 19 genes were differentially expressed between women who breastfed and those who did not. Eleven genes, including HAPLN1, had significantly higher and 8 genes, including LGALS7, had significantly lower expression in tumors from women who did not breastfeed.

CONCLUSIONS: Despite the matching of tumor samples, and lack of differences in pathological characteristics between women who breastfed ≥6 months and those who did not breastfeed, differentially expressed genes were identified between tumors from the two groups. Many of the differentially expressed genes have been associated with prognosis, especially in ER negative breast tumors. These data suggest that breastfeeding does alter the underlying molecular characteristics of invasive breast tumors, and may reflect alterations in exposure to estrogen levels during breastfeeding.

P5-05-04
Bisphenol-A Modulates Estrogen Receptor Alpha and Compromises Tamoxifen-Induced Apoptosis.
Goodson III WH, Luciani MG, Sayeed A, Jaffee I, Moore II DH, Dairkee SH. California Pacific Medical Center Research Institute, San Francisco, CA; Kimmel Cancer Center, San Francisco, CA; California Pacific Medical Center, San Francisco, CA; University of California, San Francisco, CA

BACKGROUND: Antiestrogens are important for treatment and prevention of breast cancer. Such drugs influence multiple pathways involved in regulation of cell survival - including apoptosis. In previous work, exposure of human, benign, high-risk donor breast epithelial cells (HRBECs) to the xenoestrogen (XE) bisphenol-A (BPA) induced gene expression changes predicting disruption of apoptotic signaling (Dairkee et al, Cancer Research 2008). Therefore, we hypothesized that antiestrogenic, pro-apoptotic effects of tamoxifen are likely modulated under the influence of XEs. Because the environmental XE , BPA is routinely detected in a large percentage of random human blood samples, we employed functional tests to determine whether BPA interferes with tamoxifen-induced apoptosis in XE-exposed HRBECs.

METHODS: With IRB approval and written informed consent, HRBECs were obtained by random periareolar fine needle aspiration (RPFNA) from women who were high risk on the basis of personal or family history of breast cancer, breast density, or high-risk histology. Primary HRBEC cultures were treated for one week with a low concentrations of BPA corresponding to levels reported in human body fluids. Estrogen Receptor (ER)-α and -β were measured by Western blot (n=6). Altered response to tamoxifen toxicity was measured by analyzing quantitative changes in the Annexin V-positive apoptotic cell population (n=8).

RESULTS: After one-week exposure to BPA, ER-α increased in six of six cases, ER-β decreased in 5 of 6 cases, and we observed a 25 percent reduction in tamoxifen-induced apoptosis. Prior exposure to BPA at the high concentration range detected in the human population reduced tamoxifen efficacy by 50 percent. There was a dose response of evasion of apoptosis to increasing concentrations of BPA (P<0.001, two-sided test for slope fixed effect in a linear mixed effects regression). Prior exposure to another XE, methylparaben (MP), caused a similar dose-dependent decline in tamoxifen-induced apoptosis (p<0.001).

CONCLUSION: BPA and MP, in a range of concentrations measured in humans, prevent tamoxifen-induced apoptotic cell death. For BPA this involves upregulation of ER-α and downregulation of ER-β. Because these XEs are widespread in the American population, they may play a role in limiting the prophylactic and therapeutic efficacy of tamoxifen and other hormone-based therapies.

P5-05-05
Human Papilloma Virus Identification in Intraductal Papilloma and Breast Cancer Using Broad-Spectrum Primers.
Balci FL, Bender O, Coskun F, Duzgan AP, Saylam B, Yuncu E, Rota S, Fidan I, Feldman S, Soran A. Numune Training and Research Hospital, Ankara, Turkey; Okmeydani Training and Research Hospital, Istanbul, Turkey; Gazi University School of Medicine, Turkey; Columbia University College of Physicians and Surgeons, New York; University of Pittsburgh, Magee-Womens Hospital, Pittsburgh

BACKGROUND: There is limited data about Human Papilloma Virus (HPV) presence in intraductal papilloma, and there are some conflicted studies about the effects of HPVs on breast cancer. Most
of these studies have methodological pitfalls as well. We conducted a retrospective paraffin block study to understand the presence of HPV in papilloma and cancer tissues with broad-spectrum primers. **Methods:** Twenty seven intraductal papilloma and 18 breast cancer patients' paraffin blocks were obtained from the patients who underwent ductoscopy aided papillomectomy or mastectomy. In totally 87 histopathological samples, HPV-DNA were identified by real time PCR and broad-spectrum genotyping was performed by in situ hybridization. The cancer patients were evaluated according to the status of Estrogen Receptor (ER), Progesteron Receptor (PR) and ErbB-2 positivity. **Results:** The mean age±SD was 49±16 in papilloma and 52±14 in breast cancer patients. We found that 29.6% (8 of 27) of intraductal papillomas and 44.4% (8 of 18) of breast cancer paraffin blocks had HPV-DNA positivity by PCR in situ hybridization with broad spectrum primers. Fifty percent (4 of 8) of HPV-DNA positive papillomas had only type 11; in one, only type 6; in one, mixture of type 6,11; in one, mixture of type 11, 39; and in one, mixture of type 11, 39, 82 was detected. Breast cancer lesions had only type 11 of HPV-DNA positivity in 62.5% (5 of 8) of cases; in one, mixture of type11, 39; in one, mixture of type 11, 82; in one, mixture of type 6, 11, 39 was detected. In seven HPV-DNA positive cancer patients, ER /PR and/or ErbB-2 was positive, but it was only positive in one triple negative patient. **Conclusion:** HPVs may have a role in developing papilloma and breast cancer. Validation of HPVs role in the etiology of breast cancer/ papilloma, require further studies to understand whether the HPVs are episomal or integrated during the tumorigenesis.

**P5-05-06**  
Roe T, Hoar F, Tzelepis C. University of Birmingham, Birmingham, United Kingdom; City Hospital, Birmingham, United Kingdom  
**Background:** Mounting evidence implicates iron in the development of a number of cancers, including breast. The responsible mechanism is poorly understood in breast cancer, although recent work has demonstrated irregular expression of various molecular iron transporters.  
**Materials and Methods:** Immunohistochemistry on archived material was used to evaluate differences in expression of iron and haem exporters, importers and storage proteins between breast cancer, DCIS and normal breast tissue. The results were corroborated by Western blotting and RT-qPCR on protein and RNA samples generated from matched normal and cancer specimens collected at mastectomy. The ability of benign and malignant breast cells in vitro to accumulate excess iron in the presence of exogenous iron/ haem was evaluated with a ferrozine assay. In addition the effect of exogenous iron and haem on cell phenotype in vitro was assessed in benign and malignant cell lines. Assays utilised included viability (MTT), proliferation (BrdU), migration, anchorage-independent growth (colony formation) and invasive capacity. These assays were then repeated in the presence of iron chelators to investigate their potential utility as a therapeutic modality.  
**Results:** Statistically significant increases (p<0.05) were observed in expression of the iron importers DCytB, DMT1 and TFR in breast cancer relative to normal tissue. Levels of the storage protein ferritin were also significantly raised. The iron exporters ferroportin and hephaestin were significantly under-expressed in breast cancer, while hepcidin (which induces exporter degradation) was over-expressed. Levels of the haem importer HCP1 and the exporters BCRP and FLVCR were all significantly down-regulated in cancer relative to normal. Both benign and malignant breast cells were capable of importing excess iron, although only malignant cells could import excess haem. Iron induced increased viability and proliferation in benign cells but had no effect on their migratory or invasive capability, or their ability to form colonies. Haem had no effect on benign cell phenotype. Iron and haem both had significantly positive effects on all these aspects of cell phenotype when introduced to malignant breast cells in vitro. Iron chelators were capable of abrogating these positive effects.  
**Discussion:** Archived material and prospectively collected matched tissue pairs demonstrate that breast cancers exhibit altered expression of the proteins involved in transporting iron and haem through the cell. In vitro experiments reveal malignant cells to be capable of taking up both substances, which both appear to drive a more malignant phenotype. These in vitro changes can be reversed through the introduction of iron chelators, implying possible efficacy as a novel therapy in breast cancer.

**P5-05-07**  
The Msp1 Polymorphism of Cytochrome P-450 CYP1A1 in Asymptomatic Women with Breast Cysts.  
Fenile R, Nazário A, Facina G. Federal University of São Paulo, São Paulo, SP, Brazil; Federal University of São Paulo, Brazil; Federal University of Sao Paulo, Brazil  
The objective of this study was to determine the prevalence of the cystic form of fibrocystic breast changes among women from different age groups correlated with the presence of the Msp1 polymorphism of cytochrome P-450 CYP1A1. **Methods:** A retrospective, case-control study (was carried out with ultrasound examination) was performed on 197 women divided into two groups: 44 women with cystic breast disease (cases) and 153 women without breast disease (controls). The Msp1 polymorphism of CYP1A1 was detected by PCR and DNA sequencing. The Msp1 polymorphism was defined as the presence of the Msp1 allele within the CYP1A1 gene. **Results:** The mean age±SD was 49±16 in papilloma and 52±14 in breast cancer patients. We found that 29.6% (8 of 27) of intraductal papillomas and 44.4% (8 of 18) of breast cancer paraffin blocks had HPV-DNA positivity by PCR in situ hybridization with broad spectrum primers. Fifty percent (4 of 8) of HPV-DNA positive papillomas had only type 11; in one, only type 6; in one, mixture of type 6,11; in one, mixture of type 11, 39; and in one, mixture of type 11, 39, 82 was detected. Breast cancer lesions had only type 11 of HPV-DNA positivity in 62.5% (5 of 8) of cases; in one, mixture of type11, 39; in one, mixture of type 11, 82; in one, mixture of type 6, 11, 39 was detected. In seven HPV-DNA positive cancer patients, ER /PR and/or ErbB-2 was positive, but it was only positive in one triple negative patient. **Conclusion:** HPVs may have a role in developing papilloma and breast cancer. Validation of HPVs role in the etiology of breast cancer/ papilloma, require further studies to understand whether the HPVs are episomal or integrated during the tumorigenesis.

**P5-05-06**  
Roe T, Hoar F, Tzelepis C. University of Birmingham, Birmingham, United Kingdom; City Hospital, Birmingham, United Kingdom  
**Background:** Mounting evidence implicates iron in the development of a number of cancers, including breast. The responsible mechanism is poorly understood in breast cancer, although recent work has demonstrated irregular expression of various molecular iron transporters.  
**Materials and Methods:** Immunohistochemistry on archived material was used to evaluate differences in expression of iron and haem exporters, importers and storage proteins between breast cancer, DCIS and normal breast tissue. The results were corroborated by Western blotting and RT-qPCR on protein and RNA samples generated from matched normal and cancer specimens collected at mastectomy. The ability of benign and malignant breast cells in vitro to accumulate excess iron in the presence of exogenous iron/ haem was evaluated with a ferrozine assay. In addition the effect of exogenous iron and haem on cell phenotype in vitro was assessed in benign and malignant cell lines. Assays utilised included viability (MTT), proliferation (BrdU), migration, anchorage-independent growth (colony formation) and invasive capacity. These assays were then repeated in the presence of iron chelators to investigate their potential utility as a therapeutic modality.  
**Results:** Statistically significant increases (p<0.05) were observed in expression of the iron importers DCytB, DMT1 and TFR in breast cancer relative to normal tissue. Levels of the storage protein ferritin were also significantly raised. The iron exporters ferroportin and hephaestin were significantly under-expressed in breast cancer, while hepcidin (which induces exporter degradation) was over-expressed. Levels of the haem importer HCP1 and the exporters BCRP and FLVCR were all significantly down-regulated in cancer relative to normal. Both benign and malignant breast cells were capable of importing excess iron, although only malignant cells could import excess haem. Iron induced increased viability and proliferation in benign cells but had no effect on their migratory or invasive capability, or their ability to form colonies. Haem had no effect on benign cell phenotype. Iron and haem both had significantly positive effects on all these aspects of cell phenotype when introduced to malignant breast cells in vitro. Iron chelators were capable of abrogating these positive effects.  
**Discussion:** Archived material and prospectively collected matched tissue pairs demonstrate that breast cancers exhibit altered expression of the proteins involved in transporting iron and haem through the cell. In vitro experiments reveal malignant cells to be capable of taking up both substances, which both appear to drive a more malignant phenotype. These in vitro changes can be reversed through the introduction of iron chelators, implying possible efficacy as a novel therapy in breast cancer.
P5-06-01
Gene Expression Analysis of Resistance to Bevacizumab in a VEGF-Reinforced Xenograft Model of ER-Positive Breast Cancer.
Gökmen-Polar Y, Toroni RA, Goswami C, Sanders KL, Mehta R, Sirimalle U, Tanasa B, Shen C, Li L, Ivan M, Badve S, Sledge GW. Indiana University School of Medicine, Indianapolis, IN; University of Medicine and Pharmac, La Jolla, CA

Background: Bevacizumab, a monoclonal antibody targeting vascular endothelial growth factor (VEGF), had promising therapeutic efficacy in breast cancer. However, intrinsic or acquired resistance is common in the clinic. To improve our understanding of the underlying mechanisms of resistance to bevacizumab (BEV), we report the gene expression analysis of resistance to bevacizumab in a VEGF-overexpressing xenograft model of ER-positive breast cancer.

Methods: We developed a nude mouse xenograft model of resistance to anti-VEGF therapy with BEV in which MCF-7 control (ML20) or MCF-7 VEGF (MV165) transfectants were implanted in mammary fat pads, allowed to grow, then treated with BEV, with collection of tumor at early or late time points (while responding (R) to or progressing (NR) on anti-VEGF therapy). To elucidate differentially expressed gene profiles associated with tumor resistance to BEV, we performed whole-genome gene expression analysis (Human WG-6v2 Expression Beadchips, Illumina) and miRNA profiling (TaqMan ArrayHuman MicroRNA A+B Cards Set v3.0, Applied Biosystems). Validation of the chosen genes was performed using quantitative real-time RT-PCR (qRT-PCR).

Results: Gene expression analysis revealed differentially regulated genes in the MV165-NR group compared with the MV165-R group. Among the significant genes, Follistatin (FST) and HEY2 were the top genes upregulated in NR compared to R by ANOVA. Expression of HEY2 is induced by the Notch signaling pathway. Using qRT-PCR, we validated the expression of FST and Notch in our system. FST1 was significantly decreased (Fold change= -3.2; P=0.03) in the R group compared with vehicle in MV165 xenografts. In contrast to R group, FST was upregulated significantly (Fold change= 9.3; P=0.05) in the NR group. Notch4 displayed increased levels of expression in NR group, but it did not reach significance (P=0.23). In addition, correlation of mRNA and miRNA profiles showed that miRNAs targeting FST and Notch4 were differentially regulated in NR group compared to R group in MV165 xenograft tumors. Among the miRNAs, TGF-β-induced oncomiR miR-181a is up-regulated in NR and targets both FST and Notch4. Other miRNAs that target both Notch4 and FST include miR-1, miR-133a, miR-133b, and mir-449b.

Conclusion: Our data serve as a potential mechanistic explanation for acquired resistance to bevacizumab. These data may shed light on the transitory effect of BEV observed in the E2100 first-line metastatic breast cancer trial, where VEGF-targeted therapy prolongs progression-free survival in metastatic breast cancer without improving overall survival.

P5-06-02
Response and Acquired Resistance of BRCA1-Deficient Triple-Negative Breast Cancer Xenografts to Alkylators or PARP Inhibitors.
Sirimalle U, Tanasa B, Shen C, Li L, Ivan M, Badve S, Sledge GW, Jonkers J. Netherlands Cancer Institute, Amsterdam, Netherlands; Bellvitge Biomedical Research Institute (IDIBELL), Barcelona, Spain; Gene function, Breakthrough breast cancer research centre, London, UK

Background. BRCA1 mutated breast tumor cells are defective in DNA repair by homologous recombination and therefore especially sensitive to treatment with DNA double-strand break (DSB) inducing agents, such as alkylators or PARP inhibitors. However, such tumors can eventually develop therapy resistance. Understanding therapy resistance mechanisms may help in designing treatment strategies to overcome therapy resistance.

Methods. We have developed BRCA1-deficient triple-negative breast cancer (TNBC) xenograft models by implantating fresh human breast tumor pieces and subsequent serial passaging. These models show epigenetic loss of BRCA1 due to promoter hypermethylation or genetic inactivation of BRCA1 due to a frameshift mutation (c.2210delC) resulting in a premature stop codon (p.Thr737LeufsX15). We have used these BRCA1-deficient TNBC models to study response and acquisition of resistance to alkylating therapy (cisplatin, melphalan) and the clinical PARP inhibitor olaparib.

Results. Treated tumors were sensitive to the alkylators cisplatin or melphalan or the PARP inhibitor olaparib, in some cases resulting in complete remission with no palpable tumor left. However, relapses did occur in most cases and repeated treatment of recurrent tumors eventually led to acquired resistance.

Since restoration of BRCA1 function has been suggested as a mechanism of therapy resistance (Swisher et al., Cancer Res 2008; 68: 2581), we determined BRCA1 expression in therapy-sensitive and -resistant tumors by Western blot analysis. While no full length BRCA1 protein could be detected in the therapy-sensitive tumors, expression of full length BRCA1 protein was found in the majority of cisplatin resistant and olaparib resistant tumors. BRCA1 reexpression in the therapy-resistant BRCA1-c.2210delC tumors was caused by genetic restoration of the reading frame due to reversion to the wildtype sequence or additional deletions near the c.2210delC mutation. BRCA1-re-expression in the therapy-resistant TNBC xenografts with epigenetic loss of BRCA1 was caused either by loss of BRCA1 promoter methylation or by complex rearrangements at the BRCA1 locus.

Conclusion. Although BRCA1-deficient TNBC xenografts are initially very sensitive to alkylating agents and olaparib, resistance to treatment develops in almost all treated tumors. This acquired resistance is frequently associated with re-expression of BRCA1 due to secondary mutations or loss of promoter methylation.
P5-06-03
Gene Expression Associated with Breast Cancer Primary and Secondary Resistance to Neoadjuvant Chemotherapy.
Fujiki FK, Katayama MLH, Brentani H, Carraro DM, Abreu APS, Barros Filho MC, Oliveira CT, Caldeira JRF, Góes JCS, Brentani MM, Folgueira MAK. Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil; Faculdade de Medicina da USP, Sao Paulo, Brazil; Hospital do Cancer A.C. Camargo, Sao Paulo, Brazil; Instituto Brasileiro de Controle do Cancer, Sao Paulo, Brazil; Hospital do Cancer A.C. Camargo, Sao Paulo, Brazil; Hospital Amaral Carvalho, Jau, Sao Paulo, Brazil

In breast cancer, neoadjuvant chemotherapy may provide valuable information on tumor resistance mechanisms, as variable degrees of tumor response, from pathological complete response until progressive disease, may be observed. To have a better insight of the resistance process to chemotherapy, we have compared resistant pre chemotherapy samples (representing primary or intrinsic resistance) and residual post chemotherapy from partially responsive tumors (secondary or acquired resistance), by means of their transcriptional profile. Tumors from 36 patients submitted to neoadjuvant chemotherapy (4 cycles doxorubicin and cyclophosphamide) were collected (12 pre-chemotherapy from primary resistant samples and 24 post chemotherapy from residual samples) and analyzed by cDNA microarray (training set, n=25, 9 resistant; 16 residual) and/or by qRT-PCR (technical validation set, n=11, and biological validation set, n=11; 8 resistant; 14 residual). In samples from the training set analyzed using a cDNA microarray platform with 4608 genes (Student’s t test; p <0.01; FDR <10), 138 genes were differentially expressed between resistant and residual tumors, which correctly classified tumors in unsupervised hierarchical clustering analysis, with high confidence. Genes were mainly involved in regulation of cell cycle, regulation of cell growth, cell division, protein modification and DNA dependent DNA replication. Among genes involved in cell growth and cell division, 12 were selected to be further evaluated, using qRT-PCR: MORF4L2, NOTCH2, HTRA1, DLC1, CYR61, MLH1, CHFR, CDC16, CDKL1, NOTCH2, HRAS, CDK2, in technical and biological validation sets of samples. In the technical validation group, a significant positive correlation was observed for the expression of five genes (as evaluated by microarray and qRT-PCR, Spearman correlation, p<0.05), which were then tested in discriminant analysis to detect the best combination to classify resistant and residual tumors. The best combinations included all the five selected genes, CYR61/DLC1/CDKL1/NOTCH2/HTRA1, as well as three of them, CYR61/DLC1/HTRA1, which correctly classified 100% and 91% of tumors from the technical and biological validation groups (100% and 73% in leave one out cross validation, respectively). CYR61 was more expressed in residual samples, however no other main individual gene expression differences were detected. Our data indicate that primary and secondary chemoresistance may present some differences, involving mainly cell growth and cell proliferation processes. CYR61, a CCN growth factor family member, may be synthesized by tumor cells as well as by adjacent fibroblasts, exhibiting autocrine and paracrine actions, stimulating proliferation, migration and chemoresistance. CYR61 enhanced expression in post chemotherapy samples suggests that epithelial stromal interactions may be active players in the chemoresistance process, deserving more detailed analysis for targeted therapies. Supported by FAPESP.

Ekalyongco RC, Mukohara T, Kataoka Y, Kiyota N, Fujiwara Y, Minami H. Kobe University Graduate School of Medicine, Kobe, Japan; Kobe University Hospital Cancer Center, Kobe, Japan

Background: No studies have yet clarified the mechanism of acquired resistance to insulin-like growth factor-1 receptor (IGF-1R) tyrosine kinase inhibitor (TKI). Our previous study of 16 breast cancer cell lines found that only MCF-7 expressed high levels of insulin receptor substrate (IRS)-1 and was sensitive to the IGF-1R-TKI NVP-AEW541.

Material and Methods: We developed a model of acquired resistance to NVP-AEW541 by continuously exposing MCF-7 cells to NVP-AEW541, naming the model MCF-7-NR. To explore the mechanism of acquired resistance to NVP-AEW541, the effects of NVP-AEW541 on cell growth and IGF-1R signaling in MCF-7 and MCF-7-NR cells were examined.

Results: With Western blot analysis, we found that MCF-7-NR had much lower levels of IRS-1 than parental MCF-7. While phosphorylation of Akt was completely inhibited by administration of NVP-AEW541 (3 μM) in both cell lines, phosphorylation of S6K remained high only in MCF-7-NR. The notion of Akt-independent S6K phosphorylation in MCF-7-NR was further supported by the fact that cell growth and phosphorylation of S6K was affected by administration of the Akt inhibitor perifosine to a lesser degree in MCF-7-NR than in MCF-7. Further, the mTOR inhibitor everolimus inhibited phosphorylation of S6K and cell growth equally in both lines. Screening of MCF-7 and MCF-7-NR lines for phosphorylation of 42 receptor tyrosine kinases with and without 3μM NVP-AEW541 showed that Tyro3 phosphorylation remained high only in MCF-7-NR cells. Gene silencing of Tyro3 using siRNA resulted in reduced cell growth, decreased phosphorylation of phosphoinositide-dependent kinase-1 (PDK-1) and protein kinase C α/βII, reduced expression of cyclin D1 in the MCF-7-NR line, with minimal effects evident in the MCF-7 line.

Discussion: Findings from our current study support the possibility of predicting sensitivity to NVP-AEW541 by measuring IRS-1 expression, as hypothesized in our previous study. Akt-independent activation of mTOR/S6K by an as-yet-undefined mechanism appears to induce acquired resistance to NVP-AEW541, and as such mTOR inhibitors may have therapeutic value. Tyro3 upregulation and migration of control of cellular growth and cyclin D1 expression may also induce resistance to NVP-AEW541. Although the validity of these findings should be evaluated in further preclinical studies and eventually in clinical trials, our observations may lead to individualized use of NVP-AEW541 and the development of “back-up drugs” against tumors that acquire resistance to NVP-AEW541.

Switching Addictions between HER2 and FGFR2 in HER2-Positive Breast Tumor Cells: FGFR2 as a Potential Target for Salvage after Lapatinib Failure.
Tsurutani J, Azuma K, Sakai K, Aro T, Nishio K, Nakagawa K, Kinki University Faculty of Medicine, Osaka, Japan; Kobe University Graduate School of Medicine, Osaka, Japan

Agents that target HER2 have improved the prognosis of patients with HER2-amplified breast cancers. However, patients who initially respond to such targeted therapy eventually develop resistance to the treatment. We have established a line of lapatinib-resistant breast cancer cells (UACC812/LR) by chronic exposure of HER2-amplified and lapatinib-sensitive UACC812 cells to the drug. The mechanism
by which UACC812/LR acquired resistance to lapatinib was explored using comprehensive gene hybridization. The FGFR2 gene in UACC812/LR was highly amplified, accompanied by overexpression of FGFR2 and reduced expression of HER2, and a cell proliferation assay showed that the IC \textsubscript{50} of PD173074, a small-molecule inhibitor of FGFR tyrosine kinase, was 10,000 times lower in UACC812/LR than in the parent cells. PD173074 decreased the phosphorylation of FGFR2 and substantially induced apoptosis in UACC812/LR, but not in the parent cells. FGFR2 appeared to be a pivotal molecule for the survival of UACC812/LR as they became independent of the HER2 pathway, suggesting that a switch of addiction from the HER2 to the FGFR2 pathway enabled cancer cells to become resistant to HER2-targeted therapy. The present study is the first to implicate FGFR in the development of resistance to lapatinib in cancer, and suggests that FGFR-targeted therapy might become a promising salvage strategy after lapatinib failure in patients with HER2-positive breast cancer.

The RNA Binding Protein FUS Is A Potential Marker for Breast Cancer Progression and Therapy Response.

Brooke GN, Bevan CL, Rudraraju B, Palmieri C. Imperial College London, London, United Kingdom

Background: The RNA binding protein FUS is a multifunctional protein that has recently been demonstrated to be directed to target genes via non-coding RNA, where it represses transcription via disruption of the transcriptional complex. We have shown that FUS is an important regulator of prostate cancer cell growth; FUS over-expression causes G1 arrest, promotes apoptosis and blocks proliferation \textit{in vitro} and \textit{in vivo}, whereas knock-down increases proliferation. This regulation appears to be, at least in part, via direct regulation of \textit{cyclin} D1. Further, analysis of patient samples demonstrated that FUS levels are inversely correlated with Gleason grade and directly correlated with survival and the presence of bone metastases. We hypothesised that FUS is a predictive and/or prognostic marker for hormone-dependent cancers. Materials and Methods: FUS expression in breast cancer was analysed \textit{in silico} and using Western blotting and immunohistochemistry on a tumour microarray. FUS levels were knocked down by siRNA in MCF-7 cells and chemosensitivity analysed using caspase 3/7 assays.

Results: Analysis of the Finak dataset (2008) demonstrated that FUS expression is significantly lower in breast cancer compared to normal breast. Immunohistochemistry revealed that FUS expression is also inversely correlated with grade. Importantly, FUS expression was also correlated with survival (Kaplan-Meier Plotter); significantly longer relapse free survival was seen in patients whose tumours had high levels of FUS. FUS expression also appears to correlate with therapy response since analysis of the Chang dataset (2003) revealed that FUS levels are significantly lower in patients resistant to Docetaxel and we found FUS levels to be lower in the tamoxifen resistant MCF-7 cell line (MCF-7 TAMR) compared to the parental line. We therefore hypothesised that loss of FUS expression may be driving therapy failure. In support of this, reducing FUS expression in the parental MCF-7 line resulted in a significant reduction in docetaxel-induced Caspase 3/7 activity, suggesting that FUS is a regulator of chemosensitivity. Discussion: FUS may be an important regulator of breast cancer progression since its levels are inversely correlated with grade and directly correlated with relapse free survival. Further, lower FUS expression is also correlated with reduced hormone therapy and chemo-sensitivity. Since knock-down of FUS reduced MCF-7 chemosensitivity, we believe that the observed changes in FUS expression are, in part, driving therapy failure and hence propose that FUS is a novel target and biomarker for breast cancer.

**P5-06-07**

The Mechanisms of Autophagy Involved in the Effects of Everolimus (RAD001) on Overcoming Multidrug Resistance of Breast Cancer Cell Line MCF-7/ADR.

Liu Z-B, Hou YF, Xu W-H, Ling H, Shao Z-M. Breast Cancer Institute, Shanghai, China

To investigate the effects of everolimus on overcoming multidrug resistance of breast cancer cell line MCF-7/ADR and to explore its mechanisms of action. MCF-7 and MCF-7/ADR cells were treated with ADM, everolimus alone or by combination at different concentrations and different times. Changes of cell morphology were observed by microscopy. Apoptosis induced by ADM or everolimus were measured by flow cytometry with PI staining and ANNEXIN V-FITC staining. Western blot was used to evaluate the expression level of apoptosis and autophagy-related molecules. To investigate specifically the role of autophagy in everolimus treated breast cancer cell lines, we used a siRNA approach, targeting autophagy gene, ATG5. The CI for each experimental combination was calculated. Dose-dependent inhibition of cell proliferation was observed with ADM and everolimus for both 24 and 48h. MCF-7/ADR was resistant to ADM. The addition of everolimusid increased the sensitivity of MCF-7/ADR cells to ADM, as indicated by the ID \textsubscript{50} by 2.6 fold for 24h; but for 48h, everolimus is even able to reduce the ID \textsubscript{50} of ADM much higher to 5-10 times. Thus, inhibition of mTOR does appear to restore ADM sensitivity in MCF-7/ADR cells, especially for a longer synergistic time (48h). Everolimus alone induced a decrease in the phosphorylation of two downstream molecules of mTOR, including p70S6K and 4E-BP1, confirming the role of everolimus in mTOR signaling regulation, whereas everolimus in combination with ADM caused an almost complete suppression of p70S6K and 4E-BP1 phosphorylation. When cells were exposed to both everolimus and ADM for 24h, there was no loss of procaspase-3 nor was there a concentration-dependent increase in cleaved caspase protein. On the contrary, ADM administration induced the proteolytic cleavage of caspase 3, and when ADM was combined with everolimus, a further increase in the expression of cleaved caspase 3 was detected in 48h. Cells treated with CQ markedly enhanced ADM-induced cell death in MCF-7/ADR cells in early stage (24h). As observed with immunoblot analysis, cotreatment of everolimus and ADM increased expression level of ATG5 and LC3-II to -I ratios, also accelerated the rate of cell death. That’s why cotreatment with CQ resulted in a rapid drop in cell viability with complete cell death observed by CCK-8 test. Immunoblot analysis also revealed non significant change of ATG5 and LC3-II within 48h of everolimus on the base of ADM treatment. Silencing ATG5 resulted in a marked downregulation of ATG5 but increased the level of proteolytic cleavage of caspase 3 induced by ADM alone and cotreatment of everolimus and ADM when cells were exposed to both everolimus and ADM for 24h. This result was consistent with our finding using the Annexin-V apoptotic assay. For 48h, the results of proteolytic cleavage of caspase 3 were similar as when cells weren’t silenced by ATG5 siRNA. In conclusion, autophagy plays bidirectional roles in the mechanisms of tumor cells suppression of everolimus combining MCF-7/ADR. Especially in late stage, inhibiting autophagy helps to overcoming resistance of everolimus and sensitizes cancer cells to ADM-induced apoptosis.

**Mesenchymal Stem Cells and Carcinoma-Associated Fibroblasts Sensitize Breast Cancer Cells in 3D Cultures to Kinase Inhibitors.**

Dittmer J, Dittmer A, Oerlecke I, Leyh B, Martens JWM, Thomssen C. Clinic for Gynecology University Halle, Germany; Erasmus University Medical Center

Background: Bone-derived mesenchymal stem cells (MSCs) are attracted to cancer lesions and may differentiate to CAFs. By interacting with cancer cells, MSCs and CAFs may promote cancer progression and modulate drug sensitivity.

Material and Methods: To analyze ability of MSCs and CAFs to modulate drug response, we generated spheroids of MCF-7 or MDA-MB-231 breast cancer cells in the absence or presence of human (h) MSCs or hCAFs and tested the susceptibility of the breast cancer cells to three different kinase inhibitors (TKI258, RAD001 and RAF265) as used in cancer therapy.

Results: While MSCs and CAFs did not affect the response of either breast cancer cell line to PDGFR/FGFR/VEGFR inhibitor TKI258, they sensitized breast cancer cells to the mTOR inhibitor RAD001. In MCF-7 cells, this was accompanied by increased apoptosis. hMSCs and to a lesser extent hCAFs also enhanced the cytotoxic effect of RAF inhibitor RAF265 on MDA-MB-231 cells. Searching for the mechanism that underlies the effect of stromal cells on RAF265 response we found that stromal cells inhibited RAF265-induced increase in ERK1/2 phosphorylation, supported RAF265-dependent downregulation of PKCalpha (protein kinase Calpha) and prevented RAF265-induced conversion of LC3B, a marker of autophagy. To mimic the changes in ERK1/2 phosphorylation and PKCalpha expression in response to the stromal cells, we treated cells with MEK1 inhibitor U0126 or PKCalpha inhibitor Gö6976, respectively. U0126, but not Gö6976, was as effective as hMSCs in sensitizing MDA-MB-231 cells to RAF265.

Discussion: Our data suggest that hMSCs and hCAFs increased the cytotoxic effect of RAF265 on MDA-MB-231 cells by downregulating ERK1/2 phosphorylation. In summary, this study shows that hMSCs are able to render breast cancer cells more susceptible to kinase inhibitors and that, to the most part, hCAFs to which hMSCs can differentiate are able to mimic the drug-sensitizing effects of hMSCs.

**P5-06-09**

**Acquired Sensitivity to TRAIL Mediated Apoptosis in Lapatinib Resistant SKBR3 Cells.**

Eustace AJ, Browne BC, McDermott M, Gallagher C, Watson W, Crown J, O’Donovan N. Dublin City University, Dublin, Ireland; University College Dublin, Dublin, Ireland; St. Vincents University Hospital, Dublin, Ireland

**Introduction**

Lapatinib, a dual EGFR/HER2 tyrosine kinase inhibitor is approved for the treatment of trastuzumab-refractory HER2 positive metastatic breast cancer. However, not all HER2 positive tumors respond to lapatinib and patients who initially respond frequently relapse. Understanding the molecular alterations associated with acquisition of lapatinib resistance may lead to the identification of targets to overcome resistance. Thus, the aim of this study was to examine changes in apoptosis in a model of acquired lapatinib resistance.

**Methods**

SKBR3 cells were treated with 250 nM lapatinib twice weekly for 6 months to establish the lapatinib resistant cell line SKBR3-L. The effects of TNF-related apoptosis-inducing ligand (TRAIL) and tumour necrosis factor-α (TNF-α) on cell survival and apoptosis induction were examined in SKBR3 and SKBR3-L cells, using the acid phosphatase proliferation assay and the terminal deoxynucleotidyl transferase dUTP nick end labelling (TUNEL) assay. Cleavage of poly ADP ribose polymerase (PARP) was used to confirm apoptosis. TRAIL-1 and TRAIL-2 receptor expression were measured by flow cytometry (FACS).

**Results**

In SKBR3-L cells, TRAIL treatment (25 ng/ml) significantly inhibited cell survival (94.0 ± 12.0 %) compared to the SKBR3 cells (11.0 ± 2.2 %). Treatment with TNF-α (0.5 ng/ml) also resulted in significant inhibition of cell survival (68.2 ± 10.1 %) in SKBR3-L cells compared to SKBR3 cells (9.4 ± 9.0 %). TRAIL (25 ng/ml) induced a low level of apoptosis in SKBR3 cells (7.0 ± 4.0 %), whereas in SKBR3-L cells, TRAIL (25 ng/ml) induced significant apoptosis (54.8 ± 2.6 %, p < 0.001), as determined by the TUNEL assay. We confirmed by western blotting that TRAIL treatment for 72 hours resulted in higher levels of PARP cleavage in SKBR3-L cells compared to SKBR3 cells. Both western blotting and FACS analysis of TRAIL receptor expression showed that neither TRAIL-1 nor TRAIL-2 receptor expression was significantly elevated in SKBR3-L cells compared to SKBR3 cells.

**Conclusions**

SKBR3-L cells, a model of acquired lapatinib resistance, display significant sensitivity to TRAIL induced apoptosis compared to the parental cell line SKBR3. Thus, targeting TRAIL may represent a novel therapeutic strategy to overcome acquired lapatinib resistance.

**Leptin Signaling Impacts Notch and Wnt Crosstalk in Breast Cancer.**

McGlothen TZ, Gillespie C, Colbert L, Blaylock-Hogans D, Guo S, Gonzalez-Perez RR. Morehouse School of Medicine, Atlanta, GA; Spelman College, Atlanta, GA

**Background:** Triple negative breast cancer (TNBC: ER-, PR- and Her2/neu-) is an aggressive form of the disease that disproportionately affects women of color, has an early onset, and is associated with poor survival and a resistance to common therapeutic treatments. We have previously demonstrated an association between the adipocytokine leptin and Notch signaling pathways in breast cancer. Notch participates in a crosstalk relationship with many signaling pathways involved in carcinogenesis, including Wnt and leptin, which could in turn increase tumor burden and cell survival of MMTV-Wnt1 obese mice. We hypothesize that leptin signaling crosstalk with Notch and Wnt is instrumental in the development of drug-resistant features (increased survival and proliferation) of TNBC.

**Objective:** The aim of this study was to determine whether leptin mediated crosstalk of the Notch and Wnt pathways has a differential impact on TNBC compared to ER+ cells.

**Materials & Methods:** ER+ MCF-7 and TNBC-MDA MB-231 cells (96-well plate; 1x104 cells/well) were serum deprived for 24 hours and treated with varying doses of Doxorubicin and Cisplatin for 24h in conjunction with pharmacological doses of leptin, leptin peptide antagonist (LPrA2), Wnt agonist (Wnt-1) and antagonist (Wnt-2f-1). Cell proliferation was measured via WST assay. The effect of the various treatments on the activation of Wnt (total/p85-catenin), Notch (Notch 1-4 and JAG1/DI-4 and targets survivin/Hey2), and leptin (STAT3 and targets VEGF/VEGFR-2) signaling pathways were measured using Western blot and ELISA. β-Catenin levels were also investigated by IHC in DMBA-breast cancer samples from lean and DIO (diet-induced obese mice) mice treated with LPrA2. Apoptosis was also measured.

**Results:** Leptin increased the levels of beta-catenin mainly in TNBC cells. This leptin-induced effect was also detected in breast
tumors from DIO-mice. Interestingly, leptin increased survival (bcl-2 and Caspase-3 activation) /proliferation (cell number and Cyclin D1), expression of Notch and attenuated the detrimental effects of Doxorubicin and Cisplastin on breast cancer cells. Wnt-1 had similar but less pronounced effects compared to leptin. We also observed differences in Notch expression. Moreover, MDA-MB-231 cells showed decreased response to Wnt1 in the presence of leptin.

Conclusions: Our findings suggest that leptin could play a negative role in TNBC by increasing drug-resistance through its crosstalk with Wnt and Notch signaling pathways. This may imply that obesity, characterized by elevated leptin levels, could negatively affect the outcome of TNBC treatment. Taken together, this data supports the theory that inhibition of leptin signaling could be a novel way to prevent and treat TNBC, particularly in the context of obesity and abnormal Wnt and Notch signaling. P5-06-11 Quercetin-3-Methyl Ether Inhibits Lapatinib-Sensitive and Lapatinib-Resistant Breast Cancer Cell Growth by Inducing G2/M Arrest and Apoptosis.

Bode AM, Li J, Zhu F, Normanno NE, Ericson ME, Lubet RA. University of Minnesota, Austin, MN; INT-Fondazione Pascale, Naples, Italy; University of Minnesota, Minneapolis, MN; National Cancer Institute, Rockville, MD

Background: Lapatinib, an oral, small-molecule, reversible inhibitor of both EGFR and HER2, is highly active in HER2 positive breast cancer as a single agent and in combination with other therapeutics. However, resistance against lapatinib is an unresolved problem in clinical oncology. Recently, interest in the use of natural compounds to prevent or treat cancers has gained increasing interest because of presumed low toxicity. Quercetin-3-methyl ether, a naturally occurring compound present in various plants, has potent anticancer activity.

Material and Methods: Quercetin-3-methyl ether was obtained from Analyticon Discovery (Potsdam, Germany). Lapatinib-resistant SK-BR-3 (SK-BR-3-Lap R) cells were isolated in the laboratory of Cell Biology and Biotherapy at the Istituto Nazionale dei Tumori, Naples, Italy. Parental SK-BR-3 and SK-BR-3-Lap R cells were cultured in monolayers at 37 °C in a 5% CO2 incubator in 10% FBS/McCoy supplemented with penicillin/streptomycin (100 units/ml; Invitrogen). SK-BR-3 Lap R cells were routinely maintained in 1 µM lapatinib. Anchorage-dependent and -independent growth and cell cycle were assessed in the presence and absence of quercetin-3-methyl ether.

Results: Here, we found that quercetin-3-methyl ether caused in a significant growth inhibition of lapatinib-sensitive and -resistant breast cancer cells. Western blot data showed that quercetin-3-methyl ether had no effect on Akt or MAPKs signaling in resistant cells. However, quercetin-3-methyl ether caused a pronounced G2/M block mainly through the Chk1-Cdc25c-cyclin B1/Cdk1 pathway in lapatinib-sensitive and -resistant cells. In contrast, lapatinib produced a pronounced G2/M block mainly through the Chk1-Cdc25c-cyclin B1/Cdk1 pathway in lapatinib-sensitive and -resistant cells. Moreover, quercetin-3-methyl ether induced significant apoptosis, accompanied with an increase in the levels of cleaved caspase 3, caspase 7 and poly(ADP-ribose) polymerase (PARP) in both cell lines.

Conclusion: Overall, these results suggested that quercetin-3-methyl ether might be a novel and promising therapeutic agent in lapatinib-sensitive or -resistant breast cancer patients.

P5-07-01 Novel Alternative Splice Variants of HER2 in Invasive Breast Cancer.

Assam EE, Rhodes A, Ladomery M, Harries L, Sohail M. University of the West of England, Bristol, Gloucestershire, United Kingdom; Royal Devon and Exeter NHS Foundation Trust Hospital, Exeter, Devon, United Kingdom; United Hospitals Bristol Foundation Trust, Bristol, Gloucestershire, United Kingdom

Background: The Human Epidermal Growth Factor Receptor 2 (HER2) is an oncogene expressed in 25-30% of invasive breast cancers. HER2 shares extensive homology with other members of the HER family (HER1, HER3 and HER4), and is constitutively active as an homo- and heterodimer. The HER2 gene encodes an 185kDa transmembrane protein with tyrosine kinase activity. Gene amplification or protein expression of HER2 is a predictor of poor clinical outcome and decreased survival in women with breast cancer, and also indicates a favourable response to Trastuzumab (Herceptin) therapy, or a combinational therapy comprising Herceptin plus chemotherapy. However, resistance to Trastuzumab remains the case in approximately 50% of HER2 amplified/overexpressing tumours. Understanding the molecular mechanisms of Trastuzumab resistance and identifying more effective therapies, is critical in the treatment of patients whose breast cancers express this aggressive disease phenotype. In this study, it is postulated that the abnormal generation of mRNA splice variants may be responsible for the continued tumour growth and progression.

Aims: The aim of this study is to increase our understanding of the role of HER-2 splice variants in the development and progression of breast cancer. This will inform the development of more sophisticated and effective therapies that target specific HER-2 isoforms, rather than Herceptin, which targets just the generic wild type HER-2 protein.

Materials and Methods: The entire coding region of HER-2 cDNA was PCR amplified using 12 sets of HER-2 specific primers in HER-2 positive cell lines (SKOV-3, SKBR-3, MDA-MB-453 and MDA-MB-361).

Results: RT-PCR results showed multiple bands in various regions of the HER2 mRNA. Sequencing of these bands revealed novel alternative splice variants with deletions in exons 13 and 18 of the HER2 gene expressed in addition to the wild type HER2. Bioinformatic analysis of the deletions revealed a cassette exon deletion in exon 13, and a loss of 42 base pairs in the 3' end of exon 18 compared to the full length HER2. Both the full length HER2 sequence and the sequence containing the deletions were translated using the ExPaSy Translate Tool. This revealed an in-frame deletion of 14 amino acids and revealed a novel splice isoform with a deletion in the HER2 protein which encompasses the entire ATP binding pocket. This was determined by analysis using UniProtKB to identify the composition of amino acids for each domain of HER2.

Discussion: Our studies have identified novel splice variants in the tyrosine-kinase domain of the HER-2 gene using HER-2 positive cell lines. The loss of an ATP binding site in the HER2 gene may lead to a less active HER2 isoform which may play a significant role in prognosis. Further work is being carried out to study the regulation of these splice variants and to study the role of splice factors ASF/SF2 and SRPK1 in the regulation of HER2 splicing, and to elucidate any
significant changes in the HER2 signalling pathways. In addition, the expression of these isoforms are currently being investigated in tissues from formalin fixed, paraffin embedded and frozen breast tumours.

**P5-07-02**
**Could the Combination of COX-2 Inhibitor and Calcitriol Be a New Chemopreventive Approach To Decrease the Incidence of Breast Cancer?**
Thill M, Cordes T, Fischer D, Hoellen F, Friedrich M, Diedrich K, Dittmer C. University Hospital Schleswig-Holstein, Campus Luebeck, Luebeck, Germany; Helios Klinikum Krefeld, Krefeld, Germany

**Background:** COX-2 is a potential molecular prognostic factor for breast cancer and 15-hydroxyprostaglandin dehydrogenase (15-PGDH) is described as a tumour suppressor in cancer. The antiproliferative effects of calcitriol (1,25(OH)2D3) mediated via the vitamin D receptor (VDR) render vitamin D a promising target in breast cancer therapy.

**Material and Methods:** The expression of the prostaglandin (PG) metabolising enzymes (COX-2, 15-PGDH), the PG receptors, the vitamin D metabolising enzymes (1-alpha-hydroxylase, 24-hydroxylase) and the VDR were determined in benign and malignant breast cell lines as well as in normal and malignant breast tissue. Measurement of PGE2 and 25(OH)2D3 serum level in healthy women and breast cancer patients was performed in winter and summertime. Additionally, the influence of calcitriol on cell proliferation was determined. In addition we examined the effect of calcitriol on the enzyme expression.

**Results:** We found an inverse correlation between the expression of the PG metabolising enzymes with the VDR as well as with the vitamin D metabolising enzymes by investigating the tissue samples. Moreover, we detected an inverse correlation between the PGE2 and 25(OH)2D3 serum level in breast cancer patients during wintertime. Furthermore the PG receptors were associated with an increased carcino genesis. The breast cell experiments presented a dysregulated vitamin D metabolism, especially in the invasive breast cell line. Calcitriol showed an antiproliferative effect only in the benign but not in the malignant cell lines, and the expression of COX-2 and 15-hydroxyprostaglandin dehydrogenase was influenced by calcitriol only in the benign breast cell line.

**Conclusions:** These results suggest a link between vitamin D and PG metabolism and therefore a possible synergism between COX-2 inhibition and calcitriol in breast cancer cells. For the first time, we could show an inverse correlation between the two metabolisms in breast cancer on different levels. Thus, the chemopreventive combination of calcitriol and/or vitamin D analogue with a COX-2 inhibitor might decrease the incidence of breast cancer.

**P5-07-03**
**Modulation of Autophagic Activity by Extracellular pH.**
Xu T, Su H, Ganapathy S, Yuan Z-M. University of Texas Health Science Center at San Antonio, San Antonio, TX

Reprogramming energy metabolism from oxidative phosphorylation to aerobic glycolysis, a common feature of human cancer, results in a relative acidic tumor microenvironment which is further accentuated by hypoxia operating within most tumors. We report that alteration of extracellular pH induces marked and rapid changes of autophagic activity in a variety of cell lines including mammary non-transformed cells and breast cancer cells. Interestingly, acidic and basic conditions induce completely opposite effect on autophagy, with its activity suppressed at lower pH whereas stimulated at higher pH. Gene knockdown experiments indicate that pH induced-autophagy requires Beclin 1, Vps34 and ATG5, key components of the autophagy pathway. Of note, acidic condition not only inhibits the basal but also blocks starvation-induced autophagy activity. Significantly, examination of different areas of tumor mass reveals a lower autophagic activity within the inner region than the outer region. These findings have important implications on the connections between autophagy and cancer as well as a wide range of other physiological and pathological processes.

**P5-07-04**
**Is α-L-Fucose Overexpressed on Cells of Aggressive Human Breast Cancers?**
Listinsky JJ, Siegal GP, Listinsky CM. University of Alabama at Birmingham, Birmingham, AL; Case Western Reserve University, Cleveland, OH

Enzymatic removal of α-L-fucose (fucose) was shown over 20 years ago to abolish metastases in vivo in a rat model of mammary adenocarcinoma [J Cell Biochem 1988; 37: 49-59]. Since that time, evidence has accumulated to indicate that fucose is a functional effector in human breast cancer; essential for construction of the invasive and metastatic phenotypes. In light of these findings, the role of fucose in aggressive breast cancers is worthy of further investigation.

Our group has modified the method of Wright et al. in order to selectively remove cell surface fucose from viable human breast cancer cells in vitro. In our experience, a 30 min incubation of breast cancer cells with α-L-fucosidase (3.2.1.51) leads to a loss of tumotransformer abilities including decreased cancer cell adhesion to select extracellular matrix components, decreased invasion into complex extracellular matrices, decreased binding by relevant antibodies and lectins, and decreased adhesion of cells (rolling) to model endothelium under shear stress flow conditions.

From this work we postulated that decisive differences in phenotypic and functional properties between treated and control human breast cancer cells should be obtainable with currently available models of aggressive disease. To that end, we and others have subsequently shown that human breast cancer cells express cell surface CD44 which carries fucosylated ligands and that its’ defucosylation altered its’ malignant phenotype. Based on these precedents, it is reasonable to hypothesize that CD44-enriched breast cancer stem cell populations require fucose in order to exert their aggressive behavior. Assays to assess the role of fucose in these stem cells are apparent and include a battery of tests involving stem cell invasion into extracellular matrices, cell binding of antibodies or fuclectins, stem cell aggregation into spheroids, colony formation in soft agar, assessment of stem cell rolling/adhesion to endothelial cells or purified E-selectin under both static or physiological flow conditions and the ability to initiate tumors upon inoculation into animal models.

We believe that new insights into aggressive breast cancer cell behaviors can be gained through the depletion of cell surface fucose from breast cancer cells. Knowledge gained from these studies should yield new insights when using current models of human breast cancer in vitro and in vivo.

**Hypoxic Mammary Epithelial Cells in Three-Dimensional Culture Develop a Cancer-Like Phenotype.**
Vaapil M, Helczynska K, Pählman S, Jögi A. Lund University, Sweden; Lund University

Due to inadequate vascularization and tumor cell proliferation solid tumors are hypoxic compared to corresponding normal tissues. Tumor
hypoxygenation has been associated with increased metastatic potential and worse patient outcome. The hypoxic response is mainly driven by the hypoxia inducible transcription factors; HIF-1α and HIF-2α. We have reported that hypoxia leads to a less differentiated phenotype in breast cancer and neuroblastoma, and in the clinic low tumor cell differentiation is related to poor prognosis in these diseases. We have shown that high levels of HIF-2α protein correlate to distant metastasis and poor survival in invasive breast cancer. The aim of the present study was to investigate the effect of hypoxia on mammary epithelial cell differentiation and epithelial organization. We employed the well-characterized model of acinar morphogenesis on extra cellular matrix substrate. In this model mammary epithelial cells that are cultured in three-dimensional culture on a laminin-rich matrix differentiate and form acini-like structures with evacuated lumen surrounded by polarized palisade cells. We found that hypoxia (1% oxygen) impaired the process of acinar morphogenesis and the hypoxic cells failed to obtain polarity and that markers of differentiation were affected at expression levels as well as cellular localization. The hypoxic cells remained proliferative whereas normoxic cells lost Ki-67 expression within a week. We found that hypoxia impaired the global histone deacetylation that has been shown by others to take place in the process of acini formation in mammary epithelial cells. Three days post-seeding, during the proliferation stage, both normoxic and hypoxic cells stained positive for acetylated histone 4. When the normoxic cells went through morphological changes and acinar formation, the acetylation of histone 4 was reduced whereas it was maintained in the hypoxic cell-clusters at day 10 post-seeding. Thus, the hypoxic conditions maintained the epithelial cells in an acylated state, which is generally associated with an open chromatin structure, high level of transcription and an undifferentiated stage. These data indicate that hypoxia promotes loss of differentiation also at a non-malignant stage and render the cells a cancer-like phenotype. We are currently extending this study in primary cells.

Effect of Angiotensin-(1-7) and Angiotensin II on T47D Breast Cancer Cells in the Proliferation and cAMP Production.

da Silva IDCG, Correia-Noronha SSAA, Noronha SMR, Alecrim C, Shimuta SI, Nakai CR, Gebrim LH, Nazario ACP. UNIFESP, São Paulo, SP, Brazil

Angiotensin-(1–7) [Ang(1–7)] is a peptide hormone that produces opposite responses to those of the well-characterized peptide angiotensin II (Ang II). The main actions of Ang(1–7) and AngII are mediated by MAS and Angiotensin type 1 receptor (AT1R), respectively. Ang(1–7) has blood pressure and proliferative effects contrary to those of AngII, exhibits significant angiogenic activity and may be a novel therapeutic agent for lung cancer treatment targeting a specific AT(1-7) receptor (Soto-Pantoja et al., 2009). Here, our aim was to evaluate T47D breast cancer cell proliferation and cAMP production after treatment with Ang (1–7) and AngII. By means of the cyclic AMP (cAMP) competitive enzymeimmunoassay system we measured cAMP content of T47D cells. Cell proliferation was measured using incorporation of BrdU after Ang (1–7) and AngII. In this model mammary epithelial cells that are cultured in threedimensional culture on a laminin-rich matrix differentiate and form acini-like structures with evacuated lumen surrounded by polarized palisade cells. We found that hypoxia (1% oxygen) impaired the process of acinar morphogenesis and the hypoxic cells failed to obtain polarity and that markers of differentiation were affected at expression levels as well as cellular localization. The hypoxic cells remained proliferative whereas normoxic cells lost Ki-67 expression within a week. We found that hypoxia impaired the global histone deacetylation that has been shown by others to take place in the process of acini formation in mammary epithelial cells. Three days post-seeding, during the proliferation stage, both normoxic and hypoxic cells stained positive for acetylated histone 4. When the normoxic cells went through morphological changes and acinar formation, the acetylation of histone 4 was reduced whereas it was maintained in the hypoxic cell-clusters at day 10 post-seeding. Thus, the hypoxic conditions maintained the epithelial cells in an acylated state, which is generally associated with an open chromatin structure, high level of transcription and an undifferentiated stage. These data indicate that hypoxia promotes loss of differentiation also at a non-malignant stage and render the cells a cancer-like phenotype. We are currently extending this study in primary cells.

Follistatin Suppresses In Vitro Growth of Breast Cancer Cells and Its Reduced Expression in Breast Cancer Associated with Poor Differentiation and Prognosis.

Ye L, Mansel RE, Jiang WG. Cardiff University School of Medicine, Cardiff, United Kingdom

Background: Bone morphogenetic protein (BMP) belongs to TGF-β superfamily, being widely involved in prenatal and postnatal development and homeostasis of various tissues and organs. BMP signaling has been implicated in tumorigenesis and disease progression of certain malignancies. Recent studies demonstrated a profound role played Noggin, a BMP antagonist in bone metastasis from breast cancer. Current study examined expression of Follistatin, another BMP antagonist in a breast cancer cohort, and its relevance to pathological and clinical parameters.

Methods: Expression of Follistatin was examined in breast cancer tissues (n=93) and normal background tissues (n=30) using quantitative real time PCR and immunohistochemistry (IHC). The breast tissue samples were collected immediately after surgery. The clinical follow-up was routinely performed after surgery. The median follow-up period was 120 months (June 2004). Full-length human Follistatin coding sequence was cloned into a plasmid vector. Following transfection and verification, effect of Follistatin overexpression on cell growth was examined using an in vitro growth assay.

Results: IHC revealed cytoplasmic staining of Follistatin in mammary epithelial cells in breast tissues. The staining appeared to be weaker in breast cancer, but there was no significant difference in its transcripts levels compared with that of normal background tissues. Follistatin transcripts were decreased in both moderately differentiated and poorly differentiated tumors, p=0.0165 and p=0.0169 in comparison with well differentiated tumors respectively. Transcript levels of Follistatin in primary tumors tended to be lower in the patients with poor prognosis (33.8±14.7) including those patients had local recurrence, metastases and died of breast cancer, p=0.09 when compared with that of patients remained disease free (17.0±46.0). Its expression appeared particularly lower in the patients with breast cancer. Current study examined expression of Follistatin in primary tumors and metastases of breast cancer. Overexpression of Follistatin exerted inhibitory effect on in vitro growth of MDA-MB-231 cells.

Conclusions: Decreased expression of Follistatin in primary tumors of breast cancer correlates with poorer differentiation and mortality. Follistatin suppresses in vitro growth of breast cancer cells. It suggests that Follistatin is a negative regulator for tumor growth and disease progression of breast cancer.

Quantitative Analysis of Strain Ratio of Microcalcification Lesions with Surgical Specimen Mammography.
Hung S-H, Chen R-C, Wu Y-T, Chen T, Lin C-H. Taipei City Hospital, Taiwan; National Yang-Ming University, Taiwan

Measurement of the strain induced by compression can be useful in the diagnosis of breast tumors. Microcalcification (MC) detected by mammography could be the only symptom of early breast cancers. The purpose of this study was to develop a quantitative method for a differential diagnosis of MC lesions based on the strain ratio (SR) obtained by applying different breast compression pressure during mammography.

Methods: This prospective study was conducted with institutional review board approval and the written informed consent was obtained. Twenty-five mastectomy specimens (24 for treatment of breast cancer and 1 from contralateral prophylactic mastectomy) with MCs were examined by digital mammography. There were 24 malignant MCs (mean size of 18.8 mm) detected in the 24 separate specimens, including 14 lesions of invasive carcinoma and 10 lesions of carcinoma in situ. Five benign MCs (mean size of 21.6 mm) were detected, including four lesions which coexisted with malignant MCs in the four separate specimens, and one was discovered in the prophylactic mastectomy specimen. Each specimen experienced four different magnitudes of compression force and the corresponding images were acquired for further analysis. Images in Digital Imaging and Communications in Medicine format (DICOM) were exported into custom software, written in Matlab, to contour the region of interest. Stress was defined as the force divided by the whole specimen area, and the square root of MC area was calculated to represent strain deformation. The SR was the slope of the best-fit line through the four points of each lesion. Histology of the MC was correlated with SR. Receiver operating characteristic (ROC) curve analysis was performed to evaluate the diagnostic performance of SR for discrimination between benign and malignant MC.

Results: The SRs were higher in the malignant MC group (139.10 a.u.) than in the benign MC group (34.09 a.u.; p = 0.024). The SR between invasive carcinoma and carcinoma in situ showed no statistical significance (127.03 a.u. vs. 156.00 a.u.; p = 0.642). The area under the ROC curve for the diagnosis of benign and malignant MC was 0.825 (95% CI, 0.667 to 0.982).

Conclusion: This study demonstrated that the SR detected by mammography showed potential for distinguishing benign from malignant MCs. Further in vivo investigations of larger cohorts are necessary to validate these results.

P5-08-02
Mammographic Breast Texture Predicts Benign Biopsy Results and Composition.
Duewer FW, Kerlikowske K, Tlsty T, Fan B, Parvin B, Ma L, Shepherd J. UCSF, San Francisco, CA; LBNL, Berkeley, CA

Purpose: Investigate the relationship between pathology diagnosis, biopsy composition, and breast texture measured in digital mammogram in women who have had previous benign findings in their breast. The long-term goal of this project is to determine whether or not global breast texture is associated with tissue composition and biopsy results. Such a finding would be of interest because it would provide evidence that mammography images contain information related to breast biology beyond average density.

Materials and Methods: A total of 124 women who had previously received benign biopsies underwent an additional dual-energy/low dose full-field digital mammography (DXA) scan of the unaffected breast. Three measures of breast density (percent dense area (PD), percent fibroglandular volume (%FGV), absolute fibroglandular volume (FGV)) from mammogram, 15 biopsy types including apocrine metaplasia and non-secretory papillary adenoma, and four tissue compositions (collagen percent area, fat percent area, ductal percent area, epithelial percent area) were estimated from biopsies for each participant. In addition 45 breast texture features were measured on each screening image taken during the dual-energy mammography using custom software. Tissue composition at the biopsy location was estimated based on the average percent area of stained collagen, fat, ductal, and epithelial from up to 3 slides taken from the biopsy.

Results: Neither mammographic percent density, %FGV, nor FGV showed significant association with either biopsy type or tissue composition. However, some of breast texture features were significantly associated with tissue type and tissue composition. The strongest associations were found between collagen percent area and the neighborhood gray tone difference matrix texture strength (R=-0.26, P=0.005) and ductal percent area and the gray level contrast matrix homogeneity (GLCM HOM) (R=-0.30, P=0.001).

Conclusion: This study demonstrated that the SR detected by mammography showed potential for distinguishing benign from malignant MCs. Further in vivo investigations of larger cohorts are necessary to validate these results.

P5-08-03
How Reader’s Training, Software, and Image Formats Impact Percent Dense Area Measures.
Fan B, Duewer F, Wu FF, Kerlikowske K, Vachon C, Shepherd JA. University of California San Francisco, San Francisco, CA; Mayo Clinic College of Medicine, Rochester, MN

BACKGROUND: Mammographic percent dense area, the percent ratio of dense to total breast area in a mammogram, is one of the strongest measures of a woman’s risk of breast cancer. However, systematic differences have been observed between readers and mammography technologies (film and digital) that could cause clinically inconsistent associations with risk. The purpose of this study was to evaluate inter- and intra-reproducibility of percent dense area between readers and between film and digital technologies.

METHODS: One hundred digitized film mammograms were randomly selected with 25 films in each of quartile of percent density and read by two readers at two different sites (Mayo Clinic and UCSF). The readers had extensive experience and were also jointly trained at university of Toronto using Cumulus software. After training, all films were read twice with at least one year between duplicate readings. The Mayo clinic reading used Cumulus while UCSF used custom semiautomatic software to estimate total and dense tissue area. In addition, digitized films and unprocessed full field digital mammograms of the same women were assessed by one reader.
reader. The time between the film and digital acquisitions ranged from nine to twenty-four months. Interclass correlation coefficient (ICC) was calculated for each comparison.

RESULTS: The intra- and inter-observer ICCs, consistency for film images, were 0.96 (UCSF) and 0.97 (Mayo), and 0.96 (UCSF vs. Mayo). We found ICC between film and digital mammograms for percent dense area was 0.88. The digital mammogram had 9% significantly higher total breast area and 5% significantly lower percent density area compared to film.

CONCLUSIONS: Similarly trained readers had a high reproducibility regardless of the software used. Our results suggest centralized reader training should enable pooling of film breast density results from different clinics. However, pooling film and digital results would need careful calibration due to lower measured percent dense areas than on film.

P5-08-04
Mammographic Microcalcifications and Breast Cancer Tumorigenesis: A Radiologic-Pathologic Analysis.
Naseem M, Murray J, Hilton JF, Han D, Hogevsein S, Heersink RL, Muradali D, Simmons C, Bell D, Haq R, Brezden-Masley C. St. Michael’s Hospital, Toronto, Canada; University of Toronto, Toronto, Canada

Background: Microcalcifications (MCs) are tiny deposits of calcium in breast soft tissue. They serve as key diagnostic radiological features for localization of malignancy. Approximately 30% of early invasive breast cancers have fine, granular MCs detectable on mammography; however, their role in breast cancer tumorigenesis is currently unknown. The purpose of this study was to investigate the relationship between mammographic MCs and breast cancer pathology.

Methods: A retrospective chart review was performed for 882 women treated for breast cancer between 2000-2010 at St. Michael’s Hospital. Demographic information (age and menopausal status), tumor pathology (size, histology, grade, nodal status and lymphovascular invasion), hormonal status (ER and PR), HER-2 overexpression and presence of MCs were collected for breast cancer patients. Chi-square tests were performed for categorical variables and t-tests were performed for continuous variables. All tests were two-sided and p-values less than 0.05 were considered statistically significant.

Results: A total of 826 patient charts were included; 56 (6.4%) patients had metastatic carcinoma and were excluded from analysis. Only 37.0% (326/882) of the patients presented with mammographic MCs. Patients were more likely to have MCs if they were HER-2 positive (51%) as opposed to being HER-2 negative (33.4%) (p=0.001). There was a significant association between MCs and being perimenopausal with a mean age of 50 (65.2%) (p=0.012). Patients with invasive ductal carcinomas (39.7%) were more likely to present with MCs than were patients with other tumor histology (p=0.001). There was a positive correlation between MCs and tumor grade (p=0.051), with grade III tumors (41.8%) presenting with the most MCs, followed by grade II (37.9%) and grade I (29.8%). There was no significant association between mean age, mean tumor size, ER and PR status with the presence of MCs.

Conclusion: This is the largest study that suggests the appearance of MCs on mammograms is strongly associated with HER-2 overexpression, invasive ductal carcinoma and perimenopausal status. Since HER-2 is implicated in mediating aggressive tumor growth and metastasis, future studies should investigate the molecular pathways underlying HER-2 overexpression and MC development. This would help better understand the role of MCs in breast cancer tumorigenesis.

Comparison of Mammographic Density between Ductal Carcinoma In Situ and Benign Breast Disease.
Lee JW, Shin EJ, Yi OV, Lee JW, Shin HJ. Asan Medical Center, Seoul, Korea

Background: High breast density is an independent risk factor for breast cancer as well as benign breast diseases. However there are few studies about breast density of ductal carcinoma in situ (DCIS) and benign breast disease (BBD). In this study, we investigated patterns of breast density of DCIS and BBD, and comparatively analyzed breast densities of DCIS and BBD.

Material and Methods
From 2008 to 2009, 345 patients underwent surgery for DCIS at Asan Medical Center, and 295 patients for BBD at 2010. We retrospectively reviewed each groups and estimated cranio-caudal view of digital mammogram of unaffected breast by computer-assisted thresholding methods, using Cumulus 4, version 4.0. For BBD we included atypical ductal hyperplasia, fibroadenoma, papilloma(atypical/intraductal), phyllodes tumor(benign/borderline), and excluded unavailable mammogram(mostly, because of scanned films from outside hospitals and previously diagnosed breast cancer).

Results
Mean ages of each group were 46.51 year old in DCIS group and 41.43 year old in BBD group, and the mean percentage density(PD) were 44.89% and 45.27%, respectively.

Mean PD of the BBD group and the DCIS group

</tr>
</tbody>
</table>

There was no significant difference between two groups in total population (p=0.79). We categorized into two groups according to the age, ≥50 and <50, for each DCIS and BBD group. Mean percentage density of below 50 year old was 52.92% in DCIS group and 49.58% in BBD group (p=0.031). Mean percentage density above 50 year old was 33.67% in DCIS group and 33.29% in BBD group (p=0.867).

Mean PD of each group in the subgroup aged under 50 and over 50

</tbody>
</table>

Conclusion
The mean values and distribution patterns of PD were similar between BBD group and DCIS group. However, in the subgroup aged under 50, the DCIS group has significantly higher breast density than the BBD group. Although the causal association of breast density with breast cancer has been relatively well documented, this kind of cross-sectional study has an inherent limitation. The absolute difference between the DCIS group and the BBD group under age 50 (3.34% in table2) needs more investigation for its clinical implications.

Breast Cancer Annual Screening Program Núcleo Mama Porto Alegre (NMPOA): Imaging Results after Seven Years.
Caleffi M, Amaral C, Zignani J, Grauendz M, Duarte Filho D. Hospital Moinhos de Vento, Porto Alegre, Rio Grande do Sul, Brazil

Introduction: The NMPOA cohort started in 2004 with the purpose of testing a breast screening model for underserved women in limited resource countries. In the city of Porto Alegre (South Brazil with
1.5 million population), breast cancer incidence rate is 127/100.000 (Brazilian NCI, 2010) with increasing mortality due to 45% of Stage III and IV and no public health care early detection program, it was mandatory to test the feasibility of an organized screening program for women with very low income and level of education (64% under 6 years of schooling). In this scenario, there was always a concern of over diagnosis that will increase costs (more biopsies and surgeries) and under diagnosis by the radiologists involved in the program. We present here the results of all breast biopsies performed in this period, and its correlation with the attributed BI-RADS classification in order to optimize care and costs. Also, this study has a long term proposal and other results have been published concerned to the baseline profile of the population (Cancer Epidemiol Biomarkers Prev. 2010 Oct;19(10):2673-9. Epub 2010 Aug 17).

Methods: Since April 2004, 5592 women from 40 to 69 years were enrolled in the program and underwent to clinical breast exam and annual mammography screening at NMPOA. Initially, lesions were classified as B1, B2 or B0. After complementary views or exams, B0 was classified as B3, B4 (A, B or C) or B5. B4 and B5 were considered positive tests and immediately submitted to biopsy (open surgical or ultrasound guided core biopsy). B3 was followed according to recommended in BI-RADS fourth edition, and subsequently classified as benign (annual follow up) or suspicious findings (biopsy performed). The evaluation included histological analysis of breast biopsy specimens by two independent pathologists. Predictive positive value (PPV), predictive negative value (PNV) and accuracy (Acc) were calculated.

Results: A total of 259 breast lesions were initially classified as BI-RADS 0 (recall rate of 2.8%), and further classification of these was: 166 B3 (64.1%), 60 B4 (23.2%) and 33 B5 (12.7%). Thirty seven B3 (14.3%) were considered suspicious after 6 months and submitted to biopsy. Correlation results of the 130 biopsies performed are summarized on [Table1]. PPV of 63.4% (52.8%-73.1%), PNV of 97.3% (85.8%-99.9%) and an Acc of 73.1% were observed. In this sample, 71.7% of BC were ductal invasive carcinoma, 11.7% ductal carcinoma in situ, 5% lobular invasive carcinoma and 11.6% were other types of neoplasia.

Conclusion: Recall rate is in accordance with the medical audit benchmarks recommended of less than 10% published in BI-RADS fourth edition. NMPOA is model for limited resource countries in breast cancer imaging diagnosis. The radiologists involved in the program are classifying breast lesions in accordance with the established parameters, with a high accuracy in diagnosis. Even though we are dealing with a poorly educated cohort not used to any form of screening, our adherence is 57% in 12 months and 71% in 24 months.

P5-09-02
Reducing Excess Biopsies: Improving Screening through Risk Stratification and New Thresholds for Intervention.
Kim DN, Kim J-H, Flowers CI, Elias S, Moore DH, Esserman LJ. Athena Breast Health Network, San Francisco, CA; Moffitt Cancer Center, Tampa, FL; University Medical Center Utrecht, Utrecht, Netherlands; University of California, San Francisco, CA

Background
BI-RADS Category 4 patients have a 2-95% risk for malignancy and are generally recommended for breast biopsy with little discrimination for risk level or distinction between risk of invasive or in situ disease. Our study sought to determine if higher thresholds for biopsy based on stratifying for risk and distinguishing between risk of invasive cancer and DCIS could reduce biopsy rates and increase cancer-to-biopsy yields without missing cancers urgent for resolution.

Methods
108 BI-RADS 4 cases with final outcomes data were evaluated from a prospective cohort of 215 consecutive patients seen at a same-day multidisciplinary breast clinic for women with mammograms categorized as BI-RADS 0, 4, or 5 in 2006-07. Final outcomes were determined from pathologic diagnosis or two-year follow-up. Risk estimates (RE) for DCIS and invasive cancer were collected prospectively and re-assessed by a radiologist blinded to outcomes and prior reading assessments. Cases were stratified according to the risk ranges of the BI-RADS 4 subcategories and risk of invasive or in situ disease. Biopsy rates, cancer-to-biopsy yields, and number of malignancies missed were calculated for various thresholds for intervention.

Results
A ROC curve for invasive cancer risk for the radiologist demonstrated a 98.5% level of accuracy (95% confidence interval [CI]: 96.9%, 100%). 60 cases had some risk for invasive cancer and 48 had some risk for DCIS. There were 14 invasive cancer and 11 DCIS outcomes, of which were high-grade. Pathologic assessment from biopsy or surgery was available for 100 patients. The outcomes of 8 cases were determined by benign two-year follow-up.

There are several strategies for intervention that improve biopsy yield and reduce biopsies for benign disease as shown in Table 1.

If cases with RE between 2-10% for DCIS or invasive cancer were not biopsied, 23% of biopsies would be avoided and the yield would increase to 30%. If cases with invasive cancer RE between 10-95% and DCIS RE between 50-95% were biopsied, 52% of biopsies would be avoided and the yield would increase to 39%. One invasive ductal carcinoma (3 mm, Grade 2) would be missed, although with six-month follow-up, this would not be a problem.

Limitations
Small sample size; one radiologist providing RE may not be representative of general mammographic assessment.

Conclusion
Setting higher biopsy thresholds for BI-RADS 4 lesions can safely reduce biopsy rates and increase biopsy yields. Given evidence suggesting that low/intermediate grade DCIS may be overdiagnosed, distinguishing between DCIS and invasive cancer risk at screening by offering active surveillance as an alternative to biopsy for BI-RADS 4 lesions suspicious for non-high-grade DCIS may be a promising approach for reducing biopsies. This will be prospectively tested in a reader study using several radiology readers in a series of 750 cases in the Athena Breast Health Network. New biopsy thresholds can be set if the results of our study can be validated.
P5-09-03
Health Literacy Affects Use of Screening Mammography in an Underinsured Population.
Komenaka IK, Nodora J, Hsu C-H, Machado L, Klemens AE, Zenuk R, Bouton ME, Martinez ME, Weiss BD. Maricopa Medical Center, Phoenix, AZ; University of Arizona, Tucson, AZ

Background: In late 2009 significant controversy arose when some screening recommendations were changed to advocate screening mammography starting at age 50 rather than the long standing recommendation of starting at age 40 years. Few would argue, by contrast, that patient compliance with screening mammography, starting at either 40 years or 50 years, is at optimal levels. National data indicate that many more lives would be saved by improving compliance with screening recommendations in individuals ≥50 than would be saved with screening individuals age 40-50 years. The current study was performed to determine if health literacy was associated with use of screening mammography in an underinsured population.

Methods: Maricopa Medical Center is the county safety net hospital in Phoenix, Arizona. 944 patients were seen at the Breast Clinic from January 2010 to January 2011. 638 were at least 40 years old and therefore candidates for screening mammography. Sociodemographic variables were collected. Use of mammography was asked of patients and checked by medical records. Health literacy was assessed using the Newest Vital Sign (NVS) validated screening instrument, which categorizes health literacy on 6-point scale as low health literacy likely (0-1 point), low health literacy possible (2-3 points), or health literacy adequate (4-6 points). Differences in patient characteristics were evaluated based on a Fisher’s exact test for categorical variables and one-way ANOVA for continuous variables. Multivariate analysis was then performed to determine which patient factors were associated with use of screening mammography.

Results: Among women 40 years or older, only 35% used routine screening mammography. For women 50 years or older, 38% underwent screening mammography. Among women 40 years or older and those 50 years or older, significantly more with health literacy adequate (NVS 4-6) obtained screening mammography than did women in the two lower groups (NVS 0-1 and 2-3). In groups (40+: 65% vs. 30% and 30%, p = 0.001, 50+: 65% vs. 33% and 37%, p = 0.001). Multivariate analyses adjusted for insurance status, employment, white race, Hispanic ethnicity, marital status, language, use of alcohol, family history, NVS and education level demonstrated that patients with adequate health literacy were more likely to use screening mammography (OR 3.66; 95% CI 2.14 – 6.27; p < 0.01) than patients in the two lower literacy groups. Similarly, uninsured patients were significantly less likely to undergo screening mammography (OR 0.57; 95% CI 0.38 – 0.86; p = 0.01) than those with insurance. Patients with adequate health literacy and insurance were (OR 8.61) more likely to use screening mammography than patients who were uninsured and were in the two low literacy groups. Patient race, ethnicity, language, employment, income, education level, and family history of breast cancer were not associated with use of screening mammography in this underinsured, undereducated population.

Conclusions: Use of screening mammography was poor in this underinsured population. Limited health literacy and lack of insurance are risk factors for failure to obtain mammography. Interventions to increase use of screening mammography among uninsured patients with limited health literacy are needed.

P5-09-04
Predictors of Malignancy and Surgical Outcomes Following Indeterminate Core Needle Biopsy in the British Breast Screening Programme.
Gillespie HS, Lowry K, Somerville J, McIntosh SA. University of Aberdeen., Foresterhill, Aberdeen, Aberdeenshire, Scotland, United Kingdom; Belfast City Hospital, Belfast, County Down, United Kingdom

Background: The National Health Service Breast Screening Programme (NHSBSP) invites women between 50 and 70 years for mammography every three years, with abnormal imaging leading to further assessment. Core needle biopsy (CNB) is the standard for obtaining a definitive pre-operative diagnosis. However a proportion of CNBs will be reported as showing indeterminate pathology, with uncertain malignant potential. This necessitates surgical diagnostic excision biopsy, with attendant potential morbidity, and highlights the importance of pre-operative diagnosis. This study aimed to categorise the histological lesions prompting B3 classification arising within a screening programme, and to quantify the definitive surgical outcomes following excision biopsy.

Material and Methods: Data was collected retrospectively from January 2000 – December 2010, including demographic details, radiological presentation, relevant clinical findings, results of pre-operative investigations, reports of diagnostic excision biopsy and subsequent surgical management. Patients were included if they had a B3 CNB result and subsequent excision biopsy, following attendance for screening mammography. Primary outcome was classification of B3 lesions and positive predictive values (PPV) for malignancy. Secondary outcomes were subsequent surgical procedures.

Results: There were 239 B3 lesions, representing 7.1% of all CNB carried out within the screening programme. Mean patient age was 55.6 years, and median lesion size was 14.5 mm (range: 4-25mm). Eighty seven lesions (36.4%) were malignant on excision: 28 (11.7%) invasive and 52 (21.8%) in situ. Lesion specific PPVs for malignancy were as follows: phylloides tumour 50.0%, atypical ductal hyperplasia 40.0%, columnar cell lesion 40.0%, papillary lesion 26.7%, lobular neoplasia in situ 25.7%, and radial scar/complex sclerosing lesions (RS/CSL) 25.9%. The PPV of RS/CSL with atypia was 65.2%, and without 25.8%. Of 87 malignant cases, 55 (63.2%) went on to have a further surgery. 27 (50.9%) had re-excision of surgical margins, 10 (18.2%) had a mastectomy, 8 (14.5%) had a wide local excision, 2 had an axillary biopsy and one patient had a quadrantectomy. 18 patients had two further operations, the second was most commonly an axillary clearance, and 3 patients had three further operations. Discussion: B3 lesions are heterogeneous in nature, and continue to mandate surgical excision, demonstrated by a PPV of 36.4%, the highest reported figure in the literature to date. B3 CNB represents a significant surgical workload, demonstrated by the fact that 63.2% cases go on to have further surgery, and that 8.8% will require more than one further operation. Currently there is no pre-operative investigation that reliably predicts the likelihood of B3 associated malignancy. It has been demonstrated that the use of large volume vacuum assisted biopsy can reduce the rate of under diagnosis of both in situ and invasive malignancy, and this would clearly reduce the requirement for repeated surgery reported in this study.
P5-09-05
Non-Palpable Lesions Findings in a Breast Cancer Opportunistic Screening in South Brazil.
Rockenbach R, Rombaldi RL, Caleffi M. Hospital L Geral, Caxias do Sul, Rio Grande do Sul, Brazil; Hospital Moinhos de Vento, Porto Alegre, Rio Grande do Sul, Brazil

Introduction: Today breast cancer is a major public health challenge in developing countries with increasing mortality rates due to the lack of early detection programs and access to care. Mammography has been considered the most sensitive test for breast non-palpable lesions. The Brazilian National policy recommends mammography from age 50 and every two years. This study investigates only radiological findings in a set of women seeking for long term breast care surveillance. Objectives: To evaluate patients characteristics of cases with non-palpable breast lesions.

Material and method: A prospective and transversal study was undertaken between March, 2009 and April, 2010 on 110 women with non-palpable breast lesions, diagnosed by mammography or ultrasound. Histo-pathological evaluation was performed in core biopsy specimen. The following variables were studied: pregnancy, parity, menarche, menopause, hormone replacement therapy, breast lesion location, tumor size, histopathology findings, mammographic and ultrasound classification – BI-Rads.

Results: 23.7% (n=26/110) out of 110 women were diagnosed with breast cancer and 76.3% (n=84/110) were diagnosed with benign mammary pathology. Mammography, according BI-Rads classification, strongly suggested (p<0.000) the presence of benign and malignant pathologies. In the breast cancer group, 14 were diagnosed with stage I (TNM), compared to the official data from INCA where stage I is 10% of the cases.

Mean 52±10.7 49.5±2.8 0.153
> 60 years 5 0.150
50-59 years 9 25.7 26 31.1
30-39 years 2 7.7 14 16.7
Age range of non-palpable breast lesions (n=110)

Conclusion: Mammographic screening reduces mortality by 30% after 50 years of age and also provides important benefit (20%) in younger women (30-49). Our study showed a cancer detection rate of 25.7% and 34.6%, respectively, demonstrating the importance of screening also in younger ages. Overall, the rate of biopsy positive was very satisfactory (1 out of 4 cases). Among the studied non-palpable breast lesions, our findings resulted in 53.8% stage I breast cancers (TNM) which reinforces the urgent need of a structured screening program in Brazil to save more lives.

Financial support: Avon Institute.

Metabolic Pharmacodynamic Effect Evidenced by 18FDG-PET as a Tool for Early Prediction of Iniparib Efficacy in Metastatic Triple Negative Breast Cancer (MTNBC): A Proof of Concept Study.
Kerrou K, Gligorov J. Eastern Paris University Hospitals, APHP Tenon, Paris, France; Eastern Paris University Hospitals, APHP Tenon - APREC, Paris, France

Rationale:
It was hypothesised that Iniparib or 4-iodo-3-nitrobenzamide acts as an irreversible inhibitor of PARP1 and possibly other enzymes. It is shown to maximally promising then confusing results in MTNBC in combination with chemotherapy. To date, its mechanism of action has not been completely elucidated but since 1992, inhibition of glycolysis by iniparib and subsequent necrotic cell death has been described. We hypothesised that early inhibition of glycolysis evidenced by in-vivo imaging with 2-((18)F)Fluoro-2-Deoxy-D-Glucose Positron-Emission Tomography (18FDG-PET) may be a predictor of efficacy in iniparib, as it was previously reported for other anticancer drugs.

Objectives:
To detect metabolic pharmacodynamic effect of iniparib plus chemotherapy by means of 18FDG PET and proof the concept of its use as an early predictive tool of Iniparib efficacy in MTNBC.

Patients & Methods:
From March to November 2011, 8 pts were included in our institution in a randomized phase II study comparing bi-weekly versus weekly iniparib treatment in combination with gemcitabine and carboplatin. All patients had 18FDG-PET at baseline, at day 7 (D7). The maximum value of standardized uptake value (SUVmax) of all measurable metastatic lesions was measured and the median SUVmax was calculated for all patients at baseline and D7. The metabolic response was defined as the percentage of reduction of SUVmax (SUVmax Baseline – SUVmax D7) / SUVmax Baseline and the median SUVmax response was correlated to RECIST 1.1 response at six weeks and to disease-free survival (DFS).

Results:
The median decrease in SUVmax of evaluable lesions measured at D7 was predictive of RECIST 1.1 response at six weeks and was correlated to the best obtained response during the treatment phase. Furthermore, it showed a linear correlation with DFS (y = -0.0007x - 0.1325; R² = 0.3402).

Conclusion:
Metabolic pharmacodynamic effect as evidenced by 18FDG PET as soon as one week of treatment act as an early predictive tool of Iniparib plus chemotherapy efficacy in MTNBC. Considering the lack of a predictive biomarker of response and if confirmed on larger study, 18FDG PET could be used as a surrogate predictive biomarker in this setting. These results may be considered as an in-vivo proof of concept for the inhibition of glycolysis by iniparib.

P5-10-02
Relevance of Magnetic Resonance Imaging To Predict Disease-Free Survival after Neoadjuvant Chemotherapy of Breast Cancer.
Loo CE, Vrancken Peeters M-JTFD, Wesseling J, Gilhuijs KG. NKI-AVL (Netherlands Cancer Institute - Antoni van Leeuwenhoek Hospital), Amsterdam, Netherlands; University Medical Centre Utrecht, Utrecht, Netherlands; NKI-AVL, Amsterdam, Netherlands

Purpose:
To explore the relevance of magnetic resonance imaging (MRI) to predict disease free survival (DFS) after neoadjuvant chemotherapy (NAC) of breast cancer.

Patients and Methods:
Between July 2000 and December 2007, MRI examinations were performed in 188 women before, during and after NAC in the context of a single-institution review board approved study. Patients were consecutively included after informed consent. Interpretation of MRI
was revised by an experienced breast MR radiologists and included assessment of lesion morphology, changes in morphology, size, and contrast uptake kinetics (initial and late enhancement).

MRI features and known prognostic markers of breast cancer (age, tumor response at pathology, tumor size at baseline, immunohistochemistry-derived breast cancer subtype (triplet-negative; HER2-positive or ER-positive/HER2-negative)) were correlated with DFS. Multivariate Cox regression analysis was used to explore the impact of relevant associations.

**Results:**

Follow-up data were available for 184 women. The median follow-up time was 57.6 months (range 32.4 - 125). In 30 women events were found (26 breast cancer related deaths; 29 distant metastasis and 12 local/regional recurrences).

At multivariate analysis, only breast cancer subtype (p=0.004) and largest diameter of late enhancement at MRI after NAC (p=0.006) retained prognostic value in favour of response at final pathology, age and tumor size at baseline. Cumulative survival at 60 months (kaplan-meyer curves) was 70%, 86.7%, and 89.7% for triple-negatives, HER2-positive and ER-positive/HER2-negative subtypes [figure 1], respectively, and 88.5%, 81.4 % and 55.1% for absence of washout/plateau after NAC, between 0 and 30 mm washout/plateau, and ≥ 30 mm washout/plateau, respectively [figure 2].

**Conclusions:**

MRI after NAC in conjunction with breast cancer subtype has potential as complementary predictor for DFS. Larger diameters of residual late enhancement at MRI after NAC are associated with inferior DFS at 60 months.

---

**P5-11-01**

**The Accuracy of Preoperative Ultrasonography Guided Vacuum-Assisted Breast Biopsy in Determining Histological Type, ER Status, PgR Status, HER2 Status and Ki67 Level in Invasive Breast Cancer.**

**Fujita T, Sawaki M, Hattori M, Kondo N, Horio A, Ushio A, Gondo N, Adachi E, Iwata H. Aichi Cancer Center Hospital, Nagoya, Japan**

**Background:** Recently, ultrasonography guided vacuum-assisted breast biopsy (US-guided VABB) has been widely used as alternative to surgical open biopsy. Enough breast tissue samples obtained by US-guided VABB are important because of increasing neoadjuvant treatment. Although the information obtained from US-guided VABB may be the only information available for determining the candidates for neoadjuvant treatment, only few studies evaluated the concordance of histological type, estrogen receptor (ER) status, progesterone receptor (PgR) status, human epidermal growth factor-2 (HER2) status, and Ki67 level between US-guided VABB and surgical specimen. The aim of this study was to evaluate the accuracy of preoperative US-guided VABB.

**Materials and Methods:** In 439 breast cancer patients without neoadjuvant treatment who underwent US-guided VABB and surgical resection from April 2004 and March 2011 at Aichi Cancer Center hospital, we examined the concordance of Histological type, ER status, PgR status, HER2 status, and Ki67 level between US-guided VABB and surgical specimen. All the US-guided VABB were performed using 11-gauge Mammotome® or 10-gauge VACORA®. The ER and PgR status were assessed using Allred scoring system by IHC. These statuses were categorized as positive when the total score was more than two. HER2 expression status was tested by IHC and FISH. HER2 3+ by IHC, or 2+ and FISH positive were judged as HER2 positive. In this study, the Ki67 cut-off level for positivity was defined at 20% (Penaulet-Llorca et al, JCO 2009).

The agreement on histological type, ER status, PgR status, HER2 status, and Ki67 level were tested using the absolute concordance rate and the kappa statistic values.

**Results:** The concordance rate of histological types between US-guided VABB and surgical specimens was 93.4% (410 of 439 cases) with a Kappa statistic value of 0.82. In 115 cases diagnosed as DCIS by US-guided VABB, 28 cases (24.3%) were subsequently diagnosed as invasive cancer by surgical specimens. However, among these cases, 78.6% (22/28) were T1mic and T1a. And one case (0.3%, 1/324) diagnosed as invasive cancer by US-guided VABB changed DCIS by surgical specimens. The concordance rate of ER, PgR, and HER2 status were 96.6% (112/116), 89.5% (102/116), and 97.4%(113/116), respectively (kappa statistic value of 0.99, 0.76, and 0.90). In HER2 status, the concordance rate between US-guided VABB and surgical specimens was better than between core needle biopsy and surgical specimens (the concordance rate: 88%, kappa statistic value: 0.65, Usami et al, Jpn J Clin Oncol 2007). The agreement of Ki67 level was 85.7% (24/28) with a Kappa statistic value of 0.71.

**Conclusions:** The judgment of histological type, ER status, and HER2 status by preoperative US-guided VABB can be used with confidence to determine the treatment strategies according to molecular subtype.

**P5-11-02**

**Prediction of Results of MammaPrint’s 70 Gene Signatures by Conventional Histopathological and Biological Approaches in Patients with Breast Cancer.**

**Background:** Several studies have shown that MammaPrint’s gene signatures allow prognostic stratification of breast cancers that is superior to the currently used clinico-pathological risk factors. MammaPrint has also been reported to predict chemotherapy response. The aim of this study was to find out whether conventional histopathological and biological approaches can be used to predict MammaPrint results.

**Materials and Methods:** 96 invasive breast carcinomas were studied (of them, 34 cases with positive lymph nodes). For MammaPrint, fresh material from breast carcinomas was sent to Agendia (Amsterdam) in the provided RNA-laters. Conventional assays included: (i) histopathologic parameters combined according to a so called “Graz Risk Assessment” scheme (“GRA”, see below), (ii) immunohistochemistry for MIB-1 (Ki-67) as the “only parameter”, (iii) Nottingham Prognostic Index (NPI), (iv) uPA/PAI-1 (Elisa, cut-off for uPA: 3 ng/mg, cut-off for PAI-1: 14 ng/mg), and (v) flow cytometry (either >6% or >10% for SPF). The “GRA” consisted of 4 “main” factors (high nuclear grade, MIB-1 >20%, Her2/neu pos. (immunohistochemistry or FISH), vascular invasion (either lymphatic or blood vessels) or lymph node metastasis) and 5 “minor” factors (ER neg., PR neg., p53 >10%, tumor necrosis and age > 40 y.o.). Tumors were classified as high risk when at least 4 parameters or 2 “main” factors were present. For MIB-1 scoring, at least 500 cancer cells were counted in each case. Different MIB-1 cut-offs (10%, 15%, 20%, 25%, and 30% or more) were tried. All analyses were performed independently and the results of each method were blinded. Overall accuracy, sensitivity, specificity, positive predictive value (PPV),
P5-11-03
Real-Time Imaging of Human Breast Tissue with Reflectance Confocal Microscopy: Correlation with Routine Pathology.

Fogarty SP, Shiffert MT, Berezowski K, Hartmann D, Cabrera MC, Sidawy MK, Furth PA, Liu MC. Georgetown University, Washington, DC

Background: Near-infrared reflectance confocal microscopy (RCM) allows for immediate noninvasive 3-D optical sectioning of opaque objects, such as human tissue, without using the potentially destructive staining and fixing methods used with routine pathology. Recently, RCM has been used to differentiate between malignant and non-malignant dermatologic conditions. We hypothesize that this technique can be used to efficiently and reliably evaluate human breast tissue for the presence of malignancy without compromising the ability to perform routine immunohistochemical (IHC) analyses that accompany the diagnosis of invasive breast cancer.

Methods: 45 core needle breast biopsies (12mmx2mm) were collected under sonographic guidance. Biopsy specimens were immediately placed in phosphate buffered saline, injected with 5% acetic acid to enhance reflectivity of the nuclei, and imaged within 5-10 minutes. Digital images of the nuclear and cellular morphology from each intact specimen were acquired and catalogued within 1 hour of biopsy using the VivaCell 5000. Tissue samples were then formalin-fixed and sectioned for routine H&E evaluation or IHC assays. A board certified pathologist trained on 16 paired RCM images and H&E slides was given the blinded test set created from these 45 breast biopsies and asked to evaluate the RCM images for the presence of carcinoma. Preliminary evaluation was also done on 5 biopsy samples with known estrogen receptor (ER) and progesterone receptor (PR) status to determine the feasibility of assessing ER/PR on tissue treated with acetic acid for RCM.

Results: Routine H&E staining identified invasive carcinoma 10/45 biopsy samples (9 invasive ductal [IDC], 1 invasive lobular [ILC]); 2 specimens with IDC also contained ductal carcinoma in situ (DCIS). Evaluation of the RCM images led to the same diagnosis of invasive carcinoma vs. not in all 45 samples and correctly identified 6/9 IDC and 1/1 ILC. RCM correctly identified 1/2 specimens known to contain DCIS. RCM misclassified 3 IDC as DCIS (1), ILC (1), or lobular carcinoma in situ (1), and 1 DCIS as ILC. With respect to the determination of ER/PR status, RCM accurately assessed positivity for both receptors in all 5 specimens.

Conclusions: RCM is comparable to standard microscopy for the reliable identification of carcinoma, and the ability to evaluate breast tissue for malignancy using this technology allows for real-time pathology and may negate the need for repeat diagnostic biopsies to ensure adequate sampling for diagnosis. Importantly, the ability to perform routine IHC for ER/PR status after tissue processing for RCM appears to be preserved. Further evaluation applying the existing technology to a larger sample size for histopathologic correlation, assessment of ER/PR status, and evaluation for HER2 status are planned. These encouraging findings support interest in tailoring RCM for breast tissue to improve the ability to distinguish between invasive vs. in situ disease, and ductal vs. lobular histology.

A New Immunohistochemistry-Based Assay SBrC5 Classifies Invasive Breast Cancer Subtypes – Profiling Five Biomarkers in One Single Test.

Liu H, Muralitharan S. Thermo Fisher Scientific, Fremont, CA

Background: Obtaining expression status of estrogen receptor (ER), progesterone receptor (PR) and Her2 is essential for guiding treatment and predicting outcome for breast cancers. By adding cytokeratin 5/6 and EGFR to the above mentioned three common biomarkers, a five-biomarker breast cancer panel has been validated in previous studies for identifying the basal-like subtype with superior prognostic values than the triple negative subtype1. The current study aimed to evaluate a new immunohistochemical assay, named Subtyping Breast Cancers 5-in-1 Assay (abbreviated as SBrC5, or “the assay” in this poster), for classifying breast cancer subtypes.

Material and Methods: A cocktail of ER, PR, Her2, cytokeratin 5/6 and EGFR antibodies (SBrC5 Cocktail) and the MultiVision Detection Kit (TFS Cat. #: TL-012-MARH) were used in generating the data for this poster. The Multivision Detection Kit is a double staining system with two visualizing colors, red and blue. The assay was performed on a breast cancer tissue microarray containing 75 cases in duplicate. Both color and cellular localization of the staining generated from the assay was used for the result interpretation. There were three staining clusters: 1) Red Nuclei indicated ER or PR positive; 2) Red Membrane indicated Her2 expression; and 3) Blue Membrane or Cytoplasm indicated EGFR or cytokeratine 5/6 positivity. The concordance for the assay when compared to the above mentioned three common biomarkers, and predicting outcome for breast cancers. By adding cytokeratin 5/6 and EGFR to the above mentioned three common biomarkers, a five-biomarker breast cancer panel has been validated in previous studies for identifying the basal-like subtype with superior prognostic values than the triple negative subtype1. The current study aimed to evaluate a new immunohistochemical assay, named Subtyping Breast Cancers 5-in-1 Assay (abbreviated as SBrC5, or “the assay” in this poster), for classifying breast cancer subtypes.

Results: Significant association with MammaPrint on univariate analysis for both receptors in all 45 specimens and correctly identified 6/9 IDC and 1/1 ILC. RCM correctly identified 1/2 specimens known to contain DCIS. RCM misclassified 3 IDC as DCIS (1), ILC (1), or lobular carcinoma in situ (1), and 1 DCIS as ILC. With respect to the determination of ER/PR status, RCM accurately assessed positivity for both receptors in all 5 specimens.

Conclusions: RCM is comparable to standard microscopy for the reliable identification of carcinoma, and the ability to evaluate breast tissue for malignancy using this technology allows for real-time pathology and may negate the need for repeat diagnostic biopsies to ensure adequate sampling for diagnosis. Importantly, the ability to perform routine IHC for ER/PR status after tissue processing for RCM appears to be preserved. Further evaluation applying the existing technology to a larger sample size for histopathologic correlation, assessment of ER/PR status, and evaluation for HER2 status are planned. These encouraging findings support interest in tailoring RCM for breast tissue to improve the ability to distinguish between invasive vs. in situ disease, and ductal vs. lobular histology.
obtain subtypes information in biopsy settings where the tumor tissue obtained is often insufficient for multiple tests required to accomplish such task by existing methods. 

P5-11-05

Garcia-Saenz JA, Romero A, Lopez Garcia-Asenjo JA, Roman JM, Moreno A, Fuentes M, Furio V, Pelayo A, Diaz-Rubio E, Caldes T, Martin M. Hospital San Carlos, Madrid, Spain; Hospital Principe de Asturias, Alcalá de Henares, Madrid, Spain; Hospital Gregorio Maranon, Madrid, Spain

Background: Measurement of residual disease following neoadjuvant chemotherapy that accurate predicts long-term survival in locally advanced breast cancer (LABC) is an essential requirement for new drugs efficacy evaluation. Several methods to assess neoadjuvant chemotherapy tumor response have been described. However, to our knowledge, agreement between methods and correlation with survival in independent prospective cohorts has not been reported.

Patients & Methods: In this study we report neoadjuvant chemotherapy tumor response and survival in 151 consecutive LABC patients, included in a neoadjuvant clinical trial (http://www.clinicaltrials.gov; NCT00123929). Patients were randomized to either neoadjuvant docetaxel 100 mg/m² every 21 days or neoadjuvant doxorubicin 75mg/m², every 21 days, for 4 cycles. Following surgery, response was established according to three methodologies: the measurement of residual breast cancer burden (RBC) as described by Symman’s (Symmans WF et al. J Clin Oncol. 2007;25:4414-22), Miller and Payne classification (Ogston KN et al. Breast. 2003;12:320-7) and RECIST criteria. Regarding to Symmans classification we have evaluate both RBC index, as a continuous variable, and RBC classes as a categorical variable (RBC-0,I,II,III). Kappa Cohen’s coefficient (K) was used to test agreement between methods. We assessed the correlation between treatment outcome and overall survival (OS) by calculating the Harrell’s C- statistic.

Results: Median of follow up was 51.9 months. All three methods showed a moderate capacity to classify patients according to OS. The C-statistic to predict OS was 0.76 (IC: 0.67- 0.84) for RBC index and 0.71 (IC: 0.64-0.78) for RECIST criteria and 0.69 (0.60-0.78) for Miller and Payne classification. Interestingly, we did not encountered any death events within RCB-0 class. No significant differences were found between C-statistic when patients were stratified according to therapy. In order to assess the agreement between techniques, we grouped categories 1 and 2 of Miller and Payne classification in 1 category. The agreement between Miller and Payne classification and Symmans method was very high (K=0.87). In contrast, we found a moderate-fair agreement between Miller and Payne classification and RECIST criteria (K=0.46) and Symmans method and RECIST criteria (K=0.27).

Conclusion: All three methods predicted fairly well OS. RCB-0 identified the best outcome group. The agreement between methodologies based in pathology analyses was very high. However, the agreement falls off when these methodologies were compared with RECIST criteria.

P5-11-06
Immunohistochemistry Discordance between Primary and Recurrent Tumors in Breast Cancer. Analysis of Potential Influence of Technique Bias by Comparing Test-Results under Two Different Conditions.

Introduction: Discordance in expression of estrogen (ER) or progesterone receptors (PgR) and HER2 has been previously described in several studies, having this discordance an important impact on therapeutic approach or even in survival. However it is unclear whether discordance is a reflex of a clonal differentiation to a more aggressive biological tumour or the consequence of technical biases or inter-explorer variability. We aimed to assess the role of technique biases in observed discordance between primary tumour (PT) and recurrent tumour (RT) by analyzing discordance in two different situations: routine versus optimal conditions.

Patients and methods: We conducted a retrospective study in patients (pts) diagnosed with a recurrent breast cancer in the Hospital Clinico of Valencia between January 2000 and June 2010. All patients had a previous histological diagnose of the PT and all underwent a second histological study of the RT. Discordance was assessed in terms of hormone-sensibility (HS) (any ER or PgR +) vs hormone-resistance (HR) (ER-/PgR -) and triple negativity (TN) (ER-, PgR-, HER2-) vs non-TN (any positive). Routine conditions were referred to the immunohistochemistry (IHC) assessment of the normal practice on the base of which therapeutic decisions were made. Routine conditions were performed in the Pathology Department of our institution but PT and RT were usually evaluated at different timing and occasionally by different pathologists. In order to assess potential laboratory biases we repeated IHC analysis under optimal conditions. For these optimal conditions analyses, paired samples from both PT and RT were re-assessed at the same time and tests were performed in the same way. Final determination of the results was made by two highly trained pathologists and in case of disagreement in any determination, both explorers re-assessed the sample at the same time.

We evaluated discordance between PT and RT under both conditions, and the accuracy of determinations in PT or RT between both conditions.

Results: 128 paired samples (from 64 different pts) were analysed. Median age of the series was 48.5 years (range 27-83). Recurrences were loco-regional in 14 pts (21.9%) and distant in 50 pts (78.1%). RT tissue was obtained from skin and soft-tissues in 18 pts (28.1%), lung in 11 (17.2%), bone in 10 (15.6%), lymph nodes in 10 (15.6%), pleura/peritoneum in 9 (14.1%) and liver in 6 (9.4%). Discordant cases between PT an RT in terms of HS/HR were 30.4% in routine conditions and 9.8% in optimal conditions. In terms of TN/non-TN were 14.3% in routine vs 8.2% in optimal conditions. Accuracy in results HS/HR between routine and optimal conditions was 80.7% in PT and 76.0% in RT. In results of TN/non-TN accuracy between both conditions was 94.2% in PT and 87.2% in RT.

Conclusions: Results suggest that an important rate of discordance observed in routine conditions might be strongly influenced by technique biases. However, changes observed in optimal conditions with 9.8% discordance in HS/HR and 8.2% in TN/non-TN suggest that in a small proportion of tumours, observed discordance might be explained by biological mechanisms.
Receptor Concordance in Triple-Negative Breast Cancer (TNBC) Recurrences.

Killian ME, De Los Santos JF, Forero-Torres A, Krontiras H. University of Alabama at Birmingham, Birmingham, AL

Background: The phenotype of TNBC is defined by absence of estrogen (ER) and progesterone receptors (PR) and lack of amplification of the HER2 oncogene. It is an aggressive form of breast cancer, and despite sensitivity to contemporary chemotherapy, TNBC have a poorer prognosis than ER positive phenotypes, marked by early relapses. This study examines the concordance of receptor status in recurrences among patients with TNBC.

Methods: After obtaining IRB approval, we identified patients with triple negative breast cancer treated at the University of Alabama at Birmingham between 1998 and 2010. Patient and tumor characteristics and disease status were recorded. Patients with ER, PR, or HER2 (3+) positivity on immunohistochemistry (IHC), or HER2 amplification by fluorescence in situ hybridization were excluded. Data regarding the receptor status of the recurrence, if known, was documented.

Results: Five hundred and two women with TNBC were diagnosed at our institution between 1998 and 2010. Of these patients, 95/502 (19%) had recurrences. Twenty-seven (28%) were local, 18 (19%) were regional, 35 (37%) were distant, and 15 (16%) were both local-regional and distant. These women ranged in age from 33 to 84 years of age. Of the women with a recurrence, 78/95 (82%) had a biopsy confirming breast cancer recurrence. Of those biopsied, 33/78 (42%) had receptor studies performed, and of these, 30 included data for estrogen, progesterone and HER2 receptors. The remaining 3 had only IHC for estrogen receptors performed. Twenty-two/thirty (73%) had concordance on their biopsy with their initial TNBC status, whereas 8/30 (27%) women developed a pathologically discordant recurrence. Conclusion: In this single institution study of TNBC patients, approximately one quarter of patients developed a pathologically discordant distant recurrence noted at biopsy. It is unclear whether patients experiencing a pathologically discordant recurrence differ in prognosis from those with concordant recurrences. Further study is necessary to evaluate this and determine whether routine biopsy based on pathologic discordance rates and outcomes are warranted.

High Concordance of 5 HER2 In Situ Hybridization Methods with Abbott FISH.

Boers JE, Netjes C, Meeuwissen HC, Prinsen C, Bart J, van der Logt EMJ, Schuuring E. Isala Klinieken, Zwolle, Netherlands; University Medical Center, Groningen, Netherlands

Background: HER2 in situ hybridization (ISH) has become a common test in breast cancer. Abbott FISH was used in most clinical studies showing the efficacy of anti-HER2 treatment in HER2 positive carcinomas. Only reports comparing one or two of newly developed ISH assays with Abbott FISH have been published previously. We conducted a comprehensive concordance study of 5 ISH methods with Abbott FISH in a large series of breast carcinomas.

Methods: Tissue Micro Arrays (TMA) were constructed by taking three 0.6 mm tissue cores from formalin-fixed/paraffin-embedded tissue-blocks from 402 primary breast carcinomas diagnosed in 2007 (supported by the Dutch Pathological Society). Up to 384 cases were analyzable in the TMA. ISH was performed after ample experience with 6 ISH assays. Scoring was performed by two independent observers without knowledge of the other ISH data according the ASCO-guidelines for HER2-testing. HER2 and chromosome 17 (Chr17) signals were counted separately, the HER2:Chr17 ratio was calculated and considered positive when the ratio was ≥ 2.0 In cases with a ratio was between 1.8 and 2.2, additional enumeration was performed. The discordant cases were reviewed and scores were reassigned on consensus of opinion. Concordance and Cohen’s kappa score were calculated.

Results: see table.

High Concordance of Microarray Based Determination of ER, PR and HER2 Receptor Status and Local IHC/FISH Assessment Worldwide in 749 Patients.

Wesseling J, Cusumano G, Tinterrri C, Sapino A, Zanconati F, Lute-Holtzoi M, Nguyen B, Deck K, Querzoli P, Perin T, Giardina C, Seitz G, Guinebretiere J, Barone J, Watanabe T. Netherlands Cancer Institute, Amsterdam, Netherlands; CHC, Liege, Belgium; Istituto Clinico Humanitas, IRCCS, Rozzano, Italy; Universita di Torino, Torino, Italy; Universita di Trieste, Trieste, Italy; Medisch Spectrum Twente, Enschede, Netherlands; Locy Beach Memorial Health Care, Locy Beach, CA; Saddleback Memorial Medical Center, Laguna Hills, CA; Instituto di Patologia, Universita di Ferrara, Ferrara, Italy; Centro di Riferimento Oncologico, Aviano, Italy; Instituto di Anatomia Patologica, Univeristità degli Studi di Bari, Bari, Italy; Klinikum Bamberg, Bamberg, Germany; Centre Rene Huguenin, Saint-Cloud, France; Comprehensive Breast Care and Sharp Memorial Hospital, San Diego, CA; Hamamatsu Oncology Center, Hamamatsu, Japan

Background

The level of estrogen receptor (ER), progesterone receptor (PR) and HER2 expression is predictive for prognosis and/or treatment response in breast cancer patients. However, differences in fixation and IHC and subjective interpretation can substantially affect the accuracy and reproducibility of the results. The commercially available TargetPrint test measures the mRNA expression level of ER, PR and HER2 and provides high quality second opinion for local IHC/FISH assessment. This study compares results from the microarray-based TargetPrint with IHC and FISH (for HER2 IHC2+) generated by local standard procedures.

Methods

Prospective tumor samples were collected for 749 patients diagnosed with breast cancer stage I to IV between February 2008 and January 2011. The mRNA level of ER, PR and HER2 (TargetPrint) was assessed in the Agenda laboratories (Agenda BV, Amsterdam, the Netherlands) in fresh tumor samples submitted from 22 hospitals from Europe, New Zealand, Japan and US. The results of the IHC/FISH assessments performed according to the local standards at the hospitals were compared to the quantitative gene expression readouts.

Results

Of the 749 samples, IHC assessment was unknown for 5 ER samples and 4 PR samples; FISH was unknown for 24 samples. TargetPrint read out was not assessed for HER2 for 11 samples. Median age of these patients was 61 years. Comparison of IHC and gene expression read out by TargetPrint showed a concordance of 95% for ER; 82% for PR and 91% for HER2.
In this study, only 4% of all IHC ER positive samples were classified negative by microarray. In contrast, 14% of IHC ER negative samples were classified positive by microarray. However for HER2, 28% of IHC/FISH HER2 positive samples were classified negative by microarray and 5% of IHC/FISH HER2 negative samples were classified positive by microarray. Samples with discordant classifications for TargetPrint and local assessment are being reviewed in greater detail by a central pathologist.

Conclusions
Microarray based readout of ER, PR and HER2 status using TargetPrint is highly comparable to local IHC and FISH analysis in 749 analyzed samples in various hospitals worldwide. The results indicate mRNA expression read out for ER, PR and HER2 by TargetPrint provides high quality second opinion for local IHC/FISH assessment.

P5-11-10
Reproducibility and Robustness of the FDA Approved INFORM HER2 Dual ISH DNA Probe Cocktail Assay.

Background: Amplification and/or HER2 overexpression is associated with poor clinical outcome for patients with invasive breast carcinoma. Determination of HER2 status dictates eligibility of patients for trastuzumab (Herceptin) therapy, which has been shown to improve prognosis. We present data from the inter-observer reproducibility and robustness studies of the FDA approved INFORM HER2 Dual ISH DNA Probe Cocktail (HER2 Dual ISH) assay, which is an alternative to FISH. The assay is fully automated and is scored using light microscopy providing morphological context.

Methods: Ninety-five human invasive breast carcinoma specimens (a mix of amplified and non-amplified cases) were stained in a study, using the HER2 Dual ISH assay. The slides were enumerated by two qualified readers. The same cohort was stained using PathVysion FISH and read by one qualified reader. To verify the robustness of the HER2 Dual ISH assay, customer selectable options for factors known to impact the staining quality and intensity, which can be varied for troubleshooting, were tested on human invasive breast carcinoma cases and xenografts. The slides were evaluated by one qualified reader. For both studies all assay steps were fully automated on a VENTANA BenchMark XT automated slide stainer using silver metallographic and red colorimetric detections for Dual ISH.

Results: In the inter-observer study the first pass staining success rate was >93% for the HER2 Dual ISH assay, while the FISH first pass staining success rate was 59%. Some cases were rescued after a second attempt, which yielded a second pass staining success rate of 80% for FISH and 97% for HER2 Dual ISH. The negative, positive and overall agreement rates and 95% confidence intervals for the 61 clinical samples of this cohort that were enumerable with both FISH and the HER2 Dual ISH assay are 94.7 (75.4-99.1), 95.2 (84.2-98.7), 95.1 (86.5-98.3) and 89.5 (68.6-97.1), 97.6 (87.7-99.6), 95.1 (86.5-98.3) for reader A vs. FISH and reader B vs. FISH respectively. The positive and negative agreement rates for the inter-observer reproducibility of the HER2 Dual ISH assay were 94.7 and 97.6 %, respectively.

In robustness testing, the recommended staining protocol was shown to be effective. All conditions tested resulted in appropriate staining (except for mildest cell conditioning and protease options).

Conclusion: The fully automated FDA approved INFORM HER2 Dual ISH assay is robust, reproducible and concordant with the manual FISH assay in determining HER2 status in invasive breast carcinoma.

Automated Quantification Methods Improve the Accuracy of PR as an Independent Prognostic Factor in Tamoxifen Treated Breast Cancer Patients.

Klimowicz AC, Kornaga EN, Yau A, Pohorelic BK, Petirillo SK, Konno M, Magliocco AM. Tom Baker Cancer Centre, Calgary, AB, Canada; University of Calgary, Calgary, AB, Canada

Background: Adjuvant endocrine therapy reduces the risk of recurrence and death in hormone receptor positive breast cancer patients. However, 40-50% of estrogen receptor (ER) positive tumors are resistant to endocrine therapy. We have previously shown that quantitative measurement of ER protein expression has limited value as a prognostic marker in tamoxifen treated patients. The presence of progesterone receptor (PR) expression has shown promise as prognostic and/or predictive marker for endocrine therapy, including adjuvant tamoxifen, but reports are contradictory. Automation of scoring methods will improve the accuracy of PR scoring and its value as a prognostic factor.

Methods: This retrospective study evaluated breast cancer patients treated with adjuvant tamoxifen (n=458) from 1985-2000 at the Tom Baker Cancer Centre, Calgary, Canada. Tissue microarrays were assembled from formalin fixed paraffin embedded tumor tissue. Clinico-pathologic data was obtained from chart review. Five-year disease-free survival (DFS) was the primary outcome. DAB-based PR staining was used to generate Allred PR scores, as well as to generate scores for PR percent area expression and PR integrated optical density (PR IOD) using the DAKO ACIS III scanner and image analysis software. PR tumor nuclear pixel intensity density scores were obtained using fluorescence-based PR staining, scanned and quantified with a HistoRx PM2000 scanner and AQUA image analysis software. Continuous variables were dichotimized using Xtile.

Results: In our tamoxifen cohort, 5-year DFS was associated with tumor grade [HR 4.9(3.5-6.9), p<0.001], tumor size [HR 2.7(1.9-3.8), p<0.001], lymph node status [HR 5.7(4.0-8.0), p<0.001] and ER status [HR 2.4(1.3-4.7), p=0.008]. Low PR was associated with significantly worse DFS regardless of the method used to quantify its expression. Methods of analysis requiring less subjective input had stronger associations between PR expression and outcome. The subjective identification of tumor and subjective biomarker quantification used in Allred scoring [HR 2.2(1.4-3.3), p<0.001] was less effective than ACIS scoring [PR percent area: HR 2.8(1.8-4.3), p<0.001; PR IOD: HR 2.9(1.9-4.6), p<0.001], which only requires subjective identification of the tumor. All methods were inferior to fluorescence-based AQUA scoring [HR 4.2(2.7-6.5), p<0.001], which automatically detects the tumor nuclear area using pan-cytokeratin and DAPI staining and measures the PR expression within this compartment. Multivariate analysis, which included age, tumor size, grade, tumor nuclear pixel intensity density and ER status, confirmed that AQUA [HR 3.7(2.0-5.6), p<0.001] was superior to ACIS PR percent area [HR 2.3(1.4-3.9), p=0.002] and ACIS PR IOD [HR 2.7(1.6-4.8), p<0.001], all of which were superior to Allred scoring [HR 1.2(0.7-2.1), p=0.511].

Conclusions: We conclude that: 1) PR is an independent prognostic marker in our cohort, 2) using less subjective, automated quantitative scoring methods improves the value of PR as a prognostic biomarker,
AQUA appears superior to other automated methods and that 4) the incorporation of digital image analysis into practice would improve the prognostic value of PR expression in the clinical setting.

**P5-11-12**
Correlation of Ki67 Expression between Initial Biopsy and Surgical Specimen in Untreated Breast Cancer Patients. Does Menstrual Cycle Matter?
Torrejón D, Rubio I, Sanchez-Olle G, Peg V, Sansano I, Jimenez J, Gomez P, De la Peña L, Di Cosimo S. Vall d’Hebron University Hospital, Barcelona, Spain; Solit Breast Cancer Research Group

**Background:** The measure of proliferative index by Ki67 expression is being increasingly used to identify breast cancer subtype and to guide treatment decisions. Findings on initial tumor biopsy are in some cases, such as for primary systemic treatment, the only data available prior to treatment. In addition, results from window studies to develop novel anti-tumor agents depends on initial breast cancer biopsy findings. This study aims to compare the Ki67 expression on initial biopsy with matched primary breast cancer surgical specimens. In addition, we aimed to explore the possible effect of hormonal levels - as reflected by menstrual cycle phase - on discordant Ki67 cases. Material and Methods: A total of 50 random cases were analyzed by 2 blinded pathologists. Ki67 expression was collected as a continuous variable. Tumors were then classified as high - or low-proliferative according to a Ki67 value of > or = 15% or < 15%, respectively. Spearman Rank test was used to study the correlation between initial and surgical biopsies. Data on menstrual cycle phase at the time of biopsy and surgery were retrieved from medical history of all pre-menopausal patients.

**Results:** Baseline patients characteristics are as follows: median age 48 (35-56 years), premenopausal 27 (54%), postmenopausal 23 (46%), invasive ductal carcinoma 38 (76%). A differential expression of Ki67 was found in 36 patients (72%), 20 pre- and 16 post-menopausal. Spearman’s Rank Order correlation did not show any significant difference between biopsy and matched surgical specimen in terms of Ki67 expression. Indeed, there was a strong positive correlation between initial and surgical biopsy, which was statistically significant across all patients (rs = .556, P < 0.001), and regardless the menopausal status. However, 15% of pre-menopausal patients transformed from Ki67 low to high. Therefore, data on pre-menopausal patients were analyzed according to the phase of menstrual cycle at the timing of initial and surgical biopsies. The Spearman’s Rank Order gave no correlation among 14 pre-menopausal patients with differential menstrual cycle phase at the timing of initial biopsy and surgical excision (rs = .411, P = 0.145).

**Conclusions:** Initial breast cancer biopsy can be used with high confidence for Ki67 determination. However, it should be noted that menstrual cycle phase could affect Ki67 expression as women with distinct menstrual cycle phase at the time of initial biopsy and final surgery do not show concordant results. Prospective evaluation of Ki67 expression in premenopausal patients is being planned.

**P5-11-13**
Rates of Upgrade to Malignancy for 271 Cases of Atypical Columnar Cell Hyperplasia Diagnosed by Breast Core Biopsy.
Peres A, Barranger E, Becette V, Boudinet A, Guinebretiere J-M, Cherel P. Lariboisiere Hospital, Paris; France; Institut Curie, Saint-Cloud, France

**Purpose:** Atypical columnar cell hyperplasia (ACCH) is a borderline lesion that might represent an early stage in the development of certain low-grade carcinomas in situ (CIS) and invasive cancers. There are no guidelines on its management. Our objectives were to determine the upgrade to malignancy rate and identify a subpopulation of patients that might undergo just mammographic surveillance.

**Methods:** We retrospectively reviewed the data for 271 ACCH cases among 5555 breast core biopsies obtained over a 7-year period (Jan. 2003 – Jan. 2010). We collated clinical data (age, history of cancer, menopausal status), radiological data (lesion type, size, Bi-Rads category), technical data (number of biopsies, needle gauge, excision quality) and histological data and sought correlations between these factors and upgrade rate.

**Results:** The 271 ACCH comprised 128 cases of pure ACCH, 135 cases of ACCH + atypical ductal hyperplasia, and 8 cases of ACCH + atypical lobular hyperplasia. Overall, 184 patients underwent surgery and 46 mammographic surveillance. Surgery detected 34 cases of malignancy (23 CIS, 7 invasive cancers, and 4 mixed cases) giving a 15% upgrade rate. Quality of excision was the only factor associated with under-diagnosis.

**Conclusion:** The presence of ACCH at biopsy warrants surgery.

**P5-11-14**
Flat Epithelial Atypia of the Breast: A Single Institution Experience.
Joh JE, Acs G, Kiluk JV, Laronga C, Khakpour N, Lee MC. H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL

**Background:** Flat epithelial atypia of the breast is a relatively new entity of unknown significance. Our objective is to evaluate our surgical experience with this diagnosis.

**Methods:** A single institution database of breast patients from 2005-2010 was used to identify women who were diagnosed with flat epithelial atypia on core biopsy and subsequently underwent surgical excision. Patient data regarding history, type and reason for biopsy, and associated pathology was collected. Individuals diagnosed with flat epithelia atypia and cancer on core biopsies in the same breast were excluded.

**Results:** There were 52 patients who underwent surgical excision for the primary diagnosis of flat epithelial atypia. There were 3 (6%) patients with a personal history of breast cancer, 14 (27%) patients with a family history of breast cancer, and 11 (21%) patients with a concurrent new diagnosis of breast cancer in the contralateral breast. Core biopsy was recommended in most (81%) cases because of suspicious calcifications on mammography. Twenty-eight (54%) patients were found to have flat epithelial atypia associated with other atypical breast hyperplasia and 24 (46%) had flat epithelial atypia as the most significant lesion on core biopsy. In 8 (15%) patients, there was a sonographic correlate that was biopsied; 5 had only flat epithelial atypia and 3 had flat epithelial atypia associated with other atypical hyperplasia. Of the 52 patients there were 4 (8%) patients who upstaged to ductal carcinoma in-situ on surgical excision. There were no cases of invasive carcinoma. All ductal carcinoma in-situ cases were associated with other atypical breast hyperplasia, not flat epithelial atypia alone.

**Conclusion:** Though flat epithelial atypia may be associated with an increased risk of breast cancer, surgical excision of pure flat epithelial atypia may not be necessary. Larger studies are needed to corroborate these findings.
P5-11-15
Should HER-2 Score 0/1+ Breast Cancer Cases Be Retested by In-Situ Hybridisation? Results of a Multicenter Retesting Study.
Reiner-Concin AM, Lax S, Regentin P, Kronberger C, Jasarevic Z, Bogner S. Danube Hospital, Vienna, Austria; General Hospital Graz West, Graz, Austria; Medical University Graz, Graz, Austria; LKH Salzburg, Salzburg, Austria; LHK Feldkirch, Feldkirch, Austria; LKH Linz, Linz, Austria

Background: HER-2 status is vital for selection of appropriate therapy for breast cancer patients. Accuracy of immunohistochemistry (IHC) varies with a major problem of false negative testing. To assess the false negative rate retesting by in situ hybridisation was performed on a group of primary breast cancers in which according to guidelines routine retesting is not recommended.

Material and Methods: 570 breast cancers from 5 pathology departments scored 0/1+ by IHC (HercepTest or 4B5-antibody) were retested by HER2-Dual-SISH (BDISH) in a central laboratory. CAP/ASCO guidelines were applied. Cases showing ratios in the amplified or equivocal range by BDISH were further analysed by fluorescence in situ hybridisation (FISH) using Pathvysion® and ZytoLight® and retested centrally by IHC using 4B5 antibody (Ventana).

Results: 25/570 cases (4.38%) were amplified by BDISH, the majority with low level amplification (ratios ≤ 3.26). Only two cases showed high level ratios (6.35 and 6.48). 17/570 cases (2.98%) showed ratios by BDISH in the equivocal range (1.8 – 2.2). 24 amplified and 17 equivocal cases underwent further retesting. In one case no tumor tissue was available for further testing.

On further testing 17/24 (71%) BDISH-amplified cases showed high level amplification (ratios ≥ 4). Subsequently 3/13 score 2+ cases were amplified by Pathvysion® and 9/13 by ZytoLight®, 3/4 score 3+ cases were amplified by both FISH assays. In case of amplification ratios of BDISH and both FISH assays appeared to be in the same range. Only 2/17 BDISH-equivocal carcinomas were confirmed equivocal by Pathvysion® and 6/17 were confirmed equivocal by ZytoLight®. All other BDISH-equivocal cases were non-amplified by both FISH assays. Discrepant results between different methods could partly be caused by interobserver variability. This question is currently under investigation. Overall, after multistep retesting amplification occurred in only 17 cases (2.98%).

Discussion: Amplification is rare in immunohistochemically HER-2 negative breast carcinomas and occurred predominantly at low level in our study. Low level amplification seemed to be diagnosed more frequently by BDISH compared with FISH. Since clinical data demonstrate a benefit of therapy even in carcinomas with low level amplification the identification of these carcinomas might be of interest.

Conflicts of Interest: The study was supported by Roche Austria GmbH.

P5-11-16
CD44 and CD24 Expression in Ductal Invasive Breast Carcinomas, Classified by Molecular Subtypes and Its Association with Prognostic Factors.
Bernardi MA, Logullo AF, Pasini FS, Nonogaki S, Soares FA, do Socorro Maciel M, Brentani MM, Hospital AC Camargo, São Paulo, Brazil; Universidade Federal de São Paulo, São Paulo, Brazil; Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil; Hospital A.C. Camargo, São Paulo, Brazil

Background: Breast carcinomas (BC) exhibit intra tumoral heterogeneity being stratified into several subgroups based in gene expression profiles or histochemical biomarkers. It was suggested that this heterogeneity is derived in part from the transformation of different subsets of cancer stem cells (CSC) in each intrinsic subgroup. The presence of CSC can be evidenced by phenotypic analysis of CD44 e CD24. This study aimed to identify the CD24 and CD44 immunophenotypes within invasive ductal breast carcinoma (IDC) subgroups defined by immunohistochemistry markers and determine its influence on prognosis as well as its association with the expression of Ki67, citokeratins (CK5 and CK18) and claudin-7.

Methods: Immunohistochemistry expression of CD44 and CD24 alone was investigated in 95 IDC cases arranged in a tissue microarray (TMA). The association with subgroups defined as luminal A and B;HER2 rich and triple negative, or with the other markers and prognosis was analyzed. Results: CD44+/CD24- and CD44+/CD24+ were respectively present in 8.4% and 16.8% of the tumors, a lack of both proteins was detected in 6.3%, while CD44+/CD24+ was determined in 45.3% of the tumors. Although there was no significant correlation between subgroups and different phenotypes, the CD44+/CD24- phenotype was more common in the basal subgroups but absent in HER2 tumors, whereas luminal tumors are enriched in CD44-/CD24+ and CD44+/CD24+ cells. The frequency of CD44+/CD24- or CD44-/CD24- have not been associated with clinical characteristics or biological markers. There was also no significant association of these phenotypes with the event free (DFS) and overall survival (OS). Single CD44+ was evident in 57.9% and was marginally associated to grading and not to any other tumor characteristics, while CD24+ was positive in 74.7% of the tumors, showing a significant association with ER, PR and Ki67 and a marginal association with CK18 and claudin-7. Expression of claudin-7 and Ki67 did not associate with the cancer subgroups, while a positive association between CK18 and the luminal subgroups was found (p=0.03). CD44+ was not significantly associated with OS and DFS whereas CD24+ frequency although not significantly associated with OS was associated with a decrease in DFS (p=0.07). CK5, CK18 and Ki67 expression had no influence in OS or DFS, claudin-7 positive was associated with reduced DFS (p=0.05). Conclusions: There was no significant correlation between CD44+/CD24+ tumor cells frequency and event-free or OS. However, a tendency toward a favorable prognosis, was noted. Contrariwise the presence of CD44+/CD24+ suggested a worse prognosis. Both single CD44 and claudin-7 positivity were associated with reduced time of recurrence, suggesting a contribution of these markers to aggressiveness. Supported by FAPESP and CNPq.

Evaluating Tumor Heterogeneity in Immunohistochemistry Stained Breast Cancer Tissue.
Potts SJ, Landis N, Eberhard DA, Schmechel SC, Young D, Lange H. Flagship Biosciences, Flagstaff, AZ; University of North Carolina, Chapel Hill, NC: University of Minnesota, Minneapolis, MN

Context: Quantitative clinical measurement of heterogeneity in immunohistochemistry staining would be useful in both evaluating patient therapeutic response and identifying underlying issues in histopathology laboratory quality control.

Objective: To create a heterogeneity scoring approach (HetMap) that allows the visualization of an individual patient’s IHC heterogeneity in the context of a population.

Design: We combined HER2 semi-quantitative analysis with the use of ecology diversity statistics to evaluate cell-level heterogeneity (consistency of protein expression within neighboring cells in a tumor nest) and tumor-level heterogeneity (differences of protein expression across a tumor as represented by a tissue section). We evaluated the

Vacuum Assisted Biopsies of Ductal Carcinoma In Situ and Concordance with Post-Operative Histology: Implications for the Low Risk DCIS Trial.

Soumian S, Down SK, Roked F, Chaudhri S, Francis A. Queen Elizabeth Hospital, University Hospitals Birmingham, Birmingham, England, United Kingdom

Aim
The enormous increase in the diagnosis of ductal carcinoma in situ (DCIS) by the NHS Breast screening has not lead to an expected decrease in the incidence of invasive breast cancer. It is not clear if all grades of DCIS progress inexorably to invasive cancer if left untreated. There is recognition that DCIS is overtreated, if left alone may not cause harm during the woman’s lifetime. In the absence of new clinical trial data, surgery still remains the universal treatment. It is known that a higher proportion of patients with screen detected DCIS receive mastectomy than those with screen detected invasive cancer. Recently a randomized trial called the Low risk DCIS Trial has been proposed which intends to specifically compare the current treatment of low grade DCIS ie surgery with active monitoring using annual mammography. In order to effectively implement this, concordance between diagnostic biopsy and excision histology is vital and therefore vacuum assisted mammotome biopsy (VAB) and a central pathology review of diagnostic biopsy specimens prior to randomization will be mandatory. Therefore, in this study, we assessed the concordance between diagnostic biopsies performed by VAB technique and the post operative histology for DCIS in our institution.

Methods
Retrospective data of all diagnostic breast biopsies specifically using the VAB technique with the primary diagnosis of DCIS from year 2001 to 2010 in our institution was collected. Both screening and symptomatic patients were included. Concordance between diagnostic histology and post operative excision histology was assessed for high, intermediate and low grade DCIS. Demographic details and potential factors influencing concordance including number of cores taken and lesion size were also collected for analysis.

Results
A total of 161 cases were identified out of which 102 (63%) were of high grade, 35 (22%) of intermediate grade and 24 (15%) were of low grade histology. In the High grade group, the concordance with final histology was 70% (72/102). In this group, the diagnosis was upgraded to invasive carcinoma in 21% (21/102), 9% (9/102) were downgraded to intermediate or low grade. In the intermediate grade group, the concordance with final histology was 66% (23/35). In this group, the diagnosis was upgraded to invasive carcinoma in 11% (4/35) and to high grade in 17% (6/35). 6% (2/35) were downgraded to low grade. In the low grade group, the concordance with final histology was 71% (17/24). In this group, the diagnosis was upgraded to intermediate grade in 17% (4/24) and invasive carcinoma in 12% (3/24). All factors associated with lack of concordance were noted.

Conclusion
Concordance between VAB diagnostic biopsies of high, intermediate and low grade DCIS and post operative histology is good in this series and is to our knowledge the first to be reported using only large volume biopsies by VAB techniques. This audit has identified possible factors influencing the lack of concordance and these results with concordance data from other UK centres will be used by trial pathologists to refine protocols for the Low risk DCIS trial.

Magliocco AM, Ng ES, Kangarloo B, Konno M, Paterson A. Tom Baker Cancer Centre, Calgary, AB, Canada; University of Calgary, Calgary, AB, Canada

Background: Tamoxifen (TAM) has been commonly used as a selective estrogen receptor modulator for the treatment and prevention of breast cancer. Although this drug is effective in many patients, some develop resistant and eventually relapse. Recent studies suggest that the cancer recurrence could possibly be due to changes in drug metabolism. TAM is metabolized by the cytochrome P450 enzyme pathway into several metabolites including 4-hydroxy-tamoxifen (4-OH), N-desmethyl-tamoxifen (DMT) and N-desmethyl-4-hydroxy-tamoxifen (endoxifen). These metabolites have variable potencies in suppressing estrogen-dependent breast cancer. Differences in metabolism may contribute to the clinical inter-individual variability in TAM response. The aim of our study was to provide a comprehensive evaluation of TAM and its metabolites through quantitative measurement in breast cancer patients to help better understand the pharmacological effects of TAM therapy. In the past, most methods used to measure the levels of TAM and its metabolites were in plasma or fresh/frozen tissue samples. These samples are typically not available retrospectively, and their long-term storage is expensive and laborious.

Methods: We therefore explored the possibility to utilize formalin-fixed and paraffin-embedded (FFPE) tissues archived post breast surgery for quantification of TAM and its metabolites. Our laboratory has developed a rapid, sensitive and specific analytical method using liquid chromatography and tandem mass spectrometry (LC-MS/MS) for the measurement of TAM and its metabolites in FFPE tissues. The FFPE tissues were thin sectioned and deparaffinized by incubating twice with xylene for 10 min at room temperature. Sample clean-up was carried out subsequently using C2 solid-phase extraction, and detection was performed in the multiple-reaction monitoring mode with a triple quadrupole mass spectrometer. This method allows simultaneous quantification of TAM and three metabolites in FFPE tissues with a run time of 12 min.

Results: The assay had good inter- and intra-assay precisions (2-6 %CV), and was linear over the range of 0.01–5 ng/g for 4-OH and endoxifen, and 0.1–50 ng/g for TAM and DMT. The extraction recoveries were between 83-88%. The validated method was successfully applied to analyze the FFPE tissues obtained from two groups of breast cancer patients. Patients were categorized into those with tumor recurrence (R) and those without recurrence (NR) after at least 2 months of 20 mg/d TAM treatment. Levels of TAM, 4-OH, DMT and endoxifen in FFPE tissues were compared between the two groups. Our preliminary data show that the ratio of DMT/TAM was significantly higher in the R (6.7, n = 13) than the NR patients (14.2, n = 9) (p<0.05).

Discussion: The assay described here not only allows accurate quantification of TAM and metabolites in FFPE tissues, but also opens up an incredible opportunity and new challenges for researchers to excavate precious information from FFPE tissues, especially when these archival samples represent the only source of biomaterial available.

P5-12-04
Genetic Linkage between Acquired and Primary Lymphedema Evaluated through Whole Exome Sequencing and NIR Fluorescence Lymphatic Imaging.
Sevick-Muraca EM, Gonzalez-Graray ML, Fife CE, Guilliod R, Hall O, Marshall MV, Rasmussen JC, Aldrich MB, Darne C, Zhu B, Tan F-C, Caskey CT. University of Texas Health Science Center, Houston, TX; Memorial Hermann Hospital, Houston, TX

Acquired lymphedema is thought to arise from the damage of the lymphatic vasculature that transports excess fluid and macromolecules away from tissues for return to the blood vasculature. The onset of the cancer acquired disease can occur months to years after lymph node dissection and manifests itself as an accumulation of fluid and macromolecules in tissues that leads to edema and irreversible swelling. The rare disease of primary lymphedema is identical to cancer acquired lymphedema, with the exception that there is no trauma or cancer treatment that can be attributed as its cause. Primary lymphedema has been attributed to genetic causes since the late nineteenth century. Although there are five known genetic causes of hereditary or primary lymphedema, the majority of patients with lymphedema do not possess mutations in these genes. More recently, it has been proposed that a genetic link between cancer acquired and primary lymphedema exists. If a genetic susceptibility for cancer acquired lymphedema could be found, then we could predict which survivors will encounter the disease and could develop new therapies which are more effective than the current treatments that have remained unchanged for the past 80 years.

In an FDA approved investigational study, we used near-infrared (NIR) fluorescence imaging to phenotype the lymphatic architecture of subjects with both acquired and primary lymphedema, as well as their unaffected family members. We collected blood for DNA analyses. NIR fluorescence provided the phenotype of abnormal lymphatic function while whole exome sequencing provided the genotype. Bioinformatics analyses were then used to identify causative genes using cosegregation of familial genotypes using the phenotypes found through NIR fluorescence imaging.

The first family analyzed had members with primary and acquired lymphedema, in which mutations encoding for proteins that participate in the HGF/c-MET and PI3K pathways could potentially explain the inheritance of lymphedema in this family. The father and affected daughters were heterozygous for a de novo SNP HGF in the kringle binding domain that interacts with tyrosine kinase receptor c-MET. The father had a normal lymphatic phenotype. On the other hand, the mother and daughters were heterozygous for the de novo mutation of INPPL1 (SHIP-2), adjacent to the SH2 domain of the protein that is known to bind to the multifunctional docking site of c-MET and associates with proteins in the Rho pathway for cytoskeletal reorganization. The daughters possessed both HGF and INPPL1 mutations and were diagnosed with primary lymphedema while the mother, who possessed the INPPL1 mutation, was diagnosed at the time of NIR imaging with acquired lymphedema. Analyses of remaining families as well as breast cancer related lymphedema patients are underway to confirm whether INPPL1 may be a candidate susceptibility gene for acquired lymphedema. Supported in parts by R01 HL092923 and CA128919, The Texas Star Award, and the Cullen Foundation.

(In-)Efficiencies in the Preoperative Imaging Evaluation of the Medicare Breast Cancer Patient.
Bleicher RJ, Ruth K, Sigurdson ER, Evers K, Wong Y-N, Boris M, Egleston BL. Fox Chase Cancer Center, Philadelphia, PA

Introduction: Breast cancer evaluation requires a combination of physical examination and imaging for preoperative diagnosis and assessment of surgical treatment options. While imaging remains a critical component of that assessment, the burden of patient (pt) return visits for imaging is unknown.

Methods: Medicare claims linked to Surveillance Epidemiology and End Results data were reviewed for women developing breast cancer between 1992 and 2005. The preoperative interval was defined as the period from the first physician encounter for a breast-related diagnosis until therapeutic surgery. Pts without ≤6 mos of data prior to that interval, those having DCIS or Stage IV disease, and those having preoperative chemotherapy or radiotherapy were excluded. Imaging modality counts exclude image-guidance claims for biopsies.

Results: Among 353,265 Medicare pts developing breast cancer between 1992 and 2005, 67,751 women ≥65 y of age had invasive, nonmetastatic breast cancer, and simultaneous breast surgery (lumpectomy or mastectomy) with lymph node staging. Median age was 75 y and preoperative interval length was 27 d. In the 6 mos before the preoperative interval, mammograms (MMGs), breast ultrasounds (USs), and breast MRIs were performed exclusive of the preoperative interval in 34,192 (50.5%), 16,936 (25.0%), and 180 (0.3%) pts respectively, while during the preoperative interval, MMGs, USs, and MRIs were performed in an additional 30,414 (44.9%), 17,983 (26.5%), and 1,409 (2.1%) respective pts. Imaging was performed on ≥2 separate dates during the preoperative interval in 4.9% of pts in 1992, rising to 19.4% in 2005 (trend, p<0.0001). During that interval, there were ≥2 encounter dates for MMGs in 7.0% of pts, rising from 3.9% in 1992 to 8.8% in 2005 (trend, p=0.0001); for US, 3.6% overall, rising from 0.2% in 1992 to 6.6% in 2005 (trend, p<0.0001). Multiple MRI encounters were rare, occurring in 0.2% overall, and increasing to 0.6% in 2005 (trend, p=0.0001), while single MRI use increased from <0.1% in 1994 to 8.3% in 2005 (trend, p<0.0001). In the preoperative interval, use of more than one imaging modality on any given date increased from 4.3% in 1992, to 27.1% in 2005. Among those with imaging, there was low correlation between number of imaging dates and number of modalities on any given date (r = 0.13, p<0.0001). MMGs accounted for 71.9% of the days where one modality was performed alone, but MRI was performed alone 94.1% of the time. The total number of imaging dates have been increasing substantially since 1992, suggesting that the patient’s time burden for such evaluation is increasing. This trend is present despite the fact that multiple imaging modalities are being performed more frequently on the same date. Efforts to further consolidate preoperative breast imaging visits to lower that burden should be undertaken where possible in the Medicare population, for whom advanced age, in itself, may provide its own challenges.

P5-13-01
Survival Outcome with Bevacizumab: Activation of the Phosphatidylinositol-3 Kinase (PI3K) Pathway Due to PIK3CA Mutations or PTEN Loss Makes a Difference.
Vidal M, Di Cosimo S, Torrejon D, Saura C, Gómez-Pardo P, Pérez-García J, Muñoz-Couselo E, Bellet M, Sanchez-Olle G, De Mattos-Arruda L, Oliveira M, Tabernerio J, Baselga J, Cortes J. Vall d’Hebron Institute of Oncology, Vall d’Hebron University Hospital, Universitat Autònoma de Barcelona, Barcelona, Spain; Massachusetts General Hospital Cancer Center. Harvard Medical School, Boston

Background: The PI3K pathway is known to regulate the transcription of Vascular Endothelial Growth Factor (VEGF) in endothelial and cancer cells. The inhibition of VEGF is the rationale behind the development therapy with anti-angiogenics. We investigated the activation of PI3K pathway, defined as PTEN loss and/or PIK3CA mutations, and the relationship with survival in metastatic breast cancer patients treated with the anti-VEGF monoclonal antibody bevacizumab.

Patients and methods: Records for patients with HER2 negative metastatic breast cancer (MBC), treated with bevacizumab from July 2005 to June 2010, and with known PI3K status were reviewed. Univariate and multivariate analysis were performed using SPSS 15.0.

Results: A total of 40 patients - 26 with and 14 without PI3K activation - were identified. Median age was 47 years (range 27-79). Median overall survival (OS) was 41.23 months (CI 95%: 27.29 – 55.18) and 66.23 months (CI 95%: 61.04 – 71.42) in patients with and without PI3K activation, respectively (p=0.04). Among patients with PI3K activation, OS was 34.13 months (CI 95%: 22.40 – 45.86) and 43.43 months (CI 95%: 26.9 – 59.97) in cases with PIK3CA mutations and PTEN loss, respectively. As compared to patients without PI3K activation, patients with PIK3CA mutations but not patients with PTEN loss showed a significant worse outcome (p=0.006 and p=0.3, respectively). In the multivariate analysis including grade, hormone receptor and Ki67 status, and total lines of treatment, the activation of PI3K activation proved to be an independent prognostic factor (p=0.03).

Conclusions: The activation of the PI3K pathway is significantly associated with decreased OS of MBC patients treated with bevacizumab. Prospective evaluation of PI3K activation on VEGF signaling with differential implication of PIK3CA and PTEN loss is warranted.

P5-13-02
Kawai M, Torikoshi Y, Notoya M, Gohda K, Ueno NT, Ishihara H. Sysmex Corporation, Kobe, Hyogo, Japan; The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Receptor tyrosine kinases and other membrane-associated tyrosine kinases are frequently overexpressed, activated, or mutated in cancer cells and cause aberrant signal transduction, which leads to cellular proliferation, angiogenesis, metastasis, and antiapoptosis. Blockage of these signals is considered an efficient strategy in cancer therapy, and to date, several tyrosine kinase inhibitors (TKIs) and antibody drugs targeting such kinases have been developed and are routinely used in clinics. However, the efficacy rates of the drugs are, unfortunately, limited. To provide optimum care for individual patients, an accurate prediction method for drug efficacy is now strongly demanded. Recent studies have shown that alteration of multiple kinases is involved in both primary and acquired drug resistance. Advantages of multi-targeted TKIs have also been
reported. These findings indicate the need for a comprehensive evaluation of multiple kinases for predicting drug response. To achieve this, we developed a novel method of comprehensively profiling kinase activity.

Materials and methods: We characterized the membranous tyrosine kinases of breast cancer cell lines using a newly established profiling assay. Briefly, crude membrane fractions were prepared and directly subjected to the assay with nonspecific substrate (Poly(Glu-7-Tyr)). The profile of the kinases in the crude membrane fraction was obtained by inhibiting the total activity with 13 selected kinds of adenosine triphosphate antagonists, independently. The residual activity (RA) of membranous kinases was defined as the percentage of activity with/without TKI.

Results: Nineteen breast cancer cell lines were classified as “sensitive” (n = 6) and “resistant” (n = 13) to dasatinib according to the definition in the publication (Cancer Res., 67 2226-38. 2007). The RA of tyrosine kinases targeted by different types of TKIs was determined by our assay, and we found that two RAs (src inhibitor 1 and PP1) showed statistically significant differences between the “sensitive” and “resistant” groups (p<0.017, and p<0.002, respectively, Student’s t-test). The RA of the two TKIs were also significant predictors for dasatinib sensitivity in a receiver operating characteristic curve analysis (area under the curve: 0.846 for src inhibitor 1 and 0.910 for PP1). Since the major target of dasatinib are src family kinases, protein expressions of the src family of the cell lines were quantified by a Western blotting and compared between the groups. We found that the protein expression is not a statistically significant predictor of dasatinib sensitivity.

Conclusion: We have shown that a comprehensive tyrosine kinase activity profiling assay of cancer cells can predict dasatinib sensitivity. We plan to validate this assay prospectively in patients with breast cancer who receive dasatinib.

P5-13-03
Correlation of Clinical and Molecular Findings with Pathologic Response to Preoperative Lapatinib and Trastuzumab, Separately or in Combination, Prior to Neoadjuvant Chemotherapy for HER2-Positive Breast Cancer

Holmes FA, Espina V, Liotta LA, Chang JC, Nagarvala YK, Danso M, McIntyre K, Osborne CR, Kreckow LK, Gaggin RC, Mahoney JM, O’Shaughnessy JA. US Oncology, The Woodlands, TX; Texas Oncology, Houston, TX; George Mason University, Manassas, VA; The Methodist Hospital, Houston, TX; GlaxoSmithKline Oncology, Collegeville, PA; Virginia Oncology Associates, Virginia Beach, VA; Texas Oncology Austin, Austin, TX; Baylor Sammons Cancer Center, Dallas, TX; Texas Oncology, Bedford, TX; Texas Oncology, Dallas, TX

Background: 15% of curative HER2-positive patients (pts) treated with standard trastuzumab (T)-based chemotherapy regimens recur. Our prior report (ASCO 2011 #506 using only data from paired samples N=49) identified major pathways of resistance: autophagy, stem cell, extracellular matrix, and phospho epitopes on FOXO, STAT3, EGFR.

Aim: To collect proteomic and microarray data from baseline biopsies and identify molecular correlates of pathologic complete response (pCR).

Methods: Randomized, open label, phase II. Eligibility: biopsy-proven HER2 positive stage II, III invasive breast cancer, healthy. After informed consent, pt randomized to T or Lapatinib (L) or both (T+L) for 2 weeks (wk) then continue same anti-HER2 agent with standard chemotherapy (FEC75 IV every 3 wk then Paclitaxel 80 mg/m2 wk x 12) then surgery. Research biopsy before and 2 wks after anti-HER2 agent analyzed by reverse phase protein microarray (RPMA) from laser capture microdissected cells, RNA expression microarray, and in-vitro stem cell studies. PCR in breast is no invasive tumor. ITT is Intent to Treat (all treated pts). Pathways identified by analytes (n=42): autophagy (Bcl-1, LC3B, AFG5), stem cell (CD44, Mushashi, E-Cadherin, Beta Catinin), extracellular matrix (Integrin, MMP). Additional informative analytes: phosphorylated HER3, IGFR1.

Results: 100 pts treated: T=33, L=34, T+L=33. % pCR-ITT: ER pos/ER neg by arm: T = 40%/67%; L = 21%/50%; T+L = 58%/50%. Baseline RPMA samples N= 65 (T = 22; L = 25; T+L = 18). A) Specific analytes contributory to outcome by arm by Random Forest analysis: F, Beta Catinin Ser 33/37/Thr 41, EGFR Tyr1045. L: MMP14, E-Cadherin, LC3B, Integrin alpha5B1, Stat 5 Tyr 694, IGFR Tyr 1131/1146, Erk Thr 202/Tyr204, NFKB Ser536, FOXO Thr24, HER3 Tyr1289. T+L: cerb2, EGFR, Met Tyr1235, CD44, E-Cadherin. B) Statistically significant endpoint ratios from network analysis that strongly correlate with pCR: F, HER3 Tyr1289/Beclin 1; PENTser380/ERK Thr202/Tyr204; GSK3B Ser21/Thr21/Stat5 Tyr694; 57065Thr389/LC3B; p7026 Thr389/MMP9; FOXO Thr24-32; NFKB Ser536; Beta Catinin Ser 33-37 Thr41/LC3B. L: EGFR Tyr1045/Beclin1; cerb2/Beclin1; HER3 Tyr1289/Beclin1; P43K/ FOXO Thr24, 32; IRS1 Ser612/Beclin1; Mushashi/IRS1 Ser612. T+L: only 4 pts no pCR. C) Microarray analysis confirms the critical role of extracellular matrix and autophagy.

Discussion: These findings support the concept that NO-pCR tumors can engage a diverse set of strategies to achieve cell survival in the face of therapy. The molecular correlates of response found in this small, underpowered study provide candidates for future patient stratification studies and generate insights for combination therapy.

P5-13-04
Changes in Phosphorylation Status at VEGFR2 and Basal Tumor Hypoxic Volume Assessed by Misonidazol (MISO) Positron Emission Tomography (PET/CT) as Potential Biomarkers for Predicting Response to Bevacizumab in Breast Cancer

Garcia-Foncilla J, Garcia-Vellos M, Dominguez I, Morales S, Hernandez B, Sanchez R, Alvarez I, Anton A, Illarramendi J, De Juan A, Martinez P, Lahuerta A, Llombart A, Garcia-Gonzalez M, Lao Romero J, Partolas T, Scherer S, Sabarot Luis, Lopez-Vega JM, Galve E, Plazaola A, Boni V, Clinic University of Navarra; Hospital Arnau Vilanova, Lleida; Hospital de Burgos; Hospital de La Rioja; Hospital Donostia; Hospital Miguel Servet; Hospital de Castelln; Hospital de Burgos; Hospital de La Rioja; Hospital Donostia; Hospital Miguel Servet; Hospital de Castelln; Hospital of Navarra.

Background: To evaluate the expression of novel putative biomarkers as predictors of benefit from bevacizumab in stage II-III, previously untreated breast cancers (BC) patients (pts) in the context of a phase II, single-arm, multicenter and prospective clinical trial. To address this aim, we examined baseline and induced changes after a single bevacizumab administration as potential early predictors of response.

Methods: Pts received a single infusion of bevacizumab (15 mg/ kg) (C1) 3 weeks prior to the beginning of neoadjuvant chemotherapy consisting in 4 cycles of docetaxel (60 mg/mq), doxorubicin (50 mg/mq) and bevacizumab (15 mg/kg) every 21 days (C2-C5) following by surgery. Early assessment of tumor changes was performed by paired tumor-biopsies and MISO PET/CT before and after a single bevacizumab administration (C1). Biomarker expression was assessed by immunohistochemistry (IHC) (Ki67, CD31, CD31/Ki67, VEGFR2, pVEGFR2 [Y951]) on formalin-fixed, paraffin-embedded tissue before and after bevacizumab infusion (C1). MISO SUV and
tumor volume depicted by PET were calculated. Pathological response on surgical specimens was assessed according to Miller-Payne classification. Pts with tumor reduction >90% were considered as best responders (G4-G5) whether tumor reduction <90% were considered as non responders. Association between pathological response, IHC and MISO biomarkers was analyzed using Mann-Whitney test. ROC curve was performed to test sensitivity and specificity of the biomarker found significantly associated with response and its value as independent predictor was tested in the multivariate analysis using logistic regression.

Results: This analysis was performed on the training set including 73 patients (49 yr, range 29-70). Twenty (27%) patients obtained best response (G4-G5) whether 50 (68%) were considered as no responder (G1-G2-G3). Response was associated with negative estrogen receptors expression (p=0.02) and high Ki67 basal and after C1 expression (p=0.009 and p=0.01). Six (54%) of triple negative tumors were responders (p=0.05). Interestingly, change in pVEGFR2 [Y951] staining induced by bevacizumab administration and baseline MISO tumor volume was found significantly associated with response (p=0.03 and 0.057). Decrease in the phosphorylation status of VEGFR2 (Y951) >70% yielded a receiver operating characteristic (ROC) curve area of 0.681 (95% CI: 0.536 - 0.825) with 84% sensitivity and 95% specificity. The positive and negative predictive values for this marker were 60% and 64%, respectively. The change in phosphorylation status of VEGFR2p remains a significant predictor biomarker of response in multivariate analysis (OR=0.9, IC%95 0.96-0.99, p=0.04) after adjusting for clinical-pathological characteristics.

Conclusion: These findings underline the potential value of early change in phosphorylation status of VEGFR2 after bevacizumab infusion as predictive biomarker of response to anti-angiogenic therapy in breast cancer. Moreover, tumor hypoxic volume obtained by MISO might be associated with response. A validation set is warranted to confirm these findings.

P5-13-05
Non-Invasive In Vivo 1H Magnetic Resonance Spectroscopy (MRS) Monitoring of Breast Tumor Response to IGF1R Targeted Therapy.
Sahdev D, Lin JE, Lunzer C, Marijanska M, Garwood M, Yee D. University of Minnesota, Minneapolis, MN

Drugs targeting IGF1R are in clinical trials for breast cancer therapy. To date no suitable biomarkers of response have been identified for this therapy. It is important to select patients with tumors sensitive to disruption of IGF1R signaling. In addition, predicting response in patients quickly following initial treatment would also assist in the development of these strategies. While expression of IGF1R must be a minimum requirement for enrolling patients in trials with IGF1R agents, the mere expression of IGF1R is not necessarily sufficient for IGF-driven biology. We have previously shown that monitoring levels of total choline-containing compounds (tCho) non-invasively in breast cancer patients with locally advanced breast cancer is a useful predictor of response to primary systemic therapy. The tCho measured in these studies included choline, phosphocholine (pCho) and glycerophosphocholine (GPC). In this study, we examined if changes in tCho could be used as a marker of response to anti-IGF1R therapy. We tested the effect of two antibodies against IGF1R on intratumoral tCho levels in vivo. Mice bearing MCF-7 xenografts were subjected to MR imaging (MRI) and spectroscopy (MRS) to measure baseline tCho levels. MRI was performed at 4.7 Tesla (200 mHz) with a transceive surface coil. Single-voxel 1H spectroscopy was performed using water suppression and TE-averaging. A fully relaxed, unsuppressed water spectrum from the same voxel was acquired and tCho signal was referenced against the tissue water signal and expressed as mmol/kg water. The next day, mice were treated with 500 µg of scFv-Fc or phosphate buffered saline, or 800 µg EM164 or isotype-matched control antibody. 24 hours post-treatment, tCho was measured. The percent change in tCho 24h after treatment (%tCho24) was determined using the formula 100[(tCho24-tCho0)/tCho0]. In 9 out 10 mice treated with scFv-Fc, %tCho24 ranged from -26 to -81% of baseline levels while in mice treated with PBS the change was from 0% to +46%. EM164 treatment also caused decrease in tCho levels in 3 out of 3 mice while the control antibody did not. tCho was also monitored for a period of 2 weeks during the course of treatment with EM164 or control antibody; EM164 caused a decrease in tCho with %tCho of -35% while the control antibody treated mice showed %tCho of +43% over the two-week treatment. To further delineate the precise choline species regulated by IGF signaling, MCF-7 cells were treated in vitro with IGF-I for 24h and cell extracts subjected to MR at 14.1 Tesla using a NMR scanner. IGF-I enhanced levels of pCho compared to choline and GPC. We next investigated if there is a mechanistic link between IGF signaling and choline metabolism. MCF-7 cells were treated with IGF-I for 10 minutes or 24h and levels of choline kinase (ChoK), the rate-limiting enzyme that converts choline to pCho and then phosphorylcholine were examined. Surprisingly, IGF-I signaling enhanced ChoK levels. Our data show that decrease in tCho could be a surrogate marker of early response to anti-IGF1R therapy. Thus, MRS to measure tCho levels could be included in the design of clinical trials with such reagents to quickly identify patients whose tumors are sensitive to inhibition of IGF1R.

P5-13-06
Lipidomic Profile Predicts Pathologic Complete Response to Neoadjuvant Weekly Paclitaxel Treatment.
Facina G, Calicu NMCT, Silva MFR, Bonetti TCS, Nazario ACP, Silva IDCG. Federal University of Sao Paulo, Sao Paulo, Brazil

BACKGROUND: Neoadjuvant chemotherapy is one of the main strategies for patients with advanced breast cancer. The taxane paclitaxel have an important role in inhibiting microtubule polymerization and this mechanism prevents cells from entering into the mitotic phase. The therapeutic efficacy and toxicity profile of weekly paclitaxel administration have been showed since 90s. Lipidomics may be defined as the large-scale study of pathways and networks of cellular lipids that is involved in biological systems. In the present study our aim was to evaluate the possibility to identify a lipidomic signature of good and bad responders to neoadjuvant chemotherapy.

PURPOSE: To analyze and identify the lipid fingerprint in tumor biopsy of advanced breast cancer patients who get a complete pathologic response (CPR) with weekly paclitaxel treatment and compare this with the group who get no response.

MATERIAL AND METHODS: Seventy eight patients with clinical stage IIIA breast cancer were selected to receive the neoadjuvant into the mitotic phase. The therapeutic efficacy and toxicity profile of weekly paclitaxel have an important role in inhibiting microtubule polymerization and this mechanism prevents cells from entering into the mitotic phase. The therapeutic efficacy and toxicity profile of weekly paclitaxel administration have been showed since 90s. Lipidomics may be defined as the large-scale study of pathways and networks of cellular lipids that is involved in biological systems. In the present study our aim was to evaluate the possibility to identify a lipidomic signature of good and bad responders to neoadjuvant chemotherapy.

PURPOSE: To analyze and identify the lipid fingerprint in tumor biopsy of advanced breast cancer patients who get a complete pathologic response (CPR) with weekly paclitaxel treatment and compare this with the group who get no response.

MATERIAL AND METHODS: Seventy eight patients with clinical stage IIIA breast cancer were selected to receive the neoadjuvant treatment with weekly paclitaxel (for a total of 12 doses – 80mg/m2). Fifty eight patients completed the treatment purpose. Seven presented pathologic response (CPR) with weekly paclitaxel treatment and 5 showed progressions (Group B). The lipids were extracted from biopsies and submitted to matrix-assisted laser desorption/ionization mass spectrometry (MALDI-MS). MALDI-MS spectra were acquired in the positive ion and reflection modes using Synapt Q-ToF mass spectrometers (Waters, Manchester, UK). The spectra were acquired in the m/z 700-1200 range. From each spectrum...
the most intense ions were considered as the starting point of searching m/z values which were clearly distinct from noise level in the spectra were included in the principal component analysis (PCA).

**RESULTS:** The PCA analysis of the mass spectra shows that groups can be resolved via their MALDI-MS lipid profiles, which suggest the patients who presented CPR can present distinct lipid fingerprint in the tumor biopsy compared to patients who showed progressions.

**CONCLUSION:** After genomic and proteomic innovations, it turns necessary to explore metabolic processes at the system level. Lipidomics is a developing strategy for functional genomics, since there is growing evidence that lipids are structural biomolecules, which have important function as signal transduction processes, second messenger molecules or their precursors. Is possible that lipidomic profile of tumor specimen could help us to select the patients with advanced breast cancer that might present complete pathologic response by weekly paclitaxel treatment. This study will be continued to confirm this results and carried the identification of the lipids based on earlier studies and MS/MS data using lipidmaps and chemspider databases.

**P5-13-07**

**MET and Hepatocyte Growth Factor (HGF) Increased Gene Copy Number Is Associated to Trastuzumab Failure in HER2 Positive Metastatic Breast Cancer (MBC).**

Minuti G, Duchnowska R, Jassem J, Roncalli M, O'Brien T, Fabi A, Landi L, Di Marsico R, Biernat W, Czartoryska-Arlukowicz B, Jankowski T, Zaciak D, Zok J, Szostakiewicz B, Foszczyńska-Kloda M, Tempinska-Szalach A, Rossi E, Varella-Garcia M, Cappuzzo F. Istituto Toscana Tumori, Civil Hospital of Livorno, Livorno, Italy; Military Institute of Medicine, Warsaw, Poland; Medical University of Gdańsk, Gdańsk, Poland; Milan University, Istituto Clinico Humanitas, Milan, Italy; Laboratory of Molecular Pathology, University of Colorado Cancer Center, Denver, CO; National Cancer Institute Regina Elena, Rome, Italy; Białystok Oncology Center, Białystok, Białystok, Poland; Lublin Oncology Center, Lublin, Poland; Beskid Oncology Center, Bielsko-Biała, Poland, Bielsko-Biała, Poland; Warmia and Mazuria Oncology Center, Olsztyn, Poland; West Pomeranian Oncology Center, Szczecin, Poland; District Hospital Ełbląg, Ełbląg, Poland; CINECA Interuniversity Consortium, Bologna, Italy

Background: The ErbB2-targeting monoclonal antibody trastuzumab has remarkable efficacy in metastatic breast cancer (MBC) patients (pts) with HER2 overexpression or amplification (HER2+), either alone or in combination with chemotherapy. However, the response rate to trastuzumab is modest and not all pts derive benefit from this treatment. Predictive mechanisms of sensitivity and/or resistance are largely unknown. Recently, preclinical and limited clinical data showed that aberrant MET expression in MBC is a predictor of poor prognosis and is involved in trastuzumab resistance. Aim of the present study was to investigate whether increased gene copy number of MET or its ligand, the hepatocyte growth factor (HGF), affect trastuzumab sensitivity.

**Patients and Methods:** This retrospective study included 130 HER2+ MBC pts treated with trastuzumab as monotherapy (N=21) or in combination with chemotherapy (N=109). Main inclusion criteria were presence of at least one measurable lesion and availability of paraffin-embedded tumor tissue from primary cancer. **MET and HGF** gene copy number (GCN) were assessed by fluorescence in situ hybridization (FISH). Receiver operating characteristic (ROC) analysis was used for identifying the best **MET** and **HGF** mean GCN cut-off.

Results: In the whole population response rate (RR), including complete (CR) and partial response (PR) was 49.2%, disease control rate, including CR+PR+ stable disease (SD) was 76.2%, median time to progression (TTP) 9.4 months, and median survival (OS) 28.3 months. MET FISH analysis was successfully performed in all 130 cases. Median MET mean GCN was 2.96 (range 1.66-8.40), with no gene amplification. ROC curve identified a mean of 3.72 MET GCN as the optimal cut-off value for discriminating between sensitive (CR+PR+SD) and refractory pts (pts with progressive disease [PD]) at the first disease assessment. **MET** FISH+ (N=36, mean ±3.72) had a significantly higher PD rate (44.4% versus 16.0%; p=0.001) and a significantly shorter TTP (5.7 versus 9.9 months; HR 1.74 95% C.I. 1.16-2.62; p=0.006) than **MET** FISH- pts (N=94, mean ±3.72). HGF GCN was successfully evaluated in 84 pts (64%). Median HGF mean GCN was 2.80 (range 1.14-6.90). ROC analysis identified a cut-off of 3.01 mean HGF GCN as the best discriminating between sensitive (CR+PR+SD) and refractory pts. **HGF** FISH+ (N=33, mean ±3.01) had a significantly higher PD rate (30.3% versus 7.8%; p=0.007) and a non-significant shorter TTP (9.9 versus 10.5 months, HR 1.10 95% C.I. 0.70-1.74; p=0.66).

Conclusions: High GCNs of **MET** or **HGF** associate with an increased risk of trastuzumab failure in HER2+ MBC. These data support a further development of combining anti-HER2 with anti-MET strategies in MBC.

**P5-13-08**

**Breast Cancer Index Predicts Likelihood of Breast Conservation Surgery after Neoadjuvant Chemotherapy.**

Introduction: Neoadjuvant chemotherapy increases the likelihood that breast conservation therapy for breast cancer patients will be successful. Breast Cancer Index (BCI), a gene expression assay combining HoxB13/IL17BR ratio and Molecular Grade Index (MGI), is prognostic for the risk of distant recurrence and overall survival in tamoxifen-treated and untreated breast cancer patients. It was previously reported that high risk patients, as determined by BCI, had a 10-fold greater probability of pathologic complete response (pCR) with neoadjuvant chemotherapy than low risk patients. The aim of the current study was to examine the relationship between BCI score and the use of breast conservation surgery (BCS) following treatment with neoadjuvant chemotherapy.

Material and Methods: A total of 145 women (tumor size T1, T2 and T3) were treated with neoadjuvant chemotherapy for stage I-III breast cancer. RNA was extracted from FFPE tumor samples and a real-time RT-PCR assay was completed to generate a BCI score and risk group categorization as previously described (Jerevall et al. Br J Cancer 2011). The relationship between BCS, BCI and clinicopathological factors was examined using univariate and multivariate logistic regression.

Results: Of the 145 patients (67% ER+, 54% PR+, 57% >50 y old), 48 (33.1%) underwent BCS. BCI categorized 62 (43%) of patients as low, 50 (34%) as intermediate and 33 (23%) as high risk. The rate of BCS for the three BCI risk categories was 15% (low risk), 48% (intermediate risk) and 45% (high risk). In the low risk group, the rate of BCS was 15% corresponding to a NPV of 85%. This is consistent with previous data from the same cohort, where the NPV of BCI for pCR was 98.4% with only one patient in the low risk group achieving pCR. In univariate analysis, pathological tumor size (pT), ER, PR, grade and BCI were predictors of BCS. A higher BCI score
was associated with higher likelihood of BCS (odds ratio of 3.90; CI: 1.45-10.49; p=0.0069). In multivariate analysis, pT and BCI remained significantly associated with BCS, while ER status was not (p=0.23). Results were similar in the subset of patients with T1 and T2 tumors (N=97). In this subset, BCI categorized 42% of patients as low, 37% as intermediate and 21% as high risk and the rate of BCS was 22%, 64% and 60%, respectively. In multivariate analysis of this subset, only BCI was significantly associated with BCS. In all patients, the concordance index based on a model with pT alone was 0.695. When BCI was incorporated into the model with pT, the concordance index increased to 0.801 (p = 0.0002).

Conclusion: In this study, we have shown that patients with higher BCI scores were associated with a higher likelihood of receiving BCS after neoadjuvant chemotherapy. Addition of BCI to tumor size increased accuracy in predicting likelihood of BCS. BCI along with standard pathological factors may improve estimation of individual probability of BCS after neoadjuvant chemotherapy. This study gives rise to the hypothesis that patients with low BCI should not be eligible for neoadjuvant chemotherapy since the likelihood of breast conservation is low. Further large confirmatory studies are necessary.

### P5-13-09

**Correlation of OncoType DX Recurrence Scores with Pathologic Response Following Neoadjuvant Ixabepilone and Cyclophosphamide in Patients with HER2-Negative Breast Cancer: A Sarah Cannon Research Institute Phase II Trial.**

Yardley DA, Peacock NW, Hendricks C, Huh SY, Ketchum S, Chao C, Yoshizawa C, Burris III HA, Hainsworth JD. Sarah Cannon Research Institute, Nashville, TN; Tennessee Oncology, PLLC, Nashville, TN; Center for Cancer and Blood Disorders, Bethesda, MD; Providence Medical Group, Terre Haute, IN; Mercy Hospital, Portland, ME; Genomic Health, Redwood City, CA

Background: Ixabepilone (Ixa) is active in anthracycline and taxane-refractory metastatic breast cancer as well as in the neoadjuvant setting where Ixa yielded a pathologic complete response (pCR) rate of 11%. In this study, we evaluated Ixa in combination with cyclophosphamide (C) as neoadjuvant treatment for ER+/HER2-negative breast cancer. The primary endpoint was pathologic complete response (pCR) rate, defined as no residual invasive cancer in breast or lymph nodes. The Oncotype DX Breast Cancer Assay, that uses reverse transcriptase-polymerase chain reaction (RT-PCR) to assess a panel of 21 tumor genes to calculate a score predictive of the likelihood of the magnitude of adjuvant chemotherapy benefit, was applied to pretreatment and residual disease breast cancer tissues obtained at the time of definitive surgery. The likelihood of whether neoadjuvant clinical or pathological responses may be predicted by Oncotype DX recurrence scores (RS) was assessed. An interim analysis of the first 81 patients (pts) was reported at ASCO 2011. The final analysis will be presented on all 168 pts.

Methods: Eligible women had locally advanced breast cancer that was HER2-negative (IHC 0-1+ or FISH negative). T >2 cm or lymph node positive. Pts with inflammatory breast cancer or T1N0 tumors were excluded. Pts received Ixa 40mg/m² with C 600mg/m² day 1 q21 days x6. Following 6 cycles, had definitive surgery. Postoperative locoregional radiation therapy and/or hormonal treatments were at the discretion of the treating MD per institutional guidelines. Breast core biopsy tumor samples were obtained pretreatment and at the time of surgery in those pts demonstrating residual disease at surgery. Tumor specimens were analyzed using the Oncotype DX RT-PCR assay. An interim pretreatment RS assessment in the first 38 pts and paired samples in 21 pts was conducted and correlated with clinical and pathologic responses.

Results: 168 women enrolled. Baseline characteristics and toxicity for the first 118 pts are reported (median age 52 years; 90% invasive ductal carcinoma; T2/T3 52%/31%; 42% triple negative). 81 pts have undergone surgery. 25 pts discontinued treatment early (toxicity – 12; disease progression – 8; pt/MD request – 3; pt non-compliance - 2). Grade 3/4 toxicity included: neutropenia (65%), leukopenia (47%), neuropathy (10%), and febrile neutropenia (7%). Preliminary toxicity results with this neoadjuvant treatment have been previously reported (Peacock et al, ASCO 2011 Abstract #1066). OncoType DX pretreatment evaluations for the initial 38 pts demonstrated a significant logistic regression of pretreatment recurrence score with pCR (p = 0.025).

Conclusions: Neoadjuvant therapy with Ixa and cyclophosphamide yielded a preliminary pCR rate of 19% (in 81 pts), similar to results with other 2-drug combination chemotherapy regimens. Preliminary OncoType DX assessments at baseline indicated that baseline recurrence scores may predict pCR rates. These exploratory Oncotype DX recurrence scores at baseline and paired with scores obtained at the surgery and correlations with pCR will be presented for the entire cohort.

### P5-13-10

**Discordance of Estrogen Receptor and HER-2/neu Status Can Be Seen between First and Subsequently Biopsied Metastatic Lesions in Breast Cancer.**

Lower EE, Kennedy D. Oncology Hematology Care, Cincinnati, OH

Background: We have previously reported discordance between primary and first metastasis for both estrogen receptor (ER) and HER-2/neu (HER 2) status (Breast Cancer Res Treat 2005;90:65-70 and Breast Cancer Res Treat 2009;113:301-6). Because biomarker status is the primary determinant for targeted therapy, changes in biomarkers can impact recommendations for systemic treatment.

Materials and Methods: In order to evaluate the possibility of further discordance with the development of additional metastatic sites, we examined the ER and HER 2 status of primary and first and subsequently biopsied breast cancer metastasis. In most cases, the subsequent site of metastasis was the second detected metastasis. Pathology reports were reviewed from 65 patients with biopsy proven first and additional metastasis; however, immunostain results were not available for all three timepoints for all patients. Sites of biopsied metastasis included lung, liver, bone, chest wall, and central nervous system.

Results: The time between the initial diagnosis and first metastasis was 102 (3-676) months [Median (Range)], and the time between the first and subsequent metastasis was 60 (6-273) months. For ER, there was discordance between the primary lesion and either the first or subsequent metastasis in 18 of 65 cases (27.7%). Discordance of the ER occurred between the first and subsequent metastasis in 12 (18%) of cases. Three patterns of ER discordance occurred in these 12 cases: 4 cases of both primary and first metastasis negative with subsequent metastasis positive; 3 cases of primary positive, first metastasis negative, and subsequent metastasis positive, and 5 cases of primary and first metastasis positive and subsequent metastasis negative. For HER 2, discordance was detected between the primary and either first or subsequent metastasis in 11 of 36 cases (30.6%). Further discordance between the first and subsequent metastatic lesions occurred in 8 of 51 (16%) of cases.
Conclusions: A significant level of discordance for either ER or HER 2 was detected between first and subsequent metastatic breast cancer lesions. For breast cancer patients with new metastasis, consideration of reevaluating ER and HER-2/neu status may be worthwhile.

PTEN and Tau-Protein Expression: Predictive Value of Poor Response to Trastuzumab Plus Paclitaxel in Patients with HER2-Positive Breast Cancer.  
Koo DH, Ahn J-H, Yoon DHH, Kim S-B, Lee HJ, Kong KY, Son BH, Ahn SH, Jung KH. Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea  
Backgrounds: Trastuzumab-based chemotherapy has been an active treatment in patients (pts) with HER2-positive breast cancer; however, primary and secondary resistance has occurred in pts treated with trastuzumab (H) alone or in combination with chemotherapy. Material and Methods: Biomarkers were searched using tissue microarrays (TMA) in the HER2-positive breast cancer pts treated with H and paclitaxel (P) combination chemotherapy between October 2004 and August 2010. Tumor blocks of 101 pts were analyzed for VEGF, IGF-1R, p-Akt, beta-III tubulin, CD44, Tau-protein, p27 and PTEN by immunohistochemical (IHC) analysis. Eight biomarkers were assessed to investigate the correlation with the clinical outcomes, including response rate (RR), progression free survival (PFS), and overall survival (OS).  
Results: With a median follow-up duration of 21.7 months (range, 9.1-55.2 months), 101 pts received H+P chemotherapy in neoadjuvant setting (n=36, 35.6%) and recurrent or metastatic setting (n=65, 64.4%). Median age was 48 (range, 19-83 years), and the majority of pts (n=95, 94.1%) had good performance status. Premenopausal pts and hormone receptor-negative pts were 48 (47.5%) and 52 (51.5%), respectively. The median cycle of H+P chemotherapy was six (range, H 1-43; P 1-21). Overall RR was 68.3% (n=69) including complete response with 7 pts, and PFS and OS were significantly longer in pts responsive to H+P chemotherapy compared with non-responsive patients (PFS, p=0.001; OS, p=0.015). Although VEGF, IGF-1R, p-Akt, beta-III tubulin, CD44, Tau-protein, p27 and PTEN status by IHC were not significantly associated with response to H+P chemotherapy, Tau-protein showed a trend of association without statistical significance (RR, 46.2% vs. 71.6%, p=0.066). Among 13 pts with high Tau protein expression, 9 pts with both high Tau-protein and low PTEN level showed statistically significant lower RR compared with other 92 pts (22.2% vs. 72.8%; p=0.002). None of the biomarkers was related to PFS and OS in pts with recurrent or metastatic disease, and to pathologic complete response in pts after H+P chemotherapy as neoadjuvant therapy. Conclusion: Our data showed that both low PTEN level and high Tau-protein expression were significantly associated with poor response to H+P chemotherapy in patients with HER2-positive breast cancer.

P5-13-12  
Can the Ki67 Proliferation Index Predict the Oncotype DX Recurrence Score in Lymph Node Negative, ER Positive Breast Cancer?  
Prendergast A, Martin K, Doolan P, Clarke C, Clynes M, Evoy D, McDermott E, Crown J, Kennedy S. Dublin City University, Dublin, Ireland; Conway Institute of Biomolecular and Biomedical Research, University College Dublin, Dublin, Ireland; St. Vincent’s University Hospital, Dublin, Ireland  
Background Oncotype DX is a 21-gene assay for node-negative, ER positive breast cancer. Results are expressed as a Recurrence Score (RS). This predicts a low, intermediate or high risk of distant relapse. Proliferation-related genes such as Ki67 impact heavily upon the calculation of the RS. The assay encompasses several histopathologic factors (ER, HER2) and is limited by cost, proprietary nature and turn-around time. We investigated whether Ki67 proliferation index (PI) and routine clinicopathologic parameters could be used to predict RS.  
Material and Methods We obtained clinicopathologic details for 69 patients (diagnosed 2007-2010) who had RS available. Quantitative analysis of Ki67 immunohistochemistry was performed on primary tumour. Patients were classified as having a low (≤15%), intermediate (16-30%) or high (>30%) Ki67 PI. Risk of recurrence was calculated using Adjuvant! Online. Patients with categorized as having a poor, moderate, good or excellent prognosis as per the Nottingham prognostic index (NPI) and a low, intermediate or high risk of relapse, according to the St. Gallen criteria.  
Results Mean age at diagnosis was 51.4 years (range: 34-74 years). Mean tumour size was 1.9 cm (range: 0.8-4.1cm). Mean Ki67 PI was 13.4 % (range 0.2 to 52.6%). RS was low (0-17) in 34 cases, intermediate (18-30) in 26 cases and high (>30) in 9 cases. The RS was significantly correlated with Ki67 expression (Spearman’s rank correlation, r = 0.472, p=0.001). RS was significantly higher in patients with a high Ki67 PI, when compared to patients with low and intermediate Ki67 PI (Mann Whitney U, p=0.05). RS was significantly higher in patients with grade 3 tumours, when compared to patients with grade 1 and 2 tumours (Mann Whitney U, p<0.05). Risk of recurrence as predicted by Adjuvant! Online, was significantly higher in patients with a high RS, when compared to patients with low and intermediate RS (Mann Whitney U, p<0.05). RS was significantly higher in patients with moderate prognosis, as determined by the NPI, when compared to patients classified as having a good/excellent prognosis (Mann Whitney U, p<0.05). No patients were classified by the NPI as having a poor prognosis. RS was significantly higher in patients deemed to be at high risk of relapse by the St. Gallen criteria, when compared to patients classified as low and intermediate risk (Mann Whitney U, p<0.05). The majority (66.7%) of cases in the high RS group had LVI present.  
Conclusions This pilot study indicates a trend whereby Ki67 and grade will predict whether the Oncotype DX RS is low/intermediate or high. Adjuvant! Online, St. Gallen and NPI are also able to distinguish patients with a high RS from those with low/intermediate RS. In order to verify these findings, we are developing a statistical model using these 69 patients as a training set. As there is insufficient follow-up to correlate either RS or Ki67 with relapse, a potential test set comprised of an additional 50 LN negative, ER positive patients, with an average of 13 years follow-up, has been identified. Ki67 analysis of these cases is underway to address this issue.

P5-13-13  
The Role of Topoisomerase IIα in Predicting Sensitivity to Anthracyclines in Breast Cancer Patients: A Meta-Analysis of Published Literatures.  
Lu J, Du Y, Zhou Q, Yin W, Zhou L, Di G, Shen Z, Shao Z. Shanghai Cancer Center, Fudan University, Shanghai, China; Shanghai Medical College, Fudan University, Shanghai, China  
Topoisomerase IIα is not only a proliferation marker of tumor cells but also a target for anthracycline-based chemotherapy. Both in vitro and in vivo studies have shown that there was a relationship between topo IIα and chemosensitivity to anthracyclines, but the predictive role of topo IIα is still controversial in breast cancer patients. A
meta-analysis based on published studies was performed with the aim of obtaining an accurate evaluation of the association between topo IIα and sensitivity to anthracycline-based chemotherapy. A total of 13 eligible studies including 2,633 cases and 2,118 controls were identified. Topo IIα was associated with sensitivity to anthracyclines in locally advanced breast cancer patients who received neoadjuvant chemotherapy (RR = 1.93, 95%CI: 1.27-2.94, P=0.002; RR =1.98, 95%CI: 1.37-2.86, P<0.001). In early breast cancer patients who received anthracycline-based adjuvant chemotherapy compared with non-taxane-based polychemotherapy, amplification (HR = 0.64, 95%CI: 0.49-0.83, P=0.001; HR = 0.59, 95%CI: 0.35-1.01, P=0.056) or deletion (HR = 0.82, 95%CI: 0.67-1.00, P=0.051; HR =0.58, 95%CI: 0.35-0.97, P=0.036) of topo IIα was significantly associated with better RFS and OS. The subgroup analysis in the early breast cancer patients indicated that taxane could be an interference for evaluation of the predictive role of topo IIα. In summary, the present meta-analysis suggests that topo IIα is a predictive factor for breast cancer patients who received anthracycline-based chemotherapy. Larger and well-designed prospective studies are required to further evaluate the predictive role of topo IIα in clinical practice.

P5-13-14
Drug-Metabolizing Enzyme Polymorphisms and Clinical Outcome of Anthracycline-Based Chemotherapy in Chinese Han Breast Cancer Patients.
Tang J, Zhao J, Wu J, Ji M, Zhong S. Jiangsu Cancer Hospital, Nanjing, Jiangsu, China

Background: Anthracycline is one of the most effective drugs in the treatment of breast cancer and many of our most effective treatment regimens include anthracycline. Its efficacy can be influenced by cellular detoxification mechanisms involving drug metabolism and transport pathways. This study aimed to assess whether the functional polymorphisms in drug-metabolizing enzymes (MnSOD, CAT and GSTs) and transporter MDR1 may predict anthracycline treatment-related outcomes in Chinese Han breast cancer patients.

Material and methods: Genotyping was performed by allele-specific oligonucleotide ligation reaction (MnSOD T47C, CAT C-262T, GSTP1 A131G), multiplex PCR (GSTM1 null, GSTT1 null), and PCR-RFLP (MDR1 C3435T, G2677T/A and C12367). Based on 153 evaluable patients received anthracycline-based neoadjuvant chemotherapy for breast cancer, the associations of these genotypes or their haplotypes with clinical response and recurrence-free survival (RFS) were analyzed.

Results: Of the 153 cases, the patients with GSTP1 313AA genotype had inferior response rates relative to those with AG or GG genotype (58.4% vs 77.8% or 100.0%; χ2=4.922, P=0.027). Moreover, the response rate of the combination of GSTP1 AA with both GSTT1 present and GSTM1 present was 44%, which was also lower comparing with the other groups (70.3%; χ2=6.454, P=0.011). A similar result was noticed for MDR1 3435 TT genotype, which had a significantly worse chemotherapy response compared with wild-type Callele carrier (33.3% vs 71.2%; χ2=11.586, P=0.001). Further, the response rate of the patients with 3435T-2677T, 3435T-12367T or 3435T-2677T-12367T haplotypes was lower than that of the patients with the other corresponding haplotypes (P=0.018, 0.011 and 0.019, respectively). Too. Of note, the patients with both the adverse genotypes of GSTP1 314AA and MDR 3435TT showed the worst treatment efficacy in all (14.3%; χ2=26.33, P=0.000). Mean follow-up time of the 149 patients (4 patients lost) was 51 months. The recurrence rate in the patients with GSTP1 313AA or and MDR 3435TT in the first three years was 39.0% (41/105), higher significantly than those with no adverse genotype [15.9% (7/44); OR=0.725, 95%CI: 0.594-0.885, P=0.006]. Kaplan-Meier survival analysis showed that the patients with no adverse genotype were associated with reduced hazard of relapse (long-rank test, P<0.01), compared to those with 1 or 2 adverse genotypes.

Conclusion: Polymorphisms in GSTs and MDR1 genes may help to predict clinical response and RFS of anthracycline-based chemotherapy in breast cancer, but further validation is required. These results provide support for a polygenic pathway approach for assessing the predictive potential of polymorphisms in treatment outcomes.

P5-13-15
Proteomic Identification of Predictive Biomarkers of Resistance to Neoadjuvant Chemotherapy in Luminal Breast Cancer: A Possible Role for 14-3-3 and BID?
Hodgkinson VC, ELFadd D, Agarwal V, Garimella V, Drew PJ, Lind MJ, Cawkwell L. University of Hull, Hull, United Kingdom; Castle Hill Hospital, Hull, United Kingdom; Hull York Medical School, Hull, United Kingdom

Background: Chemotherapy resistance is a major obstacle in effective neoadjuvant treatment for oestrogen receptor (ER)-positive breast cancer. The ability to predict tumour response would allow chemotherapy administration to be directed towards only those patients who would benefit, thus maximising treatment efficiency. We aimed to identify protein biomarkers associated with chemotherapy resistance, using proteomic analysis of fresh ER-positive breast cancer samples, and then to perform pilot clinical validation experiments.

Materials and Methods: Chemotherapy resistant and chemotherapy sensitive tumour samples were collected from breast cancer patients who received standard anthracycline-based neoadjuvant therapy consisting of epirubicin with cyclophosphamide followed by docetaxel. Comparative proteomics experiments were performed using invasive ductal carcinomas which demonstrated ER-positivity (luminal subtype). Protein expression was compared between chemotherapy resistant and chemotherapy sensitive tumour samples using 2-dimensional gel electrophoresis (2-DE) with MALDI-TOF/TOF mass spectrometry (MS). In addition the Panorama XPRESS Profiler725 antibody microarray, containing 725 antibodies from a wide variety of cell signalling and apoptosis pathways, was employed in the discovery phase. Differentially expressed proteins (DEPs) were submitted to Ingenuity Pathway Analysis (IPA) to identify any canonical pathway links. A pilot series of archival breast cancer samples, from patients treated with neoadjuvant anthracycline-based chemotherapy, was used for preliminary clinical validation of putative predictive biomarkers.

Results: Five datasets were generated by antibody microarray analysis, revealing 41 targets. Of these, 7 DEPs were identified in at least 2 datasets and these included 14-3-3, BID and Bcl-xL. The top canonical pathway matched in IPA was “ERK5 signaling”, which involved 6 DEPs, including 14-3-3. The “PI3/ekt” pathway also involved 6 DEPs, including 14-3-3 and Bcl-xL. Three datasets were generated using 2-DE with MALDI-TOF/TOF MS, containing over 300 DEPs. These included several isoforms of 14-3-3. Differential expression of 14-3-3, BID and Bcl-xL was confirmed by immunoblotting in samples used for the discovery phase. A pilot clinical validation using immunohistochemical analysis of archival breast cancers revealed 14-3-3 tau and tBID to be significantly associated with chemotherapy resistance.

Discussion: We have successfully utilised clinical tumour samples for the discovery of putative biomarkers of chemotherapy resistance using...
two complementary proteomic platforms. We propose a potential role for 14-3-3 tau and BID as predictive biomarkers of chemotherapy resistance in ER-positive tumours and further validation in a larger sample series is now required.

**P5-13-16**

Reduction in PET Uptake-Value Is an Early Predictor for Response to Neoadjuvant Therapy Including Anthracycline and Taxane in Stage II-IIIA Breast.

Lao Romero J, Puértolas Hernandez T, Godoy Molias A, Alvarez Alejandro M, Madani Perez J, Garcia Mur C, Ubieto MA, Cebollero de Miguel A, Artal Cortes A, Anton Torres A. Hospital Universitario Miguel Servet, Zaragoza, Spain; Clinica Quirón, Zaragoza, Spain

**Background and Aim:** Reduction in FDG-PET uptake as response predictor after induction chemotherapy for breast cancer has been described. Our aim was to determine whether a SUV reduction ≥45% in the breast lesion could accurately predict pathological Complete Response (pCR).

**Material and Method:** Stage II-IIIA breast cancer patients (p) with primary tumor ≥3cm or positive axilla were included provided they were amenable to neoadjuvant chemotherapy with Docetaxel-Doxorubicin-Cyclophosphamide (TAC). A FDG-PET scan was performed on day -1 of the first course and was repeated on day+8 of the same course. SUV-uptake differences (day 8 minus day -1) were correlated to the eventual pathological response according to Miller-Payne criteria.

**Results:** 42p were included. Median age was 45 years (30-66). 11p (26.2%) were triple-negative tumors. 2p (4.8%) were Her2+. By stage, 13p (30.9%) were IIA, 17p (40.4%) IIB and 12p (28.2%) IIIA. 23p (54.7%) were N+ (FNAB positive). Median breast-SUV on first PET scan was 5.51 (1.8-18.50). 40p (95.2 %) completed the scheduled 6 courses. 41p (97.6%) were submitted to surgery. 11p (26.2%) achieved a pCR. 40p (95.2%) were evaluable for the primary objective. 1p (0.02%) died of disease progression before surgery and 1p (0.0%) with pCR could not be assessed by PET. 7 out of 14 p (50%) with uptake reduction ≥45% with respect to the basal value, and 3/ 26p (11.5%) whose reduction was <45% achieved a pCR (p=0.007). SUV decrease >45% accurately predicted 7/ 10 pCR (70%) that could be assessed.

**Conclusions:** Our study confirmed the value of PET-SUV reduction on day 8th as an early predictor of pCR with neoadjuvant TAC chemotherapy.

**P5-13-17**

Multigene Signature Assays in Patients with Early-Stage Breast Cancer (ESBC) Receiving Neoadjuvant Chemotherapy: An NCI-Funded Systematic Review and Evidence Summary of Predictive Performance.

Lyman GH, Cukalova E, Poniewierski MS, Huang M, Barry W, Ginsburg G, Abernethy A, Marcom PK, Ready N, Kuderer NM. Duke University School of Medicine, Durham, NC; Duke University, Durham, NC

Background: A comprehensive literature search and evidence synthesis of multigene signatures predictive of response to systemic chemotherapy in patients with breast cancer was initiated as a part of an NCI-funded program on Comparative Effectiveness Research. Methods: Validation studies were sought of multigene signatures for prediction of chemotherapy response (favorable vs unfavorable) in ESBC patient cohorts different from those used for signature development. Pooled estimates [≥95% CI] of assay performance for predicting clinical outcome included sensitivity, specificity, likelihood ratio, predictive value (PV) and predictive odds ratio (POR) utilizing mixed effects models based on the method of Mantel-Haenszel. Exploratory metaregression analyses on log (POR) were also performed. Studies were classified by validation type including cell lines to patients, independent internal sample, random split sample, or external validation. Evidence for publication bias was assessed by Egger’s regression intercept and Begg and Mazumdar’s rank correlation. Results: Dual-blind review of abstracts identified 33 studies of neoadjuvant chemotherapy response of which 29 stratified treatment response by signature classifier category. Classifier development was based on tumor response prediction in 20 studies, prognosis in 5, and molecular classification in 4. The Table shows assay performance measures overall and by study validation type. Assay performance based on the POR was positively associated with overall study quality (P=.015) and journal impact factor (P=.020). However, strong evidence for publication bias was observed based on both regression intercept (P<.001) and rank impact factor (P=.005). No significant differences in assay performance were noted for assays originally developed for response prediction (POR=5.3), prognosis (POR=6.6) or molecular classification (POR=6.9) (P=.770).

Conclusions: While assay performance in predicting response to neoadjuvant chemotherapy based on multigene classifiers is encouraging, a compelling need exists for greater methodologic rigor and standardization of reporting. The predictive performance of multigene assay signatures varies with the type of validation sample utilized with external validation providing the most conservative estimates. No differences were seen for assays developed for prediction, prognosis or molecular classification. Considerable evidence for publication bias exists reflecting a paucity of smaller negative studies. The clinical validity of genomic response prediction assays should be evaluated in patient cohorts independent of those utilized for signature development. The clinical utility of these assays must then be further assessed in comparative effectiveness studies compared to commonly utilized clinical and laboratory measures.

A Study of the Usefulness of Tumor Markers CA 15-3 and TPS in Monitoring of Different Subgroups of Metastatic Breast Cancer. Lindman H, Al-Musawi S, Nilsson G, Yachnin J. Uppsala University, Uppsala, Sweden

Background: The sensitivity and specificity of the tumor markers cancerantigen 15-3 (CA15-3) and the more seldom used tissue polypeptide specific antigen (TPS) for detecting and monitoring metastatic breast cancer are relatively well known. However, most of the studies in this area were performed before the era of breast cancer subtyping and some recent reports have showed differences in the sensitivity of CA 15-3 among different subtypes of breast cancer. This implies that the usefulness of a tumor marker could vary among different subgroups. We performed a retrospective study to find out the usefulness of CA 15-3 and TPS in long-term monitoring of metastatic breast cancer subgrouped by hormonal and HER2-receptor status. Patients and methods: CA 15-3 was routinely assessed regularly in all patients with metastatic breast cancer since 2003, while TPS was
assessed during years 2005 - 2009. In total 142 patients (median age 60 years, range 22-87) with metastatic breast cancer were identified in the local data base and included. The total number of analyzed CA 15-3 samples were 4232 (mean 30/patient) and TPS 1993 (mean 14/patient). In each patient the results of the markers were compared with disease response and progression during different lines of therapy and the patients were grouped based on the ratio of correct tumor marker values: “1” (useless) if 0-49% of the values were regarded as true, “2” (poor) if 50-74% were true, “3” (good) if 75-94% were true and finally “4” (excellent) if 95-100% of the values were considered true. If a patient had no elevated values during follow-up, she was reported as tumor marker negative: “0”.

Results: In general, the usefulness of CA 15-3 was excellent (4) in 50% of patients and good (3) in 16% more, compared with only 12% and 23% for TPS. Twenty-three percent and 25%, respectively were marker negative (0). There was a marked difference in the different subgroups. CA 15-3 was very useful (group 3 + 4) in estrogen and progesterone receptor positive patients (79%) and hormonal positive HER2 positive patients (82%), compared with only 40% in the triple negative group and 27% of the patients in the hormonal negative HER2 positive group. TPS showed the opposite tendency with less value in hormonal positive patients (only 31% in group 3 and 4) compared with 40% in triple negative and 45% the hormonal negative HER2 positive group. Other factors with strong positive influence of the value of the marker were high absolute values, increased value at diagnosis of metastatic disease (initial value) and visceral metastases.

Conclusion: Metastatic breast cancer can be well monitored using CA 15-3 in about 80% of the cases if the tumor is estrogen or progesterone positive. Hormonal receptor negative disease may be well monitored with CA 15-3 and/or TPS if there are elevated initial values, high absolute values and visceral disease. HER2-status seems not to influence the usefulness of CA 15-3 and TPS.

Borderline Estrogen and Progesterone Receptor Expression and Efficacy of Anti-Estrogen Therapy Analyzed by Subpopulation Treatment Effect Pattern Plot Analysis.
Luok S-W, Ramey B, Park B, Keenan E. Oregon Health and Science University, Portland, OR; Portland Veterans Administration Medical Center, Portland, OR

Background: The American Society of Clinical Oncology (ASCO) and the College of American Pathologists (CAP) recently recommended that estrogen receptor (ER) and progesterone receptor (PR) values be considered positive in the evaluation of breast cancer specimens if high absolute values and visceral disease. HER2-status seems not to influence the usefulness of CA 15-3 and TPS.

Methods: We examined a total of 608 patient samples from the OHSU Knight Cancer Institute Breast Cancer Tissue Repository for which we have quantitative ER and PR information and their clinical outcome. Of those, 282 patients did not receive any systemic treatment and 165 have quantitative ER and PR information and their clinical outcome.

Results: Multi-variate analysis finds neither ER nor PR expression adjusted by treatment status is associated with either overall survival (P=0.20, median follow up of 63 months) or breast cancer free interval (P= 0.82, median follow up of 60 months). For both ER and PR, there is no interaction between treatment outcome (5 year survival probability) and levels of hormone receptor expression based on Kaplan-Meier estimate (P=0.36 and P= 0.65, respectively). Patients with borderline ER expression appear to benefit from anti-estrogen therapy while patients with borderline PR expression appear to have worse outcome with anti-estrogen therapy.

Conclusions: Though descriptive in nature, our STEPP analysis provides support for the recommendation by ASCO and CAP to lower the cutoff for ER positivity in breast cancer specimens. There is overall no interaction between the level of hormone receptor and treatment benefit for all patients from low ER to high ER. Therefore, treatment will benefit all patients including those with low ER levels. Extending hormone therapies to the group of patients whose tumors express borderline PR values, however does not seem to confer therapeutic benefit. More study is needed to determine the benefits of offering anti-estrogen therapy to patients whose tumors express low PR.

P5-13-20
TOP2A Amplification Have Associated with Response to Anthracycline-Based Preoperative Chemotherapy in Primary Breast Cancer.
Wang J, Xu B, Yuan P, Zhang P, Li Q, Ma F, Zhao L. Cancer Hospital, Chinese Academy of Medical Science, Beijing, China

Background: Recent studies have suggested that HER2 gene amplification or overexpression have association with sensitivity of anthracycline-based chemotherapy. Preclinical studies found that TOP2A amplification or deletion only could be detected in HER2 amplification or over-expressive cases. And TOP2A protein is the target of anthracycline. In fact, the value of HER2 for predicting response to anthracycline-based chemotherapy in breast cancer may be more likely related to the concomitant amplification of the TOP2A gene. In this study we studied the association between TOP2A gene amplification and response to anthracycline-based preoperative chemotherapy. Methods: 309 early and local advanced breast cancer cases were enrolled in our study. HER2 proteins were qualitatively analysed by IHC, and TOP2A gene alterations were quantified by real-time polymerase chain reaction (RT-PCR) in primary tumor core biopsies from all HER2 over expressive cases. The enrolled patients received an intense dose dense (IDD) (CE, Cyclophosphamide + Epirubicin) or conventionally (TE, Paclitaxel+Epirubicin) scheduled anthracycline- based preoperative chemotherapy. The tumor was evaluated every two cycles. Median time on study for 309 patients with follow-up was 38 months. Results: The pCR was 14.3%. HER2 overexpression was found in 80/309 (25.9%) breast cancer cases, of which 61/80 cases have been tested for TOP2A status. 19/80 cases have not been tested for TOP2A status because of lacking core biopsies tumor tissue after pathological diagnosis. HER2 overexpression was associated with a significantly higher pCR rate compared to HER2 lower expression (27.5% vs. 9.6%, P=0.001). Further analysis was carried on and found the significantly higher pCR rate in TOP2A co-amplified cases compared to TOP2A deleted or normal cases.
(56.3% vs. 13.8%, P=0.001). HER2 overexpression was associated with a significantly higher pathologic complete response (pCR) rate only when TOP2A was co-amplified (56.3% vs. 9.6%, P=0.001), but not when deleted or normal (13.8% vs. 9.6%, P=0.183), compared to HER2 lower expression tumors. The interaction between HER2 or TOP2A and anthracycline-based regimen was observed not only in IDD but conventionally scheduled preoperative chemotherapy.

Discussion: Previous studies demonstrate that TOP2A gene amplification may define a subtype of HER2-positive breast cancer, this subtype of breast cancer may be highly sensitive to anthracycline-based chemotherapy, which may improve progression in HER2 and TOP2A co-amplification cases. However, this viewpoint needs to support from preoperative chemotherapy. Using RT-PCR to test TOP2A status from 61 primary breast cancer tumor tissue, we demonstrate that TOP2A amplification breast cancer have highly sensitive to anthracycline-based preoperative chemotherapy. This finding suggests that TOP2A as a predictive marker in breast cancer should be included in future studies.

P5-13-21
Japanese Patients with Discordance in Estrogen Receptor between Primary Breast Cancer and Recurrent Tumor Have a Poorer Outcome.
Tanaka K, Kawaguchi H, Kuba S, Koga C, Nishimura S, Yoshiyama T, Ishida M, Nakamura Y, Ohno S. National Kyushu Cancer Center, Fukuoka, Japan

Background
Decisions of systemic treatment for recurrent breast cancer are usually based on the estrogen receptor (ER), progesterone receptor (PR), and HER2 receptor status of the primary tumor. Recently, discordance in receptor status between primary and recurrent tumors has been reported. The objective of this study was to compare receptor status between the primary and recurrent tumor, and to evaluate overall survival (OS) after the diagnosis of recurrence between patients with discordant and concordant receptor status.

Material and Methods
Patients with recurrent breast cancer treated at National Kyushu Cancer Center between January 2004 and May 2011 were reviewed retrospectively. Primary and recurrent lesions were analyzed for ER and PR by immunohistochemistry (IHC) and HER2 by IHC or fluorescence in situ hybridization (FISH). OS in discordant and concordant groups for each receptor was estimated by Kaplan-Meier method and compared by log-rank test.

Results
Among 283 recurrent breast cancer patients both primary and recurrent tumor information for ER, PR, and HER2 was available in 69. Among these, recurrent biopsy specimens were obtained from locoregional recurrence in 72.5% and from distant metastases in 27.5%. Discordant rate in receptor status between the primary and recurrent tumor was 36.2%. Discordant rate in ER, PR, and HER2 was 14.4%, 23.1%, and 4.3%, respectively. Two-year OS after the diagnosis of recurrence in discordant and concordant ER group was 66.7% and 84.7%, respectively. The discordant ER group had significantly worse OS than the concordant ER group (P = 0.040). There was no significant difference in OS between the discordant and concordant PR group (P = 0.950).

Conclusions
Because discordance of receptor status between primary and recurrent tumors may exist, tissue confirmation of receptor status of recurrent tumor should be considered. Japanese patients with discordant ER between primary and recurrent tumor had a poorer outcome.

P5-13-22
Gene Expression Profiles Predict Pathological Complete Response to Standard Neoadjuvant Fluorouracil, Doxorubicin, and Cyclophosphamide and Paclitaxel with or without Trastuzumab in Early Breast Cancer.
Tamura K. National Cancer Center Hospital, Tokyo, Japan

Background: To examine the feasibility of gene expression signature as a predictor of pathological complete response (pCR) to sequential fluorouracil, doxorubicin, and cyclophosphamide (FEC) and weekly paclitaxel (P) with or without trastuzumab (T) neoadjuvant chemotherapy.

Materials and Methods: We have conducted consecutive two phase II, establishing training and validation sets, with similar eligible criteria include, stage IIA-IIIC, chemotherapy-naive, measurable disease, age ≥ 20, PS 0/1, and adequate organ function. Patients were treated preoperatively with 4 cycles of FEC (500/100/500 mg/m²) followed by 12 cycles of weekly P (80 mg/m²) with or without T (2mg/kg). Patients underwent pretreatment fine-needle biopsy for cDNA microarray using Affimetrix Gene Chip U133 plus 2.0 arrays with 30,000 differential expressions of various genes. We ranked gene probes from training sets according to a predictive power concerning pCR by Wilcoxon, and validated them using validation sets by SVM.

Results: Between July 2007 and December 2010, 122 patients were enrolled in the two consecutive prospective studies (training: 89 pts, validation: 33 pts). Median age was 51. PS 0/1: 115/7; Stage IIA/IIB/IIC: 30/57/20/14/1; Histological subtype: ER+HER2− (LA) / ER+HER2+ (LB) / ER-HER2− (TN) / ER-HER2+ (enrich-HER): 51/18/24/29. All patients have received curable operations. pCR rate was 31.1% (LA: 2.0%, LB: 44.4%, TN: 37.5%, enrich-HER: 69.0%).

104 (85.2%) sufficient mRNA for cDNA microarray from individual primary breast cancer tissues fine-needle biopsy are available. As reported previously, the breast cancers were classified into a Luminal A/B, Basal-like, HER2-enriched, Claudin-low intrinsic subtypes, indicating a high quality of the representative method. In HER2 positive breast cancer, HER2-enriched subtype was a reproducive predictive marker. In contrast, In HER2 negative breast cancer, three genes (N-myc and STAT interactor, Tryptophanyl-tRNA synthetase, and IQCE) and basal-like subtype were validated as the predictors of pCR. The three genes were also identified as predictors of pCR in the triple negative population.

Conclusions: Specific gene expression profiles predict pCR to standard neoadjuvant regimen, especially in triple negative breast cancer.

P5-13-23
Individualized Treatment Strategies for HER2-Negative Breast Cancer Subtypes.
Ishikawa T, Shimizu D, Yamada A, Sasaki T, Morita S, Tanabe M, Kawachi K, Nizawa A, Chishima T, Kimura M, Ichikawa Y, Endo I. Yokohama City University Medical Center, Yokohama, Kanagawa, Japan; Yokohama City University, Yokohama, Kanagawa, Japan

Background: Human epidermal growth factor receptor (HER2)-negative breast cancers are more heterogeneous than HER2-positive cancers, and tailored treatment is therefore required for luminal A and triple-negative breast cancer subtypes (LABC and TNBC). We therefore examined predictive factors for the efficacy of standard chemotherapy in LABC and TNBC subtypes.

Methods: A total of 109 LABC and 61 TNBC patients were treated with standard neoadjuvant chemotherapy (NAC) consisting of an anthracycline and/or taxane. The pathological treatment response
and prognosis were examined for each subtype. Expression levels of the following factors were examined in association with quasi-pathological complete response (QpCR): estrogen- and progesterone-receptor (ER and PgR) status, HER2, nuclear grade, MIB-1, p53, topoisomerase IIα (topoIIα), cytokeratin (CK) 5/6 and epidermal growth factor (EGFR).

**Results** QpCR rates in LABC and TNBC were 9.1% (10/109) and 54.1% (33/61), respectively. In LABC, the expression of PgR tended to be inversely associated with pathological response (p=0.087), while in TNBC, increased expression of topoIIα (p=0.006) and MIB-1 (p=0.018) were identified as predictors of QpCR. TopoIIα expression was also significantly associated with pathological response in multivariate analysis (p=0.014). The QpCR rate was higher in TNBC lacking CK5/6 and/or EGFR expression, defined as non-basal subtype (p=0.053).

**Conclusions** Low expression of PgR may be a possible predictor of the efficacy of chemotherapy in LABC, while a high level of proliferative activity, indicated by topoIIα and MIB-1, is associated with chemosensitivity in TNBC. Further subclassification into basal- and non basal-subtypes may also be helpful for the development of individualized treatments.

**P5-13-24**

**A Predictive Model of Early Systemic Disease Relapse after Standard Adjuvant Therapy for Breast Cancer.**

**Background:** Early relapse after adjuvant therapy for breast cancer is very discouraging and remains a major problem. We sought to identify predictors of early relapse risk and build a predictive model for relapse using prospectively collected data for patients seen at the Markey Cancer Center starting 2007 to date.

**Methods:** Of the 1098 new patients seen, 814 patients had stage I-III disease and were further analyzed for predictors of early relapse risk. Univariate analyses were performed for key variables including patient age, tumor size, grade, estrogen receptor (ER) status, progesterone receptor (PgR) status, and HER2 status. A multivariate Cox regression model was built to identify predictors of systemic relapse and model-building was performed using step-wise model selection to determine candidate models. A risk score was developed based on the linear combination of covariates in the final Cox model. Time-dependent predictive curves, a newly developed statistical methodology, were used to evaluate the predictive accuracy of the proposed risk score.

**Results:** Median patient age was 57 years (Range 25-92) and 88% were white. Forty six (46%) had stage I disease, 36% stage II, and 18% stage III. Median follow up time was 2.3 years. Of this 814 patient cohort, 706 patients had complete baseline covariate data and were used to build the candidate models. The final Cox regression model included 5 covariates that were significantly associated with risk of early relapse: stage III disease (p = 0.0011), grade III (p = 0.0028), PgR-negative status (p = 0.0121), HER2-negative status (p = 0.0305), and node-positive status (p = 0.0360). These five covariates were then used to calculate an early recurrence risk score, which is the weighted average of these risk factors when present, with the weights being the coefficients from the Cox regression model. The 1-year, 2-year and 3-year predictive curves for this risk score decrease considerably, especially for the 2-year and 3-year curves, indicating good predictive accuracy of the risk score. The highest risk score group, which represents 4.8% of the population, has a 1-year, 2-year and 3-year relapse probabilities of 13.0% (95% CI: 4.1%, 27.3%), 39.4 % (95% CI: 20.1%, 58.3%), and 52.3% (95% CI: 28.5%, 71.5%), respectively. In comparison, for the overall population, the corresponding 1-year, 2-year, and 3-year relapse probabilities were only 1.1% (95% CI: 0.5%, 2.1%), 4.2% (95% CI: 2.7%, 6.1%) and 6.2% (95% CI: 4.2%, 8.6%), respectively.

**Conclusions:** The developed risk score based on stage, tumor grade, PgR, HER2, and node status is highly predictive of early relapse in breast cancer patients after standard adjuvant therapy. Our model can be used to identify patients with high risk of early disease relapse who may otherwise benefit from enrollment on novel adjuvant therapeutic trials to improve their outcome.

**P5-14-01**

**Differences in Efficacy by Assessment Method: NCIC CTG Adjuvant Breast Cancer Trials MA.5, MA.12, MA.14, MA.21, MA.27 Meta-Analysis.**

Dong B, Chapman J-AW, Yerushalmi R, Goss PE, Pollak MN, Burnell MJ, Bramwell VH, Levine MN, Fritchard KJ, Whelan TJ, Ingle JN, Parulekar W, Shepherd LE, Gelmon KA. NCIC Clinical Trials Group, Queen’s University, Kingston, ON, Canada; Vancouver Cancer Centre-BCCA, Vancouver, BC, Canada; Harvard Medical School, Boston, MA; McGill University, Montreal, QC, Canada; Atlantic Health Sciences Corporation, Saint John, NB, Canada; Alberta Cancer Board, Calgary, AB, Canada; McMaster University, Hamilton, ON, Canada; University of Toronto, Toronto, ON, Canada; Mayo Clinic, Rochester, MN

**Background:** Based on recent breast cancer literature, we hypothesized that there could be substantive differences in apparent efficacy estimates using a log-normal (LN) survival model rather than with standard Kaplan-Meier (K-M) or Cox model methods. While both Cox and LN survival analyses offer greater specificity by individual patient characteristics, the LN model may more robustly estimate survival under model misspecification. Methods: We recently pooled data for 5 NCIC CTG primary breast cancer trials: MA.5, MA.12, MA.14, MA.21, and MA.27. The total patient count for patients who received at least 1 dose of trial therapy is 11,253. Compilation included definition of STEEP endpoints (C Hudis, JCO, 2008) and standardized factor categorizations. The primary endpoint is Breast Cancer Free Interval (BCFI) defined as the time from randomization until recurrence: first local invasive or DCIS; regional, or distant; contralateral invasive or DCIS; or death from breast cancer. We found substantive evidence of non-proportionality for 7 factors compiled for the meta-analyses. In this work, we fit multivariate Cox and LN models with these 7 factors, lymph node status and pathologic T status. We then compare BCFI efficacy estimates for patient and tumour characteristics at 1-, 3-, and 5-years obtained with K-M, Cox, and LN models. Results: There was evidence that the Cox assumption of proportional hazards was violated for 7 factors: age, menopausal status, hormone receptor status, anthracycline use, chemotherapy use, race, and ECOG performance status. Differences between models were intrinsically affected by timing and extent of non-proportionality; there was no consistent pattern. In particular, investigations to date indicate efficacy estimates with absolute differences between K-M, Cox and LN estimates which varied by time of assessment: at 1-year 0.0 to 6.7%, at 3-years 0.4 to 18.6%, and at 5-years 0.2 to 17.0%. BCFI estimates with the K-M were inconsistently closer to those with the LN or Cox model: for K-M to Cox at 1-year 0.4 to 5.2%, at 3-years 0.4 to 15%, at 5-years 0.4 to 14.3%; for K-M to LN at 1-year 0.0 to 6.7%, at 3-years 0.5 to 18.6%, at 5-years 0.2 to 17.0%; for Cox to LN at 1-year 0.8 to 1.8%.
at 3-years 1.9 to 6.0%, at 5-years 0.6 to 5.7%. K-M and Cox models have step-wise adjustments at events for K-M and Cox, rather than smooth modeling with the LN. Discussion: Even with reasonably large population subgroups, there were substantive differences in apparent survival (0.0 to 18.6%) between K-M, Cox and LN model types. The magnitude of differences in survival estimates was large enough to be clinically relevant and warrant further consideration as we evaluate new therapies and prognostic/predictive factors. We will be statistically investigating framework robustness under differing levels of model misspecification.

P5-14-02
Clinicopathologic and Prognostic Difference of Screen Detected Breast Cancer Compared with Symptomatic Breast Cancer.
Kim J, Lee SK, Kim S, Koo MY, Choi M-Y, Cho DH, Bae SY, Lee J, Jung SP, Lee JE, Yang J-H, Nam SJ. Samsung Medical Center, Seoul, Korea; Konkuk University Medical Center, Seoul, Korea
Background: Breast cancer screening program makes it possible to detect early cancer, thus to reduce breast cancer mortality. The authors studied clinicopathologic characteristics and prognosis of screen detected invasive breast cancer compared with symptomatic breast cancer. Furthermore, we compared the result according to molecular subtypes (luminal A, luminal B, Her2, triple negative), so intended to identify the role of screening in each subtypes.
Material and Methods: From January 2002 to June 2008 , 3141 patients who underwent operation for the treatment of invasive ductal carcinoma (NOS) at Samsung medical center were included. Among them, 1025 patient were screen detected, 2116 patient were symptomatic, out of screening over 2 years. We reviewed the medical records retrospectively.
Result: Screen detected breast cancer was associated with older patients, smaller tumor size, more hormone receptor- positive, less lymph node involvement, lower stage and reduced mortality compared with symptomatic breast cancer (P < .001). According to the molecular subtype, in luminal A subtype, the result shows better pathologic feature and also favorable overall and recur-free survival significantly.

Effect of screen detection on survival (screen detected vs symptomatic)

HR : hazard ratio, TNBC : triple negative breast cancer

Conclusion: Compared to symptomatic breast cancer patients, screen detected breast cancer patients have favorable pathological and molecular characteristics, so better outcomes. According to the molecular subtype, only in luminal A subtype, screen detected breast cancer shows both overall and disease free survival benefit, and also acts as an independent prognostic factor itself. So, screening program seems to have a different efficacy depending on the molecular subtype of breast cancer

P5-14-03
Boobol SK, Kirstein L, Harshan M, Klein P, Cohen J-M, Chadha M, Baehner FL, Malamud SC. Beth Israel Medical Center, New York, NY; Genomic Health Inc., Redwood City, CA
Background: NCCN guidelines now include consideration of the 21 gene RT-PCR assay in node negative, hormone sensitive breast cancers greater than 0.6 cm. Recent data suggests a potential role for testing of node positive(N1), hormone sensitive patients as well. Currently, no data exists on testing of metastatic lymph nodes. We sought to establish the feasibility of Oncotype DX® testing in the metastatic lymph nodes and, furthermore, to evaluate the genomic concordance between the primary tumor and the nodal deposit. These results may further our understanding of tumor heterogeneity and biological selectivity in the process of lymph node metastasis and ultimately systemic metastases.
Methods: We examined the formalin fixed paraffin embedded tumor tissues (FPET) from 100 breast cancer patients from our institution’s pathology database with available paired primary tumor and macrometastatic nodal deposits by Oncotype Dx® testing. Inclusion criteria included patients with macrometastatic lymph node disease, hormone receptor positive, HER2 negative primary breast cancer. The testing laboratory was blinded from the clinical outcomes data available on these patients. All FPET samples had H&E slides made which were reviewed by board certified surgical breast pathologists to determine if there was sufficient invasive tumor and to direct dissection of all lymph node samples. The Recurrence Scores and quantitative single gene values from the paired samples will be examined descriptively with scatterplots and Pearson correlation coefficients and reported at the meeting.
Results: All 100 paired specimens were sent for Oncotype DX testing. 24 samples were found during standard H&E review to not have sufficient tumor for the assay. Of the 176 samples created for RNA extraction 173 samples had sufficient RNA for the Oncotype DX assay: 85 lymph node and 88 primary breast carcinoma samples. Recurrence Scores and quantitative single gene values from the paired primary breast carcinoma and lymph node samples will be examined descriptively and reported at the meeting.
Conclusion: Previous comparisons of paired primary and metastatic samples have used immunohistochemistry and FISH which are susceptible to variability in preanalytic variability such as delay to fixation, choice of fixative and duration in fixative. This study, using quantitative RT-PCR, will be one of the largest comparisons of tumor biology in paired samples yet reported in the era of genomic subtyping and may have implications for systemic adjuvant treatment.

P5-14-04
RANK Expression in Primary Tumor Tissue at the Time of Diagnosis Correlates with Risk of Subsequent Bone Metastases in the I-SPY 1 Trial (CALGB 150007/150012; ACRIN 6657).
Li J, Moore D, Yau C, Campbell M, Park J, I-SPY-1 TRIAL Investigator, Rugo HS. University of California, San Francisco, CA; Cancer and Developmental Therapeutics Program, Buck Institute for Age Research, Novato, CA
Background: RANK (receptor activator of nuclear factor kappa B) is a tumor necrosis factor receptor family protein that is expressed on the surface of osteoclasts and critical to bone turnover. RANK is also expressed on breast cancer (BC) cells, especially in the metastatic
setting. Pre-clinical mouse models have shown that the ligand to RANK (RANKL) can induce migration of RANK-expressed tumor cells to bone and lung, and that treatment with a RANKL inhibitor can reduce BC metastases. ISPY is a multicenter neoadjuvant study with well annotated gene expression data. We evaluated RANK expression in primary tumor tissues at the time of diagnosis (dx) in patients (pts) with BC and correlated expression with risk of subsequent metastases. Methods: We evaluated expression of genes in the RANK/RANKL pathway in core biopsies at dx, and correlated this data with risk of recurrence as well as risk of site specific metastases using the student t-test. Results: A total 221 pts were enrolled in this clinical trial, all had locally advanced BC (LABC) and received neo-adjuvant chemotherapy (96.6% pts received adriamycin + cyclophosphamide-based regimens), tumor samples were collected at the time of dx by core biopsy, and underwent gene array study. Total 38508 genes were tested and 149 pts had available gene array data. Average age was 48.0 yr, pt characteristics are listed in the Table. Analysis of variance (ANOVA) was then used to adjust clinical variability, after adjusting the difference of ER status, pathology subtypes, and menopausal status, RANK expression is even more highly expressed in the ER- group than ER+ group (p=0.006) and between the 2 groups. In addition, RANK was also significantly more expressed of RANK (p=0.05) in primary tumor tissues than those in primary tumor tissues at the time of diagnosis (dx) in patients (pts) who developed BDM had a significantly higher (p=0.07). When comparing gene expression in the RANK/RANKL pathway, pts who developed BDM had a significantly higher expression of RANK (p=0.05) in primary tumor tissues than those with NBDM, while there was no difference in RANKL expression between the 2 groups. In addition, RANK was also significantly more highly expressed in the ER- group than ER+ group (p=0.006) and in the basal group compared to the luminal A/B group (p= 0.002). Analysis of variance (ANOVA) was then used to adjust clinical variability, after adjusting the difference of ER status, pathology subtypes, and menopausal status, RANK expression is even more significantly correlated with the bone-dominant group (p=0.002).

Conclusion: Higher RANK expression in primary tumor tissues correlates with increased risk of subsequent BDM in pts enrolled in iSPY-1 trial. The sample size is small (n=149) and all pts had LABC. Our study suggests that targeting RANK/RANKL pathway is a promising strategy in preventing BDM in pts with high risk BC, further analysis in larger data sets is ongoing.

PS-14-05

Anti-Müllerian Hormone (AMH) Levels in Premenopausal Breast Cancer Patients Treated with Adjuvant Chemotherapy – A Translational Research Project of the SUCCESS Study.

Neugebauer JK, Rack BK, Kupka M, Dinkel C, Schneeweiss A, Schrader I, Tesch H, Rezai M, Söling U, Friese K, Beckmann MW, Janni W, Müller V. Ludwig-Maximilians-Universität, Munich, Germany; University Hospital Heidelberg, Heidelberg, Germany; Henriettestiftung Hannover; Hannover, Germany; Fachpraxis für Onkologie, Frankfurt, Germany; Luisenkrankenhaus Dusseldorf, Dusseldorf, Germany; Gemeinschaftspraxis Siehl & Söling, Kassel, Germany; University Hospital Erlangen, Erlangen, Germany; Heinrich-Heine-Universität, Dusseldorf, Germany; University Medical Center, Hamburg-Eppendorf, Germany

Background: Premenopausal women undergoing chemotherapy are at risk of premature ovarian failure and long term side-effects caused by premature menopause. However, knowledge about the rate of ovarian failure and potential markers to evaluate the ovarian reserve is limited, especially in the context of modern chemotherapy concepts. Therefore, Anti-Müllerian hormone (AMH) was measured at before, immediately after and 2 years after chemotherapy in premenopausal patients of the SUCCESS study.

Materials and Methods: The German SUCCESS trial is a multicenter phase III study comparing FEC-Docetaxel vs. FEC-Docetaxel+Gemcitabine as adjuvant treatment in patients with node positive or high risk node negative primary breast cancer. Blood samples were taken prior to and 4 weeks after last cycle of adjuvant chemotherapy, as well as after 2 years of follow up. We retrospectively identified 170 patients stratified premenopausal and aged 40 years or younger at trial entry, who received 3cycles of FEC (500/100/500ng/m2) q3w followed by 3 cycles of docetaxel (100mg/m2) q3w as one of the most commonly used chemotherapy regimens in Europe. Serum AMH levels were evaluated in a central laboratory by a manual immunoassay AMH DSL ELISA (Diagnostic Systems Laboratories, Webster, USA).

Results: Median age within this subgroup was 36 years (21-40 years). 48% of the patients had a tumor stage pT1 and 54% were node positive. 69% were hormone receptor positive and 29% Her2 positive. Median serum AMH level before adjuvant chemotherapy was 1.32 ng/ml (range <0.1-11.32). Immediately after chemotherapy AMH levels dropped in 96% of the patients below the threshold of detection (<0.1 ng/ml, range <0.1-3.9 ng/ml). Immediately after chemotherapy AMH levels dropped in 96% of the patients below the threshold of detection (<0.1 ng/ml, range <0.1-3.9 ng/ml). No association to classical prognostic markers, such as tumor stage, lymph node involvement, etc. was observed. After a follow up period of 2 years, serum was available from 95 patients. 76% of those patients showed no evidence of ovarian function indicated by AMH (<0.1 ng/ml, range <0.1-1.43 ng/ml). AMH levels prior to and 2 years after chemotherapy were significantly correlated with older age, with a reduction of 0.14 ng/ml per life year (p=0.0025) and 0.01 ng/ml (p=0.017) respectively. 12 patients (7%) received optional gonadotropin-releasing hormone (GnRH) agonists during chemotherapy. These patients presented significantly higher AMH levels (+ 0.18 ng/ml; p=0.01) 2 years after cytotoxic treatment. Conclusion: In this retrospective analysis premenopausal patients showed a high rate of ovarian insufficiency reflected by low serum AMH levels immediately after cytotoxic treatment and after 2 years of follow up. GnRH agonists given as ovarian protectants during chemotherapy may have an influence on serum AMH 2 years after chemotherapy. Further data from prospective trials with longer follow up are needed to evaluate the role of serum AMH as a predictor of ovarian failure in breast cancer patients exposed to chemotherapy.
P5-14-06
Interaction between Stoma and Tumor Characteristics as a New Prognostic and Predictive Marker in Breast Carcinomas.
Tagliabue E, Sandri M, Casalin P, Aiello P, Pupa SM, Orlandi R, Balsari A, Triulzi T. Fondazione IRCCS- Istituto Nazionale dei Tumori, Milan, Italy; University of Milan, Milan, Italy
Background. We recently demonstrated that primary breast tumors can be classified based upon extracellular matrix composition (ECM) (Bergamaschi et al.) suggesting stroma characteristics could influence tumor progression. Aim of this study is to further investigate the robustness of this classification and its impact in tumor progression and response to therapy.
Methods. The expression profile of ECM-related genes was analyzed by unsupervised hierarchical clustering in 10 independent datasets of breast tumors, counting more than 1000 samples and the prognostic and predictive value of this signature were evaluated in two datasets of not treated patients and in one dataset of neo-adjuvant treated patients, respectively.
Results. Only one of ECM subsets (ECM3) showed a homogenous gene pattern that consistently allowed the classification of an independent group of tumors in all tested datasets. ECM3 is characterized by highly correlated over expression of 34 ECM genes encoding mainly structural proteins. From 24 to 38% of cases were ECM3-enriched and were mainly estrogen receptor-positive and low grade (p<0.0001). The ECM3 showed inconsistent association with DMFS in the two data sets of not treated patients, whereas the interaction between ECM3 and grade showed strongly and significant association with DMFS (HR=5.35, p=0.0012). In particular, multivariate analysis of covariates available (size, ER, age and ECM) indicated that ECM3 is significantly associated with worse DMFS in grade III patients (HR=2.5, p=0.0386), whereas it is slightly correlated with better DMFS in grade I-II patients (HR=0.6, p=0.088). It is noteworthy that the probability of 10-year DMFS was 90% in ECM3 versus 74% in non-ECM3 patients in differentiated tumors, and 75% in non-ECM3 versus 41% in ECM3 grade III tumors.
Conclusions. Our results provide evidence that breast carcinoma progression and response to therapy are influenced by the interaction between tumor and stromal characteristics. (Partially supported by AIRC).

Novel Interactions between Immunity and Proliferation in Breast Cancer Progression.
Nagalla S, Chou JW, Ruiz J, Vaughan JP, Black MA, Miller LD. Section on Hematology and Oncology; Department of Biostatistical Sciences; Wake Forest University Health Sciences, Winston-Salem, NC; Otago School of Medical Sciences, University of Otago, Dunedin, New Zealand
Highly proliferative breast tumors are phenotypically and clinically heterogeneous and exhibit a significant metastatic tendency. However, not all highly proliferative breast cancers will progress to distant metastasis, suggesting that other factors may play a role in limiting their clinical progression. With an interest in identifying genes that predict metastatic capacity of breast cancers in a proliferation-dependent context, we recently compiled a database of ~2,000 tumor expression profiles using microarray data from multiple large breast cancer cohorts. We randomized the dataset into training and testing sets to allow discovery and validation of novel gene-survival (ie, distant metastasis-free survival; DMFS) associations. We employed Cox regression analysis to identify genes with statistically significant associations with DMFS. Then, we hierarchically clustered the expression patterns of the significant genes to identify gene clusters lacking correlation with proliferation genes. A large cluster of genes with known functions in innate and adaptive immunity emerged. Cross referencing these genes to a published microarray dataset of pan-leukocyte expression profiles revealed cell type-specific structure within the immunity cluster, likely reflective of distinct populations of tumor-infiltrating immune cells. Specifically, 3 immune gene subclusters identified within the tumors showed predominant expression in B-cells, T-cells and natural killer (T/NK) cells, or monocytes and dendritic (M/D) cells. To evaluate the prognostic relevance of these immune gene clusters, we averaged the gene expression measurements within each cluster to generate “metagenes” that could be used to divide breast cancer cases into population tertiles based on the low, intermediate and high expression of the immune genes. The same was done for a large cluster of proliferation genes known to reflect the proliferative capacity of breast cancer cells. Strikingly, we found that that prognostic power of the B-cell, T/NK and M/D metagenes was not consistent among the proliferation tertiles, but rather, was exclusively statistically significant in the highest proliferation tertile, enriched for basal-like, luminal B and HER2+-like tumors. In these tumors, all 3 immune metagenes stratified cases into low, intermediate and high risk of recurrence with high statistical significance (p<0.0001), wherein the highest expression tertile of the immune metagenes corresponded to reduced risk of metastatic recurrence (at 5 and 10 years), consistent with a long-term anti-metastatic immune response. Comparative analysis of the B and T/NK metagenes revealed a highly significant prognostic interaction between the two, whereby the low expression tertile of either the B-cell or T/NK metagene portends a poor prognosis that is not overcome by a high expression tertile of the other. Our results suggest that cell type-specific immune signatures in breast cancer can predict survival in highly proliferative subtypes of breast cancer, with potential to spare some patients from aggressive adjuvant treatment while identifying others who will require more than standard of care. Furthermore, our results provide novel insight into the important roles of T and B cell-mediated immunity in breast cancer progression.

P5-14-08
Impact of Progesterone Receptor Semiquantitative Immunohistochemical Result on Oncotype DX® Recurrence Score: A Quality Assurance Study of 1078 Cases.
Bhargava R, Dabbs DJ. Magee-Womens Hospital of UPMC, Pittsburgh, PA
Background: The oncoype DX® recurrence score (RS) is predominantly dependent on estrogen and progesterone receptor content of the tumor, proliferation and HER2 status. We have previously shown (Mod Pathol. 2008;21:1255-1261) that using a regression equation that incorporates the above along with tumor grade components is capable of estimating the RS score. In the present study, we tested this formula in 1078 prospectively collected breast cancer cases.
Methods: We employed a logistic regression equation that incorporates the above along with tumor grade components to estimate the RS score. Using this formula, we assigned an RS score to the tumors. We then compared this calculated RS score with the RS score derived from the Dimethylaminoazobenzene modified avidin-biotin immunoperoxidase method. We also noted clinical outcome of the patient.
Results: We assigned an RS score of 18 to 25% of cases and an RS score of 26 to 30% to 39% of cases. There was no significant difference in the calculated RS score and the RS score derived from the staining method. Furthermore, we observed no correlation of RS score with the type of surgery, tumor size, nodal status, lymphovascular invasion, and hormone receptor status.
Conclusions: Our data suggest that the RS can be estimated accurately and reliably by using a formula that incorporates the above factors and tumor grade components.
Results: A total of 1078 cases were analyzed (see table below).

RS: recurrence score; CI: confidence interval; IHC: immunohistochemical

Conclusions: Within each grade, PR IHC score is inversely related to the RS. The dramatic impact of PR IHC score on RS is noteworthy. If PR IHC score is combined with traditional histopathologic features (nuclear grade, mitotic activity score), and other IHC variables (ER IHC score, HER2 status, Ki-67 labeling index), then a tumor’s risk of recurrence and need for chemotherapy can be reasonably estimated. OncoType DX® test may not be necessary in more than half of cases that are currently sent for testing.

P5-14-09
Malignant Calcification Is an Important Prognostic Factor in Women with Invasive Breast Cancer – Suggestion for Regarding It as High-Risk Factor in Current Staging and Adjuvant Treatment Guidelines.
Ling H, Shao Z-M, Liu Z-B, Xu X-L, Yang W-T, Xu L-H, Gu Y-J. Fudan University Shanghai Cancer Center, Shanghai, China

Purpose:
To investigate whether calcification is a prognostic factor for breast cancer.

Methods:
A total of 804 patients with invasive breast cancer diagnosed between 2001 and 2003 were recruited and divided into two groups based on whether they had malignant calcification on mammogram. The association of calcification with lymph node status, grade, tumor size, ER, PR and Her2 status, 8-year disease-free survival (DFS) and overall survival (OS) was evaluated. Survival difference was analyzed by Kaplan-Meier technique. The relative importance of each of the potentially prognostic variables was tested using Cox regression analysis.

Results:
The incidence of malignant calcification in all breast cancer was 41.5%. Compared with tumor without calcification, those with calcification had a larger size (2.6cm vs 2.1cm, P=0.000), higher axillary lymph node (LN) positive rate (40.1% vs 31.5%, P=0.012), more LN involvement (14.8% vs 9.2%, P=0.000), lower ER (54.3% vs 65.1%, P=0.002) and PR (42.7% vs 60.6%, P=0.000) expression and higher Her2 expression (27.3% vs 14.7%, P=0.000).
The 8-year DFS was lower for patients with calcification than those without (89.9% vs. 76.8%, P=0.000). The 8-year OS for tumor with calcification was 82.2%, compared with 92.8% for those without (P=0.000).

Subgroup analysis showed that the shorter survival and higher relapse rate for tumors with calcification could be found in both LN- and LN+ patients, also could be found in T1, T2, Grade II, ER+, PR+ and Her2- patients.
The existence of calcification, LN stage, tumor size, ER status, and grade were significantly associated with survival in univariate analysis. Further Cox regression analysis demonstrated that calcification and LN stage maintained their prognostic significance in both DFS and OS. The hazard ratios of these factors are listed in Table 1.

*Univariate analysis shows there’s no significant difference of survival between Grade I and II

Conclusions:
The existence of calcification is a poor prognostic factor for patients with invasive breast cancer. Its prognostic value is only second to LN status and is higher than the other factors evaluated, including tumor size, grade, and ER, PR status. Thus, breast cancer with calcification should be regarded as a high-risk factor when determining cancer stage and selecting the adjuvant treatment.

Discussion:
Given the strong prognostic value of calcification revealed in this research, the biological mechanism of its formation and related cell signal pathway should be investigated. Further adjuvant clinical trial should be done to select certain sensitive chemotherapeutic agent or regimen. Some biomarkers have been found to have a role in the formation of calcification and may be targets for treatment.

P5-14-10
Ethnic Differences in the Association between Tumor Size and Lymph Node Status among Breast Cancer Patients in South East Asia.
Saxena N, Verkooijen HM, Bhoo Pathy N, Siew EL, Jau P, Lee SC, Yip CH, Hartman M. National University of Singapore, Singapore, Singapore; University Medical Center Utrecht, Utrecht, Netherlands; Julius Center University of Malay, Kuala Lumpur, Malaysia; National University Cancer Institute, National University Health Systems, Singapore, Singapore; Faculty of Medicine, University of Malaya Medical Center, Kuala Lumpur, Malaysia

Background: South East Asia consists of three major ethnic groups, i.e. Chinese, Malays and Indians. Previous work from our breast cancer research group showed that Malay ethnicity is an independent
predictor of poor survival. In this study we evaluate whether (part of) these ethnic survival disparities may be due to ethnic differences in the association of tumor size and lymph node involvement.

Methods: We included all patients diagnosed with breast cancer at the National University Hospital (Singapore) and University of Malaya Medical Center (Kuala Lumpur) between 1990 and 2007, for whom information on tumor size and axillary lymph node status was available (n = 3805). Ethnic differences in the association between tumor size and lymph node involvement were studied and logistic regression analysis was performed to determine the independent effect of ethnicity on the association of tumor size and lymph node involvement.

Results: 1474 patients were categorized as T1 (>0 to 2 cm), 1777 as T2 (2.1 to 5 cm) and 554 as T3 (>5 cm). Within the small tumor size range (>0 to 2 cm) the Malays were significantly more likely to present with node positive disease as compared to the other ethnic groups (36.9% as compared to 24.5% for Chinese and 25.9% for Indians, p-value <0.001). Similarly, for tumors measuring 2.1-5 cm, Malays were more likely than Chinese and Indians to have lymph node involvement (59.5%, 50.2% and 52.1%, respectively, p-value 0.016). After adjustment for age, Progesterone Receptor (PR) status, grade and treatment received, Malay ethnicity was an independent predictor of lymph node involvement, with adjusted Odds Ratio’s of 1.4 (95% CI 1.0 to 2.1) for T1 tumors and 1.4 (95% CI 1.1 to 1.9) for T2 tumors compared to Chinese women.

Conclusion: Malay patients are more likely to present with lymph node metastasis especially for the small and midsized tumors as compared to the Chinese and Indians. This could reflect differences in tumor biology between the three ethnic groups with the Malays possibly having more aggressive disease than the others.

P5-14-11
Elevated Serum Ferritin Predicts Reduced Progression-Free and Overall Survival in Trastuzumab-Treated Metastatic Breast Cancer.
Alkhateeb AA, Connor J, Leitzel K, Ali S, Campbell-Baird C, Evans M, Koestler W, Fuchs E-M, Lipton A. The Pennsylvania State University Hershey Medical Center, Hershey, PA; Lebanon VA Medical Center, Lebanon, PA; Medical University of Vienna, Vienna, Austria

Background: Approximately one-half of HER2-positive breast cancer patients will not respond to first-line trastuzumab-containing therapy. Since trastuzumab is now used in the HER2-positive adjuvant breast cancer setting, trastuzumab resistance will continue to be a vexing clinical problem, and better predictive and prognostic biomarkers are urgently needed.

One potential biomarker is serum ferritin. Although serum ferritin has been used as an indicator of total body iron, a specific functional role has not been proposed thus far other than perhaps recycling iron for erythropoiesis. Increased serum ferritin levels have been reported in breast cancer patients. However, the prevailing paradigm on ferritin at the time of these observations did not encourage speculation on its role or significance and was dismissed as a non-specific parameter for cellular damage. There are now multiple lines of evidence that have challenged this traditional paradigm and suggested ferritin to be a multi-functional factor involved in key cellular and systemic processes including immune regulation, angiogenesis, and iron delivery.

Methods: Pretreatment serum ferritin was measured using an ELISA assay in 66 metastatic breast cancer patients before starting first-line trastuzumab-containing therapy. Serum ferritin was determined using an ELISA from Assaypro, St. Charles, MO. Progression-free survival (PFS) and overall survival (OS) were analyzed using the Kaplan-Meier method and Cox modeling, with separate analyses as continuous serum ferritin, or as dichotomous categorical groups using the median pretreatment serum ferritin level as a cut off point. To interrogate a functional impact of elevated serum ferritin, we used a cell culture model.

Results: When analyzed as dichotomous categorical groups using the median pretreatment serum ferritin level as a cut off point, the elevated serum ferritin patient cohort had a significantly reduced OS (P<0.0001, median OS 12.73 vs. 69.57 months) and PFS (P=0.004, 8.30 vs. 23.90 months). In the cell culture model, ferritin bound to breast cancer cells promoted proliferation and activated AKT signaling. These novel observations suggest that the iron storage protein ferritin has a signaling role in tumor biology. Since the elevation in serum ferritin is unlikely a consequence of a change in total body iron, we also examined several possible sources for this elevation. Macrophages, but not breast cancer cells, were capable of ferritin secretion.

Conclusions: Elevated serum ferritin predicts reduced PFS and overall survival in metastatic breast cancer patients treated with first-line trastuzumab-containing therapy. The ability of ferritin to activate AKT signaling could underlie the trastuzumab resistance in patients. Therefore, serum ferritin may not only have predictive value as a clinical tool but also has direct functional significance in the treatment response, progression and survival of breast cancer patients.

P5-14-12
Bayesian Belief Network Mortality Analysis of a Breast Cancer Registry Data Set.
Eberhardt JS, Hyslop T, Mitchell E, Hu H, Rui H. DecisionQ Corporation, Washington, DC; Thomas Jefferson University, Philadelphia, PA; Windber Research Institute, Windber, PA

Introduction: Bayesian Belief Networks have been used in medicine to evaluate clinical data and develop predictive and prognostic models. As classification models, they allow us to represent pattern complexity beyond what can be accomplished with traditional Kaplan-Meier or regression models. We sought to evaluate the use of machine-learned Bayesian Belief Networks (ml-BBNs) to develop mortality models in breast cancer and to evaluate classification performance for this method.

Methods: A set of 2,300 breast cancer cases from a tumor registry at Thomas Jefferson University were used to train ml-BBNs. The registry set was broken into cohorts for modeling by follow-up times of 1 (n=2,202), 2 (n=2,183), 3 (n=2,157), and 5 (n=2,027) years. Each cohort was then used to train a ml-BBN and each model was evaluated for structure. Variables were recoded into categories: biomarkers (ER, PR, Ki67, HER2, p53) as positive or negative; grading, staging, and size were broken in categories; while race was recoded into Caucasian or African-American. Income and poverty level by census tract were also included. Models were evaluated for ability to classify mortality (yes/no) within the follow-up period using 10-fold cross-validation and Receiver Operating Characteristic curves.

Results: Area Under the Curve (AUC), Positive Predictive Value (PPV), and Negative Predictive Value (NPV) were calculated for each set of cohort training models and mean values and 95% confidence intervals were calculated for mortality (yes/no) within the follow-up period. AUCs (and CIs) for 1, 2, 3, and 5 years were: 0.81 (0.70 – 0.91), 0.74 (0.69 – 0.79), 0.81 (0.77 – 0.86), 0.77 (0.74 – 0.80). PPVs for 1, 2, 3, and 5 years were: 12.3% (7.5% – 17.1%), 18.8% (15.4% – 22.1%), 18.0% (15.1% – 20.9%), 28.2% (24.7% – 31.7%). NPVs for 1, 2, 3, and 5 years were: 99.2% (98.8% – 99.7%), 97.4% (96.9% – 97.8%), 96.4% (95.1% – 97.7%), 91.7% (89.1% – 94.3%). Predictors
of mortality at 1 year were Tumor Stage, at 2 years were Estrogen Receptor and Tumor Stage, and at 3 and 5 years were Diagnosis Age, Tumor Stage, Estrogen Receptor status, and Ki-67 receptor status.

Discussion / Conclusion: We were able to successfully train mLBNNs to estimate mortality using breast cancer registry cohorts. Cross-validation showed the models to be robust. The structure of the models can inform us how different data elements contribute to the estimate of mortality. These models can be used to calculate individual probabilities for prognostic guidance given age, staging criteria, and biomarkers. Overall 5-year mortality in the study set is 15.2%, however we can derive subject-specific mortality estimates. For example, a 43-year old Stage 3, ER-Negative, Ki-67 Negative subject has a 19.9% probability of 5-year mortality, while the same subject with positive Ki-67 has a 37.8% probability of mortality. Meanwhile, the same probabilities for a 70 year old woman are 67.0% and 59.0%, respectively.

P5-14-13
Favorable Prognosis in Patients with T1a,b Node-Negative Triple Negative Breast Cancers Treated with Multimodality Therapy.
Ho AY, Gupta G, Perez CA, King TA, Patil SM, Rogers KH, Brogi E, Morrow M, Hudis C, Traina T, McCormick B, Powell SN, Robson ME. Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: To evaluate the clinical characteristics, natural history and outcomes in patients with ≤1 cm, node-negative triple negative breast cancer (TNBC).

Materials and Methods: After excluding patients who received neoadjuvant therapy, 1,022 TNBC patients who received definitive breast surgery from 1999 to 2006 were identified from an institutional database. Among these, 194 patients had node-negative tumors ≤1 cm and comprise the study population. Clinical data was abstracted and survival outcomes were analyzed.

Results: Median follow-up time was 71 months (range 2-143). Median age at diagnosis was 55.5 years (range 27-84). T stage was T1mic in 16 (8.2%), T1a in 49 (25.3%), T1b in 129 (66.5%). The majority of tumors were poorly differentiated (N=142,73%), lacked lymphovascular invasion (N=170,87.6%) and were screening-detected (69%, N=134). Breast-conserving surgery (BCS) was employed in 129 (66.5%) and mastectomy in 65 (33.5%) patients. 113 (58%) patients received adjuvant chemotherapy and 123 (63%) received whole breast radiation. Patients who received chemotherapy tended to have more adverse clinical and disease features (younger age,T1b, poor tumor grade; all p<0.05). For the entire group, 5 year local recurrence-free survival was 96% and distant metastasis-free survival was 95%, with no difference in distant relapse rates between T1mic/T1a vs. T1b patients (94.5% vs 95.5%, p=0.81) or by receipt of chemotherapy (95.9% vs 94.5%, p=0.63).

Conclusion: Excellent 5-year locoregional and distant control rates were achievable in patients with TNBC tumors ≤1.0 cm, 58% of whom received chemotherapy. These results identify a group of TNBC patients with favorable outcomes following early detection and multimodality treatment.

Van den Eynden GG, Van Laere SJ, Smid M, Martens JW, Foevens JA, Vermeulen PB, Dirix LY. Augustinus Hospital, Antwerp, Belgium; Erasmus Medical Center Rotterdam, Rotterdam, Netherlands

Introduction: The fibrotic focus (FF) is a practical, easily assessable and reproducible integrative histological prognostic parameter in breast cancer. Its prognostic value has been shown before (Van den Eynden et al. Histopathology 2007). In this study we investigated whether the assessment of the FF adds prognostic information to the relapse score based on gene expression analysis of 76 genes as previously described (Wang et al. Lancet 2005).

Materials and Methods: All patients of 2 previous prognostic breast cancer gene expression studies for whom FFPE slides of the tumor were available (Wang et al. Lancet 2005 and Yu et al. BMC Cancer 2007) were selected, leading to a study population of 176 lymph node negative breast cancer patients. The presence and size (<1/3 or >1/3 of tumor area) of a FF were assessed on standard HE slides. These data were compared to the 76-gene relapse score, to standard clinicopathological variables and to metastasis-free survival.

Results: A small and large FF were found in 31 (17.6%) and 20 (11.4%) of patients, respectively. In 120 (68.2%) patients there was no FF and in 5 patients the presence of a FF could not be assessed due to insufficient FFPE material. 64 (36.4%) and 112 (63.6%) patients had respectively a good and poor prognostic 76-gene relapse score. There was a significant correlation between the presence of a FF and a poor 76-gene relapse score, 18 of 20 patients with a large FF had a poor relapse score (p = 0.03). Patients with a tumor with a FF and especially with a large FF had a significantly reduced metastasis-free survival (Log rank p<0.001). The same was true for patients with a poor 76-gene relapse score (Log rank p<0.001). When only patients with a poor relapse score were taken into account, patients with a tumor with a large FF had a significantly decreased metastasis-free survival compared to patients without a FF or with a small FF (Log rank p<0.005). In patients with a good relapse score, the number of patients with a FF was too small for a separate analysis. In a multivariate Cox regression model for metastasis-free survival including age, ER and PR status, T stage, the FF and the 76-gene relapse score status, the FF (OR 1.5, p=0.02) and the relapse score (OR 2.0, p=0.001) were independent prognostic factors. Comparable results were found if the presence of a FF was dichotomized in large FF versus no or a small FF.

Conclusion: The assessment of the presence and size of a FF adds independent significant prognostic information to the prognostic 76-gene expression signature, especially in selecting a subgroup of patients with a very poor prognosis. Since the assessment of the FF is practical, easy, reproducible and cheap it should be considered to become part of the standard pathological examination of breast cancer resection specimens.
P5-14-15
Prognostic Impact of Chemotherapy-Induced Amenorrhea (CIA) in Premenopausal Breast Cancer: A Meta-Analysis of Published Literatures.
Lu J, Zhou Q, Yin W. Fudan University Shanghai Cancer Center, Shanghai, China

Background: Various studies have reported inconsistent results on the prognostic effect of chemotherapy-induced amenorrhea (CIA) in premenopausal breast cancer. Therefore, we conducted a meta-analysis to assess the effect of CIA on prognosis of premenopausal women with breast cancer.

Methods: The PubMed database was searched for all relevant studies published before March 2011. Relative risks (RRs) were used to estimate the association between CIA on various survival outcomes. Subgroup analyses were also performed by age, nodal status and hormone receptor (HR) status.

Results: With thirteen eligible studies identified, this meta-analysis included 5790 cases and 2159 controls. This meta-analysis demonstrated that CIA was associated with improved DFS (RR=0.39, 95%CI: 0.32-0.47, p<0.001) and OS (RR=0.30, 95%CI: 0.21-0.44, p=0.001). In the subgroup analyses, the effect of CIA on DFS and OS also existed in HR-positive subjects (for OS, RR=0.19, 95%CI: 0.07-0.49, p=0.001; for DFS, RR=0.47, 95%CI: 0.35-0.63, p=0.001) while similar results failed to be observed in HR-negative patients (for OS, RR=0.62, 95%CI: 0.07-5.75, p=0.671; for DFS, RR=1.48, 95%CI: 0.50-4.37, p=0.474). Furthermore, significant difference was achieved between women with and without CIA, irrespective of age and nodal status.

Conclusion: This meta-analysis clarifies that CIA might contribute to the improvement of prognosis in HR-positive premenopausal breast cancer patients, which is at least partially responsible for the benefit of adjuvant chemotherapy in premenopausal women through chemical castration.

Molecular Classification in Primary Breast Cancer and Corresponding Lymph Node Metastasis Show Impaired Prognostic Profile in the Metastatic Node.
Falck A-K, Ferno M, Bendahl P-O, Rydén L. Clinical Sciences, Lund, Sweden

Introduction
The heterogeneity of breast cancer disease has emphasized the need to optimize prediction of outcome by molecular classification of the primary tumor. Clinical management of primary breast cancer is based on biomarkers measured in the primary tumor, whereas biomarker analysis in metastatic lymph nodes is not used for clinical decision making. Recently, microarray-based expression profiling and subsequent immunohistochemical studies have identified biologically distinct subtypes using a combination of biomarkers. The present study aimed to classify primary breast cancer tumors and corresponding lymph node metastases by multiple biomarkers into Luminal A, Luminal B, HER2 type and Triple negative phenotype and compare outcome.

Material and method
The study is based on a cohort of patients where biomarker expression (hormone receptor status (ER, PR), human epidermal growth factor receptor 2 (HER2) and Ki67) in primary breast cancer and ipsilateral lymph node metastasis recently were reexamined and individually related to prognosis. In the present study, 85 patients of the original cohort were possible to classify into the four subtypes: Luminal A (ER+, PR+/- and Ki67 ≤ 20%), Luminal B (ER+, PR+/-, HER2+/- and Ki67 > 20%), HER2- type (ER-, HER2+) and Triple negative (ER-, PR-, HER2-). The classifications of primary tumors and corresponding lymph node metastases were compared using the McNemar-Bowker test of symmetry and the molecular subgroups were related to clinical outcome in terms of 5-years distant disease-free survival (DDFS) by Cox analysis with luminal A as the reference group.

Results
In 7 cases (16%) the biomarker classification was discordant between the primary tumor and the lymph node metastasis. All of the discordant cases shifted to a subtype with a worse prognosis according to the lymph node metastasis (p=0.06, McNemar-Bowker test of symmetry). When comparing Luminal A to non-Luminal A in the primary tumor and the lymph node, the deviation from symmetry was significant, p=0.02. DFS was worse in all subtypes compared to the prognosis for Luminal A using Cox analysis in both primary tumors and lymph node metastasis.

Conclusion
Our data shows discordance in classification according to a multiple molecular phenotype between primary tumors and lymph node metastasis in breast cancer patients. The discordant cases were shifted from Luminal A to a subtype where survival analysis showed an impaired prognosis compared to this subgroup. The finding that the molecular phenotype is shifted from a “good” prognostic signature in the primary tumor to a “bad” prognostic signature in the metastatic node can be of clinical importance for the choice of adjuvant systemic therapy in primary breast cancer with lymph node positive disease.

P5-14-17
Stage IV at Presentation – Are HER2 Positive Tumors Overrepresented?

Background: A minority of patients are diagnosed with Stage IV breast cancer at presentation. Recent studies (Dawood 2010) have suggested a better outcome for de novo vs. recurrent Stage IV but they did not account for the variation of molecular subtype. We questioned whether HER2 overexpressing tumors were over-represented in de novo Stage IV disease, and whether this impacted on survival compared to other subtypes. Further, if different subtypes are more likely to present with metastatic disease, then this factor may need to be considered when developing guidelines for staging. With such considerations in mind, the purpose of this study was to determine the breast cancer subtypes according to stage. The main hypothesis was that HER2 positive tumors would be more prevalent in stage IV presentations.

Methods: Using the Breast Cancer Outcomes Unit database from the BC Cancer Agency (BCCA), patients referred to the BCCA with a new diagnosis of breast cancer between 2005 and 2010 were selected. Patients with a previous or synchronous contralateral breast cancer, male cases, and patients with referrals for reasons other than new disease were excluded. Four subtypes according to available markers were defined: ER+/HER2-, ER+/HER2+, ER-/HER2+, and ER-/HER2-.

Results: Using these criteria, 485 cases of de novo stage IV disease and 10,723 stages I - III cases were extracted. After excluding cases with missing data, our final cohort consisted of 10,186 stage I-III cases and 425 stage IV cases. Distribution by subtype is presented in the Table below.
Assessment of other patient characteristics for the group of Stage IV de novo patients revealed that age (younger for HER+ subgroups), site of metastases (more visceral vs. non-visceral for ER-/HER2+ and ER-/HER2-), and type of systemic therapy (chemotherapy (CT), hormone therapy (HT), trastuzumab (T) and not) were significant. Surgery rates for both mastectomy and breast-conserving surgery were similar for all subtypes. The ER-/HER2- subtype had the worst overall survival ($p < 0.001$).

### Conclusion

Young age and HER2 overexpression is more common in stage IV de novo presentations (26.6% of stage IV tumors were HER2+ vs. only 16% of stage I-III tumors). This data may be important in considering routine staging guidelines at diagnosis to ensure correct diagnosis and treatment recommendations.

## P5-14-18

Madsen EV, Elias SG, Gobardhan PD, van Oort PM, van der Ent FW, Nieweg OE, Valdés Olmos RA, Smidt M, van Dalen T. Diakonessenhuis Utrecht, Utrecht, Netherlands; University Medical Centre Utrecht, Utrecht, Netherlands; The Netherlands Cancer Institute - Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands; Maastricht University Medical Centre, Maastricht, Netherlands; Orbis Medical Centre, Sittard, Netherlands

Background: Her-2-neu receptor (Her2) positive and triple negative breast cancer patients have a poor prognosis. The majority of cancers are characterized as estrogen receptor (ER)+/Her2- and these patients may now have a better prognosis compared to before the introduction of the Her-2-neu receptor.

Material and methods: Since 1997 3424 patients were treated for cT1-2N0 breast cancer in three hospitals. Determination of Her2-neu status was introduced between 1999 and 2004. Trastuzumab treatment has been given routinely since 2005. Survival was evaluated for the different groups: ER+/Her2-, ER+/Her2+, ER+/Her2 unknown (status not determined).

Results: 2284 patients had ER+/Her2- tumors, 259 had ER+/Her2+ tumors and 262 had ER+/Her2 unknown tumors. Systemic treatment was given to 48.4%, 71.0% and 43.9% respectively. Estimated 5- and 10-year overall survival was 92.0% and 82.2% for ER+/Her2-, 91.6% and 70.8% for ER+/Her2+ and 83.4% and 72.2% for ER+/Her2 unknown ($p < 0.001$). The outcome differences between ER+/Her2- and ER+/Her2 unknown tumors remained following adjustment for tumor malignancy grade, nodal status and adjuvant systemic treatment (OR 0.8: CI 0.72 - 0.88; $p<0.001$). For patients with ER+/Her2 tumors 5 year overall survival was comparable with ER+/Her2+ tumors but 10 year overall survival was comparable with ER+/Her2 unknown tumors.

Discussion: Patients with ER+/Her2- tumors have a significantly better outcome than patients who were classified as ER+ before the assessment of Her-2-neu over-expression. Current prognostic models do not take this effect into account.

The branching off of the survival curve for patients with ER+/Her2+ tumors can be explained by the standard use of trastuzumab during the last five years.
and medical decision making, but prior to using whole Korean patients, this model requires validation with multiple Korean sources.

References

P5-14-20

Purpose of the study: In a new database harbouring the patients of several prospective phase II neoadjuvant trials (fec 50-100, net, tncf, taxotere/tncf, taxotere alone), the predictive value of tumour factors (SBR grade, RH, Ki-67 and cycline D1) was studied in 466 women with stage II-III operable breast cancer treated between 1991 and 2006.

Patients and methods: Median age of the patients was 48 years [27-76]. Median diameter of the invasive tumour was 40 mm [10-130]. 382 (82%) patients had a canalar, 57 (12.2%) a lobular, 14 (3%) a mixed or invasive carcinoma, 3 (0.6%) neoplastic cells only and 10 (2.2%) another carcinoma. Before chemotherapy, 33% were grade III SBR. The median number of NCT courses was 6 [1-8] followed by a surgery for 98%, a radiotherapy for 93%, an adjuvant chemotherapy (20%) and/or a hormonotherapy (56%).

Results: Overall response rate was 73% (18% complete). The complete pathological response (pCR) rate was 17.2% according to Chevallier’s classification. On 455 patients operated, 324 (71%) had a conservative surgery. On 390 patients with an axillary dissection, 195 (50%) had involved nodes (median number : 2 [1-20]). After a median follow-up of 135 months, DFS and actuarial survival at 120 months were 61.9% and 73%, respectively.

After chemotherapy, we found a significant variation for SBR grade: there was five fold more patients for whom we observed a down grading of the SBR grade (grade 2/3 to grade 1) than up grading (grade 1 to grade 2/3), p=6.1.10^-6. For patients in objective response, we observed a significant decrease of SBR grade (p=1.7.10^-8).

Moreover, the variation of SBR grade was also prognostic. Indeed, the disease-free survival for patients who presented a SBR down grading after chemotherapy was significantly better (p=0.031) compared to patients for whom SBR grade remained stable or was in up grading. There was a tendency for overall survival (p=0.15).

Conclusion: Down grading of SBR grade appears linked to response and so may constitute a parameter of better prognostic. At the opposite, up grading of SBR grade is an adverse prognostic factor. To conclude, it is interesting to emphasize that SBR grade variations can be assessed when patients are not in pCR, ie plays a complementary role.

P5-14-21

Purpose. Lymph node involvement is the most important prognostic factor in breast cancer. It is a multifactorial event determined by tumour and patient characteristics. Several predictors of axillary lymph node metastasis (ALNM) in breast cancer have been described. The purpose of this study was to determine clinical and pathological factors predictive for ALNM in patients with early breast cancer and to build a model to portend lymph node involvement.

Methods. We evaluated 1300 consecutive patients surgically treated in our institution (2007-2009) for cT1-T2 invasive breast cancer. The patient and tumour characteristics evaluated included: age at diagnosis, number of foci, histologic grade, location, tumour size, histologic subtype, lymphovascular invasion (LVI), estrogen-receptor (ER), progesterone-receptor (PR) and Her2 status. Univariate and multivariate analyses were performed. Factors significantly associated with lymph node metastasis by univariate analysis and histologic subtype were included in the multivariate model. We validated our model with the same 1300 patients on the basis of a multivariable logistic regression model containing the variables, using a correction factor.

Results. By univariate analysis, the incidence of ALNM was significantly higher in patients with a tumour with LVI (P < 0.0001), larger tumours (P < 0.0001), tumours with a higher histologic grade (P < 0.0001), tumours located retroareolar or lateral in the breast (P < 0.0001), tumours with multiple foci (P = 0.0002) and in patients who underwent an axillary lymph node dissection. We found no effect of ER/PR nor HER-2 status.

By multivariate analysis, lymph node involvement was significantly associated with the presence of lymphovascular invasion (P < 0.0001), larger tumour size (P < 0.0001), axillary lymph node dissection (P = 0.0003), retroareolar and lateral tumour location in the breast (P = 0.0019) and the presence of multiple foci (P = 0.0155).
Results: The first 65 patients evaluated are presented. Disease stabilization beyond 3 years. The interim results from the randomized regimen who maintained a partial or complete remission or disease stabilization during at least 3 years. The preliminary findings support that trastuzumab provides a substantial long-term survival benefit with a manageable safety profile in HER2+ MBC patients. This study adds to the evidence that there may be benefit in continuing trastuzumab after achieving remission or disease stabilization. Final results will be presented in the forthcoming congress.

Prospective Observational Study To Describe the Clinicopathological and Biological Characteristics and the Management of Metastatic Breast Cancer Patients Who Experienced Complete or Partial Remission or Disease Stabilization during at Least 3 Years.

Zamora P, Pérez-Carrión R, Manso I, Crespo C, Mendiola C, Álvarez-López I, Margeli M, Bayo-Calero JL, González-Farre X, Santaballana A, Ciruelos EM, Afonso R, Lao J, Catalán G, Álvarez-Gallego JV, Miramón-López J, Salvador-Boffil FJ, Ruiz-Borrego M, Hospital La Paz, Madrid, Spain; Hospital Quiron, Madrid, Spain; Hospital 12 de Octubre, Madrid, Spain; Hospital Ramón y Cajal, Madrid, Spain; Hospital Donostia, San Sebastián, Spain; Hospital Germans Trias i Pujol, Badalona, Spain; Hospital Juan Ramón Jiménez, Huelva, Spain; Hospital Clinic de Barcelona, Barcelona, Spain; Hospital La Fe, Valencia, Spain; Hospital Nuestra Señora de la Candelaria, Santa Cruz de Tenerife, Spain; Hospital Miguel Servet, Zaragoza, Spain; Hospital Son Llàtzer, Mallorca, Spain; Complejo Hospitalario de Zamora, Zamora, Spain; Hospital Serranía de Ronda, Ronda, Spain; Hospital Virgen de Valme, Sevilla, Spain; Hospital Virgen del Rocio, Sevilla, Spain

Background: Trastuzumab has shown an improvement in survival outcomes among patients with HER2+ metastatic breast cancer (MBC). Identification of pathological, clinical factors and tumor genetic profile that may predict long-term remission has become a key-issue. We aimed to describe the clinicopathological and biological characteristics of MBC patients who experienced complete response (CR), partial response (PR), or stable disease (SD) during at least 3 years and their management in routine clinical practice.

Methods: Multicenter, observational, cross-sectional study. Data were collected from women with HER2+ MBC treated with a trastuzumab-based regimen who maintained a partial or complete remission or disease stabilization beyond 3 years. The interim results from the first 65 patients evaluated are presented.

Results: Median age: 59 (52-70) years. Metastatic disease was diagnosed after a median of 23.5 (1.6-48.8) months since primary tumor diagnosis. The predominant tumor type was ductal carcinoma (89.2%) and 47% showed histological grade III. Mean tumor size: 3.6±2.2cm (anatomical pathology), 5.1±2.8cm (imaging studies). Hormonal status: Progesterone receptor positive 46% and estrogen receptor positive 43%. Most common metastatic sites: lung (23%), liver (17%) and bone (14%). Overexpression of HER2 was assessed by IHC in 97% of patients, of whom 94% were HER2+ (3+) and 17% had FISH+HER2 status. Tumor was positive for p53 and Ki67 in 23% and 41.5%, respectively. Surgery was performed on 83% of patients, of which 73% underwent radical mastectomy; 96% had their axillary nodes removed. Surgery of metastases was performed on 7.8%. First line chemotherapy was received by 91% with the most frequent schemes being paclitaxel (24%), vinorelbine (15%) and paclitaxel/carboplatine (14%). First line hormonal therapy and radiotherapy was used in 45% and 12%, respectively. All patients received first line trastuzumab, administered on a weekly schedule in 51%. Trastuzumab was used in combination in most of patients (89.2%) with a median number of cycles of 18 (7.0-41.5) and during a median of 53.3±25 months. 66% of patients achieved a CR, 21% PR and 13% had SD. Median time since trastuzumab was initiated to CR, PR or SD was 5 (4-7) months. Median duration of CR, PR or SD was 36 (44.5-78.0) months. Trastuzumab was maintained beyond CR, PR or SD in 99% during a median of 46.5 (35-67) months. 75% of patients continue on treatment with trastuzumab. Only 2 patients discontinued trastuzumab due to toxicity. At the time of the analysis, 19% had progressed, 57% were alive and free of disease and among patients on treatment (93%), 54% were on trastuzumab. Cardiac toxicity was the most common toxicity (36%) among those suffering at least one (22%).

Conclusions: The preliminary findings support that trastuzumab provides a substantial long-term survival benefit with a manageable safety profile in HER2+ MBC patients. This study adds to the evidence that there may be benefit in continuing trastuzumab after achieving remission or disease stabilization. Final results will be presented in the forthcoming congress.

P5-14-23
Clinical Outcomes of Different Subtypes Detected by Immunohistochemistry of Early Invasive Breast Cancers in a Monoinstitutional Series.

Ferro A, Ecccher C, Caulara A, Triolo R, Barbareschi M, Cuervo LV, Aldovini D, Dipasquale M, Galligioni E. S Chiara Hospital, Trento; FBK, Trento; S. Chiara Hospital, Trento

Background: Early invasive breast cancer (EIBC) is an heterogeneous disease. Immunohistochemical (IHC) markers can be used to classify tumors in different biological subtypes with different clinical behavior.

Purpose: The aim of our study was to evaluate survival outcomes for patients (pts) with different subtypes of EIBC as classified using four ICH markers (ER, PR, HER2 and Ki67).

Methods: We evaluated data from 3403 consecutive cases of EIBC treated from 1995 to 2008 and classified as: luminal A (positive ER and PR, negative HER2 and Ki67<14%), luminal B (positive ER and/or PR, negative HER2 and Ki67<14%), Luminal B (positive ER and/or PR, positive HER2, any Ki67), HER2+ (negative ER and PR, positive HER2, any ki67), triple negative (negative ER and PR, negative HER2, any ki67). Log-rank test and Kaplan-Meyer estimator were performed to evaluate the impact of ICH subtypes on overall survival (OS), Event Free Survival (EFS) and their correlation with other known prognostic factors such as N, G, Size, Age.

Results: We identified 917 luminal A (26.9%) , 1731 luminal B (50.9%), 279 (8.2%) luminal C, 183 HER2 + (5.4%) and 293 triple negative (8.6%). Median age was 61 years. Luminal A was more frequently (p<0.001) associated with older age, smaller size, negative axilla involvement, low grading. Observed events (relapses, contralateral and second tumors) were: 54 in luminal A (6%), 215 in luminal B (16%) , 40 in luminal C (14%), 42 in HER2+ (23%) and 59 in triple negative (20%). Disease free interval (DFI) was shorter in luminal C, HER2 and TN (median DFI: 30, 26 and 19 months) than in Luminal A and B (median DFI: 51 and 41 month). Luminal A and B presented more bony and less visceral recurrences than luminal C,
HER2 and triple negative tumors. At median follow up of 51 months EFS was 94.1% in luminal A, 87.5% in luminal B, 85.5% in luminal C, 76.8% in HER2+ and 79.7% in triple negative. Corresponding OS was 95.3% in luminal A, 89% in luminal B, 89.2% in luminal C, 80.9% in HER2+, 81.9% in triple negative. Different subtypes EFS according to nodal status, grading, tumor size and age, was reported in table 1.

In multivariate Cox-regression analysis correcting for tumor size, differentiation grade, lymph node status, hormone receptor status, tumor stage and treatment modalities (surgical procedure, chemotherapy, radiotherapy and antimetabolite therapy), the CK19 bone marrow status still was a significant predictor of IDFS. (p-value = 0.042)

Differences in BCSS (78% of CK19+ patients and 84% of CK19- patients) and OS (75% in CK 19+ patients and 74% in CK 19- patients) were not statistically significant. (log rank p-values 0.087 and 0.883, respectively).

**Conclusion:** This study demonstrates the long term (>ten years) prognostic effect of CK19 mRNA detection with RT-PCR in the bone marrow of operable breast cancer patients.

### P5-14-25

#### Disease Presentation, Treatment, and Outcome in Young and Elderly Women with Breast Cancer.

Yu E, Yu D, Godette K, Mister D, Torres M. Emory University, Atlanta, GA

**Aim:** To determine the influence of age on disease presentation, treatment, and outcome in breast cancer patients who are not routinely screened by mammography, women younger than 40 and women older than 69 years.

**Methods:** The records of 272 breast cancer patients who presented to the Emory University Department of Radiation Oncology between 1997 and 2010 were reviewed. We excluded women with inflammatory or Stage IV breast cancer and those diagnosed between the ages of 40 and 69. We compared presentation, staging, treatment, and outcomes in women younger than 40 with those older than 69.

**Results:** The median age of the young and older patient groups were 31 (range 16-40) and 76 years (range 70-91), respectively. Young women more often presented with a symptomatic breast mass than older women whose cancers were more frequently detected on screening mammography (p<.001). Young women were less likely than older women to present with significant co-morbidities including hypertension, diabetes, or cardiac disease (2% vs 76%, p<.001). A higher proportion of young women had high grade (50% vs 25%), T2/ T3 tumors (69% vs 26%), and node positive disease (50% vs 23%) (p<.001 for all comparisons) than older women. Also, more young women had triple negative (25% vs 12.5%, p<.048) or HER2 positive breast cancers (34.4% vs 18.3%, p=.02). Regarding treatment, older patients were less likely to undergo surgical axillary nodal staging (72% vs 88%, p<.04) or chemotherapy (23% vs 84%, p<.001). Among women treated with chemotherapy, older women more often received a non-anthracycline based regimen (82% vs 7% of young patients, p<.001). Following neoadjuvant chemotherapy, significantly more young women had a complete pathological response (23% vs 13% in older women, p<.03). Fifty-two percent of young women received mastectomy versus 14% of older women (p<.001). In part due to their low rates of breast conserving surgery, younger women trended toward less radiation treatment (81% vs 90% in older women, p=.12). Among estrogen receptor positive patients, more young women received adjuvant endocrine therapy than older women (91.4% vs 72%, p=.05). The median follow-up period for the entire group was 38 months (range 1-160). At 3 years, young women were more likely to recur locoregionally (10% vs 2%, p=.06) and distantly (16% vs 5%, p=.04) than older women, though both groups had comparable breast cancer-specific (96% vs 96%, p=0.2) and overall survival (96% vs 93%, p=.3). On multivariate analysis, old age was

Considering only Luminal subtypes, Luminal B and C were significantly associated with poor EFS vs Luminal A EIBCs in both N0 (p=0.046) and N+ pts (p=0.001), in T1 (p=0.013) and T2 (p=0.03) pts, in pts older than 40 years (p=0.002).

**Conclusions:** Luminal A showed better prognosis in term of EFS and OS than other subtypes regardless other prognostic factors as clinical features (age) and tumor extent (T and N).
Conclusion: The results of our study suggest that Oncotype DX is applicable and feasible to perform in UK patients with a reduction in the use of adjuvant chemotherapy consistent with findings of reported studies. RS added prognostic information beyond information provided by Adjuvant!

**P5-14-26**

Results from a Prospective Clinical Study on the Impact of Oncotype DX on Adjuvant Treatment Decision Making in a Cohort of 142 UK Patients.

Holt S, Bertelli G, Brinkworth E, Durrani S, Jones S, Khawaja S, Laggner U, Moe M, Pudney D, Pitcher S, Rolles M, Sharaia Y, Whelan S, Prince Philip Hospital, Llanelli, Carmarthenshire, United Kingdom; Singleton Hospital, Swansea, West Glamorgan, United Kingdom; Bronglais Hospital, Aberystwyth, Ceredigion, United Kingdom

Objectives: International guidelines support the use of the Oncotype DX derived Recurrence Score (RS) to provide additional prognostic and predictive information in early breast cancer but experience in the UK is limited. In our prospective study we evaluate this test for the NHS and its impact on costs (subject of a separate abstract) and treatment recommendations by UK oncologists.

Methods: 150 tests were made available to consecutive patients with ER+, pN0, pN1ic or pN1mic early breast cancer who had no contraindication to adjuvant chemotherapy (CT) and who would accept CT + hormone therapy (HT) if recommended. CT recommendations of oncologists based on Adjuvant! Online figures were recorded at an initial consultation. Eligible patients were consented to Oncotype DX testing and review arranged once the result was available. After a second consultation a final decision on adjuvant therapy was recorded.

Results: Analysis is based on 142 patients. (150 tests performed, 3 failed to give a result, 3 repeated tests giving a result on the second block, one bilateral and one test stopped because the patient withdrew from the study). Initial treatment recommendations changed in 13 (26.8%) cases. Of the patients initially recommended CT + HT (total 57 patients), 26 (45.6%) patients were spared chemotherapy after review with the RS. Of the 85 patients initially recommended HT only 12 (14.1%) were changed to HT + CT.

Further analysis shows that Grade, estrogen receptor status by immunohistochemistry (ER by IHC) and progesterone receptor by immunohistochemistry (PR by IHC) are correlated to RS but in our cohort age, size and node status were not. (Spearman rank correlation for grade is 0.05, 95%, CI 0.36 to 0.61; for ER by IHC is -0.36, CI -0.49 to -0.20; and for PR by IHC is -0.49, 95%, CI -0.60 to -0.35). Apart from HER2 positive patients who are already recognized to return a high RS, further analysis of our series shows no clear combination of currently available prognostic factors that would predict RS and therefore reliably avoid testing of any subset of patients.

**P5-14-27**

Prognostic Factors of Node-Negative, High Risk and 1-3 Positive Lymph Nodes Breast Cancer by Intrinsic Subtype in Patients with Adjuvant Chemotherapy.

Kojima Y, Hashimoto K, Harano K, Shimizu C, Yunokawa M, Yonenori K, Tamura K, Katsumata N, Ando M, Kinoshita T, Fujiiwara Y. National Cancer Center Hospital, Tokyo, 5-1-1 Tsukiji, Chuo-Ku, Japan

Purpose: St. Gallen 2007 categorized high risk, node-negative breast cancer (HNBC) and 1-3 lymph nodes positive BC (LNBC) without HER2 overexpression as intermediate risk. We hypothesized that triple negative BC (TNBC) and hormone-receptor positive without HER2 overexpression (H-BC) in intermediate risk have different prognostic factor in patients with adjuvant chemotherapy (AdC).

Methods: We examined disease-free survival (DFS) and overall survival (OS) of TNBC and H-BC with regard to potential prognostic factors. All the patients included in this study were categorized intermediate risk by St.Gallen 2007 and received AdC.

Results: A total of 470 patients were identified; H-BC (n=360) and TNBC (n=110). Age (<35) was significantly associated with DFS in TNBC while it was not in H-BC (p=0.0.1 and p=0.63, respectively). Tumor size (>2cm) and tumor grade related to DFS in H-BC but not in TNBC. Tumor grade was not associated with DFS in both H-BC and TNBC (p=0.64 and p=0.91, respectively). Lymph node metastasis was a significant factor of DFS only for H-BC (p=0.009 and p=0.19). Conclusions: In TNBC, age was only a significant factor associated with DFS while in H-BC, lymph node status and tumor size rather age related to DFS.

**P5-15-01**

Words Matter: Influence of DCIS Diagnosis Terminology on Patient Treatment Decisions.

Omer Z, Hwang ES, Esserman LJ, Ozanne EM. University of California, San Francisco; Massachusetts General Hospital

Background: Treatment of ductal carcinoma in-situ (DCIS) poses significant challenges. Although retrospective studies suggest that most cases of low grade DCIS will never progress to invasive disease, it remains difficult to accurately identify those patients at greatest risk. In this situation where many diagnosed tumors could follow an indolent course for the patient’s lifetime, both systemic therapy and watchful waiting could be reasonable options, similar to those currently offered to patients with early prostate cancer. One strategy that has been suggested to reduce overtreatment is to use terms other than “ductal carcinoma in situ” when explaining a diagnosis of DCIS to a patient. In the current study, we have investigated the effect of terminology on women’s stated treatment preference for DCIS.

Methods: Women 40-65 years of age were recruited from a database of volunteers at an academic hospital. Subjects with a personal history of breast cancer were excluded. Endpoints were gathered from a web-based survey. Each subject was presented with three different scenarios, each of which used a different terminology for DCIS: non-invasive breast cancer, breast lesion, and abnormal cells. The scenarios included a detailed explanation of the risks and benefits of three treatment options: surgery, systemic treatment only and active surveillance. After reading each scenario, the subject was asked to...
choose among the treatment options and to explain her choice. Results: 187 subjects completed the survey. More women chose active surveillance when DCIS was described using the terms “abnormal cells” or “breast lesion” than using the term “non-invasive cancer” (Table 1). The majority of women (97/187, 52%) changed their treatment preference when a different term was used to describe DCIS. Of the 97 women who changed their treatment preference, 47 (48%) chose surgery when the term “non-invasive cancer” was used to describe DCIS, but chose a less invasive treatment when “cancer” was not used in the diagnosis. Of 90 people who did not change their treatment preference, 39 (43%) chose active surveillance.

Among the three treatments, the percent of women who chose surgery was the highest (84/187; 46%) when the term “non-invasive cancer” was used. 47/84 (56%) of the women who chose surgery when using the term “non-invasive breast cancer” changed their treatment preference when a different term was used. 36/84 (43%) switched to active surveillance while 11/84 (13%) switched to medication.

Conclusion: These results support that the specific terminology used to explain a diagnosis of DCIS influences patients' treatment preference. Moreover, we found that women may entertain treatment preferences other than surgery for DCIS when the tradeoffs of each choice are clearly explained. Avoiding the word “cancer” in the diagnosis may offer a strategy that reduces fear-based treatment decisions and may reduce the burden of overtreatment for DCIS.

P5-15-02

Patients’ Views about How Oncologists Should Explain Prognosis in Advanced Cancer.

Kiely BE, McCaughan G, Christodoulou S, Tattersall MH, Beale P, Grimison P, Stockler MR. University of Sydney, Sydney, NSW, Australia; Royal Prince Alfred and Concord Hospitals, Sydney, NSW, Australia

Background: Many women with advanced breast cancer want information about their life expectancy. Understanding the type of information patients want will help oncologists improve their discussions about prognosis. We sought the attitudes of women previously diagnosed with breast cancer to using three scenarios for survival (best case, worst case and most likely) to explain prognosis to people with advanced cancer.

Methods: Members of the Breast Cancer Network Australia (BCNA) review and survey group and oncology clinic attendees with a previous breast cancer diagnosis were invited to complete a questionnaire describing two options for explaining prognosis to a hypothetical patient with incurable cancer who wanted prognostic information: providing either 3 scenarios for survival or just the median survival time. Associations between respondent attitudes and their demographic and tumour characteristics were explored.

Results: Characteristics of the 254 BCNA respondents and the 68 outpatient respondents respectively were: median age 56 years and 54 years; median years since breast cancer diagnosis 6 and 3; college/university educated 70% and 34%; self-report of cancer spread beyond the lymph nodes 10% and 26%. Significantly more respondents agreed that explaining 3 scenarios (vs just the median survival time) would: be easy to understand (92% v 71%), be helpful (94% v 63%), convey hope (68% v 36%), reassure (56% v 30%) and help family members (92% v 65%), with all p-values <0.001.

The proportions of respondents agreeing that each of the 3 scenarios should be presented were: best case 92%, worst case 84% and most likely 93%. Although 53% agreed the worst case scenario on its own was likely to upset people, only 31% agreed that explaining all 3 scenarios together was likely to upset people. When asked how they would prefer information about their own prognosis, 92% wanted all 3 scenarios, either with (49%) or without (43%) the estimated median survival. Most respondents (88%) agreed it would be helpful to receive a printed summary of the scenarios for survival. No differences were seen between the BCNA respondents and breast cancer outpatients for attitudes to presenting all 3 scenarios; however, BCNA respondents were significantly less likely than breast cancer outpatients to agree that the median survival was helpful, reassuring or easy to understand. Women with more education were more likely to agree that presenting all 3 scenarios would be helpful (95% v 87%, p = 0.04). Age, year of diagnosis, relationship status and extent of disease were not significantly associated with particular attitudes.

Conclusion: Most respondents judged presentation of best case, worst case and most likely scenarios preferable, more helpful and more reassuring than presentation of just the median survival time when oncologists explain prognosis to people with advanced cancer.

P5-15-03

Development of a Patient Decision Aid for Women 70 Years Old and Older with Stage I, Hormonally Sensitive, Breast Cancer Considering Adjuvant Treatment Post-Lumpectomy.

Szumacher E, Wong J, D’Alimont E, Angus J, Passat L, Metcalfe K, Thelan T, Llewellyn-Thomas H. Odette Cancer Centre, Sunnybrook Health Sciences Centre, Toronto, ON, Canada; University of Toronto, Toronto, ON, Canada; Education Independent Consultant, Toronto, ON, Canada; Juravinski Cancer Centre, Hamilton, ON, Canada; Women’s College Research Institute, Toronto, ON, Canada; Dartmouth Medical School, Lebanon, NH

Background: Decision Aids (DA) are developed with the intent to support people in making specific and deliberate choices by improving information transfer about different outcomes. Previous research has shown that DAs can increase patient knowledge regarding treatment options, reduce decisional conflict, and increase patient satisfaction with the decision-making process. However, no DAs have been developed to help older breast cancer patients decide whether or not to undergo adjuvant RT. We developed and tested a DA for older women with stage I, ER/PR positive breast cancer considering adjuvant treatment post-lumpectomy and we examined its impact on treatment decision-making process.

Methods and Materials: A DA was developed and evaluated in three steps following the Ottawa Decision Aid Framework: 1) Needs assessment (N=16); 2) Pilot I, to examine the DA’s acceptability (N=12); and 3) Pilot II, a pre-test post-test (N=38) with older women with ER/PR responsive breast cancer post-lumpectomy who were receiving adjuvant RT. Measures included questionnaires to assess patient’s satisfaction with the DA, patients’ self-reported decisional conflict (DC), level of distress, treatment-related knowledge, and choice predisposition.

Results: The DA is a booklet that details each adjuvant treatment option’s benefits, risks and side-effects tailored to their clinical profile; includes a value clarification exercise; and steps to guide them towards their own treatment decision. All women felt the DA was helpful and informative. Compared with baseline scores, patients had a statistically significant (p < .05) reduction in DC (adjusted mean difference [AMD], -7.18; 95% confidence interval [CI], -13.50 to 12.59); increased clarity of the treatment benefits and risks.
Discussion: This study provides evidence that this DA may be a helpful educational tool for this group of women. The quality of care for older breast cancer patients may be enhanced by using a tailored DA to help the patient be informed of their treatment options and to prepare for decision-making.

P5-15-05

Boughey JC, Hoskin TL, Williams CI, Hartmann LC, Allers TM, Degnim AC, Frost M. Mayo Clinic, Rochester, MN

Background: Women with hereditary breast cancer risk, who develop breast cancer, face complex surgical decisions related to their breast cancer and risk to their contralateral breast. The aim of this study was to prospectively evaluate the factors influencing decision making in these women and degree of decision conflict before and after consultation with breast specialized physicians (BSP).

Methods: Women with hereditary breast cancer risk and recently diagnosed with unilateral breast cancer were enrolled in a prospective decision making questionnaire study. Questionnaires were completed prior to their initial breast clinic visit and after consultation with a breast clinic physician, nurse educator and a breast surgeon.

Results: 68 women completed both questionnaires. Mean age was 52 (range 27-84). Prior to meeting with BSP, 10 (15%) women reported having made a decision for the cancer side and 18 (26%) reported being close to deciding. Of the 20 who expressed a surgical preference prior to consultation, 5 (25%) changed their decision after meeting with the BSP [1 to mastectomy (MTX), 4 to breast conservation (BC)]. After consultation with BSP, 65 (96%) reported having made a decision (BC in 29 (45%), MTX in 35 (54%), unspecified in one).

The most commonly cited reasons influencing surgical choice were doctor’s advice (79%), family history of breast cancer (74%) and worrisome findings on biopsy (50%).

Prior to meeting with BSP, 9 (13%) women reported having made a decision regarding screening and/or risk-reducing options for the contralateral breast and another 11 (16%) reported being close to a decision. The choices in these 20 women were screening only in 10 (50%), contralateral prophylactic MTX (CPM) in 3 (15%), CPM and oophorectomy in 2 (10%), other combinations of options in 4, and unspecified in 1. After meeting with the BSP, 49 (72%) reported having made a decision regarding the contralateral breast; this decision was for screening only in 21 (43%), CPM only in 9 (18%), screening plus tamoxifen in 7 (14%), CPM and oophorectomy in 2 (4%), other combinations of options in 8, and unspecified in 2.

The most commonly cited reasons for choices on the contralateral side were: family history (81%), doctor’s advice (78%), and worrisome findings on biopsy (43%); only 25% cited psychological or emotional reasons.

For both the cancer and contralateral sides, decisional conflict was significantly lower after meeting with BSP than prior to meeting with BSP.

<table>
<thead>
<tr>
<th>Decision-conflict scale total scores (possible range 0-100; higher scores indicate more decisional conflict) summarized for each side and compared between timepoints</th>

Conclusion: The BSP consult and family history have the greatest influence on decision making among women with hereditary risk diagnosed with breast cancer. After consultation most women felt they had made decisions for both the cancer and contralateral sides and reported significantly lower decision conflict compared to prior to the consultation.

P5-16-01
Are We Going To Be Able To Train Future Surgeons How To Perform Axillary Lymph Node Dissection?

Betambeau N, Chan C. Cheltenham General Hospital, Cheltenham, Gloucestershire, United Kingdom

Background: Axillary lymph node dissection (ALND) has been performed regularly by surgeons for several decades. The sentinel lymph node era has led to a reduction in ALND procedures as node negative women are now spared further surgery and morbidity. Following the publication of the ACOSOG Z0011 trial, it is conceivable that completion ALND (cALND) may be rendered unnecessary for many women who have breast conserving surgery and have 1 to 2 positive sentinel lymph node disease. If there is a substantial drop in ALND procedures, this may impact on our ability to train surgeons in the future.

Material and Methods: We retrospectively reviewed the breast cancer practice for 2 consultant surgeons in a busy UK centre. In this centre all patients with a positive diagnosis of invasive breast cancer had pre-operative axillary ultrasound scanning (USS) and needle biopsy (fine needle aspiration or core biopsy) if enlarged or suspicious axillary lymph nodes were seen. Hence sentinel lymph node biopsy (SLNB) was only performed on patients with both clinically and radiologically negative axillary lymph nodes.

Results: In 2009 and 2010 the 2 consultants treated a total of 255 patients with invasive breast cancer. Thirty one patients (12.2%) had positive axillary lymph disease identified by USS and axillary needle biopsy; these women were treated with ALND. The remaining 224 patients had clinically and radiologically negative axillary lymph nodes and proceeded to SLNB. Of these, 58 patients had at least one positive sentinel lymph node (25.9%) and proceeded to cALND; 39 women had breast conserving surgery and 19 women had mastectomy. If our centre were to adopt a policy of observation only in those women having breast conserving surgery and whom had no more than 2 positive sentinel lymph nodes (as per ACOSOG Z0011 trial), then 33 fewer ALND would have been performed. This would leave a new total of 56 ALND procedures being performed over a 2 year period in women with pre-operatively identified positive axillary lymph nodes, those undergoing mastectomy and those women with 3 or greater positive sentinel lymph nodes on SLNB. On our service we have 2 residents which would result in a maximum number of 14 ALND procedures per year that each resident may be trained to perform. It is likely that the actual number will be less due to commitments away from the elective operating room, such as emergency duties and annual leave etc. Is this an adequate number of ALND procedures for a resident to gain competence in the technique?

Discussion: The training of surgical residents is competence based and if our centre is representative of most centres treating breast cancers in the UK, will the teaching of ALND procedures be limited to specialist, ultra-high volume centres if the ACOSOG Z0011 trial findings are to be adopted?
P5-16-02
The Impact of Educational Materials on Compliance and Persistence with Adjuvant Aromatase Inhibitors: 2 Year Follow-Up and Final Results from the CARIATIDE Study.

Neven P, Markopoulos C, Tanner MME, Marty ME, Kreienberg R, Atkins L, Franquet AA, Serin D, Culcelik MA, Deschamp V. University Hospitals Leuven, Leuven, Belgium; Medical School University of Athens, Athens, Greece; Tampere University Hospital, Tampere, Finland; Saint Louis University Hospital, Paris, France; University of Ulm, Ulm, Bade-Wurttemberg, Germany; University College London, London, United Kingdom; IDDI (International Drug Development Institute), Louvain-la-Neuve (Ottignies), Belgium; Institut St. Catherine, Avignon, France; Ankara Oncology Hospital, Ankara, Turkey; AstraZeneca, Brussels, Belgium

Rationale
Understanding and effectively addressing the factors that affect patient compliance with adjuvant aromatase inhibitors (AI) is required in order for patients to obtain maximum benefit from treatment. The CARIATIDE study sought to determine whether the provision of educational materials (EM) could improve compliance and persistence with adjuvant AI. At 1-y follow-up (FU), there was no improvement in overall compliance with AI therapy, compliance with initial AI or persistence rates when EM were provided. Final results from the 2-y FU are presented here.

Methods
This 2-y, global observational study (NCT00681122) randomized 2758 patients, across 18 countries, to Group A: Standard Therapy or Group B: Standard Therapy + EM. The EM were developed in collaboration with patient advocates, and consisted of a range of information on breast cancer-related topics. Compliance rate with adjuvant AI medication was the primary endpoint. Secondary endpoints included persistence rate after 1 and 2y, and reasons for, and time to, discontinuation of AI therapy. Compliance rate was defined as the proportion of patients being ‘compliant’ with the adjuvant AI medication; switching from AI therapy to tamoxifen would result in a non-compliance score at time of switching. For compliance with initial adjuvant AI medication, switching to another AI or hormone therapy would result in a non-compliance score. A patient was considered a ‘persistent’ user if they did not switch AI medication, AI medication was uninterrupted and there was no discontinuation of the AI medication during the second year. Patients’ compliance and behavior were evaluated using compliance questionnaires, EM feedback and validated questionnaires (EORTC IN-PATSAT32, GHQ-12, FACT-ES).

Results
Of the 2758 patients randomized at study initiation, 2242 were available for analysis at 2-y FU. The results confirmed those obtained at 1-y FU. No statistically significant difference in compliance with AI therapy was observed between Group A and Group B (82% and 82%, respectively, p=0.9926). Compliance with initial AI was 81% in Group A and 80% in Group B (p=0.5541), with persistence rates of 90% and 88%, respectively (p=0.2425). Of the proportion of patients who had compliance data for both years (Group A n=1118; Group B n=1111) 72% were compliant for the whole 2-y FU period. Across the full 2-y FU, AI treatment discontinuation rates of 8% and 9% were observed in Group A and B, respectively, with discontinuation most frequently attributed to AI-related side effects. Analysis showed that no specific baseline demographic characteristics were associated with compliance behavior. Compliance rates differed widely between countries.

Conclusions
At 2-y FU, EM were not found to improve overall patient compliance, compliance with initial AI, or persistence with therapy. In total, 72% of patients were compliant across the full 2-y FU. AI-related side effects remained the most frequent cause of AI treatment discontinuation across the full FU period. The 2-y CARIATIDE data confirm the 1-y findings.

P5-16-03
The Breast Cancer Novela, Se Valiente...Son Tus Senos, an Innovative Tool To Educate Latina Women about Breast Cancer. Fehus-Sampayo I, Mota R, Yaker A. SHARE: Self-Help for Women with Breast or Ovarian Cancer, New York, NY

Background:
The Hispanic population is the fastest growing population and largest minority group in the United States. Breast cancer remains the leading cause of cancer death among latina women in part because they are more frequently diagnosed at a later stage than non-Hispanic whites. Critical information about early detection, diagnosis and treatment options is often inaccessible due to cultural and language barriers. There is a need to reach the Hispanic community in new and compelling ways. The purpose of this initiative was to reach diverse Spanish speaking communities, particularly in New York City, with information about breast health and breast cancer that was culturally-sensitive, language appropriate, scientifically and medically accurate and, most importantly, relevant to the lives of the people in the community.

Methods:
The Hispanic population is the fastest growing population and largest minority group in the United States. Breast cancer remains the leading cause of cancer death among latina women in part because they are more frequently diagnosed at a later stage than non-Hispanic whites. Critical information about early detection, diagnosis and treatment options is often inaccessible due to cultural and language barriers. There is a need to reach the Hispanic community in new and compelling ways. The purpose of this initiative was to reach diverse Spanish speaking communities, particularly in New York City, with information about breast health and breast cancer that was culturally-sensitive, language appropriate, scientifically and medically accurate and, most importantly, relevant to the lives of the people in the community.

Methods:
Latina breast cancer survivors and non-survivors from diverse Hispanic communities were identified and three 8 person focus groups, two for non-survivors and one for survivors, were organized to explore breast cancer-related issues relevant to these communities. The women’s personal stories and common issues and experiences as well as medical information reviewed by a medical advisory group, formed the basis for the development of a breast cancer novela. The novela is a popular Spanish-language comic book style publication widely distributed in the Hispanic communities. The breast cancer novela used the real life stories of the women to address barriers to accessing health care and empower women in Hispanic communities. A distribution plan was developed and a curriculum created for in-person educational seminars at community organizations. Surveys prior to and following the educational intervention were conducted.

Results:
We distributed over 25,000 novelas in Spanish to 478 sites within New York City and to 89 other sites throughout the U.S. We printed and distributed 2500 copies of an English version of the novela at the request of health providers. Attendees at a launch event helped identify distribution sites and educational seminar venues. Peer facilitators conducted these seminars, with the novela as the primary communication tool. The content of the workshops included information about breast health, risk, early detection, myths and realities about a diagnosis, managing relationships, survivorship and resources. To date, 17 seminars have been conducted and attended by more than 330 attendees. Results of the surveys as well as detailed information describing the distribution sites of the novela and feedback we received about its impact, will be presented at SABCS

Discussion:
Se Valiente...Son Tus Senos, is an innovative educational tool that conveys information about breast health, breast cancer detection, diagnosis, treatment and survivorship that is personal, relevant, compelling and accessible. The breast cancer novela serves as a vehicle to change information levels and increase women’s knowledge and to provide health providers with insights that enable them to treat members of Spanish-speaking communities in a culturally competent manner.

Evaluation of Psychosocial Distress in Main Care-Givers of Patients with Metastatic Breast Cancer Who Receive Treatment in a Community Based Oncology Group Practice.
Weide R, Feiten S, Friesenhahn V, Heymanns J, Kleboth K, Mergenthaler U, Thomalla J, van Roye C, Köppler H. Hematology/Oncology Group Practice, Koblenz, Germany; Institute for Health Care Research in Oncology, Koblenz, Germany

Introduction: It is well-known that people who care for patients with a metastatic carcinoma are exposed to an above-average level of psychosocial distress. No data are available concerning the distress of main care-givers of female patients with metastatic breast cancer, who are treated in a community based oncology group practice.

Methods: Standardized cross-sectional survey of main care-givers and patients with metastatic breast cancer who were treated in a community based oncology group practice in Germany between 04/2010-03/2011. Psychosocial distress of the patients and their main care-givers were evaluated using the German versions of the Distress Thermometer (DT) and the Problem List (PL). In addition anxiety and depression of the main care-givers were assessed using the Hospital Anxiety and Depression Scale (HADS-D).

Results: 83 female patients with a median age of 65 (41-93) were interviewed. 6% did not have a main care-giver, 7% indicated that they needed no support, 48% reported one main care-giver and 39% several. Partners (60%), children (47%), siblings (11%) and friends (10%) were the most important care-givers. 47% of patients preferred visiting the practice in companion with their care-givers. The patients' median score on the DT was 5 (0-10), with 34% scoring above cut-off (>5) for psychosocial distress.

52 main care-givers (61% male, 39% female) with a median age of 57.5 (41-86) were interviewed. The relationships to the patients were as follows: partners 62%, children 27%, mothers, siblings and friends each with 4%. The main care-givers themselves were supported by partners (54%), children (21%) friends (17%) and siblings (8%), 23% did not receive any support. The median score on the DT was 5 (0-10), with 44% scoring above cut-off (>5) for psychosocial distress. According to the HADS-D 37% (cut-off ≥8) of the care-givers reported anxiety, with a mean score of 6.6 (0-14). 15% could be regarded as depressed (cut-off ≥8), with a mean score of 4.1 (0-15).

Conclusions: The main care-givers are distressed even more than the patients themselves. 37% of care-givers reported anxiety; depression can be observed too, but less frequently in 15%. Both issues should be addressed by healthcare professionals.

P5-17-02
Associations between Breast Cancer Patients’ Satisfaction with Nursing Staff and Hospital Characteristics, Results of a German Multicenter Study.
Wuerstlein R, Kowalski C, Diener S, Krebs S, Pfaff H, Harbeck N. University Hospital Cologne, CIO, Köln, Germany

Background: Only few studies have investigated the association between breast center characteristics such as teaching status, number of patients, whether clinical trials are conducted, or whether breast care nurses are employed and patients’ perceptions of care.

Objective: The aim of the study was to determine whether or not the satisfaction of newly-diagnosed breast cancer patients with nursing staff correlates with hospital characteristics after adjusting for relevant patient characteristics. The study is part of a national process-identifying project focusing on breast cancer of the MAGS NRW (Ministry of work, health and social affairs, North Rhine Westfalia, Germany).

Methods: Multilevel regression analysis was applied combining data from newly-diagnosed breast cancer patients (n= 3733) on patient characteristics and satisfaction with nursing staff and data on characteristics of the hospitals (n= 93 breast centers in Germany) in which patients were treated. Patients’ perspectives were measured for six month using the Cologne Patient Questionnaire for Breast Cancer (CPQ-BC), the other informations and hospital characteristics were collected by medical personnel.

Results: Full data of 2945 patients from 81 hospitals were analysed in the multilevel logistic regression model. The odds for patients being satisfied with nursing staff were significantly higher in hospitals which employed breast care nurses at the time of the survey. At the patient level, patients were significantly more likely to be satisfied with nursing staff if they were native speakers, and with higher self-rated health. Cross-level interaction analysis suggested that higher patient satisfaction resulting from employing breast care nurses was largely limited to native speaking patients. Other hospital characteristics were not significantly associated with the perception of nursing staff (teaching hospital, required number of surgeries, clinical trial participation).

Conclusions: The results demonstrate that patient satisfaction with nursing staff is higher if breast care nurses are employed in the treating hospital. Further work will focus on the description of the breast care nurses work as it is interpreted individually in every breast center. However, only the satisfaction of native speakers was significantly higher when breast care nurses were employed.

Implications for Practice: Findings suggest that hospitals should invest in employing specialist nurses. Special attention should be paid to the care of non-native speaking patients.

P5-17-03
The Association between Breast Cancer Related Lymphedema’s Risk Factors and Likelihood of Edema Progression.
Skolny MN, Miller CL, O’Toole J, Sadek B, Ancukiewicz M, Taghian AG. Massachusetts General Hospital, Boston, MA

Purpose/Objective(s): Breast cancer related lymphedema (BCRL) is one of the most feared long term side effects of treatment. Although emergence of the sentinel lymph node biopsy (SLNB) has decreased the rate of BCRL, it continues to be an issue for this population. The goal of this study is to evaluate the prognostic risk factors for BCRL development and progression based on longitudinal prospective limb volume (LV) measurements and associated surgical, radiation and medical oncology factors.

Materials/Methods: Since 2005 newly diagnosed breast cancer (BC) patients were prospectively screen via perometry (Pero-System). For this analysis patients were required to have undergone at least four measurements and have at least 24 months of follow up to allow for adequate time for LE development. Bilateral pre-operative volume measurements of the upper extremity were compared to post-operative measurements and at 4 to 6 month intervals to assess for limb volume changes. At each time point (tx), relative volume change (RVC) of the treated arm was calculated using volume ratios of treated (T) to non-treated (N) side compared to the pre-operative baseline (t1) (RVC=(Tx/Ntx)/(Tt1/Nt1)-1) as described in Ancukiewicz et al 2010. Our institution utilizes >5% RVC as an indicator of lymphedema. For this analysis, mild lymphedema was classified as a RVC of 5-9.9% and moderate lymphedema was classified as a RVC ≥10%. A univariate analysis was performed to identify risk factors and likelihood to LE progression.

Results: In a cohort of 415 women, 14.4 % (60) and 6.7% (28) developed mild and moderate BCRL, respectively. Twenty percent
(14) and 75 % (21) of patients in the mild and moderate cohorts, respectively, had a persistent edema that was documented at least 2 consecutive data points. Eighty percent (56) and 25% (7) of patients that had a documented incidence of an elevated RVC had returned below an RVC<5% and their subsequent visits. Based on Kendall’s Tau P-value of <0.0001 persistent edemas were associated with axillary lymph node dissection (ALND), number of lymph nodes removed, axillary fields and dose of radiation.

Conclusion: Breast cancer related lymphedema is a feared long term side effects and negatively impacts the physical and psychological aspects of an individual’s life. A condition that is considered manageable but not curable, it is essential providers identify high risk individuals. Establishing a a lymphedema screening program may identify early lymphedema which could be potentially be treated successfully.

P5-17-04
Association between Breast Cancer and Osteoporosis among Women 85 Years or Older.

Okanami Y, Homma N, Arai T, Sawabe M, Maeda I, Takagi M, Younes M, Takubo K. St. Marianna University School of Medicine, Kawasaki, Kanagawa, Japan; Tokyo Metropolitan Institute of Gerontology; Baylor College of Medicine

Background: The pathogenesis of breast cancer in very elderly women is of interest, because estrogen levels are likely to be extremely low during the development of the disease. Estrogens have opposing effects on the pathogenesis of breast cancer and osteoporosis. In an effort to understand the significance of estrogens in the pathogenesis of breast cancer in this group, we examined the association between breast cancer and osteoporosis in women at least 85 years old, taking body mass index (BMI) and hormone receptors status into consideration.

Methods: Clinical records of consecutive elderly women (≥ 85 y/o) who underwent breast cancer surgery at Tokyo Metropolitan Geriatric Hospital (BC) and control women of the same age group (Cont) were reviewed; osteoporosis and BMI status in both groups were recorded and compared. The status of estrogen receptor (ER) and progesterone receptor (PR) of breast cancers was examined immunohistochemically and compared between BC with and without osteoporosis (BC-OP and BC-nonOP, respectively).

Results: Frequency of osteoporosis was significantly lower among BC than Cont. There was no difference in BMI measured after 85 y/o between BC and Cont; however, percentage of women, whose BMI measured when they were in their sixties or seventies was ≥ 20% higher than BMI measured when they were 85 y/o or older, was significantly higher among BC than Cont (31% and 2%, respectively. P = 0.0001). ER positivity of breast cancer did not differ between BC-OP and BC-nonOP, whereas PR positivity was significantly higher among BC-nonOP than BC-OP (P = 0.0359).

Discussion: The inverse relationship between the incidence of breast cancer and osteoporosis suggests an important role for estrogens in the pathogenesis of breast cancer in the very elderly women. Our finding that one third of BC had ≥ 20% higher BMI when they were in their sixties or seventies suggests they may also have elevated serum estrogens during these earlier years, because increased BMI has been reported to be associated with increased serum estrogens in postmenopausal women. Expression of PR is regulated by estrogen-ER signaling, and PR positivity is considered to reflect the effectiveness of estrogen-ER pathway. Significant difference of PR positivity between BC-nonOP and BC-OP suggests the more importance of estrogens in BC-nonOP than BC-OP.

Conclusion: Estrogens seem to play an important role in the pathogenesis of breast cancers in very elderly women, especially without osteoporosis. With increasing aging population in developed countries, those findings may have implications for breast cancer prevention in this age group.

P5-17-05
24 Months Follow-Up Results from PACT (Patient's Anastrozole Compliance to Therapy Programme), a Non-Interventional Study Evaluating the Influence of a Standardized Information Service on Compliance in Postmenopausal Women with Early Breast Cancer.

Lueck H-J, Hadji P, Harbeck N, Jackisch C, Blettner M, Zaun S, Windemuth-Kieselbach C, Beck T, Köhler U, Schmitt D, Krüenberg R. Gyn-Oncological Practice, Hannover, Germany; Phillips-University, Marburg, Germany; Breast Center, University of Cologne, Cologne, Germany; City Womens Hospital Offenbach, Offenbach, Germany; Institute of Medical Biostatistics, University, Mainz, Germany; AstraZeneca Germany, Wedel, Germany; Alcedis GmbH, Germany; Hospital Rosenheim, Rosenheim, Germany; Hospital St. Georg, Leipzig, Germany; Consulting Doctor-Patient Communication, Radolfzell, Germany; University Womens’ Hospital, Ulm, Germany

Introduction: According to recent retrospective studies, compliance to adjuvant endocrine therapy for early breast cancer (EBC) may drop to below 70% after one year and to as low as 50% by year 4. PACT aimed to increase treatment adherence in postmenopausal women taking an adjuvant aromatase inhibitor via a standardized information service (educational arm). Yet, after 12 months, there was no difference in compliance between the standard and educational arm (reported at this meeting 2010). Methods: PACT is a prospective, randomised, two-arm parallel-group study in Germany, sponsored by AstraZeneca (NCT00555867). Postmenopausal women on anastrozole for hormone-receptor positive (HR+) EBC were randomized to routine clinical care alone or to receive additional standardized information service (educational arm) at nine times over the first 12 months of adjuvant therapy. Primary endpoints were compliance and persistence rates in the educational versus routine arm after 12 months. Secondary endpoints included longer follow-up, reasons for non-compliance, influence of baseline characteristics, and clinical outcome parameters (DFS, OS). Compliance was evaluated via patient questionnaires, prescription data and physician recall. Per protocol compliance was analysed only for patients with full documentation both by patients and physicians. Persistence was defined as the duration of time from initiation to discontinuation of therapy (Cramer et al 2007) and measured by prescription data.

Results: PACT enrolled 4,923 female patients at 109 breast centres and 1,361 registered specialist practices from all regions in Germany. 4,397 patients were evaluable for baseline characteristics. 2,707 patients were evaluable for the primary endpoint (full documentation on tablet intake both by patients and physicians). No difference in compliance could be shown between the standard (88.2%) and the educational arm (88.3%) at 12 months (p=0.92, Fisher’s exact test). Compliance rates were 40.3% for the standard arm and 43.0% for the educational arm, respectively (p=0.17, Fisher’s exact test). At 24 months, data from 1539 patients was available for analysis per protocol. Compliance rates were 88.7% (educational arm) and 87% (standard arm; p=0.29). Persistence again much lower at 41.1% and 42.1% (p=0.68). Variables influencing compliance were regular attendance to follow-up visits, participation in a cancer rehabilitation program, number of co-morbidities and current employment status. Persistence was influenced by factors such as tumour stage, joint pain...
and cancer rehab program participation. **Conclusion:** The addition of standardized information materials to standard clinical care did not lead to a significant increase in compliance or persistence rates at 12 or 24 months. With 4,923 women included, the PACT study represents the largest prospective study to evaluate the influence of educational material as well as baseline demographic and histopathological characteristics on the compliance and persistence to adjuvant endocrine therapy in postmenopausal patients with HR+ EBC.

**P5-17-06**

Pilot Study of a Questionnaire To Assess Impact of a Breast Cancer Diagnosis in Young Women on Their Relationship with Their Mothers.

Ali A, Fergus K, Wright F, Pritchard K, Kiss A, Warner E. Sunnybrook Health Sciences Centre, Toronto, ON, Canada

**Background:** Breast cancer in young women (≤40) is associated with greater morbidity, both physical and psychological, and mortality than in older women. For women in their 20s and 30s we would expect the mother-daughter relationship to be uniquely impacted by breast cancer. However, no study has apparently looked at the effects of a breast cancer diagnosis in this situation. We completed a pilot study to assess the clarity, content and sensitivity of a questionnaire that will be used in a comprehensive assessment of this relationship in young women with breast cancer. **Methods:** A questionnaire with a mixture of Likert and open-ended items was developed after a literature review, obtaining input from an interdisciplinary panel of experts in psychology, medical oncology, research methodology, and breast cancer, and informal interviews with 3 young breast cancer survivors. Topics covered include demographics, nature of the mother-daughter relationship pre and post diagnosis and sources of support to daughters and mothers. Ten breast cancer survivors (≤ age 40 at diagnosis and > 36 months after their diagnosis) were asked to assess the questionnaire. **Results:** Ten patients, median age 37 years (range 31-52), participated in the pilot study. The average time to complete the questionnaire was about 30 minutes. No questions were reported to be upsetting. All but 1 patient indicated that the questionnaire was clear. The questionnaire was modified based on patient feedback. The number of items was reduced from 51 to 38. Items concerning, for example, nature of the mother-daughter relationship during childhood or teenage years, and openness to discussing personal gynecological matters prior to breast cancer diagnosis were ultimately excluded. A question inquiring about the most difficult issues the daughter faced after diagnosis was added. Some questions were changed from open ended format to relevant tick box options after reaching response item saturation during the pilot phase. Of the 10 patients, 8 felt close to their mothers in the year prior to their diagnosis. Seven patients reported turning to their mothers for support when they first learned of the diagnosis, and 4 stated their mother was the first person they turned to. All 10 felt their mothers were emotionally and practically supportive. Five indicated that their relationship got closer post-diagnosis. One patient reported that her mother was not coping, and 3 indicated that their mothers did not have adequate support. Many patients felt that health care providers could help mothers by being empathetic, providing information, and linking mothers with supports. **Discussion:** The mother-daughter relationship is an important source of support for young breast cancer survivors. Our questionnaire will be used in 100 women ≤ age 40 and within 3 years of diagnosis to further study the impact of breast cancer in a young woman on the mother-daughter relationship and to determine whether any intervention targeted to the mothers (eg. information or support groups) might be helpful.

**P5-17-07**

HER2+ Metastatic Breast Cancer Patient Experiences on Treatment in the Biologic Era: Findings from a Community Web-Based Survey.

Mayer M, Doan JF, Lang K, Hurvitz SA, Lalla D, Woodward RM, Bramer MG, Menzin J, Tripathy D. AdvancedBC.org; Genentech, Inc., South San Francisco, CA; Boston Health Economics, Waltham, MA; UCLA Jonsson Comprehensive Cancer Center, Los Angeles, CA; USC/Norris Comprehensive Cancer Center, Los Angeles, CA

**Background:** HER2-directed biologic therapy is part of recommended treatment for women with HER2+ metastatic breast cancer (MBC). However, little is known regarding the quality of life (QoL) experience and symptom burden in these women outside of clinical trials. **Methods:** This one-time, web-based survey was conducted with 6 independent U.S. breast cancer support groups. Respondents were required to be female, aged 18+ with HER2+ MBC, and to have received active treatment in the past month outside of a clinical trial. Data were collected on demographic, clinical, employment, QoL (Rotterdam Symptom Checklist and EQ-5D), and other measures. Survey responses were stratified by active treatment (biologic alone, biologic in combination with other therapy, no biologic) and number of months since diagnosis of MBC. **Results:** Of 337 possible respondents, 185 women with HER2+ MBC completed the survey. The majority were aged 45-59 years (53.5%), white (94.6%), living with a spouse or partner (74.6%), and had at least some college education (93.5%). Most (64.9%) reported bone as a site of metastasis, followed by liver (36.2%), lung (31.9%), and brain (21.6%). During the prior month, 60 respondents (32.4%) had received biologic therapy only (trastuzumab, lapatinib and/or bevacizumab), 93 (50.3%) received biologic with another treatment, 21 (11.4%) received no biologic and 11 (5.9%) did not report a specific active treatment. Demographic and clinical characteristics were similar across therapy groups, with some geographic variation. Overall, the tumor receptor status was ER+/PR+ for 43.2% of respondents. Mean months since MBC diagnosis ranged from 46 among those taking a biologic with another treatment to 60 for those taking biologics only. Average Rotterdam subscale scores indicate that psychological symptoms caused the greatest impairment (mean= 0.8, P<.05), followed by physical symptoms (74.1) and activity limitations (87.3). There were no clinically meaningful (≥8 point) differences across biologic groups, with the greatest difference between the biologic with other therapy (73.5) and biologic-only (80.8) groups for “overall evaluation of life.” The average EQ-5D utility index score was 0.8 (1.0 is perfect health), with minimal variation across therapy groups. Most respondents reported no problems with mobility (62-77%) or self-care (≥90% across groups). However, pain/discomfort and anxiety/depression were problematic for more than 50% of all respondents, and were most commonly reported among the biologic plus other treatment group (61.3% and 51.6% respectively, P<.05 for differences in usual activity problems). Rotterdam and EQ-5D dimension scores indicated less impairment with more time since MBC diagnosis, particularly for EQ-5D mobility, self-care, usual activities, and pain/discomfort. Pain and mobility scores for those diagnosed 72+ months ago were significantly better than for those diagnosed 0-17 months ago (both P<.05). **Conclusions:** This community survey of women with HER2+ MBC provides valuable insight into treatment, quality of life and symptom burden. Pain and psychological issues continue to be challenges for this population.
P5-17-08
Hurvitz SA, Mathias SD, Doan JF, Crosby RD. UCLA School of Medicine/Translational Oncology Research International, Los Angeles, CA; Health Outcomes Solutions, Winter Park, FL; Genentech, Inc., South San Francisco, CA

Background: While PFS indicates the period of time a patient’s disease does not progress, there is debate about the relative value of longer PFS in the absence of a meaningful difference in OS. However, there are no known published reports about the value of PFS from the patient’s perspective.

Material and Methods: This was a 2-part project consisting of instrument development (via focus groups) and cross-sectional administration to 2 groups of women, those who had vs. those who had not experienced disease progression. Based on input from 19 women with MBC in the US, we developed an MBC-specific questionnaire (MBC-P). The questionnaire focuses on unique aspects relevant to MBC patients including concerns about the future, social isolation, fear, activity limitations, mental health, social functioning, and activity limitations. The MBC-P also presented descriptions of two hypothetical treatments: Treatment X, associated with 12 mos of PFS and Treatment Y with 16 mos of PFS, which had the same side effect profile. Respondents were asked to state which treatment was associated with better overall quality of life (O-QOL), physical functioning (PF), emotional well being (EWB), and which treatment was preferred. We compared mean scores at the item level for respondents based on progression status. One final aspect of the questionnaire asked respondents to rate (on a 0-100 scale) O-QOL, PF, EWB at the time of initial breast cancer (BC) diagnosis, MBC diagnosis, and MBC progression (if applicable). Ethics approval was obtained.

Results: 282 women completed the survey [mean age: 50 yrs (range: 21-80)]; 56% had experienced progressive disease. Women whose disease had progressed were more likely (p < 0.05) to report putting their life on hold, worrying about there not being a treatment that will work, feeling less confident about their treatment, and experiencing greater limitations in recreational or physical activities and accomplishing things/tasks. For the hypothetical descriptions, no differences emerged based on progression status. Despite being told that side effects and OS were the same for both scenarios, significantly more women responded that treatment Y (vs. treatment X) would result in better QOL, physical functioning, and emotional well being. Additionally, 88% of respondents preferred treatment Y over treatment X. Ratings for different stages of disease on O-QOL, PF and EWB were lowest the first time a woman was told her MBC had progressed and highest when told she had responded to treatment (O-QOL: 58 vs. 77; PF: 61 vs. 71; EWB: 51 vs. 77).

Discussion: The MBC-P questionnaire with input from women with MBC and is a useful tool to evaluate the value of PFS from the patient’s perspective. Women with MBC whose cancer had progressed were more limited in areas pertaining to treatment and activity limitations compared to women who had not experienced progression. Surprisingly, even when told that side effects and OS were similar, women rated O-QOL, PF, and EWB as being better for a hypothetical drug that provided 4 additional months of PFS. Results should be confirmed with a larger, more diverse sample of MBC patients and eventually in a prospective study.

P5-18-01
No Effect of Adjuvant Chemotherapy in Postmenopausal Patients with Invasive Lobular (Mixed) Breast Cancer.
Troll W, Voogd A, Vreugdenhil G, Van der Heiden-van der Loo M, Siesling S, Roumen R. Maxima Medical Centre, Veldhoven, Netherlands; Maastricht University, Maastricht, Netherlands; Comprehensive Cancer Centre, Utrecht, Netherlands; Comprehensive Cancer Centre, Enschede, Netherlands

Background: Although the literature is clear concerning the lack of response of invasive lobular breast cancer to neoadjuvant chemotherapy, no studies exist on the effectiveness of the adjuvant use of chemotherapy in these patients, as compared to those with ductal and mixed type lobular cancer.

Methods: All women with primary non-metastatic invasive ductal or (mixed type) lobular breast cancer, aged 50 to 69 years, diagnosed in the period 1995 to 2008 and treated with surgery, were selected from the Netherlands Cancer Registry and followed until January 1, 2010. Patients were divided in two groups: those who received adjuvant hormonal therapy only versus those receiving hormonal therapy in combination with adjuvant chemotherapy. Cox proportional hazards analyses were carried out to determine the impact of chemotherapy in addition to hormonal treatment, for each histological entity separately.

Results: In total 19,609 patients had ductal cancer, 3,685 had pure lobular cancer and 1,391 had mixed type lobular cancer. The patient groups were comparable with respect to the use of adjuvant systemic treatment. The 10-year survival of patients with ductal cancer treated with hormonal therapy alone was 69%, compared to 74% for those treated with hormonal therapy and chemotherapy (P<0.0001). For patients with lobular cancer, the 10-year survival rate was 68% after hormonal treatment alone and 66% after hormonal therapy with chemotherapy (P=0.45). The hazard ratio for death among the patients with ductal cancer receiving chemotherapy in addition to hormonal treatment was 0.70 (95% CI, 0.64-0.76, p<0.0001), as compared to those receiving hormonal treatment alone. In patients with pure or mixed type lobular cancer, however, the hazard ratio’s were 1.00 (95% CI, 0.82-1.21, p=0.97) and 0.98 (95% CI, 0.70-1.33, p=0.83), respectively. A statistically significant interaction was observed between the use of adjuvant chemotherapy and histological tumor type.

Conclusions: Adjuvant chemotherapy confers no additional beneficial effects in postmenopausal patients with pure or mixed type lobular breast cancer receiving hormonal therapy.

P5-18-02
A Population Level Assessment of Emergency Room Visits and Hospitalizations for Women Undergoing Adjuvant Chemotherapy for Early Breast Cancer.
Enright KA, Trudeau M, Yun L, Grunfeld E, Krzyzanowska M. Peel Regional Cancer Centre, Credit Valley Hospital, Mississauga, ON, Canada; Sunnybrook Odette Cancer Centre, Toronto, ON, Canada; Institute for Clinical Evaluative Science, Toronto, ON, Canada; University of Toronto, Toronto, ON, Canada; Cancer Care Ontario, Toronto, ON, Canada; Princess Margaret Hospital, Toronto, ON, Canada

Background: Adjuvant chemotherapy is considered the standard of care for women with lymph node positive and high risk lymph node negative breast cancer. While the acute toxicities of chemotherapy are well documented in clinical trials, the frequency of serious treatment related toxicities of adjuvant chemotherapy in the general population is not well described. We undertook a population based assessment of the frequency of serious treatment related toxicity in women
undergoing adjuvant chemotherapy for early breast cancer (EBC).

Methods: All incident EBC patients diagnosed between January 2007 and December 2008 in Ontario, Canada were identified from the Ontario Cancer Registry. Patient records were linked deterministically to multiple provincial administrative health care databases to provide comprehensive medical follow-up. Exclusion criteria were set to exclude patients on chemotherapy for advanced breast cancer. Any patient with who received at least 1 cycle of adjuvant chemotherapy was included in the analysis. Serious toxicities resulting in emergency room (ER) visits or hospitalizations occurring between the start date of chemotherapy and 30 days after the last dose of chemotherapy were identified. Logistic regression models were used to identify the impact of chemotherapy regimen, age, comorbidity and duration on therapy on the likelihood of experiencing serious toxicity.

Results: Of the 3090 women identified in our cohort, 1440 (46.6%) experienced at least 1 serious toxicity resulting in an ER visit during their adjuvant treatment. Of the ER visits, the majority (1107, 87%) were attributable to treatment-related toxicities. Febrile neutropenia (FN) was the most common treatment-related toxicity occurring in 27.1% of patients in the cohort. Docetaxel containing regimens were associated with a significantly higher rate of ER visits and FN (54.6% vs. 34.6%) compared with paclitaxel (38.0%, 17.9%), or anthracycline alone (epirubicin 45.8%, 23.8%; doxorubicin 32.8%, 15.4%). Table 1 displays the impact of clinical and patient factors on multivariable analysis.

Multivariable analysis for serious toxicity on adjuvant chemotherapy in EBC

Conclusion: Serious toxicities are a common in women undergoing adjuvant chemotherapy for EBC and result in significant acute health care utilization.

P5-18-03

First Interim Toxicity Analysis of the Randomized Phase III WSG Plan B Trial Comparing 4xEC-4xDoc Versus 6xTC in Breast Cancer Patients with HER2 Negative Breast Cancer (BC).

Nitz U, Gluz O, Krepe H, Liedtke B, Aitak B, Henschel S, Polminn A, Krabichl P, Zuna I, Shuk S, Thomsseen C, Harbeck N. West German Study Group, Moenchengladbach, Germany; Breast Centre Niederrhein/Bethesda Hospital, Moenchengladbach, Germany; Bethesda Hospital, Wuppertal, Germany; Medizinische Hochschule, Hannover, Germany; Evangelical Hospital, Bergisch Gladbach, Germany; University Hospital, Essen, Germany; Johanner Hospital, Stendal, Germany; Evangelical Hospital, Oberhausen, Germany; City Hospital Chemnitz, Chemnitz, Germany; Genomic Health Inc, Redwood City, Germany; University Hospital Halle/Saale, Halle/Saale, Germany; University Hospital Cologne, Cologne, Germany

Background: Anthracycline-taxane based adjuvant chemotherapy (cht) is considered standard in node-positive and high-risk node-negative BC. However, retrospective analyses suggest that in HER2-BC, benefit from anthracyclines may not outweigh acute and long term toxicities. Recurrence Score (RS) identifies patients who are not candidates for cht based on their low relapse risk, as well as minimal, if any, benefit of cht. The WSG Plan B trial investigates anthracycline-free cht in HER2-BC and is the first trial in Europe prospectively incorporating RS for decision making regarding adjuvant cht in both N0 and N+ BC.

Methods: Plan B trial randomizes HER2-BC patients with high-risk N0 (at least one risk factor: ≥pT2; negative HR status; ≥23-3 age ≤35 years old; high upPA/PAI-1) or N+ disease to 6xTC (Docetaxel 60mg/m2Cyphosphamide vs. 4xEC (Epirubicin60mg/m2Cyphosphamide) vs. 4xDocetaxel100mg/m2 G-CSF prophylaxis is recommended according to current ASCO guidelines. The statistical design previews n=2.448 randomized to cht; patients with HR+ BC, N0-3 and a RS ≤11 receive endocrine therapy only.

Results: From April 2009 to June 2011, 3037 patients have been recruited and 2296 randomized (TC/EC-Doc: 1146/1150; age <65 years old: 900/911; ≥65 years old: 246/239). From the patients with HR+ disease (n=2368) 18% had a RS 0-11, 61% a RS 12-25 and 21% a RS ≥25. In patients with 0-3 positive LN and RS of 0-11 (n=329) who opted for no cht 257 are in the observational arm. In the group with an intermediate risk (RS 12-25) 14% drop outs before start of cht have been reported. In 1172 fully monitored patients 22 toxicity-related therapy stops have been reported in the TC and 34 in the EC-Doc arm (p=0.12).

614 serious adverse events (SAE) have been reported (299 TC vs. 315 EC-Doc). There is no difference in patients <65 years old (TC vs. EC-Doc: 218/218), but slightly more SAE’s in patients ≥65 years old treated by EC-Doc (97 vs. 81, p=0.13). The most frequent SAEs were: leucopenia, febrile neutropenia (TC/EC-Doc:37 (3.3%)/31 (2.7%), n.s.), infections and heart/vascular events (TC/EC-Doc: 29/40, n.s.). In patients ≥65 years old, there is a trend towards more febrile neutropenia (13 vs. 5; p=0.12).

Detailed data on relationship between the protocol specified, RS-guided treatment assignment and toxicity, and use of G-CSF support will be updated for the meeting.

Conclusions: The Plan-B trial is one of the largest randomized phase III trials currently evaluating anthracycline-free adjuvant cht in HER2-BC. The cht administered within the study was generally well tolerated, but higher number of treatment-related deaths has been observed within the TC arm. The short term toxicity profile seems be different between both study arms, particularly in patients ≥65 years old. On the basis of prognosis as determined by RS, cht has been spared after a shared decision process in a substantial group of patients.

Safety Profile of Ixabepilone as Adjuvant Treatment for Poor Prognosis Early Breast Cancer: First Results of the Unicancer-PACS 08 Trial.
Campone M, Spielmann M, Wilders H, Cotta P, Kerbrat P, Levy C, Mayer F, Bachelot T, Winston T, Eymard J-C, Uwer L, Machiels J-P, Verhoeven D, Jaubert D, Facchini T, Orfeuvre H, Canon J-L, Asselain B, Roca L, Lacroix Triki M, Martin AL, Roche H, Centre René Gauducheau, Nantes, France; Institut Gustave Roussy, Villejuif, France; Katholique Universiteit, Leuven, Belgium; Institut Curie, Paris, France; Centre Eugène Marquis, Rennes, France; Centre François Baclesse, Caen, France; Centre Georges-François Leclerc, Dijon, France; Centre Léon Bérard, Lyon, France; Mayo Clinic Florida, Jacksonville; Institut Jean Godinot, Reims, France; Centre Alexis Vautrin, Nancy, France; UCL Cliniques Universitaires SAINT-LUC, Bruxelles, Belgium; AZ Klina Oncology, Brasschaat, Belgium; Clinique Tivoli, Bordeaux, France; Polyclinique de Courfancy, Reims, France; Centre Hospitalier de Fleyriat, Bourg en Bresse, France; Grand Hospital de Charleroi, Charleroi, Belgium; Centre Val d’Aurelle, Montpellier, France; Institut Claudius Regaud, Toulouse, France; R&D Unicancer, Paris, France

Purpose: PACS 01 trial demonstrated that the sequential adjuvant chemotherapy with FEC100 followed by docetaxel (D) significantly improves disease-free and overall survival in node-positive (N+) early breast cancer (BC). However, Triple negative (TN) and ER+/PR-/HER2- subgroups are significantly associated to a worse prognosis even after adjuvant of D. As Ixabepilone (Ixa) has notable preclinical and clinical activity in these subgroups, the PACS 08 trial aims to compare standard FEC100-D regimen to 3 cycles of Ixa followed by 3 cycles of Ixa. We report the preliminary results of the toxicity profile.

Patients and methods: Patients (pts) had localized resectable unilateral ER-/PR-/HER2- or ER+/PR-/HER2- BC. Main inclusion criteria were: age<70 years, normal cardiac, hepatic, haematological and renal functions. Arm A: pts received 3 cycles of FEC100 (F and C, each at 500 mg/m2, E 100 mg/m2, every 3 weeks) followed by 3 cycles of D (100 mg/m2 every 3 weeks); Arm B, Ixa 40 mg/m2 replaced D. Radiotherapy was mandatory after conservative surgery and endocrine therapy was given to ER+ pts. A 5% absolute difference in disease-free survival at 5 years is the main statistical end-point.

Results: Between October 2007 and September 2010, 762 pts with a mean age of 57.9 years (range 30.5 to 83.6 years) were included. Of these, 204 (61.4%) did not receive primary prophylaxis with CSF. Results: 332 patients with a mean age of 57.9 years (range 30.5 to 83.6 years) were included. Of these, 204 (61.4%) did not receive primary prophylaxis with CSF. The true incidence of FN in community based patients may be higher than in the original clinical trial population as non-trial patients may have risk factors known to increase the risk for chemotherapy-induced FN, including increased age or other comorbid conditions. We wanted to know the incidence of FN in patients receiving TC chemotherapy who were not given primary prophylaxis with CSF.

Methods: Using our electronic medical record system, a retrospective review of patients starting TC for breast cancer in 2010 at Kaiser Permanente Northern California was included. Patients had started a four or six cycle regimen of docetaxel 75 mg/m2 and cyclophosphamide 600 mg/m2 every 21 days. Patients were stratified into two groups: (1) CSF primary prophylaxis given with the first cycle versus (2) no CSF primary prophylaxis given with the first cycle. CSF prophylaxis was given by physician choice. FN episodes were defined with a clinical diagnosis code for FN from emergency department visits or hospitalizations. The primary outcome was the incidence of TC-induced FN in patients who did not receive CSF primary prophylaxis with the first cycle of treatment.

Results: 332 patients with a mean age of 57.9 years (range 30.5 to 83.6 years) were included. Of these, 204 (61.4%) did not receive primary prophylaxis with CSF (mean age 57.4 years, range 30.5 to 83.6 years), and 128 (38.6%) received primary CSF prophylaxis (mean age 58.5 years, range 36.6 to 84.2 years). The incidence of FN during any cycle was 24.5% (50/204) in those who did not receive primary CSF prophylaxis and 8.6% (11/128) in those who did (p=0.0003). Patients were hospitalized for FN for a total of 174 days (mean 3.2 days, range 1 to 13 days). Mean days hospitalized were 3.2 in each group. We will present risk factors associated with the development of FN.

Conclusion: In the largest population based report to date, we report the incidence of febrile neutropenia to be 24.5% in patients not
P5-18-06
Taxanes and Cyclophosphamide Are Equally Effective in Breast Cancer: A Meta-Analysis of Ten Phase III Trials in Early and Advanced Disease.

Vriens BE, Lobbezoo DJ, Voogd AC, Veeck J, Tjan-Heijnen VC. Maastricht University Medical Centre, Maastricht, Netherlands; ZonMw, Maastricht, Netherlands

Background: Overall taxanes did not improve survival in metastatic breast cancer trials (n=10 trials), whereas they do so in (neo-)adjuvant breast cancer trials (n=28 trials). Taxanes are widely used but no evidence of survival benefit in metastatic disease. This meta-analysis was conducted to evaluate the efficacy of taxanes and cyclophosphamide in (neo-)adjuvant breast cancer trials.

Methods: We searched MEDLINE, EMBASE, Cochrane Central Register of Controlled Trials, and grey literature databases. Seven meta-analyses were included. Taxane regimens were compared with regimens not containing taxanes (control) or with cyclophosphamide alone. The primary endpoint was disease-free survival (DFS).

Results: In total, 46 studies in early and advanced breast cancer were included and analyzed for their primary endpoint. In metastatic breast cancer studies, the hazard ratio of overall survival was 1.95 (95% CI 1.53 to 2.48) for taxanes compared with cyclophosphamide. In early breast cancer, taxanes showed no improvement for DFS (hazard ratio HR=1.01, 95% CI 0.82 to 1.25). For all studies substituting taxanes for prolonged cyclophosphamide, i.e., AT versus AC, a pooled analysis was performed using RevMan 5 (RevMan 5) providing complete data.

Conclusion: Taxanes were at least as effective as cyclophosphamide in the adjuvant setting. Based on this meta-analysis, taxanes may be considered as an alternative for cyclophosphamide as the first-line agent in hormone therapy-resistant metastatic breast cancer. Further studies are needed to determine if taxanes can replace cyclophosphamide in future trials or in daily practice.

P5-18-07
Presence of Disseminated Tumor Cells after Adjuvant Chemotherapy in Breast Cancer and Disseminated Tumor Cells Monitoring during Secondary Adjuvant Treatment.

Synnestvedt M, Borgen E, Wist E, Wiedswang G, Weyde K, Risberg T, Kersten C, Mjaaland I, Vindi L, Schirmer CB, Nesland JM, Naume B. Oslo University Hospital, The Radium Hospital, Oslo, Norway; Lilleløkks gate, Oslo, Norway; Hospital Innlandet, Gjøvik, Norway; University Hospital Northern Norway, Tromsø, Norway; Sorlandet Hospital Kristiansand, Kristiansand, Norway; Stavanger University Hospital, Stavanger, Norway; Ålesund Hospital, Ålesund, Norway; University of Oslo, Norway

Introduction: Detection of disseminated tumor cells (DTC) after completion of systemic adjuvant treatment is a strong predictor of early systemic relapse and death. This analysis can discover early failure of a chosen adjuvant systemic treatment. In this study, we wanted to evaluate the value of DTC detection in bone marrow (BM) as a surrogate marker for response to docetaxel rescue treatment, to predict the effect of this treatment. Further, we wanted to compare disease-free survival between patients treated with docetaxel resulting in eradication of DTC after treatment and patients treated with docetaxel where DTC persists after treatment. The follow-up of the study is still ongoing. Here, we present the preliminary descriptive data from the study.

Materials and Methods: A total of 1128 pts with node positive or high risk node negative disease (T1c/T2GII-IIIN0) was enrolled in the period from October 2003 to May 2008. All patients had completed primary surgery and received 6 cycles of adjuvant antracycline containing chemotherapy. The first BM aspiration was performed 8-12 weeks after termination of adjuvant chemotherapy (BM1). A second BM aspiration was performed 6 months later (BM2). The processing of BM and DTC analysis (by ICC) were performed as previously described (Wiedswang G et al, J Clin Oncol 2003). If BM2 was positive (+) for DTC, the patient was treated with docetaxel (3qw; 6 courses) D docetaxel-treated patients were reexamined at the inclusion hospital with new BM analysis at approximately 1 month (BM3) and 13 months (BM4) after the last docetaxel infusion.

Results: Of 997 patients with conclusive DTC results for both BM1 and BM2, 83 patients (8.3%) were BM1 positive and 78 (7.8%) BM2 positive. Among the BM1+ patients, 15 (18.1%) were BM2+. The concordance between BM1 and BM2 were 87%. Of the patients positive at one or both time points, the concordance was 10% (15/146). The BM1 was not significantly associated with primary tumor characteristics (although borderline significance for Grade and ER status), whereas for BM2, DTC+ patients had increased frequency of node positive disease and pN2-3 stage (p=0.001, chi-square), and were positively associated with lobular carcinoma (p=0.01, chi-square).

Conclusions: Detection of DTCs after adjuvant antracycline containing chemotherapy changes during the first 9 months of FU, with increased DTC positivity among patients with pN+ disease and lobular carcinomas. After docetaxel rescue treatment, the majority of patients experience disappearance of the DTCs. The clinical significance of these results awaits mature FU data, but the present results may indicate possibility for eradication of residual disease by alternative chemotherapy.

P5-18-08
A Comparative Effectiveness Analysis of Trastuzumab Persistence between Two Adjuvant Breast Cancer Treatment Regimens among US Health Plan Enrollees.

Lalla D, Pelletier EM, Goodman S, Brammer M, Schabert VF. Genentech Inc., South San Francisco, CA; IMS Consulting Group, Watertown, MA; IMS Consulting Group, Woodland Hills, CA

Background: Approved US indications for trastuzumab include adjuvant treatment of HER2-overexpressing breast cancer in anthracycline-based (ACTH) or non-anthracycline-based (TCH) regimens. The objective of this study was to compare trastuzumab persistence across adjuvant breast cancer treatment regimens for US health plan enrollees.
Materials and Methods: This retrospective cohort study using the IMS LifeLink™ Health Plan Claims Database included adjuvant breast cancer patients, defined as those with a mastectomy or lumpectomy and a primary breast cancer diagnosis (index diagnosis) from 1/1/2006 to 12/31/2008. Additional inclusion criteria were: aged ≥18 years; a second primary breast cancer diagnosis ≤90 days of the first; no other primary or secondary neoplasms ≤180 days before or ≤90 days after the index diagnosis; a first trastuzumab claim (index claim) and ≥1 carboplatin, cyclophosphamide, taxane, or anthracycline claim ≤210 days of the index diagnosis; and no trastuzumab claim before the index diagnosis. Regimens were classified as ACTH (doxorubicin, cyclophosphamide, a taxane, trastuzumab) or TCH (docetaxel, carboplatin, trastuzumab) from therapies observed after the index claim. Trastuzumab persistence (days from the index claim to earliest of trastuzumab discontinuation, a new malignant neoplasm, end of plan enrollment, 360 days after the index claim, or end of available data) was reported for patients with ≥2 trastuzumab claims and compared across regimens using the Kaplan-Meier estimator and Cox proportional hazards models.

Results: 550 breast cancer patients met all study criteria (291 ACTH, 259 TCH, 46 unassigned); patients receiving TCH were older (median 52 vs. 50 years; P=0.018). For years 2006-2008, the annual share of the cohort initiating ACTH decreased from 69.3% to 35.2%; patients initiating TCH increased from 26.7% to 56.5%. Patients receiving ACTH were treated with trastuzumab for fewer days (mean=256, median=334) versus patients on TCH (mean=282, median 344, P=0.018). Fewer patients on ACTH remained on trastuzumab at day 90 (83% vs. 91%), day 180 (71% vs. 79%), day 270 (61% vs. 72%), and day 360 (20% vs. 26%). Compared to patients on TCH, patients on ACTH continued to be treated with trastuzumab for a shorter duration post-index after adjusting for age, region, plan type, prescriber specialty, and comorbidities (HR=0.77, 95% CI [0.63, 0.95]; P=0.016).

Discussion: The share of adjuvant breast cancer patients initiating TCH increased from 2006 to 2008, while use of ACTH decreased over the same time period, and patients treated with TCH remained on trastuzumab for a longer period of time. From a clinical standpoint, patients derive maximum benefit from their medications when they are persistent long-term, which can lead to economic benefits with regards to lower overall healthcare costs. Further analyses will evaluate whether adjuvant breast cancer regimens differ in weight-adjusted cumulative trastuzumab doses received during therapy.

P5-18-09

The Incidence of Febrile Neutropenia in the First Course of Adjuvant Chemotherapy with Docetaxel/Cyclophosphamide with or without Pegfilgrastim.

Jones S, Paul D, Sedlacek S, Vukelja S, Wilks ST, Stokoe C, Osborne CR, Krekow L, McIntyre K, Holmes FA, Guerra L, Zhan F, Asmar L, O’Shaughnessy J, Blum JL. US Oncology, The Woodlands, TX; Baylor-Sammons Cancer Center, Baylor University, Dallas, TX; Rocky Mountain Cancer Center; Denver, CO; Texas Oncology-Tyler, Tyler, TX; Cancer Care Centers of South Texas, San Antonio, TX; Texas Oncology, Plano, TX; Breast Cancer Center of North Texas, Bedford, TX; Texas Oncology-Dallas Presbyterian Hospital, Dallas, TX; Texas Oncology-Houston Memorial City, Houston, TX

Background: In our original doxorubicin-cyclophosphamide/docetaxel-cyclophosphamide (AC/TC) adjuvant study (JCO 27: 1177-1183, 2009), we reported an incidence of febrile neutropenia (FN) of 5% (8% in women ≥65 years) with the TC regimen without prophylactic WBC growth factors but with a recommendation for prophylactic antibiotics. There is a paucity of data on the incidence of FN with the TC regimen aside from this clinical trial. Because we have been conducting a randomized adjuvant study of TC compared to other regimens, we used this opportunity to analyze the incidence of FN during the first course of chemotherapy with TC in the first cohort of randomized patients (US Oncology Network study 06090). The prophylactic use of WBC growth factors was at the investigator’s discretion.

Patients and Methods: The study included 1298 patients entered between May 2007 and May 2009. Of these, 649 were included in the TC arm. Median age was 54 years (range 27-71), 75.5% were Caucasian, 561 (86.4%) were in PS 0 at baseline, and about half were node negative. Eight patients did not receive study treatment for various reasons. Among the 641 patients who received TC; 213 (33.3%) received pegfilgrastim, 48 (7.5%) received filgrastim and were not included in this analysis, and 380 (59.2%) patients did not receive either during the first cycle. Thus, this analysis focused on 593 women who did or did not receive prophylactic pegfilgrastim in cycle 1.

Results: All patients with a reported adverse event of FN or with a reported AE of fever with some degree of neutropenia (in order to capture all possible cases of FN) during the first cycle of TC were identified [Table 1]. FN and fever + neutropenia occurred in a total of 6 (2.8%) patients who received pegfilgrastim and 36 (9.5%) patients who did not. A comparison of age, race, performance status and stage of disease between these 2 groups revealed that they were similar. The 213 patients who received pegfilgrastim were slightly older (median 56 years, range 27-71) compared to those who did not (median 53 years, range 30-71).

During all 6 cycles, 41 patients reported FN, and 30 (73%) of these patients experienced FN during cycle 1.

Conclusion: Among 593 women who received TC as adjuvant chemotherapy, the incidence of FN during the first cycle was under 10% whether or not the patients received prophylactic pegfilgrastim.

P5-18-10

Chan A, McGregor S. Mount Hospital, Perth, WA, Australia

Background: Chemotherapy for early breast cancer (EBC) confers significant survival advantages. However, myelosuppression is a common cause of chemotherapy dose reduction that may subsequently compromise survival benefits. Primary prophylaxis (PG) with granulocyte-colony stimulating factor (G) is indicated for TAC regimen, but rates of grade 3/4 neutropenia (G3/4N) associated with other adjuvant regimens in a non-trial setting are not well documented. Optimal use of G will likely enable planned dose delivery, leading to optimal BC outcomes. This retrospective study reports dose delivery outcome with judicious use of G in a single institution.

Methods: Consecutive patients (pts) with EBC who received chemotherapy at Mount Hospital from January 1999 - December 2010 were included. Data was collected prospectively for pt characteristics, regimen given and neutropenic complications. Only pts who received a minimum of 1 cycle of chemotherapy were included. PG
was only available in pts receiving TAC after 1/4/2007; Secondary G propha	xlsis (SG) was given for G3/4N in first cycle, febrile neutropenia (FN) or delay in neutrophil recovery (DN). Primary outcome measure was dose delivery defined as relative dose intensity (RDI - fraction of dose per unit of time of standard regimen) and fraction planned dose received (PDR). Secondary endpoints included EBC outcome and incidence of haematological malignancies.

Results: Over the 12 year period, 1655 pts (62% node positive) with mean age of 51yr (24-88yr) were included. Chemotherapy given - n (%): Non-anthracycline(A)/taxane(T) 63 (3.8); A 671(40.5); AT 666(40.2); T-only 258(15.4). Overall 64% of pts received G; PG given for TAC in 167(10); SG was given for first cycle G3/4N 677(41), FN 87(5) - 89% during first cycle, DN 109(7). Mean RDI and PDR was 0.97 v 0.95 and 0.98 v 0.97 for pts who received G and did not, respectively. Amongst pts aged < or ≥65yr, rate of G use and >85% PDR were comparable (65% v 66%; and 4% v 6%, respectively). Five cases of myelosuplasia or acute leukemia were reported (4 pts received G) -0.37% v 0.17% of pts having G or not, respectively. All cases received an anthracycline with cyclophosphamide. At median follow-up of 44.9 months [Q1: 25.1- Q3: 69.6], DFS was 88.9% and OS 92.6%. PDR <85% occurred in 5% pts, with OS of 78% v 93% if pts received < or ≥85%, respectively.

Discussion: Significant rates of myelosuppression occur with regimens commonly used in the community. These regimens are not associated with FN rates >20% and thus PG is not advised. Routine monitoring of first cycle neutrophil nadir enabled the identification of those pts at high risk of developing further neutropenic complications and consequent need for dose reduction or delay. Utilisation of G in these high risk pts enabled a high RDI to be delivered, comparable to pts who did not experience significant myelosuppression. Further, pts who did not develop significant first cycle myelosuppression were largely spared the need for G. In this manner, concerns regarding haematological toxicity and costs associated with G use are minimised.

P5-18-11 Incidence of Chemotherapy Dose Reductions and Dose Delays, and Reduced Chemotherapy Dose Intensity in Early Stage Breast Cancer.

Weckler D, Edelsberg J, Kartashov A, Barron B, Lyman G. Policy Analysis Inc. (PAI), Brookline, MA; Amgen Inc., Thousand Oaks, CA; Duke University, Durham, NC

Background: Chemotherapy is widely used to treat early stage breast cancer (ESBC). Dose reductions and dose delays--e.g., due to advanced age or severe/febrile neutropenia--are generally believed to increase risk of disease progression and reduce survival. Little is known about incidence of chemotherapy dose reductions and dose delays among women with ESBC in clinical practice.

Methods: This study employed a retrospective cohort design and electronic medical records from over 60 community oncology clinics in more than 20 states (2004-2010). Study population included adult women who received myelosuppressive chemotherapy for ESBC (stages I-IIIA). For each such woman, each unique cycle of chemotherapy within their first observed course was identified. Incidences of chemotherapy dose delays (≥7 days for any drug in ≥1 cycles), chemotherapy dose reductions (≥15% for any drug in ≥1 cycles), and low relative chemotherapy dose intensity (<85% over the course) -- relative to physician-reported planned chemotherapy administration -- were descriptively analyzed for the seven most frequently observed regimens among subjects.

Results: 2,350 women received seven most frequently observed regimens (80% of study population); mean age -- across regimens -- ranged from 51-56 years, and 31-94% received primary prophylaxis against severe/febrile neutropenia with a colony-stimulating factor. Incidence of dose reductions ranged from 17-48%, and dose delays, from 24-45%. Overall mean relative dose intensity (RDI) ranged from 80%-99%, and 17-50% of subjects received RDI <85%; mean RDI among those with low RDI ranged from 40%-67%.

Discussion: Chemotherapy dose delays and dose reductions are common in ESBC, among those receiving dose-dense as well as conventional regimens.
higher with TCH. For example, there were fewer dose modifications/delays for AC-TH than TCH (31% vs. 46%, p=0.07). This may have been due to common use of GCSF with AC-TH (77% vs. 33% use with TCH). Neutropenic fever (NF) was higher with TCH, reaching 25% incidence when administered without GCSF. However, NF did not occur in the 8 TCH patients who received cycle 1 GCSF. There was no correlation between NF and patient age. The incidence of left ventricular EF decline leading to cessation of trastuzumab was similar for both regimens (19.4% AC-TH vs. 14.6% TCH; p = 0.64). Trastuzumab was completed as planned in 70% of patients. Although EF decline was most common explanation, 13% of early trastuzumab discontinuations occurred for other reasons.

CONCLUSION: TCH and AC-TH are the most commonly administered adjuvant regimens for WI women with HER2+ BrCa. Amongst WI oncologists, TCH is perceived as safer, but is less likely to be recommended for node-positive BrCa. This retrospective analysis suggests that acute myelosuppression is greater for TCH, with a significant rate of NF. Per ASCO guidelines, these data suggest GCSF should be used routinely with TCH due to high rate of FN.

Cancer Research; 71(24 Suppl.) December 15, 2011

P5-18-13
Adjuvant Chemotherapy with Vinorelbine+5FU or Capecitabine in Poor Responders to Neoadjuvant EC-Docetaxel Chemotherapy (NAC) for Locally Advanced Breast Cancers.

Background: Post-operative chemotherapy in poor responders after NAC is questionable. We evaluated the use of adjuvant Vinorelbine (NVB) + continuous infusion 5FU or Capecitabine (Cap) in women with poor pathological response to preoperative sequential Epirubicin Cyclophosphamide-Docetaxel (ECT).

Materials and methods: From May 2004 till October 2007, 340 patients (pts) with stage II or III breast adenocarcinoma received neoadjuvant ECT +/- Trastuzumab (HER2+), +/- Celecoxib (HER2 negative) in a randomized phase II trial (Pierga, 2010). 53 patients (15.5%) had pathological complete response (no infiltrative or in situ carcinoma in the breast and lymph nodes). Eleven pts were not operated. 276 pts had grade 3-4 Chevallier residual disease. These poor responders could be optionally offered post surgery chemotherapy (NVB+5FU or Cap)+/- Trastuzumab. This regimen started concomitantly with post-operative RT. All positive hormonal receptors received hormone therapy. We attempted to evaluate DFS according to post operative CT in the 276 pts. To take into account the differences between populations, treated and untreated patients were matched (1:1) according to variables with a significant difference between the two groups, analyses were adjusted with all other prognostic factors.

Results: Out of 276 pts with 3-4 Chevallier’s grade after NAC, 198 pts did not receive any CT (group A), 78 received adjuvant CT (group B); NVB + 5-FU (FUN: N=41) or Cap (N=17) + Trastuzumab (21pts, 11 FUN and 10 CapNVB), 28 pts HER2+ in the group A receive Trastuzumab alone after surgery. The main characteristics of these patients differed for the initial lymph nodes status (N0: 15 (19 %) in group A vs 88 (44 %) in group B, p = 0.0001 and the number of positive lymph nodes after surgery (mean: 4.39 vs 1.95, p = 0.0004 respectively in groups A and B).

With a median follow up of 38.9 months, 63/276 pts (22.8%) recurred, 44 (22 %) in the group A and 19 (24.3 %) in the group B. DFS for the 276 pts is 95% at 12 months (m) and 86% at 24 m, 95% and 87% in group A and 96% and 83% in group B (logrank test : p = 0.63). We matched the 2 groups (124 pts; 62 [group] according to initial lymph nodes status, local response (Chevallier grade 3 or 4) and pN status after NAC. Characteristics of this matched population were similar except for more ER negative in chemo group, 19 pts (30.6 %) and 9 pts (14.5 %) in non chemo arm. In this population, 27 events occurred, with 13 in the chemo group and 14 in the non chemo’one. Treatment effect was non significant in univariate analysis (p = 0.93).

In multivariate analysis adjusted for initial tumor size (TNM), age, molecular status (hormonal receptor and HER2 status), histological grade, initial lymph node status, histological response after NAC, treatment effect was non significant (Hazard Ratio = 1 IC95% [0.38 ; 2.67]; p = 0.99). There was no difference in treatment effect according to molecular status (test for interaction p = 0.30). This multivariate analysis was also completed in the 276 pts with similar results.

Conclusion: In poor responders patients after Anthracyclins-Taxanes NAC, adjuvant chemotherapy with Vinorelbine- 5-FU or Capecitabine- did not appear to prolong DFS.

P5-19-01

Campone M, Dobrovolskaya N, Tjulandin S, Chen S-C, Fourie S, Mefti F, Konstantinova M, Lejresne F, Meheust N, Jasson J. Institut de Cancérologie de l’Ouest/René Gauducheau, Saint Herblain, Nantes Cedex, France; Russian Research Center of Roentgenoradiology, Moscow, Russian Federation; Russian Oncological Research Center, Moscow, Russian Federation; Chang Gung Memorial Hospital, Taichung, Taiwan; Wilmed Park Oncology, Klerksdorp, South Africa; Centre René Huguenin, Saint-Cloud, France; Moscow Regional Oncology Dispensary, Moscow, Russian Federation; Institut de Recherche Pierre Fabre, Boulogne, France; Medical University of Gdansk, Gdansk, Poland

Purpose: Owing to the increasing number of patients treated with anthracycline-based adjuvant chemotherapy, there is a need for new effective and tolerable non-anthracycline based regimens in metastatic breast cancer.

Patients and methods: Patients with HER2-negative metastatic breast cancer previously treated with anthracyclines in (neo) adjuvant setting were randomised to fully oral 3-weekly cycles of the combination of oral vinorelbine with capcitabine (V+C), to the same drugs alternating every 3 cycles (V+C), or to the combination of docetaxel and capcitabine (D+C). V was given at 80 mg/m² (after the first cycle at 60 mg/m²) on days 1 and 8 in the V+C arm and weekly in the V+C arm, 100 mg/m² bid from days 1 to 14, and D on day 1 at 75 mg/m². The primary endpoint was disease control rate (CR+PR+NC ≥ 3 months).

Results: A total of 139 patients were randomly assigned to V+C (44 patients), V+C or D+C (47 patients) and D+C (48 patients). After an independent review, the disease control rate in the intent-to-treat population in the V+C, V+C and D+C arms (95% CI) was 70.5% [54.8-83.2], 37.0% [23.2-52.5] and 70.8% [55.9-83.1]. The response
rate was 31.8% [18.6-47.6], 8.7% [2.4-20.8] and 35.4% [22.2-50.5], respectively. The median duration of progression-free survival in the V+C, V=C and D+C arms [95% CI] was 7.2 months [5.3-8.9], 3.4 months [2.6-5.6] and 8.9 months [7.2-12.0]; the median overall survival [95% CI] was 22.2 [18.8; 29.9], 19.4 [12.5; 35.4] and 24.2 [14.2; 38.5] months, respectively. Lower efficacy observed in the sequential arm could be due to higher prevalence of patients with visceral disease in this arm (91.3% in comparison to 65.9% in V+C and 64.6% in D+C arm). Combinations of V+C or D+C showed similar efficacy and a different toxicity profile; V+C induced less neutropenia, infection, hand-foot syndrome, fatigue/asthenia and alopecia, whereas D+C- less gastrointestinal toxicity.

Conclusions: V+C combination constitutes a valuable fully oral alternative option to D+C in patients with metastatic breast cancer previously treated with anthracyclines in (neo)adjuvant setting, while offering the advantages of an all-oral treatment.

P5-19-02
Comparison of the Incidence of Peripheral Neuropathy with Eribulin Mesylate Versus Ixabepilone in Metastatic Breast Cancer Patients: A Randomized Phase II Study.
Vahdat L, Gopalakrishna P, Garcia AA, Vogel C, Pellegrino C, Lindquist D, Iannotti N. Weill Cornell Medical College, New York, NY; Eisai, Inc., Woodcliff Lake, NJ; University of Southern California Keck School of Medicine, Los Angeles, CA; Sylvester Comprehensive Cancer Center, University of Miami, Miller School of Medicine, Deerfield Beach, FL; Montefiore Medical Center, New York, NY; US Oncology, Sedona, AZ; Hematology-Oncology Associates of the Treasure Coast, Port Saint Lucie, FL

Background: Peripheral neuropathy (PN) is a common toxicity and treatment limiting factor in heavily pretreated patients (pts) with metastatic breast cancer (MBC). Consequently, tolerability is important when choosing treatment. Eribulin mesylate has recently been approved in the US for patients with MBC who have previously received at least two chemotherapeutic regimens for metastatic disease including an anthracycline and a taxane. Eribulin was associated with a 34.6% incidence of PN (7.8% grade 3; 0.4% grade 4), however, over half of pts experiencing grade 3/4 PN continued eribulin. Ixabepilone (IXA) is frequently used in late-line MBC pts and registration studies reported an overall PN incidence of 63% (14-21% grade 3/4). We sought to define incidence of PN of eribulin and IXA in a late-line setting since indirect comparisons suggest eribulin may have a more favorable neurotoxicity profile compared with IXA.

Methods: This randomized, two-arm, multicenter, open-label, phase II study stratified pts by pre-existing neuropathy (grade 0 or 1) and number of prior chemotherapy (CT) regimens (≤3 or >3). 104 pts with locally recurrent or MBC, who had received at least one prior cytotoxic CT, including a taxane for MBC were randomized to receive eribulin mesylate (n=52; 1.4 mg/m² 2- to 5-min IV on Days 1 and 8 of a 21-day cycle) or IXA (n=52; 40 mg/m² as a 3 h IV infusion on Day 1 of a 21-day cycle). The primary objective was to compare the incidence of neuropathic adverse events. Secondary objectives were: 1) to compare the severity of neuropathy using CTCAE grading, a patient-reported neurotoxicity questionnaire (SRNO), and vibration sensitivity (VS); 2) to evaluate efficacy as measured by objective response rate (ORR), clinical benefit rate (CBR), disease control rate (DCR), and progression-free survival (PFS); and 3) to evaluate safety.

Results: Of 51 eribulin and 50 IXA pts who received treatment, eribulin-treated pts experienced a trend towards less PN and treatment-emergent neuropathy (TEN) than IXA-treated pts (31.4% vs 44.0%, p=0.1632; and 33.3% vs 48.0%, p=0.1284, respectively).

The incidence of grade ≥3 neuropathy was 9.8% and 22% for eribulin and IXA, respectively. Time to onset of severe neuropathy was earlier for IXA relative to eribulin (4.8 vs 9.9 weeks, respectively); by cycle 4, 44% of subjects receiving IXA experienced TEN compared with 24% on eribulin. SRNO and VS results will be analyzed separately. Treatment-emergent adverse events (TEAEs) and serious TEAEs were comparable (98% and 96%; 37% and 34% in eribulin- and IXA-treated subjects, respectively). Eribulin-treated pts experienced less discontinuation of treatment due to neuropathy (3.9% vs 18%) or TEAEs in general (11.8% vs 32.0%) relative to IXA pts. The efficacy data for eribulin vs IXA was 15.4% vs 5.8% for ORR, 26.9% vs 19.2% for CBR, 67.3% vs 55.8% for DCR, and 104 days vs 95 days for median PFS, respectively.

Conclusions: Although the difference in overall incidence of PN and TEN was not significant for eribulin vs IXA, eribulin tended to show less PN and TEN. Eribulin also had less severe and longer time to development of grade 3/4 PN and fewer discontinuations due to toxicity.

P5-19-03
Gradishar WJ, Krasnojon D, Chepovor S, Makhson AN, Manikhas GM, Clawson A, Bhar P. Northwestern University, Chicago, IL; Leningrad Regional Oncology Center; Russian Federation; Yaroslavl Regional Clinical Oncology Hospital; Yaroslavl, Russian Federation; City Oncology Hospital, Moscow, Russian Federation; St. Petersburg Oncology Center, St. Petersburg, Russian Federation; Celgene Corporation, Summit, NJ

Background: We previously reported the results of a phase II study evaluating the efficacy and safety of 3 different dosing regimens of ab-pac and docetaxel for the first-line treatment (Tx) of MBC (Gradishar et al. J Clin Oncol. 2009;27:3611-3619). Here, we report final overall survival (OS) and an analysis of safety and associated dose reductions (DRs). Methods: Patients (pts; N = 300) with previously untreated MBC were randomized to 1 of 4 Tx arms (table). A step-down statistical approach was used for pairwise comparisons of Tx arms. The trial was powered for antitumor activity and safety. Results: Tx arm C produced the longest OS (33.8 months) with an 11.6-month longer median OS vs arm B (HR 0.575; P = .008) and a 7.2-month longer median OS vs arm D (HR 0.688; P not statistically significant). OS data were consistent with previously reported investigator assessment of overall response rates and progression-free survival. Grade (gr) 4 neutropenia (np) was significantly less frequent in the ab-pac arms vs. the docetaxel arm (5-9% vs. 75%); Febrile np occurred in 1% of each ab-pac arm vs 8% in the docetaxel arm. Rates of gr 3 sensory neuropathy (SN) were 21%, 9%, 22% and 12%, respectively, in arms A-D (P = .083). No gr 4 SN occurred. Median time to improvement to ≤ gr 2 SN was 20-22 days in the ab-pac arms vs 41 days in the docetaxel arm. Gr 3 fatigue occurred in 5, 0, 4, and 19% of pts in arms A-D, respectively. In arm C, best response was observed at cycle 2, whereas DRs due to toxicity occurred later, at cycle 4 (table). The percentage of pts dose reduced due to ≥ 1 Tx-related toxicity were 18%, 17%, 47%, and 28% in arms A-D. The median cycles at which DRs occurred were 7, 5, 4, and 3, respectively. Np and SN were the most common toxicities leading to DRs.
Conclusions: Although it is a small sample size phase II study, it strongly suggested that cisplatin-contained TP regimen improved patient outcome, as measured by ORR, CBR, PFS and OS, compared with non-cisplatin-based TX regimen in the first-line treatment of advanced TNBC patients. This is the first prospective study to show superiority of cisplatin over capecitabine in TNBC. Together with additional ongoing clinical trials comparing platinum with other chemotherapeutic agents in various settings, the role of platinum in TNBC can be further elucidated.

P5-19-05
Age-Related Changes in the Pharmacokinetics (pK), Response, and Toxicity of Weekly nab-Paclitaxel in Patients with Metastatic Breast Cancer (MBC).

Background: Although cancer is a disease of aging, few studies have evaluated the association between patient age and the pK or pharmacodynamics (pD) of cancer therapeutics. The goals of this study were 1) to evaluate the age-related changes in the pK and pD of weekly nab-paclitaxel in patients with MBC, 2) to determine response rate; and 3) to explore the relationship of age with pK and pD parameters (i.e., dose reductions, dose delays and grade ≥ 3 toxicities).

Patients and Methods: Forty patients with MBC, receiving 1st or 2nd-line chemotherapy, entered an IRB approved protocol to evaluate the age-related changes in the pK of nab-paclitaxel administered at 100 mg/m² IV for 3 weeks followed by a 1-week break. Patients were accrued from 4 age strata <50, 50-60, 60-70, and >70 years of age. Blood samples were collected for pK analysis with the first dose of nab-paclitaxel administered.

Results: Of the 40 patients who entered the study, 39 (98%) were evaluable with a mean age of 60 (SD=13.4; min=30; max=81). Patients were accrued in the following age cohorts: <50 (n=10; 26%), 50-60 (n=5; 13%), 60-70 (n=15; 38%), and >70 (n=9; 23%) years of age. The median number of courses completed was 4 (min=1, max=21). The response rate was: 0% (n=0) CR, 31% (n=12) PR, 38% (n=15) SD. Grade 3 toxicity was experienced by 26% (n=10). We observed 8% (n=3) grade 3 hematological toxicities [neutrophils (n=1; 3%), leukocytes (n=2; 5%)] and 18% (n=7) grade 3 non-hematological toxicities [nausea and hypophosphatemia (n=1; 3%), diarrhea and infection without neutropenia (n=1; 3%), fatigue (n=2; 5%), hyponatremia (n=1; 3%), and infections without neutropenia (n=2; 5%)]. There were no cases of grade 4 or 5 toxicity. Grade 2 sensory neuropathy was experienced by 8% (n=3; no cases in the 70+ age cohort). Dose reductions or course delays were experienced by 62% (n=24) and 21% (n=8), respectively. There was a borderline significant positive association between age and natural logarithm of

P-values: P<0.05; C=control group; T=treatment group; OS=overall survival; PFS=progression free survival; ORR=overall response rate; CBR=clinical benefit rate; PFS=progression free survival; OS=overall survival; ORR=overall response rate; CBR=clinical benefit rate; 5-week nab-paclitaxel regimen.
Background: Triple-negative breast cancer (TNBC) contributes to poor prognosis and there is no established standard chemotherapy this subtype of patients. It has been postulated that related cancers would confer sensitivity to certain cytotoxic agents like cisplatin. Cisplatin and gemcitabine have single-agent activity in metastatic breast cancer and preclinical data support synergy of the combination. The objective of this study was to evaluate doublet with gemcitabine/Cisplatin (GP) as first-line therapy in patients with metastatic TNBC.

Material and Methods: This is a prospective single-institutional, open-label, phase II trial. The primary endpoint was progression free survival (PFS). Eligible subjects were aging from 18 to 75 years old, with no prior chemotherpay for MBC, with tumors negative for ER, PR or HER2, with at least one measurable disease according to the RECIST criteria, with EOCG PS of 0-1, and with adequate organ function. All patients received 21-day cycles of gemcitabine 1,000mg/m² on days 1 and 8 and cisplatin 25 mg/m² on days 1 through 3. Treatment was continued until disease progression or unacceptable toxicity or up to 8 cycles. (ClinicalTrials.gov number, NCT00601159)

Results: A median age was 49 years (range: 29-74 years). 58 patients had received neo/adjuvant chemotherapy (53 patients with anthracycline and/or taxane). The median number of treatment cycles was six (range: 2-8 cycles). In 64 assessable patients, we observed 10 complete response (CR; 15.6%), 30 partial responses (PR; 46.9%), 17 patients (26.6%) with stable disease (SD), and 7 patients (10.9%) with progressive disease, for an overall response rate of 62.5% (95% CI, 50.3% to 74.7%). The median PFS was 7.7 months (95% CI, 6.0 to 9.4). With a median follow-up time of 28 months, the median overall survival was 19.1 months (95% CI, 12.5 to 25.7). Grade 3 or 4 toxicities were neutropenia 42.2%, thrombocytopenia 29.7%, anemia 18.8%, nausea/vomiting 15.6%, fatigue 14.1%, constipation 3%, sensory neuropathy 1.6%, 2 patients developed febrile neutropenia. The chemotherapy doses were reduced in 13.3% (6 pts) because of toxicity. There were no treatment-related deaths.

Conclusion: Significant activity and favorable toxicity profile of GP regimen as first-line chemotherapy in patients with metastatic TNBC. It provided a basis for considering GP for further evaluation in phase III trials for women with metastatic TNBC in China. (ClinicalTrials.gov number, NCT01287624)
Median age: 55 years (range 23–90). Most pts were Caucasian (81%) with ECOG PS of 0 (55%). Baseline demographics were balanced across treatment lines. Data on A/T treatment history were available for 719 pts; 557 pts received prior A/T therapy, 176 were A-refractory, 234 T-refractory and 154 A- and T-refractory. Pooled overall response rate (ORR) was 21.0% (1.7% complete; 19.3% partial). ORR was 25.0% and 19.0% for pts treated in the 1st- and 2nd-line settings (OR 0.70, 95% CI: 0.5–1.0; p=0.0486). Median PFS was 126.9 days (95% CI: 119–132) in the pooled analysis, and significantly longer in pts receiving 1st- vs ≥2nd-line C: 150.0 vs 112.0 days (HR 1.45, 95% CI: 1.23–1.71; p<0.0001). Pooled median OS was 482.1 days (95% CI: 438–516). Significantly longer median OS was seen in pts receiving 1st- vs ≥2nd-line C: 666.0 vs 396.0 days (HR 1.98, 95% CI: 1.62–2.41; p<0.0001). 62 pts (8%) withdrew due to C-related AEs, which were severe in 4% of pts and life threatening in 2%. AEs of special interest occurred in 489 pts (63%); these were severe in 24% of pts and life threatening in 2%. Gastrointestinal disorders were most frequent (417 pts [53%]), and were severe or life threatening in 13% and 1% of pts.

Conclusions: This pooled analysis of pt data (n=805) revealed significantly longer ORR/survival in pts receiving 1st- vs ≥2nd-line C for A-/T-pretreated MBC. Univariate and multivariate analyses are ongoing; results will be presented. Safety data were in-line with findings from phase III trials of C in MBC.

### P5-19-09

**Phase II Trial of Ixabepilone Plus Carboplatin in Patients with Metastatic Breast Cancer: The ECLIPSE Study.**

*Osborne C, Challagulla JD, Fanning SR, Eisenbeis CF, Holmes FA, Monaghan GG, Neubauer MA, Rabe AC, Raja V, Robbins GJ, Taboada C, Vikela SJ, Wilks SF, Wang Y, Brown J-A, Asmar L, O’Sheaughnessy J. US Oncology, The Woodlands, TX; Baylor-Sammons Cancer Center; Dallas, TX; Texas Oncology, Witchita Falls, KS; Cancer Centers of The Carolinas, Greensboro, SC; Cancer Centers of North Carolina, Raleigh, NC; Texas Oncology-Houston Memorial City, Houston, TX; Texas City Cancer Center, Kansas City, MO; Kansas City Cancer Center-Southwest, Overland Park, KS; Kansas City Cancer Center, Kansas City, KS; Florida Cancer Institute-New Hope, New Port Richey, FL; Texas Oncology-Methodist Charlton Cancer Center, Dallas, TX; Texas Oncology-Tyler, Tyler, TX; Cancer Centers of South Texas, San Antonio, TX*

**Introduction:** Ixabepilone adds to the antitumor effectiveness of capecitabine in both ER+ and triple negative (TN) breast cancer. Ixabepilone has antitumor activity in taxane-refractory patients, and novel combinations are needed in this poor prognosis population. Carboplatin combined with gemcitabine or paclitaxel has activity in metastatic breast cancer; there is also demonstrated activity of the gemcitabine/carboplatin combination in the ER+ versus TN subsets. A Phase I study of ixabepilone + carboplatin in solid tumor patients demonstrated the safety of this combination.1 We conducted a Phase II trial of ixabepilone + carboplatin at the doses and schedule used in the Phase I trial to determine its effectiveness in hormone receptor positive (HR+) and TN patients.

**Methods:** This was a Phase II, open label, nonrandomized parallel, noncomparative study of 2 groups. Patients could have received up to 2 lines of treatment for metastatic disease. All patients received ixabepilone 20 mg/m² on Days 1 and 8 and carboplatin AUC=2.5 on Days 1 and 8 of each 21-day cycle. Patients were stratified as either (HR+) (n=50) or (TN) ER−/PR−/HER2− (n=53). Patients received drug until PD or intolerable toxicity. Patients continued treatment for as long as they responded (CR, PR, or SD). The primary objective was to evaluate objective response rate (ORR). Secondary objectives included evaluation of clinical benefit rate (CBR) defined as ORR (CR+PR)+SD≥6 months, progression-free survival (PFS), overall survival (OS), duration of responses, and toxicity.

**Results:** Based on preliminary data, 96 patients (55 [57.3%] HR+ and 40 [41.7%] TN) received study treatment, with 1 patient found ineligible. Median age was 55.2 years; all were females; baseline PS of 0/1/2 was 50/44/2; stage at diagnosis I/II/III/IV/unknown was 12/38/21/2/1, respectively. PR was 26.3% overall. There were no CRs. CBR overall was 41.1% (39), 52.7% (29) for HR+ patients, and 25.6% (10) for TN patients. Median PFS was 7.6 months, and median OS was 12.7 months. The median time to response and duration of response in patients achieving a PR was 1.7 and 6.5 months, respectively. Grade 3/4 hematological toxicities included 49% neutropenia, 10.4% anemia, and 4.2% thrombocytopenia. The most common grade 3/4 non-hematologic toxicities included fatigue (8.3%), nausea (6.3%), neuropathy (6.3%), vomiting (5.2%), and dehydration (5.2%). Of 32 deaths during the study, one was due to neutropenic sepsis, and 25 were due to PD.

**Conclusion:** The combination of ixabepilone plus carboplatin was a tolerable and active regimen for both HR+ and TN breast cancer. In general, it had expected hematologic and manageable non-hematologic toxicities. Further follow-up of the remaining 12 patients still on treatment is ongoing. 1. Plummer R, et al. Clin Cancer Res. 2008 Dec 15;14(24):8288-8294.

### P5-19-10

**Correlation of Response of Weekly Paclitaxel and Paraplatin as First Line Treatment of Metastatic Breast Cancer with p53 Status.**

*El-Sadda W, Magdy M, Abdel-Halim I, Abdel-Wahab A. Mansoura University Hospital, Mansoura, Egypt*

**Background:** Paclitaxel is one of the most active drugs in metastatic breast cancer. Weekly paclitaxel seems less toxic & more efficient compared with paclitaxel every 3 weeks (possibly because of the proapoptotic and antiangiogenic activity), the dose intensity is quiet higher with tolerable toxicity. The sensitivity of tumors overexpressing p53 to paclitaxel is a matter of debate.

The purpose of study is to evaluate weekly paclitaxel and paraplatin in patients with metastatic breast cancer in terms of response rate, toxicity profile, relation of response to p53 status, progression free survival & overall survival.

**Patients & Methods:** Between September 2006 & September 2008, 60 patients with measurable metastatic breast cancer after adjuvant anthracycline treatment, WHO PS <2, adequate renal, liver & bone marrow function. Patients received no prior chemotherapy for metastasis. Pathology specimens were evaluated for p53 status by immunohistochemistry (IHC). All patients received weekly paclitaxel 80 mg/m2 D1, D8, D15 (one hour IV infusion) and paraplatin AUC 5 D1 (IV infusion over
Tesetaxel, an Oral Taxane, as First-Line Therapy for Women with Metastatic Breast Cancer.

Schwartzberg L, Rubin P, Patnaik A, Itri L, Olson AL, Seidman AD. The West Clinic, Memphis, TN; The Moses H. Cone Regional Cancer Center, Greensboro, NC; START Center - South Texas Accelerated Research Therapeutics, San Antonio, TX; Genta Incorporated, Berkeley Heights, NJ; Memorial Sloan-Kettering Cancer Center, New York, NY

Background: Parenteral taxanes (docetaxel, paclitaxel) are among the most active agents in treating metastatic breast cancer (MBC). However, their use is limited by inherent or acquired multidrug resistance, hypersensitivity, and neurotoxicity. Tesetaxel is an advanced-generation, orally available taxane that is formulated as a capsule for oral administration and has a long terminal half-life in plasma (~180 hrs). Unlike standard taxanes, tesetaxel is not a substrate for P-glycoprotein (P-gp), a major cause of taxane resistance. The drug is highly concentrated in cells that overexpress P-gp. In taxane-resistant breast cancer xenografts (DU4475), tesetaxel induced a 94% reduction in tumor size, substantially exceeding the activity of docetaxel and paclitaxel (46% and 26%, respectively). Neurotoxicity was also substantially lower with tesetaxel compared with equivalent doses of docetaxel. Among more than 350 patients (pts), there have been no occurrences of hypersensitivity reactions. An initial phase 2 study as 2nd-line therapy for pts with MBC who progressed after multidrug anthracycline-containing regimens showed a 38% partial response (PR) rate using tesetaxel Q3 wks at a dose of 27-35 mg/m². We conducted a Phase 2, open-label, multicenter study of the efficacy and safety of tesetaxel as first-line therapy in women with MBC.

Methods: Eligible pts have Stage IV, HER2-negative MBC; ECOG PS 0-1; and adequate organ function. No prior chemotherapy is allowed (other than 1 regimen in the adjuvant setting). Tesetaxel was administered orally Q3 wks at a starting dose of 27 mg/m² with escalation to 35 mg/m² as tolerated. No premedication for potential hypersensitivity was used. RECIST response rate was the primary endpoint. A Simon min-max two-stage design was used with a target response rate of 30% in 25 pts.

Results: To date, 20 women have been enrolled and treated. The median age was 62 years (range, 45-78). Time from diagnosis was > 4 years in 5 pts and ≤ 4 years in 6; MBC was newly diagnosed in the remaining 9. Hormone receptor status was triple negative in 5 pts at diagnosis and 10 at the time of metastasis. The most common sites of metastases were lung (13 pts) and bone (9). Prior treatment included hormonal therapy in 13 pts, adjuvant chemotherapy in 16 (most commonly, ACT), and radiotherapy in 9. Of 11 pts currently evaluable for response, PR was achieved in 6 (55%), with confirmation of response in 4 and an ongoing PR in 1 of the 2 pts with an unconfirmed PR. SD was observed in 2 and disease progression in 3. Neutropenia was the most common adverse event, affecting 50% of pts; Grade 3-4 neutropenia occurred in 13.3%, G2 neuropathy occurred in 15%. Median time to progression & median survival were 18.5 & 28 months respectively.

Conclusions: The overall response rate achieved with weekly paclitaxel plus paraplatin is among the highest in metastatic breast cancer. However, the poor response rate seen in patients with p53 overexpression for response, PR was achieved in 6 (55%), with confirmation of response in 4 and an ongoing PR in 1 of the 2 pts with an unconfirmed PR. SD was observed in 2 and disease progression in 3. Neutropenia was the most common adverse event, affecting 50% of pts; Grade 3-4 neutropenia occurred in 13.3%, G2 neuropathy occurred in 15%. Median time to progression & median survival were 18.5 & 28 months respectively.

P5-19-12

Integration of Capecitabine Monotherapy with Capecitabine Combination Therapy in Metastatic Breast Cancer Patients: First Report on Safety and Efficacy of Single Agent Capecitabine Maintenance Study.

Xu B, Wang J, Yuan P, Ma F, Li Q, Zhang P, Fan Y, Li Q. Cancer Hospital Chinese Academy of Medical Sciences, Beijing, China

Background: Giving the high degree of efficacy and safety profile, Docetaxel/Paclitaxel in combination with Capecitabine are indicated as 1st line standard chemotherapy for anthracycline pretreated or resistant metastatic breast cancer (MBC) patients. Maintenance chemotherapy is chemotherapy administered to patients without progression after an initial chemotherapy, generally as 1st line treatment. Unfortunately, no clinical studies has prospectively evaluated the efficacy and safety of capecitabine single agent maintenance in MBC. Methods: Previously untreated patients with metastatic breast cancer (MBC) were randomly assigned to receive Capecitabine 1,000 mg/m² orally twice daily on day 1-14, Vinorbinb 25 mg/m² on day 1 and 8 (NX) in 21-day cycle or Capecitabine 1,000 mg/m² orally twice daily on day 1-14, Docetaxel 75 mg/m² on day 1 (TX), in 21-day cycle. The primary endpoint was to compare progression free survival (PFS), second endpoints were safety profiles (NCI-CTC 3.0), overall survival and response rate. During Initial study treatment, 21 days as one cycle and 6-8 cycles are required; Patients who were responding (complete or partial), or whose diseases were stable followed by Capecitabine: 1,000 mg/m² PO twice daily (day 1-14) 21 days as one cycle until progression or unacceptable toxicity. This was designed as a non-inferiority study. The efficacy analysis was based on the intent-to-treat population (all patients randomized and received at least one dose of test drug). Safety was assessed on the safety population who received at least one dose of study medication. Results: Ninety one women were enrolled in fourteen months. Fifty six patients were treated with TX and 35 with NX. The median PFS was 7 (NX) versus 9 months(NX) (P=0.1888). According to RECIST criteria, similar objective response rates (19(54.2%) on TX versus 28(50%) on NX, P= 0.158)
clinical benefit (CR+PR+SD) [29(82.9%) on TX versus 48(85.7%) on NX, P=0.216] were achieved. The main adverse events included grade 3-4 neutropenia (40.0% versus 30.4%; P=0.115), hand-foot syndrome (2.8% versus 12.5%; P=0.006), grade 2-3 gastrointestinal adverse events (37.2% versus 19.7%; P=0.037), myalgia and arthralgia (2.9% versus 5.4%; P=0.363), with NX and TX, respectively. 2.8% versus 12.5% were discontinued treatment for toxicity with NX and TX(P=0.092). Numbers of patients transferred into maintenance treatment with Cepacitabine were 22(70.9%) versus 36(64.3%) in NX and TX arm respectively. 13.6% versus 13.9%(P=0.303) of the patients were discontinued treatment for toxicity with NX and TX respectively. The main toxicity in maintenance phase was grade 2-3 hand-foot syndrome. The median cycles of maintenance treatment was 4 cycles, 4 patients received Cepacitabine maintenance treatment for more than 12 cycles. Discussion: There are few clinical study to compare the two regimens, especially with Cepacitabine maintenance treatment. Our preliminary study found that NX and TX regimen have similar efficacy but different toxicity. Both regimen can be used as front-line treatment of MBC.

P5-19-13
A Randomized Phase II Trial of First-Line Metastatic Breast Cancer (MBC) Patients: Sub-Set Analysis of Albumin-Bound Paclitaxel (ab-pac) Given Weekly at 150 mg/m².

Gradishar WJ, Krasnojon D, Cheporov S, Makhson AN, Manikhas GM, Clawson A, Bhar P. Northwestern University Feinberg School of Medicine, Chicago, IL; Leningrad Regional Oncology Center, Russian Federation; Yaroslavl Regional Clinical Oncology Hospital, Yaroslavl, Russian Federation; City Oncology Hospital, Russian Federation; St. Petersburg City Oncology Center, St. Petersburg, Russian Federation; Celsegne Corporation, Summit, NJ

Background: We previously reported the results of a phase II study evaluating the efficacy and safety of 3 different dosing regimens of ab-pac and docetaxel for the first-line treatment of MBC (Gradishar et al. J Clin Oncol. 2009;27:3611). Here we report outcomes for a subset of patients (pts) during treatment with ab-pac at 150 mg/m² weekly for the first 3 weeks of a 4-week schedule (qw 3/4). Methods: Patients (N = 300) with previously untreated MBC were randomized to 1 of 4 treatment arms: arm A, ab-pac at 300 mg/m² qw3; arm B, ab-pac at 100 mg/m² qw 3/4; arm C, ab-pac at 150 mg/m² qw 3/4; arm D, docetaxel at 100 mg/m² qw3. A step-down statistical approach was used for pairwise comparisons of treatment groups. The trial was powered for antitumor activity and safety. Results: Treatment arm C produced the longest overall survival (OS) (33.8 months) with an 11.6-month longer median OS vs arm B (22.2 months, HR 0.575; P=.008) and a 7.2-month longer median OS vs arm D (26.6 months, HR 0.688; P not statistically significant). Median OS in arm A was 27.7 months. These OS data were consistent with previously published overall response rates (ORR) and progression-free survival (PFS). Forty-seven percent of pts in arm C required dose reduction due to toxicity, including 27% due to neutropenia (np), 15% due to sensory neuropathy (SN), 3% due to allergy/immunology, 1% due to febrile np, and 1% due to ulceration of the skin. The median OS for the subset of pts requiring DRs in arm C was comparable to pts not dose reduced: 35.2 and 31.8, respectively. Pts who were dose reduced in arm C received a median of 2 additional cycles of treatment compared with those without DRs: 10 (range 2 – 27) vs 8 (range 1 – 27). Investigator assessed ORR and PFS were numerically higher in pts dose reduced vs those not reduced. Baseline characteristics were similar between pts requiring DRs vs not.

P5-19-14
Platinum-Based Chemotherapy in Triple-Negative Breast Cancer. Villarreal-Garza C, Bouganim N, Khalaf D, Clemons M, Kassam F, Enright K, Verma S, Myers J, Dent R. Sunnybrook Odette Cancer Centre, Toronto, ON, Canada; The Ottawa Hospital Cancer Centre, Ottawa, ON, Canada; Princess Margaret Hospital, Toronto, ON; Credit Valley Hospital, Mississauga, ON, Canada

Background: There is increasing evidence that DNA repair defects characteristic of BRCA1-related cancers and triple negative breast cancer (TNBC) confer sensitivity to certain chemotherapeutic agents, such as platinum. However, prospective and retrospective studies comparing the efficacy of these agents versus conventional treatment in TNBC are lacking. The aim of this study was to evaluate the efficacy of platinum-based chemotherapy (PBC) in metastatic TNBC in terms of median duration of treatment and overall-survival (OS) and compare it to patients treated with conventional chemotherapy. Methods: We performed a retrospective chart review of patients with metastatic TNBC who received PBC from January 2007 to June 2010 treated at the Sunnybrook Odette Cancer Center and the Ottawa Hospital Cancer Centre. This cohort was compared to a control group that included metastatic TNBC treated with conventional agents that included anthracyclines, taxanes, capecitabine, and vinorelbine. Results: A total of 166 metastatic TNBC patients were analyzed: 60 treated with PBC and 106 managed with conventional treatment. Median age at diagnosis was 48 years and distant disease-free interval was 26 months (m) for both groups. Patients on both groups had multiple sites of metastases at diagnosis of recurrence than a single site of metastasis (69% for both groups). Of the 60 patients treated with PBC, 90% received a combination regimen, most commonly weekly cisplatin plus gemcitabine in 37% of patients and cisplatin plus vinorelbine in 17% of patients. The median number of cycles delivered was 4 (1-24). 33% received the PBC as first-line treatment, 38% as second-line, 18% as third-line, 7% as fourth line, and 3% as fifth-line. Only 8 patients (5%) discontinued PBC secondary to toxicity. The median time on treatment in first, second and third-line therapy was longer for the PBC group compared to the conventional

OS in months, median 35.2 31.8
Pts on secondary therapies, n (%) 31 (89) 26 (67)

Safety
Neutropenia, n (%) Grade 3 13 (34) 8 (24)
Neutropenia, n (%) Grade 4 1 (3) 1 (3)

group (5 vs. 2 m, p=0.108; 5 vs. 2 m, p=0.01; and 4 vs. 1 m, p=0.026). Patients treated with PBC had a longer OS compared to those managed conventionally (16 vs. 10 m, p=0.039).

Conclusions:
PBC appears to improve clinical outcomes in patients with metastatic TNBC compared to those treated with conventional chemotherapy regimens. Although this is a retrospective study with its obvious limitations, it adds to the growing body of literature, suggesting the benefit of PBC in TNBC. Prospective trials are needed to confirm its benefit in order to integrate it as part of the routine management of these patients.

P5-20-01
Patient Valuation of Reduced Risk of Side Effects during Treatment for Metastatic Breast Cancer.
Lalla D, McLaughlin T, Brammer M, Bramley T, Bare A, Carlton R. Genentech Inc., S San Francisco, CA; Xcenda, Palm Harbor, FL

Background: Chemotherapy treatment for metastatic breast cancer (MBC) has shown significant benefits in survival for breast cancer patients. However, chemotherapy is associated with several side effects that have a significant impact on patients’ quality of life. The objective of this analysis was to quantify the value patients with MBC place on reduced risk of treatment side effects.

Methods: A willingness to pay (WTP) survey was developed to assess metastatic breast cancer patients’ willingness to pay for a reduction in the risk of breast cancer treatment side effects. The survey assessed patients’ WTP for a 25%, 50% and 100% reduction in the risk of all side effects. Patients were also asked to select the side effect they would pay the most to avoid. Additionally, the survey collected demographic information such as treatment regimen, age, race/ethnicity, region, employment status, and insurance type.

Results: The survey was completed by 202 metastatic breast cancer patients. Most survey respondents were white (94%), married (62%), and over the age of 51 (78%). Most patients were covered by private insurance (67%) or Medicare (24%). Of the 58% of respondents who remembered paying out of pocket for their last treatment, the average out of pocket payment was $459. Survey respondents were willing to pay an extra $1,886, $3,837 and $7,794 for a 25%, 50% and 100% reduction in the risk of all side effects, respectively. Hair loss (28%), pain (17%) and nausea (15%) were selected most often as the side effect they would pay the most to avoid.

Discussion: Chemotherapy for MBC is associated with several adverse events that patients would like to avoid or reduce such as hair loss, pain, nausea and neutropenia. This analysis demonstrates patients with MBC place a significant value on reducing the risk of side effects and are willing to pay 4.2 times for a treatment devoid of side effects as compared to a treatment with a 25% reduction in the risk of treatment side effects.

P5-20-02
N-Terminal Pro-Brain B-Type Natriuretic Peptide (nt-pro-BNP) before and during Treatment with Trastuzumab Allows Early Detection of Cardiotoxicity in Breast Cancer Patients.
Blancois I, Carrillo J, Legérén M, Delgado M, Jurado JM, Zarcos I, Villaescusa A, Gómez FJ, Moreno E, Garcia-Puche JL. Hospital Clínico San Cecilio, Granada, Spain; University of Granada, Granada, Spain

Background: The treatment with Trastuzumab (T) is associated with a certain degree of cardiotoxicity. This study sought to evaluate the level of nt-pro-BNP as a possible marker of cardiotoxicity so accurate as the value of left ventricular ejection fraction (LVEF)

Patients and methods: Forty patients with breast cancer treated with T were prospectively measured LVFE with echocardiography and nt-pro-BNP level before and every 3 months during T treatment. Median age: 50years(27-70). Received T as adjuvant treatment: 82.5% of the patients and 17.5% for metastatic disease. Patients with previous chemotherapy: 13(32.5%),neoadjuvant, 23(57.5%)adjuvant and 7(17.5%) for metastatic disease. Patients with previous treatment with anthracyclines: 12(30%)neoadjuvant, 21(52.5%)adjuvant and 2(5%) for metastatic disease(one patient had received anthracyclines too during adjuvant treatment).None received anthracyclines and T concomitant. Chi-square analyzed the correlation of high pathological level of nt-pro-BNP (values over the normal range,adjusted by the patient age) and a significative decrease of LVEF (more than 10% when LVEF >50% or more than 5% when LVEF<50%).

Results: A decrease in LVEF was observed in 6 patients(15%) and pathological high levels of nt-pro-BNP in 7(17.5%).Two patients(5%) presented cardiac insufficiency with clinical symptoms, in both nt-pro-BNP was higher than 600pg/ml and LVEF lower than 40%. In the other patients the decreases of LVEF (never >40%) or high levels of nt-proBNP (never >600pg/ml) were not related to any clinical symptoms. Chi-square analysis showed a correlation between pathological high levels of nt-pro-BNP and significative decrease of LVEF (p=0.001). The estimated risk of a false negative nt-pro-BNP result (nt-pro-BNP normal value and significative LVEF decrease) was 2.735% (95% confidence interval: 0.878 to 8.522 %) and the estimated risk of a false positive nt-pro-BNP result (nt-pro-BNP pathological value and no significative LVEF decrease) was 0.132%(95% confidence interval: 0.39 to 0.448%)

Conclusion:The level of nt-pro-BNP is a possible marker of cardiotoxicity so accurate as the value of LVEF in patients with breast cancer treated with T.

P5-20-03
Kaderer NM, Cuklakova E, Poniewierski MS, Crawford J, Dale D, Lyman GH. Duke University; Durham, NC; University of Washington, Seattle, WA

Background: Neutropenic complications including severe and febrile neutropenia (FN) represent major dose-limiting toxicities of cancer chemotherapy. A general risk model for neutropenic complications across major solid tumors has been developed and validated (Lyman et al. Cancer 2011). Current guidelines recommend consideration of primary prophylaxis with a colony-stimulating factor (CSF) in patients at >20% risk of FN. The decision for primary CSF prophylaxis in patients on intermediate risk chemotherapy (10-20%) is based on physician assessment of individual patient risk factors for FN. This study assesses the ability of this general FN risk model to identify ESBC patients on intermediate risk chemotherapy who are at a personal high risk for developing a neutropenic complication.

Methods: A prospective cohort study accrued 4458 consenting patients starting a new chemotherapy regimen at 115 randomly selected community oncology practices throughout the United States from 2002-2006. The risk of severe or febrile neutropenia (SNFN) in cycle 1 and across 4 cycles was estimated [±95% CI] utilizing logistic regression analysis and adjusting for key clinical factors including among others: age, prior chemotherapy, abnormal hepatic or renal function, low pretreatment white blood count, immunosuppressive medications, CSF prophylaxis, and planned relative dose intensity.
as well as major chemotherapeutic agents. The cumulative risk of FN across 4 cycles was also estimated by the product limit method of Kaplan and Meier.

Results: Among 1224 patients with ESBC, 822 received intermediate risk chemotherapy based on National Comprehensive Cancer Network guidelines. Among these patients, cycle 1 SNFN occurred in 37%, at least one episode of FN over 4 cycles of chemotherapy in 17%, with 15% receiving primary CSF prophylaxis. The predicted risk of cycle 1 SNFN ranged from 1%-79%, with mean (median) risk of 33.8% (39.0%). Model performance was good with a c-statistic of 0.73 [0.69-0.76]. Based on this general FN risk model, cycle 1 SNFN occurred in 47% of predicted high risk ESBC patients [42 - 52%] compared to 13% [8-17%] of low risk patients. One or more FN events over 4 cycles occurred in 20% [17-24%] of predicted high risk versus 10% [6-14%] in low risk patients. The cumulative risk of FN by Kaplan-Meier estimation was 23% in high risk and 10% in low risk patients. Model sensitivity and specificity for FN were 83% and 33%, respectively. The majority of SNFN (76%) and FN (58%) events among high risk patients occurred in cycle 1. 50% of high risk patients who did not receive primary CSF prophylaxis went on to receive CSF during subsequent cycles.

Conclusions: Based on good test performance characteristics, this clinical FN prediction model also identifies ESBC patients receiving intermediate risk chemotherapy at high personal risk for FN (FN >20%) over the first 4 cycles of chemotherapy. Half of predicted high risk patients without primary CSF prophylaxis will be given CSF in subsequent cycles after the occurrence of a neutropenic complication. This also confirms previous clinical trial findings that the majority of febrile neutropenic events occur in the first cycle.

**P5-20-04**

Younis T, Rayson D, Thompson K. Dalhousie University at the Queen Elizabeth II Health Sciences Centre, Halifax, NS, Canada

**Background:** Adjuvant chemotherapeutic regimens incorporating docetaxel, including TC (taxotere 75 mg/m²; cyclophosphamide 600 mg/m² q 3 weekly for 4 cycles) and FEC-D (5-flououracil 500 mg/m²; epirubicin 100 mg/m²; cyclophosphamide 500 mg/m² q 3 weekly for 3 cycles followed by docetaxel 100 mg/m² q 3 weekly for 3 cycles), appear to be associated with rates of febrile neutropenia (FN) in routine clinical practice that are higher than those reported in the pivotal clinical trials (7-33% vs. 11% & 18-35% vs. 5%, respectively). Although primary prophylaxis with G-CSF (granulocyte colony-stimulating factor) is indicated for chemotherapeutic regimens associated with rates of FN >20%, the variable FN rates reported with TC and FEC-D outside of clinical trials have precluded definitive recommendations for G-CSF primary prophylaxis in most jurisdictions. A systematic review and meta-analysis was therefore conducted to assess; i) FN rates associated with TC and FEC-D without and with G-CSF primary prophylaxis outside of clinical trial settings, and ii) the potential impact of G-CSF prophylaxis on FN prevention.

**Methods:** A PubMed search was conducted and major conference abstracts were reviewed up to June 15th 2011 to identify all English language reports of FN rates associated with adjuvant TC or FEC-D outside of clinical trial settings. FN rates with and/or without G-CSF prophylaxis were abstracted, and LOS (length of stay in hospital) and mortality following FN were noted. Summary incidences and odds ratios (OR) with 95% confidence intervals (95%CI) were calculated using random- and fixed-effects models.

**Results:** A total of 902 patients treated with TC (average age 55 years, range 27-84, 19% ≥ 65 years) and 1342 treated with FEC-D (average age 52 years, range 24-78, 9% ≥ 65 years) from 13 and 9 relevant studies respectively, were included. Overall FN rates of 17% (range: 7-33%) and 24% (range: 18-35%) were reported for TC and FEC-D, with an average primary G-CSF utilization rate of 47% and 30%, respectively. For TC, the pooled random-effects meta-analysis estimates of FN rates were 7% (95%CI: 5-10%) with primary G-CSF and 29% (95%CI: 24-35%) without G-CSF (OR=0.17, 95%CI: 0.09-0.33). For FEC-D, the FN rates were 9% (95%CI: 4-19%) with and 31% (95%CI: 27-35%) without primary prophylaxis (OR=0.22, 95%CI: 0.09-0.56). For FEC-D, 50% of the FN events occurred during the 1st D cycle and 65% overall occurred during D treatments. Older age (≥ 65 years) did not appear to correlate with higher FN rates. Breakthrough FN occurred in 5% across both regimens despite G-CSF secondary prophylaxis. FN was associated with 3.7 and 4.0 LOS days and 0% and 2% mortality during TC and FEC-D, respectively.

**Conclusions:** TC and FEC-D with or without G-CSF are associated with unacceptably high FN rates in routine clinical practice. Primary prophylaxis with G-CSF should be considered for adjuvant TC chemotherapy, and for the D-component of FEC-D regimen, irrespective of patient age.

**P5-20-05**

Peripheral Blood Transcriptomics and Doxorubicin Cardiotoxicity.

Todorova VK, Beggs ML, Dhakal IB, Henningis LJ, Makhoul I, Klimberg VS. University of Arkansas for Medical Sciences, Little Rock, AR

**Background:** Doxorubicin (DOX) cardiotoxicity is dose-dependent and unpredictable. Currently, the clinical methods used for detection of pre-symptomatic DOX-induced cardiotoxicity show low diagnostic sensitivity and identify the existing cardiomyopathy rather than prevent it. It has been reported that DOX cardiomyopathy can occur at low doses, suggesting the presence of increased phenotypic sensitivity by some individuals. Studies have found specific gene expression signatures of circulating blood cells in response to physiological and pathological changes, suggesting that they can be used as biosensors for diagnostic purposes. This study aimed to characterize the peripheral blood mononuclear cells (PBMC) gene expression profile associated with DOX-induced cardiotoxicity with an ultimate goal to identify biomarkers for early prediction of DOX cardiotoxicity.

**Materials and Methods:** Twenty Sprague Dawley rats were randomized into 2 groups: DOX-treated (n=12) and controls (n=8). DOX-treated rats received a single intraperitoneal dose of 12 mg/kg DOX (similar to 65mg/m² for humans) and the controls were injected with saline. All rats were sacrificed 48 hours after DOX administration and blood, and samples from the heart left ventricle (LV) were collected. Histopathological alterations were evaluated microscopically. RNAs was isolated from cardiac LV and PBMCs. Cardiac and PBMC genome-wide expression profiling were performed using illumina Rat Ref-12 BeadChip microarrays. For statistical analysis the raw data were log, transformed and median normalized. The differential analysis per gene was performed using a 2-sample (control vs. DOX-treated) Student’s t-test. Statistical significance was set at false discovery rate (FDR)<0.05. Differentially expressed genes were mapped to known metabolic/signaling pathways using MetaCore GENEGO software.

**Results:** A total of 1406 transcripts were differentially expressed in the hearts (247 upregulated and 1159 downregulated) and 1526 in PBMCs (271 upregulated and 1255 downregulated) between DOX-treated rats and control rats. Of these 1237 genes (92%) were similarly differentially regulated (179 upregulated and 1058 downregulated) both in the hearts and PBMCs. Fifty metabolic/signaling pathways
were significantly affected by DOX-treatment. The top ten of these include oxidative phosphorylation; cell proliferation and differentiation; TGF, WNT and cytoskeletal remodeling; insulin signaling; cell adhesion; regulation of amino acid metabolism, cytoskeleton remodeling, PI3K/Akt signaling and CCR5 signaling in macrophages and T lymphocytes.

Discussion: The results from this study showed that PBMC gene expression profile reflected a similar pattern in the hearts of rats treated with DOX and provide a novel and important information about the feasibility of the PBMC as a surrogate marker for DOX cardiotoxicity. The data obtained lay a foundation for further clinical studies to identify the cardiotoxicity risk, predict DOX-treatment response and ultimately to allow the anti-cancer therapy to be tailored to individual patients.

P5-20-06
Survival in Women with Breast Cancer Who Used or Did Not Use Scalp Cooling in the Neoadjuvant/Adjuvant Setting.
Lemieux J, Perron L, Provencher L, Brisson J, Amireault C, Blanchette C, Maunsell E. Centre de Recherche FRSQ du CHA Universitaire de Quebec, Quebec City; QC, Canada; Hôpital du Saint-Sacrement, Quebec City; QC, Canada; Université Laval, Quebec City; QC, Canada; Institut Nationale de Santé Publique, Quebec City; QC, Canada; Université de Montréal, Montreal, QC, Canada

Background: Scalp cooling can prevent chemotherapy-induced alopecia. Success varies according to the type of chemotherapy. A controversy exists regarding the use of scalp cooling because of the lack of safety data. No data are available regarding the impact on survival.

Purpose: To compare overall survival in women who used or did not use scalp cooling in the neoadjuvant/adjuvant setting.

Method: The survival of women treated in a specialized breast cancer centre (the Centre des Maladies du Sein Deschênes-Fabia) in Quebec City who all used scalp cooling was compared to that of a population-based random sample of women treated in other regions of the province of Quebec (Canada) where scalp cooling is not available.

Cox proportional hazard models were used.

Results: Overall, survival was comparable (and possibly better although not at a conventionally statistically significant level: HR = 0.80, 95% CI = 0.63–1.01, p=0.06) among the 553 women who used scalp cooling compared to the 817 who did not. An interaction was found between scalp cooling and treatment in the adjuvant vs. neoadjuvant setting (p-interaction=0.015). In the adjuvant setting (n=485 scalp cooling and 740 no scalp cooling), the crude HR (in favour of scalp cooling) was 0.66 (95% CI: 0.50-0.87, p=0.003). In the neoadjuvant setting (n=68 scalp cooling and 77 no scalp cooling), the HR was 1.40 (95% CI: 0.84-2.33, p=0.2). No interaction was found with stage.

Conclusion: This is the first study to compare survival of women who used scalp cooling to that of women who did not. Scalp cooling to prevent chemotherapy-induced alopecia had no negative effect on survival in women with breast cancer who used it.

P5-20-07

Background: US Oncology Trial 9735 (Jones S, et al. JCO. 2006;24:5381-5387) established the docetaxel plus cyclophosphamide (TC) regimen as an effective adjuvant therapy for early stage breast cancer (ESBC). This trial did not specifically evaluate the incidence of febrile neutropenia (FN) as a study endpoint, but rates of 4%–8% were reported. Prophylactic granulocyte colony-stimulating factor (G-CSF) support was not allowed; reactive G-CSF support overall was not reported. Subsequent reports in the community setting have indicated FN rates of 25%–50% without G-CSF support and 0%–6.3% with G-CSF support (Table 1). To better determine the incidence of FN among ESBC patients treated with TC, we performed a retrospective clinical data review from the electronic medical record (EMR) database of Georgia Cancer Specialists, a large community oncology practice.

Methods: EMR data were captured between January 2006 and March 2010. Eligibility included women ≥ 18 years old with ESBC (stage I–IIIa) who completed ≥ 1 cycle of TC. The study time period was from the first dose of chemotherapy (CTX) to 6 weeks after the last dose of CTX, death, or loss to follow-up. The primary endpoint was the incidence of FN. Other endpoints included the incidence of severe (grade 3/4) neutropenia, neutropenia-related hospitalizations, G-CSF use, relative dose intensity (RDI), and dose delays and reductions.

Results: Data from 662 patients were included in the analysis. Median age was 55 (range: 25–81) years. 40% of patients were white. The median number of CTX cycles received was 4 (range: 1–6). Most patients (91%) received G-CSF support; 73% as primary prophylaxis. See Table 2 for additional results.

Conclusions: This is the largest retrospective, community-based study to evaluate the incidence of FN in ESBC patients treated with TC. The observed FN rate of 5% (with 91% of patients receiving G-CSF) is consistent with other published reports using TC (Table 1). Our results suggest that TC is a taxane regimen with clinically significant myelosuppression (similar to other commonly used regimens in ESBC, such as TAC [NCCN Guidelines v2.2011]) and that the use of G-CSF support should always be considered.

Multicenter Results of Scalp Cooling To Prevent Chemotherapy-Induced Alopecia in 1500 Breast Cancer Patients.
van den Hurk C, Peerbooms M, Komen M, Nortier H, Breed W. Comprehensive Cancer Centre South (IKZ), Eindhoven, Netherlands; Medical Centre Alkmaar, Alkmaar, Netherlands; Leiden University Medical Centre, Leiden, Netherlands

Background
Chemotherapy-induced alopecia (CIA) is a frequent occurring side effect of cancer treatment that has high psychological impact on many patients and their relatives. CIA may be prevented by scalp cooling.

Methods
Breast cancer patients who received scalp cooling could participate in this registration study from 2006 and onwards. Nurses and patients completed questionnaires. Scalp cooling was performed using the Paxman PSC1 or PSC2 system and was considered satisfying when patients did not wear a wig or head cover. Logistic regression analyses will be used to examine determinants of the scalp cooling result, including age, type / length / thickness / chemical manipulation (dyeing, waving, colouring) of hair, type / dose of chemotherapy, cytostatic infusion time, post-infusion cooling time, dampering hair or use of conditioner before scalp cooling and previous treatment with chemotherapy.

Results
The use of scalp cooling increased from 4 hospitals in 2005 to 60 out of 100 Dutch hospitals in 2011. The registration comprised about 1500 scalp cooled breast cancer patients of whom 79% were treated in the adjuvant setting. Overall, patients' satisfaction with the result of scalp cooling was 50%, but varied for different chemotherapy schemes and dosages from 8% in docetaxel 75 mg/m², doxorubicin 50 mg/m², cyclophosphamide 500 mg/m² (TAC) to 81% in paclitaxel 70-90 mg/m². The results of the regression analyses will be presented at the conference.

Discussion
Scalp cooling is effective in most commonly used chemotherapy regimens for breast cancer patients. Therefore, scalp cooling should be offered more often. Efficacy depends on the type and dose of chemotherapy. Other factors influencing the result have never been studied in multivariate analyses before. Scalp cooling is ineffective in patients treated with a combination of a taxane and an anthracyclin. The frequent use of scalp cooling in the adjuvant setting indicates minimal fear for an increased incidence of scalp skin metastases after scalp cooling in breast cancer patients. Multicenter registration of results improves information for medical professionals and patients and will lead to more frequent use of scalp cooling and improvement of the method.

P5-21-02
The Susan G. Komen for the Cure® Tissue Bank at the IU Simon Cancer Center: The Source for Normal Breast Tissue and Biospecimens.
Clare SE, Mathieson T, Henry JE, Zhang H, Way ES, Ridley KE, Badve S, Herbert B-S, Rufenbarger CA, Storniolo AMV. Indiana University School of Medicine, Indianapolis, IN

Background:
Our efforts to prevent and treat breast cancer are significantly impeded by a lack of knowledge of the biology and developmental genetics of the normal mammary gland. This ignorance has been the consequence of the lack of access to richly annotated, high quality normal breast specimens. The Susan G. Komen for the Cure® Tissue Bank at the IU Simon Cancer Center (KTB) was established expressly to remedy this deficiency. The KTB is a repository of specimens from volunteer donors with no clinical evidence of breast malignancy. The Bank’s mission is to make available specimens that will enable an understanding of the developmental biology of the normal breast, to provide insight into breast oncogenesis, and to provide a normal control for breast cancer research. The purpose of this presentation is to increase the awareness of this unique and rich research resource and to actively solicit the use of its specimens.

Methods:
The KTB has been prospectively banking fresh frozen breast tissue since mid-2006. Coincident with the tissue donation that traditional immunocompromised mouse models are not generally permissive for growth. We sought to circumvent some of these limitations by transplanting and growing human mammary tumors in the mammary fat pad of SCID/Beige immunocompromised mice in the absence of exogenous human fibroblasts.

Aims and Methods
To establish a set of stable human breast cancer xenografts for preclinical studies. Human breast cancer biopsies were received, minced into small fragments and then transplanted directly into “cleared” fat pads of recipient SCID/Beige immunocompromised mice. Transplanted fat pads were checked weekly. After initial tumor was palpated and harvested, tumor fragments were transplanted into new SCID/Beige hosts for subsequent transplant generations. Serial immunohistochemical evaluations were performed to confirm human origin and biomarker status. Analytical flow cytometry for evaluating expression of proposed “cancer stem cell” markers, and gene and protein expression analysis were carried out on all stable lines.

Results and Conclusions
Xenograft lines were established directly from breast cancer patient samples, without intervening culture in vitro, using the epithelium-free mammary fat pad as the transplantation site. Of the conditions tested, xenograft take rate was highest in the presence of a low-dose estradiol pellet without exogenous human fibroblasts. Thirty six stably transplantable xenograft lines representing 27 patients were established, using pre-treatment, mid-treatment, and/or post-treatment samples. Most patients yielding xenografts were “triple-negative” (ER-PR-HER2-) (n=21), we were able to establish lines from three ER-PR-HER2+ patients, one ER+PR-HER2-, one ER+PR-HER2- and one “triple-positive” (ER+PR+HER2+) patients. Serially passaged xenografts show phenotypic consistency with the tumor of origin at the histopathology level, and remarkable stability across multiple transplant generations at both the genomic, transcriptomic, and proteomic levels. Of 27 lines evaluated fully, thirteen xenografts showed metastasis to the mouse lung. These models thus serve as a renewable, quality-controlled tissue resource, and should prove useful for preclinical evaluation of experimental therapeutics.

Zhang X, Dobrolecki LE, Lai Q, Landis MD, Wong H, Tsimelzon A, Claerhout S, Contreras A, Gutierrez C, Huang J, Wu M-F, Pavlik AC, Froehlich AM, Hilsenbeck SG, Mills GB, Wiechmann L, Petrovic I, Rimawi MF, Schiff R, Chang JC, Lewis MT. Baylor College of Medicine, Houston, TX; The University of Texas MD Anderson Cancer Center, Houston, TX

Introduction
Translational breast cancer research is hampered severely by difficulties in obtaining and studying primary human breast tissue, and by the lack of in vivo preclinical models that accurately reflect patient tumor biology. These limitations are due, in part, to the fact...
two tubes of blood are obtained, which are processed for lymphocyte DNA, serum and plasma. These specimens are richly annotated with detailed information regarding the donors’ reproductive history, medical history, family history, and medications. Standard Operating Procedures have been constructed so as to control, limit and identify potential sources of bias. All of this information is recorded in an Oracle-based, searchable database.

Results: As of June 2011, the KTB and its predecessor bank, Mary Ellen’s Bank, have available fresh frozen breast tissue (10 gauge cores) from 1469 donors; formalin-fixed, paraffin-embedded tissue from 1055; DNA from 7507; serum from 2382; and plasma from 3771 donors. The KTB has also established 28 epithelial and 33 stromal cell lines from the cores; 4 of the epithelial cell lines have been immortalized using hTERT. Donors range in age from 18-86 years of age. 9% of donors to the KTB describe themselves as Hispanic/Latino. 5.2% of donors are Black or African-American. Using the Gail Risk Model, there is a bimodal distribution of life-time breast cancer risk among the donors: the largest peak is at 10% and a smaller one at 18%.

Conclusions: The KTB is a unique and invaluable research resource which is now open for business and accessible to researchers across the globe. We encourage researchers to avail themselves of this unique tissue resource and to also acquaint themselves with other sources of healthy breast tissue, i.e., the Love/Avon Army of Women [http://www.armyofwomen.org/].

The Breast Cancer Campaign Tissue Bank.
Jones L, Chelada C, Ellis I, Ekbote U, Green A, Hanby A, Jordan L, Purdie C, Quinlan P, Speirs V. Barts Cancer Institute, London, United Kingdom; University of Nottingham, Nottingham, United Kingdom; University of Leeds, Leeds, United Kingdom; University of Dundee, Dundee, United Kingdom

The breast cancer research community has recognised that access to a source of carefully collected well-annotated human breast tissue is essential for translational research. Research institutions often face barriers in gaining access to this resource as collections typically have restrictive access policies or an over burdensome application process. This was formally recognised by around 50 prominent breast cancer researchers through a Gap Analysis conducted in London, UK in 2006. As a direct result of this report, 4 leading UK centres (Barts Cancer Institute, the Universities of Dundee, Leeds and Nottingham) with multi disciplinary expertise in pathology, basic science, bioinformatics and computer science have collaborated with a leading breast cancer charity to form the Breast Cancer Campaign Tissue Bank (BCCTB; http://www.breastcancercampaigntissuebank.org). BCCTB is a unique resource of biological materials and supportive clinical data, efficiently and ethically collected from patients with breast cancer, to provide researchers with high quality, relevant materials, helping to raise the standard of breast cancer research and facilitating the co-ordinated translation of scientific findings into the clinical setting. A wide range of biological materials are banked, including fresh frozen tumour and surrounding tissue, isolated purified cell populations (which can be provided for culture or DNA/RNA/protein extraction), whole blood and serum samples, as well as formalin-fixed paraffin-embedded material. Specialised collections are also available through the Bank on a collaborative basis. BCCTB has a centralised IT system allowing efficient tracking of samples and recording of raw data from studies, and providing a user-friendly web-based search portal to view material available. A purpose-built Bioinformatics platform allows mining breast cancer literature data from multiple sources and integrating different types of -omics and clinical data alongside publically relevant annotations from a growing number of biological resources such as NCBI, Ensembl, UniProt and Reactome. This platform is also fully interoperable with the International Cancer Genome Consortium (ICGC) and can be automatically cross-queried from the ICGC data portal which allows direct cross-comparison of experimental findings generated from the ICGC breast cancer projects with literature-derived information stored in our portal. Together this results in the highly efficient and co-ordinated use of samples, reducing duplication of effort and facilitating data mining and analysis. As science is constantly evolving we have an inbuilt R&D program, including cell immortalisation, investigating improved sample storage and collection methods and on-going IT development, all of which will ensure the bank remains cutting-edge. Tissue is released following review by a Tissue Access Committee comprising clinical and non-clinical breast cancer researchers and patient advocates. Direct interaction with end users ensures the materials and data supplied meets the researcher needs. Currently BCCTB is accepting applications from UK based researchers with projects funded by Breast Cancer Campaign. It will launch to the wider breast cancer community in the next 18 months.

P5-21-04
Patient Attitudes towards Undergoing Additional Breast Biopsy for Research Purposes.
Naim FM, Ballinger R, McLauchlan R, Hadjiminas DJ, Hogben K, Palmieri C, Cleator SJ. Royal Free Hospital, Royal Free Hampstead NHS Trust, London, United Kingdom; Brighton and Sussex Medical School, Brighton, United Kingdom; Charing Cross Hospital, Imperial NHS Healthcare Trust, London, United Kingdom

Background: Acquisition of additional breast tissue for research has become integral to breast oncology research but no data exists regarding patient attitudes to additional, non-diagnostic biopsies. Baseline research biopsies may be obtained as part of the diagnostic process as extra passage(s) of the needle through a ‘generic consent’ process, or as an additional biopsy event after carcinoma diagnosis has been confirmed and eligibility for a specific study has been established. This study sought to explore patient perspectives to such biopsies. Patients and Methods: Patients attending breast clinics were recruited to complete a questionnaire prior to their consultation (and any interaction with researchers or clinicians seeking consent for research biopsies) which examined willingness to undergo an extra fine needle aspirate (FNA) and/or core needle biopsy (CNB) for research either at time of the diagnostic biopsy (B1) or after diagnosis (B2). Descriptions of FNA and CNB procedures were supplied to those with no prior experience. Patient perspectives towards donating surplus tissue left over from a diagnostic procedure and/or surgery for storage for future research was also explored. Results: 100 patients were recruited, 42% with a prior history of breast carcinoma, 23% with family history of breast carcinoma and 65% 42% with previous experience of CNB/ FNA respectively for either benign or malignant disease. Willingness to undergo additional biopsy was greater for the B1 than the B2 time point, but equivalent for CNB and FNA (willingness CNB B1 50% vs B2 26%, willingness FNA B1 50% vs B2 29%). A statistically significant increase in willingness to undergo CNB and FNA at B1 and/or B2 was seen in association with prior diagnosis of breast cancer, family history of breast cancer, previous visit to breast clinic and prior experience of breast biopsy. Reasons for willingness or unwillingness were recorded. 83% of patients expressed a willingness to allow surplus tissue to be stored in a biobank for future research.

www.aacrjournals.org Cancer Res; 71(24 Suppl.) December 15, 2011 595s
**Conclusions:** When asked by questionnaire prior to clinic consultation, additional research biopsy was much more acceptable if undertaken at time of initial diagnostic biopsy rather than at a later time point. Acceptability was equivalent for CNB and FNA. Previous experience of biopsy, previous attendance to breast clinic, a prior history of breast cancer or family history of breast cancer increased acceptability suggesting that willingness is increased with knowledge of the biopsy procedure.

Feasibility and Patient Safety of Serial Biopsies (bx) in Metastatic HER2-Positive Breast Cancer (BC) To Evaluate Alterations in Molecular Biomarkers (BM): Preliminary Results of SHERSig (Study of HER2 Signature in Metastatic Breast Cancer) a Prospective Phase II Study.

Chan A, Chan S, Price D, Bergh J, Lluch A, Redfern A, Chirgwin J, Lidbrink E, Dhadda A, López-Vega J, Lindman H, Beith J, Baron-Hay S, Kiernmaier A, Herbst F, Ellis I. Mount Medical Centre, Perth, Australia; Nottingham City Hospital, Nottingham, United Kingdom; Karolinska Institutet and University Hospital, Stockholm, Sweden; Hospital Clinico Universitario de Valencia, Valencia, Spain; Royal Perth Hospital, Perth, Australia; Eastern Health Melbourne, Australia; Scarborough Hospital, Scarborough, United Kingdom; Hospital Universitario Marques de Valdecilla, Santander, Spain; Uppsala University Hospital, Uppsala, Sweden; Royal Prince Alfred Hospital, Camperdown, Australia; Royal North Shore Hospital, St Leonards, Australia; F Hoffmann-La Roche Ltd, Basel, Switzerland; Nottingham University Hospitals, Nottingham, United Kingdom

**Background:** The use of trastuzumab (H)-based therapy for HER2-positive BC has significantly altered outcomes. Yet up to 64% of metastatic patients (pts) fail to respond (Robert JCO 2006) and most pts will progress within 24-42 months (m) following an initial response for metastatic disease. Preclinical data suggest several in vitro resistance mechanisms but confirmatory in vivo data are lacking, preventing optimal personalized care. This ongoing proof-of-concept study examines serial bx in pts with HER2-positive metastatic BC in order to assess BM profiles across multiple lines of treatment.

**Methods:** Key eligibility criteria include: centrally confirmed HER2 status, minimum of 1 disease site considered suitable for serial bx, normal coagulation profile and cardiac function, prior adjuvant/neoadjuvant taxane and H completed ≥12 m and ≥6 m respectively, ECOG ≤2. Pts receive q3wk H with clinician choice of taxane (docetaxel 75-100 mg/m² q21, paclitaxel 80 mg/m² weekly or 175 mg/m² q21 [TH]). At the time of progressive disease, pts receive capecitabine (X) and H. Two core bx and 1 optional fine needle aspirate are performed at the following times: baseline (after 3 weeks [w] of TH), at 6 w, at time of first progression prior to XH, and at the time of progression on XH. Tumor assessments are performed at 6 w, then 9 w intervals, with cardiac assessment every 6 m. Primary endpoint aims to explore and potentially define BM signatures that could alter during HER2-targeted therapy and predict for decreased or increased sensitivity to H-based treatment. Secondary endpoints include bx safety, ORR and TTP. At time of baseline bx, pts have the option to complete a pt satisfaction questionnaire.

**Results:** Between August 2009 and June 2011, 58 pts were screened; 29 enrolled. The other 29 pts were screen failures, with 3 pts (5%) specifically declining entry due to the requirement for serial bx. Median age is 53 y (range 37-86), with 9 and 20 pts having recurrent or de novo metastatic disease. Eight pts received adjuvant systemic treatment, including H in 4 pts. Baseline bx performed in the breast, n (%): 15 (52), bone: 6 (21), liver: 4 (14), and lymph nodes: 4 (14); 14 and 27 pts underwent bx at 3 and 6 w respectively. After a median of 34 w of treatment 11 pts progressed on TH and 7 pts underwent planned bx. There were 12 SAEs, none related to bx. Most AEs were grade 1/2 (95%) with 3% grade 3 and 1 death due to intercurrent illness. From a total of 43 bx, 12 (27%) grade 1/2 AEs (hematoma 2, transient hypotension 2, mild pain 8) were reported, with resolution in all instances. Fifteen pts consented to the pt satisfaction substudy.

**Conclusions:** Preliminary results of the first reported serial bx study in metastatic BC demonstrated 95% pt acceptance of this approach. Evaluation of BM profiles will be conducted following planned recruitment of 50 pts. To date, the feasibility and safety of obtaining serial bx in metastatic BC is supported by the current safety profile and patient uptake. Updated recruitment data will be presented.

**P5-23-01**

The Impact of Primary Tumor Resection on the Survival of Patients with Stage IV Breast Cancer According to Molecular Subtype.

Ahn SK, Moon H-G, Kim JS, You JM, Shin HC, Han W, Noh D-Y. Seoul National University Hospital

**Purpose:** The main treatment for stage IV breast cancer is currently systemic therapy. Surgical resection of the primary tumor is usually done for treating the tumor-related complications. Recent studies have suggested that surgery may improve the long-term survival of stage IV breast cancer patients. We evaluated the impact of the primary surgical resection site on the survival of stage IV breast cancer patients according to molecular subtype using nationwide Korean breast cancer registry data.

**Methods:** We analyzed the records of the stage IV breast cancer patients from Korean Central Cancer Registry (KCCR) between 1999 and 2008. We used clinical assays to distinguish luminal A (HR+/HER2−, n=290), luminal B (HR+/HER2+, n=154), Basal-like (HR-/HER2−, n=107) and HER2 (HR-/HER2+, n=145). The clinical and tumor characteristics, the type of treatments and the overall survival were compared between the surgically versus nonsurgically treated patients according to molecular subtype.

**Results:** Of the 1091 identified patients, 719 (65.9%) received surgical excision of their primary tumor and 372 (34.1%) did not. The mean survival was 86 months versus 43 months for the surgically treated patients vs. the patients without surgery, respectively (p<0.001). On a multivariate analysis with using the Cox model and after adjusting for tumor size, visceral metastases, the number of metastatic sites and bone only metastases, surgery was an independent factor for improved survival in patients with luminal A type (Hazard Ratio, 0.505; 95% Confidence Interval, 0.265-0.962, p=0.038) but not in those with luminal B (p=0.192), basal-like (p=0.128) and HER2 subtype (p=0.114). **Conclusion:** Surgical resection of the primary tumor in stage IV breast cancer patients was independently associated with improved survival only in luminal A subtype.
Cancer Res; 71(24 Suppl.) December 15, 2011

P5-23-02
Clinicopathological Features of Young Patients Age <35 Years with Breast Cancer in Japan.

Kataoka A, Tokunaga E, Masuda N, Shien T, Ohno S, Kinoshita T, Shimizu C. Breast Surgery Clinic, Minato-ku, Tokyo, Japan; Kyushu University Hospital, Fukuoka City, Fukuoka, Japan; National Hospital Organization Osaka National Hospital, Osaka City, Osaka, Japan; Okayama University Hospital, Okayama City, Okayama, Japan; National Hospital Organization Kyushu Cancer Center, Fukuoka City, Fukuoka, Japan; National Cancer Center Hospital, Chuo-ku, Tokyo, Japan; The Japanese Breast Cancer Society (JBCS) Study Group on Breast Cancer in Young Women

Background: The aim of this study is to clarify clinicopathological features of breast cancer in young women.

Materials and methods: Clinicopathological characteristics were compared between young (<35) patients and non-young (≥35) patients among 109,617 records of JBCS database registered from 2004 to 2009, and overall survival (10-yr OS) were calculated among 146,690 records from 1975 to 2000 with 8.6 years of median follow-up period. Results: Clinicopathological factors of 2,982 young patients (2.7%) were compared with 106,295 non-young patients. Young patients had more familial history of breast cancer, more subjective symptom, less bilateral tumor, lower tumor size, more inflammatory breast cancer, more positive node, less ER-positive, more HER2-positive, more triple-negative tumor, and more advanced TNM-stage.

</table>

Eighty-percent of patients were received adjuvant therapy, among them, treatment rate of chemotherapy, molecular targeted therapy and radiation therapy was significantly higher in young patients than non-young patients. There was significant difference in 10-yr OS between young and non-young patients with Stage I-IIIA disease (Stage I 80% vs. 90%, IIA 78% vs. 85%, IIB 67% vs. 78%, IIC 42% vs. 64%), but not with Stage IIB and IIC. Advanced TNM stage, lymph node metastasis and ER-negative tumor were significantly poorer prognostic factors for young patients by univariate analysis. Approximately 9% of young patients were at pregnancy at the time of diagnosis had more advanced disease and worse prognosis.

Conclusions: We conclude that young patients with breast cancer have an advanced or an endocrine-unresponsive tumor and have unfavorable outcome. Advocacy for awareness of breast cancer to young women and development of new targeted therapy against advanced, HER2-positive and triple-negative tumor are important to improve the survival of young patients with breast cancer.

P5-23-03
Breast Cancer in Elderly Treatment Algorithm – A New Approach To Optimize the Management of Breast Cancer in Older Patients.

Tahir M, Pretorius R, Robinson T, Walker R, Stotter A. University Hospitals of Leicester NHS Trust, Leicester, United Kingdom

Background: Elderly patients have been receiving a sub-standard treatment for early breast cancer when compared to younger age group patients. A higher percentage of them are being treated with primary endocrine therapy (PET) based on the premise that they may not survive surgery or live long enough to benefit from it. This clinical practice, however, there is no validated assessment in place to assess their surgical risk or estimate their life expectancy. This study aimed to optimize the treatment of early breast cancer in older patients using comprehensive geriatric assessment (CGA). It tested the hypothesis that CGA could be used to predict 2-year survival in older breast cancer patients. Based on that a treatment algorithm was devised which could be used to recommend whether PET or surgery plus endocrine treatment would be best indicated in individual patients.

Methods: The study included women >70 years of age with early breast cancer, seen in a dedicated Leicester clinic between 04/2005 and 04/2007. All patients had comprehensive assessment including documentation of co-morbidities, Mini-mental state examination (MMSe), Geriatric depression score (GDS), Activities of daily living (ADL), Instrumental activities of daily living (IADL) and American society of anesthesiologist score (ASA). Analysis was performed to find components of the CGA that were helpful in predicting 2-year survival in these patients.

Results: 123 patients were included; age range was 70-94 (median-82). Twenty-two patients died within 2-years. Logistic regression analysis found MMSe, ADL, and ASA score to have an independent association with 2-year survival. A statistically significant correlation (p-value 0.000) was found between the dichotomized combined-score of these components and 2-year survival. Breast Cancer in Elderly Treatment Algorithm (BCETA) was devised using the scores of these three components. Patients who scored one or higher (high-risk group), were found to have <48% two-year survival; those, who scored zero (low-risk group), have >60% chance of two-year survival. The overall accuracy for the algorithm was 81%.

Conclusion: Breast Cancer in Elderly Treatment Algorithm is a new and systematic approach to optimize the management of breast cancer in elderly patients. It is helpful in identifying high-risk patients with expected short-survival who may benefit from PET, if their cancer is hormone receptor positive. Patients with predicted longer life expectancy (low-risk) may be recommended standard treatment. A prospective study is ongoing at Leicester research clinic to validate the results.
P5-23-04
Cruz MRS, Motta E, Silva EMK, Bernardo SG, Atallah AN. Hospital Sao Jose, Sao Paulo, Brazil; Universidade Federal de Sao Paulo, Sao Paulo, Brazil

Background: Breast cancer, the most common female malignancy, is also the most frequent tumor in women of reproductive age. Young women with breast cancer usually present adverse prognostic features and higher rates of recurrence when compared with their older counterparts. Adjuvant chemotherapy is usually recommended for this group of patients and premature ovarian failure (POF) is a potential complication.

Material and Methods: We conducted a systematic search in MEDLINE, EMBASE, Cochran Systematic Reviews databases and ClinicalTrials.gov from their inception until June 2011. The search was conducted to include published peer-reviewed studies on the issue of fertility preservation in women with breast cancer undergoing adjuvant chemotherapy. The search terms were tailored individually for each database to include the following Medical Subject Headings (MeSH) and text words: gonadotropin releasing hormone, breast neoplasms, drug therapy, premature ovarian failure and fertility. No language restriction was applied. We also searched for additional studies by reviewing the reference lists of retrieved articles, and studies presented in abstract form were also located in this manner. The main outcomes were return of spontaneous menstruation, ovulation and pregnancy rate.

Results: We found 8 RCTs that met the inclusion criteria. Data were extracted from 3 RCTs. Data were only available for resumption of ovulation. There were no data available for markers of ovarian function, rate of ovulation and pregnancy. The rate of women with spontaneous menstruation demonstrated a statistically significant difference in favor of the use of GnRH-a (OR 3.11; 95% CI, 2.04–4.72).

Discussion: Use of GnRH concomitant to adjuvant chemotherapy in premenopausal breast cancer women aiming to reduce rates of POF has been subject of controversy during the last decade. Evidence from recently presented RCTs suggests there is a benefit of GnRH for ovarian function protection in this setting.

Aim: To describe the effects of the development, implementation and prospective systematic evaluation and adaptation of a clinical care pathway for the management of patients with early breast cancer between 2002 and 2010) in a single breast unit.

Materials and methods: In 2002 a clinical pathway was developed by the multidisciplinary breast team of the Sint Augustinus Hospital for de diagnosis and treatment of patients with operable breast cancer. Performance measurements were documented systematically by care providers using an order communication, planning and result reporting system. Annual analysis of predefined clinical outcome measures and indicators was performed. Based on these data and evidence based guidelines the pathway was regularly adapted to improve patient care.

Results: The annual number of patients included in the pathway (289 vs 390, p 0.01), proportion of patients with Tis-T1 tumors (42% vs 58 %, p 0.01), negative lymph nodes (44% vs 58%, p < 0.01) and no metastases at diagnosis (91.5% vs 95.9%) has risen significantly between 2002 and 2010. Histological subtypes remained the same. The average length of hospital stay (7.0 days vs 4.1 days, p 0.01) nearly halved and the proportion of breast conserving surgery (BCS) (43% vs 57%), preoperative guide wire localization (14% vs 27%) for impalpable lesions and use of sentinel node biopsy (0% vs 49%) increased significantly (p 0.01). Evolution of quality indicators defined by Eusoma (www.eusomadb.org/indicators.htm) between 2002 and 2010 shows a significant improvement of cancer care: proportion of positive of preoperative histologic diagnosis (59.7% vs 88.4%, p 0.001), more then 9 lymph nodes removed when axillary clearance performed (85.6 vs 91.4%, p< 0.04), BCS for invasive carcinoma up to 3 cm (62.0% vs 82.6%, p 0.016), BCS for DCIS up to 20 mm (43.8% vs 78.6%, p 0.016), hormone therapy in endocrine sensitive tumor (84.8% vs 97.4%, p 0.002), adjuvant chemotherapy in ER negative (PT1c or N+) invasive carcinoma (72% vs 95.6%, p 0.028), proportion of second surgery (25% vs 10%, p 0.001) and clear margins after last operation (95% vs 99%, p 0.02). All mandatory EUSOMA requirements were fulfilled in 2010. Patient satisfaction improved significantly over the years (13/19 measured parameters p <0.05 between 2002-2010). Progression free 4 year survival was significantly higher for all patients, for T1 tumors only and for T2-T4 tumors only, treated in 2006-2008 compared to 1999-2002 and 2003-2005 (respectively p 0.006, p 0.05, p 0.06). Overall 4 year survival of the entire M0 population treated in 2006-2008 was significantly better (p 0.05)

Conclusion: Although the patient characteristics changed over the years due to better screening, this clinical pathway for the treatment of patients operable breast cancer proved to be an important tool to improve the quality of patient care and patient satisfaction. Better adherence to guidelines and constant feedback of treatment data to the breast team contributes to a superior patient outcome. Measuring quality indicators proved useful to develop quality measures improving patient care.
P5-23-07
Treatment Strategy of Locally Advanced Breast Cancer in Sub Group (T3N1M0, T4bN1M0) in Developing Countries.
Gupta AK, Kaushal M. Mahatma Gandhi Memorial Medical College and Maharaja Yashwantrao Hospital, Indore, Madhya Pradesh, India

With the recent advances in modern day chemotherapy and hormonal therapy for locally advanced breast cancer [stage III, T3 N1 and T4bN1], most of the oncologist around the globe now prefer to give neoadjuvant chemotherapy and, or hormonal therapy followed by surgery in the treatment of these cases.

Randomized research have also shown that this strategy provides ‘pathological complete resolution’ as compared to surgery and then adjuvant chemotherapy in terms of decreasing in size of tumor, decrease in vascularity of tumor mass and micrometastasis. Some author believes that this improve the overall survival duration of patients.

This protocol is widely accepted but … BUT WHAT IF YOU LOSE YOUR PATIENT ON FOLLOWUP …

Especially in the developing countries of south east asian region and African continent, where there is poor socioeconomic status and lack of education among common people. The patient gets frustrated after first few doses of neoadjuvant therapy, due to side effects of chemotherapy and don’t consider chemotherapy as a treatment compare to surgery. Thus the patient loses faith in treatment strategy itself and go unretraceable after one or two sessions of the therapy.

The government of developing countries lack resources in terms of manpower and money for satisfactory completion of treatment making the above condition even worse. In our study we followed 230 patients of locally advanced breast cancer in subgroup of stage III [T3 N1, T4bN1] and divided them into two plans on random basis.

In first plan we approached with the surgical management followed by adjuvant chemotherapy & counseled the patients for completion of chemotherapy. This plan was shown to 115 patients, out of which 100 patients provided good acceptance & completed the course of chemotherapy. There were 15 patients who remained unretraceable after surgery.

On the other hand in the 2 group the patients were counseled for neoadjuvant chemotherapy and then surgery in next stage. In this group 115 patients were introduced, out of which 60 patients were lost on follow up after 2-3 sessions. The majority of patients complained about the side effects of chemotherapy and financial reasons and did not come back. Rest of the patients completed the whole course.

With no doubt about the result of the treatment, the second group has equivocal survival advantages in terms of morbidity and mortality, but we lost more than half of the patients of second group before completion of treatment.

Primarily the acceptance of surgical treatment is more in developing countries, as it is quite more feasible for government and even economical for common people. Thus we prefer the strategy of surgery followed by adjuvant chemo/hormonal therapy in locally advanced breast cancer [stage III T3N1, T4bN1] especially in developing countries like India.

THE MOTTO OF THIS STRATEGY IS TO PROVIDE BENEFIT OF COMPLETE TREATMENT TO THE PATIENT THAN TO LOSE THE PATIENT COMPLETELY BEFORE TREATMENT.

OT1-01-01
Prospective Clinical Trial Evaluating Efficacy of Zoledronic Acid (ZA) Prophylaxis for Prevention of Aromatase Inhibitor Associated Musculoskeletal Symptoms: ZAP-AIMSS Trial.
Bardia A, Blackford A, Jeter S, Tarpinian K, Fetting JF, Miller R, Slater S, Henry NL, Giles J, Stearns V. Johns Hopkins Kimmel Cancer Center, Baltimore, MD; University of Michigan, Ann Arbor, MI; Columbia University, New York City, NY

Brief background: Aromatase inhibitor associated musculoskeletal symptoms (AIMSS) occur in approximately 50% of patients receiving AIs (Henry 08). However, interventions to prevent or treat AIMSS have not been established. In a retrospective study (Muslimani 09), patients receiving bisphosphonates along with AIs were less likely to report AIMSS compared to those not taking bisphosphonates (35% vs. 60%). However, the efficacy of bisphosphonates in reducing incidence of AIMSS has not been studied prospectively, so it cannot be recommended for routine clinical practice.

Trial design: We are conducting a single arm, phase II clinical trial of 4 mg intravenous zoledronic acid (ZA) given at baseline and at 6 months, in combination with letrozole 2.5 mg daily for one year.

Development of AIMSS will be assessed using the standardized Health Assessment Questionnaire (HAQ-DI) and pain Visual Analog Scale (VAS) at baseline, 1, 3, 6, and 12 months. Secondary endpoints include mammographic breast density (when intact contralateral breast), bone mineral density, bone turnover metabolites, circulating inflammatory markers, and patient reported quality of life measures.

Prevalence of AIMSS will be compared to historical controls from a recently completed multi-institutional study designated Exemestane and Letrozole Pharmacogenetics (ELPh trial, ClinicalTrials.gov #NCT00228956). The current study has the same eligibility criteria, method and intervals of outcome assessment, and AI medication, as the ELPh trial, ensuring that the two cohorts are comparable.

Eligibility criteria: Postmenopausal women who have completed local therapy and chemotherapy for hormone receptor positive DCIS or stage I-III breast cancer and who are scheduled to receive adjuvant AI. Prior tamoxifen therapy is permitted.

Specific aims:
1. Percentage of women experiencing AIMSS at 1, 3, 6, and 12 months after initiation of ZA and letrozole, as compared to historical controls.
2. Change in bone mineral density and breast density between baseline and 12 months for those receiving ZA and letrozole, as compared to historical controls.
3. Change in bone turnover markers and inflammatory markers between baseline and 1, 3, 6 and 12 months for those receiving ZA and letrozole, as compared to historical controls.

Statistical methods: Allowing for a 20% dropout rate, a total sample size of 59 patients yields 80% power to detect reduction in AIMSS incidence from 50% to 30% with a two sided type I error rate of 5%. The rates of AIMSS and other endpoints at each time point and across all time points between controls and patients will be compared with a logistic regression model that adjusts for potential confounding variables and include random effects as appropriate to account for correlation between outcomes in the same patient.

Present accrual and target accrual: The Johns Hopkins Institutional Review Board approved the study and it opened to accrual in January 2011. Since that time, 12 participants have signed consent and started therapy, and 2 have completed the 3 month evaluation.

Funding: Trial supported by BCRF. ZA and letrozole kindly supplied by Novartis.
OT1-01-02
A Multicentre Study Assessing 12-Weekly Intravenous Bisphosphonate Therapy in Women with Low Risk Bone Metastases from Breast Cancer – The TRIUMPH Trial. Bougainin N, Hilton J, Vandermeer L, Hopkins S, Spencer P, Robbins D, Amir E, Dent S, Milano C, Oui D, Dranitis G, Clemens M. The Ottawa Hospital Cancer Center; Ottawa, ON, Canada; Princess Margaret Hospital, Toronto, ON, Canada; The Ottawa Hospital, Ottawa, ON, Canada

Background: Metastatic bone disease is a major cause of morbidity and mortality for breast cancer patients. Bisphosphonates (BP) have been shown to significantly delay the onset and frequency of skeletal related events (SREs), improve pain control and overall quality of life. Most patients receive intravenous BP every 3-4 weeks regardless of their individual risk for a SRE. This “one size fits all” strategy could expose those patients at a relatively low risk of SREs to an increased chance of adverse drug effects, as well as to the financial and quality of life burden of multiple visits to the cancer centre for treatments. This study aimed to assess whether IV BP can be safely given at reduced frequency.

Methods: The primary objective of this study is to demonstrate in women with biochemically defined low-risk bone metastases that the administration of IV BP every 12 weeks is sufficient to maintain biochemical stability for one year. Eligibility criteria include; bone metastases from breast cancer, have received at least three months of regular 3-4 weekly IV BP, satisfactory renal function, adequate dental health, no systemic treatment change or recent SRE within 4 weeks of study entry. Low risk disease will be defined as serum CTx levels <600 ng/L. Biochemical failure is defined as CTx levels >600 ng/L measured at predefined time points (6, 12, 24, 36 and 48th). Secondary objectives are to evaluate the palliative benefit of 12-weekly IV BP therapy as reflected by occurrence of SREs, analgesic use, self-reported pain using the validated BP and FACT-BP questionnaires. Sample size was calculated at 68 patients. Given the small sample size, nonparametric Bootstrapping will be employed to calculate point estimates, standard deviations and 95% confidence intervals (CIs). An exploratory multivariable analysis will also be undertaken to determine baseline factors that were associated with patient’s maintaining their telopeptide levels in the low risk range.

Conclusion: TRIUMPH opened in October 2010 and as of June 2011, has quickly accrued 54/68 patients (79%). This trial has the potential to allow lower risk women to receive less frequent dosing of bisphosphonates, thus improving their quality of life with less cancer related events (SREs), improve pain control and overall quality of life. Most patients receive intravenous BP every 3-4 weeks regardless of their individual risk for a SRE. This “one size fits all” strategy could expose those patients at a relatively low risk of SREs to an increased chance of adverse drug effects, as well as to the financial and quality of life burden of multiple visits to the cancer centre for treatments. This study aimed to assess whether IV BP can be safely given at reduced frequency.

OT1-01-04
NEO-ZOTAC: A Phase III Randomized Trial with Neoadjuvant Chemotherapy (TAC) with or without Zoledronic Acid for Patients with HER2-Negative Large Resectable or Locally Advanced Breast Cancer.

van de Ven S, Nortier JW, Liefers GJ, ten Tije A, Kessels LW, van Laarhoven HWM, van Warmenhad LJC, Vriens B, van den Bosch J, van Meersch-Klein Kranenburg E, van Leeuwen E, Kroep JR. Leiden University Medical Center. Leiden, Netherlands; Amphia Hospital, Breda, Netherlands; Deventer Hospital, Deventer, Netherlands; University Medical Center St. Radboud Nijmegen, Nijmegen, Netherlands; Catharina Hospital, Eindhoven, Netherlands; Academic Hospital Maastricht, Maastricht, Netherlands; Albert Schweitzer Hospital, Dordrecht, Netherlands; BOOG Study Center, Amsterdam, Netherlands

Background: The role of bisphosphonates (BPs) when added to the preoperative chemotherapy (TAC) regimen is unexplored in the neoadjuvant setting for breast cancer. Zoledronic acid is approved in the USA, Canada, and European countries for the treatment of bone metastases from solid tumors. In patients with castrate-resistant prostate cancer, denosumab significantly improved bone metastasis-free survival (BMFS) compared to placebo. The D-CARE trial evaluates BMFS effects of denosumab in women with stage II or III breast cancer.

Methods: Women with node-positive or locally advanced (T3 or T4) disease, and known hormone and HER-2 receptor status are eligible. Standard-of-care adjuvant or neoadjuvant chemo-, endocrine, or HER-2 targeted therapy, alone or in combination must be planned with curative intent. Women with a prior history of breast cancer (other than ductal carcinoma in situ [DCIS] or lobular carcinoma in situ [LCIS]) or distant metastasis, oral bisphosphonate (BP) use within 1 year or any intravenous BP use are excluded. Patients are randomized 1:1 to receive denosumab 120 mg or placebo subcutaneously monthly for 6 mos, then every 3 mos, for a total of 5 yrs treatment. All patients receive vitamin D (≥ 400 IU) and calcium (≥ 500 mg) supplements. Primary endpoint of this event-driven trial is BMFS. Secondary endpoints include disease-free (DFS) and overall survival. The study is powered for both, BMFS and DFS. Safety, quality of life assessments and biomarkers are additional endpoints. The trial, sponsored by Amgen Inc. and registered with the ClinicalTrials.gov identifier NCT01077154 began enrolling patients in June 2010. PG and DF are supported in part by the Avon Foundation, NY.

OT1-01-03
A Phase 3 Randomized, Double-Blind, Placebo-Controlled Multicenter Study Comparing Denosumab with Placebo as Adjuvant Treatment for Women with Early-Stage Breast Cancer Who Are at High Risk of Disease Recurrence (D-CARE).

Goss PE, Barrios CH, Bell R, Finkelstein D, Iwata H, Martin M, Braun A, Ke C, Maniater T, Braun S, Dansy R, Coleman RE. Massachusetts General Hospital Cancer Center; Boston, MA; PUCRS School of Medicine, Porto Alegre RS, Brazil; Barwon Health, Geelong, Victoria, Australia; Atchi Cancer Center Hospital, Nagoya, Japan; Hospital Gregorio Maranon, Madrid, Spain; Amgen Inc. Thousand Oaks, CA; Angen (Europe) GmbH, Zug, Switzerland; University of Sheffield, Sheffield, United Kingdom

Background: Bone is a common site of distant recurrence in women with early-stage breast cancer. Cancer cells are thought to stimulate osteoclast-mediated bone resorption, which releases growth factors and cytokines that promote tumor growth. RANK Ligand (RANKL) is the key mediator of osteoclast-induced bone destruction. In preclinical studies, RANKL inhibition reduced the incidence of bone and lung metastases, suppressed tumor progression, and prolonged survival of tumor-bearing mice. Effects were additive with hormonal, chemotherapeutic, or targeted therapies. Denosumab is a fully human monoclonal antibody against RANKL, approved in the U.S. for the prevention of skeletal-related events in patients with bone metastases from solid tumors. In patients with castrate-resistant prostate cancer, denosumab significantly improved bone metastasis-free survival (BMFS) compared to placebo. The D-CARE trial evaluates BMFS effects of denosumab in women with stage II or III breast cancer.

Methods: Women with node-positive or locally advanced (T3 or T4) disease, and known hormone and HER-2 receptor status are eligible. Standard-of-care adjuvant or neoadjuvant chemo-, endocrine, or HER-2 targeted therapy, alone or in combination must be planned with curative intent. Women with a prior history of breast cancer (other than ductal carcinoma in situ [DCIS] or lobular carcinoma in situ [LCIS]) or distant metastasis, oral bisphosphonate (BP) use within 1 year or any intravenous BP use are excluded. Patients are randomized 1:1 to receive denosumab 120 mg or placebo subcutaneously monthly for 6 mos, then every 3 mos, for a total of 5 yrs treatment. All patients receive vitamin D (≥ 400 IU) and calcium (≥ 500 mg) supplements. Primary endpoint of this event-driven trial is BMFS. Secondary endpoints include disease-free (DFS) and overall survival. The study is powered for both, BMFS and DFS. Safety, quality of life assessments and biomarkers are additional endpoints. The trial, sponsored by Amgen Inc. and registered with the ClinicalTrials.gov identifier NCT01077154 began enrolling patients in June 2010. PG and DF are supported in part by the Avon Foundation, NY.
Eligibility criteria: Main inclusion criteria are large resectable or locally advanced breast cancer (T2, T3, T4, every N, M0), measurable disease, histological proven HER2-negative breast cancer, age ≥18 years, WHO 0-2, adequate bone marrow-, renal- and liver function, written informed consent. Main exclusion criteria are evidence of distant metastases (M1), history of breast cancer, prior breast surgery, prior chemotherapy or radiation therapy, previous malignancy within 5 years, prior bisphosphonate usage, peripheral neuropathy > grade 2, current active dental problems.

Study endpoints: The primary endpoint of this study is the pathologic complete response (pCR) rate to neoadjuvant chemotherapy with or without zoledronic acid at surgery. Secondary endpoints are clinical response (RECIST 1.1), ER/PR and HER2 heterogeneity in core biopsy vs. operation specimen, toxicity, disease free survival and overall survival.

Optional side studies include fluorescent imaging (SoftScan®), changes in bone biochemical markers and the insulin-like growth factor (IGF) pathway, circulating tumor cells (CTC's) and circulating endothelial cells (CEC's), the false-negative rate of the sentinel node biopsy after neoadjuvant chemotherapy, single nucleotide polymorphisms (SNPs) and Ki-67, apoptotic index and IGF pathway in core biopsy and operation specimen.

Statistical Methods: This study is designed as a randomized, open-label, multi centre phase III trial. It is anticipated that using a 5% significance level based on the two-sided Fisher’s exact test with a power of 80%, a total number of 250 patients (125 patients in each arm) are needed to show an improvement of the pCR rates from 17% in arm B to 34% in the experimental arm A. Randomization will be done according to the Pocock’s minimization technique stratified by cT-classification, cN-classification and estrogen receptor status. The primary endpoint will be analyzed using the Cochran-Mantel-Haenszel test.

An interim efficacy analysis (analyzing pCR) after 100 operated patients is planned.

Accrual: Patients are currently being included from 27 centers in the Netherlands. Presently (16th June 2011) a total number of 116 patients have been included since start of the study (July 2010). The expected end of accrual of 250 patients will be the last quarter of 2012.

OT1-02-01
Phase II Neoadjuvant Trial of Anthracycline Based Regimens Followed by a Combination with Nanoparticle Alummin-Bound Paclitaxel and Trastuzumab in Patients with Operable T2-3,N0-1,Her2 Positive Breast Cancer.
Iwamoto M, Takahashi Y, Kimura K, Tanaka S, Uchiyama K. Osaka Medical College, Osaka, Japan

Background: Anthracycline and taxane have been widely used and studied in neoadjuvant setting for treatment of locally advanced breast cancer. Various regimens have explored the addition of newer agents to determine safety and efficacy, and pathological complete response(pCR) has been demonstrated to be associated with favorable overall survival in primary breast cancer. In addition, three year median follow-up data of the TECHNO Trial revealed that the neoadjuvant combination of trastuzumab and chemotherapy resulted in a high chance for a pCR. We conducted a clinical Phase II neoadjuvant trial of Anthracycline based regimens(EC,AC,FEC) followed by a combination with nanoparticle albumin-bound Paclitaxel and Trastuzumab in patients with operable T2-3,N0-1,Her2 positive breast cancer.

Patients and Methods: The study is designed to evaluate EC or AC or FEC followed a combination of nanoparticle albumin-bound Paclitaxel and Trastuzumab as neoadjuvant therapy in patients with Her2 positive locally advanced(T2-3,N0-1) breast cancer. Patients are treated with neoadjuvant EC(Epirubicin 90 mg/m², Cyclophosphamide 600 mg/m²) or AC(Doxorubicin 90 mg/m², Cyclophosphamide 600 mg/m²) or FEC(Fluorouracil 500mg/m², Epirubicin 100 mg/m², Cyclophosphamide 500 mg/m²) q21d x 4, followed by a combination with nanoparticle albumin-bound Paclitaxel(260 mg/m²) and Trastuzumab q21d x 4.

Patients undergo surgery 4-6 weeks later from completing chemotherapy. pCR, the primary endpoint is defined as no evidence of invasive tumors in the final surgical sample both in the breast and axillary lymph nodes. Secondary endpoints include objective clinical response rate, disease-free interval, overall survival, rate of breast concerning surgery, and the safety of the treatment.

HALT MBC: HER2 Suppression with the Addition of Lapatinib to Trastuzumab in HER2-Positive Metastatic Breast Cancer (LPT112515).
Lin N, Danso M, David A, Mascato J, Ellis C, DeSilvio M, Garofalo A, Nagarwala Y, Winer E. Dana-Farber Cancer Institute; Virginia Oncology Associates; Augusta Oncology Associates; Missouri Cancer Associates; GlaxoSmithKline

Background
Lapatinib in combination with trastuzumab enhanced anti-tumor activity in HER2-positive breast cancer (BC) preclinical models. In patients (pts) with trastuzumab-treated, HER2-positive metastatic (M) BC, treatment with the combination was associated with longer progression-free (PFS) and overall survival (OS) compared with lapatinib alone. In pts with stage II/III BC, preoperative treatment with the combination plus paclitaxel resulted in significantly higher pathological complete response rates compared with paclitaxel combined with either agent alone. This evidence supports the concept of dual HER2 blockade as a treatment strategy for HER2-positive BC. This present study is designed to evaluate whether the addition of lapatinib improves PFS among women with HER2-positive MBC receiving trastuzumab as maintenance therapy.

Trial Design
In this open-label, Phase III study, pts are stratified by line of treatment (first/second) and hormone receptor status (positive/negative) then randomized 1:1 to receive maintenance treatment with either lapatinib (1000mg once daily, continuously) in combination with trastuzumab (6mg/kg once every 3 weeks [Q3W]) or trastuzumab (6mg/kg Q3W) alone. Pts will receive study treatment until disease progression, death, discontinuation due to adverse events or other reasons.

Eligibility Criteria
Pts with HER2-positive MBC who have completed 12-24 weeks of first- or second-line treatment with trastuzumab plus chemotherapy and have objective response or stable disease. Pts with stable brain metastasis are eligible if entering the study on second-line treatment.

Specific Aims
The primary objective is to compare PFS of lapatinib in combination with trastuzumab to trastuzumab as continued HER2 suppression therapy. Secondary objectives are to evaluate OS, clinical benefit rate, safety and tolerability.

Statistical Methods
Efficacy endpoints will be analyzed in the intent to treat population. A total of 193 PFS events from 280 randomized pts will be required to detect a 50% increase in median PFS in pts who receive lapatinib
plus trastuzumab compared with trastuzumab (median PFS time is 27 versus 18 weeks, respectively); hazard ratio of 0.67 with an 80% power and a 1-sided type I error of 0.025.

Present and Target Accrual

Sixteen of the target 280 pts have been randomized. The trial is currently open for accrual in the United States and Canada.

OT1-02-03

EGF114299: Safety and Efficacy of an Aromatase Inhibitor (AI) in Combination with Lapatinib (L), Trastuzumab (T) or Both for the Treatment of Hormone Receptor-Positive (HR+), HER2+ Metastatic Breast Cancer (MBC).

Johnston S, Leigh M, Florance A, Wroblewski S, Gradishar W. Royal Marsden NHS Foundation Trust & Institute of Cancer Research; GlaxoSmithKline, Collegeville, PA; GlaxoSmithKline, Research Triangle Park, NC; Northwestern University

Background: Data from the L plus letrozole (EGF30008) and the Trastuzumab and Anastrozole Directed Against ER-Positive HER2-Positive Mammary Carcinoma (TaNDEM) studies demonstrated that HER2 targeted and endocrine therapy (ET) is a better strategy than ET alone. In EGF30008, progression-free survival (PFS) in the HER2+ population was statistically significantly longer in the letrozole plus L group compared with the letrozole plus placebo group. The HR was 0.71 (95% CI: 0.53-0.96; stratified log rank \( P < 0.019 \)). Median PFS was 35.4 weeks in the letrozole plus L group compared with 13.0 weeks in the letrozole plus placebo group.

The present study (EGF114299) is a phase III, open-label, multicenter trial designed to evaluate benefit in overall survival (OS) provided by L/T/AI and L/AI, in pts with HR+/HER2+ MBC who have received neo-/adjuvant T and ET. It will also provide further data on dual HER2 suppression in an attempt to prevent acquired endocrine resistance.

Trial Design: Pts will be randomized to 1 of 3 treatment arms: L 1000 mg po QD plus T (loading dose of 8 mg/kg followed by maintenance with 6 mg/kg IV q3w plus an AI po QD); T plus an AI; or L 1500 mg po QD plus an AI. Choices of AI include letrozole, anastrozole, or exemestane.

Eligibility Criteria: HR+ (ER and/or PgR) and HER2+ Stage IV MBC pts are to be enrolled. Pts must have received neo-/adjuvant T and ET, and are treatment naive for MBC.

Specific Aims: The primary objective is to evaluate OS of L/T/AI as compared with T/AI. The secondary objectives are to assess: OS in T/AI vs L/AI and T/L/AI vs L/AI; PFS; overall response rate; clinical benefit rate; safety and tolerability; and QoL relative to baseline.

A 4-year recruitment is anticipated. More than 200 centers across 25 countries are planned; approximately 50 centers are currently open for enrollment.

Statistical Methods: The study is powered to detect a 42% improvement in the risk of death (HR=0.70) in all pts receiving L/T/AI (median 28.5 months) compared with T/AI (median 20 months). The hypothesis will be tested using a 1-sided test for superiority with \( \alpha = 0.025 \) with a power of 80%.

Present and Target Accrual: One (1) of 525 pts has been randomized. The majority of eligible pts may reside in countries where T is commercially available and reimbursable, particularly North America and Western Europe. Patients who have participated in previous neo-/adjuvant trials including a T regimen are eligible, provided they meet all other inclusion criteria.

The study is currently recruiting pts, with an anticipated target accrual of 525 patients by March 2016.

OT1-02-04

Adjuvant Pertuzumab and Herceptin In Initial Therapy of Breast Cancer: APHINITY (BIG 4-11/BO25126/TOC4939g).

von Minckwitz G, Baselga J, Bradbury I, de Azambuja E, Scullion MJ, Ross G, Saini KS, Piccart-Gebhart M. German Breast Group, Neu-Isenburg, Germany; Massachusetts General Hospital, Boston; Frontier Science and Technology Research Foundation, Scotland; BrEAST Data Center, Jules Bordet Institute, Brussels, Belgium; Roche, Welwyn Garden City, United Kingdom; Breast International Group Headquarters, Brussels, Belgium; Breast International Group, Brussels, Belgium

Background: Approximately 20% of breast cancer (BC) patients (pts) have HER2-positive tumors. While the adjuvant use of the anti-HER2 humanized monoclonal antibody trastuzumab (T) has been shown to improve disease-free (DFS) and overall survival (OS), not all pts treated with this agent benefit from this therapy. Pertuzumab (P) is a humanized monoclonal antibody that inhibits HER2 dimerization and induces ADCC with a complementary mechanism of action to T. In HER2-positive adjuvant BC, T and P are active in pts who have progressed to T. In the neoadjuvant setting, T and P in combination with chemotherapy (CT) nearly doubled the pathological complete response rate compared to either T or P administered in combination with CT (45.8% vs 29% vs 24%, respectively). Therefore, comprehensive HER2 blockade with two anti-HER2 monoclonal antibodies warrants further investigation in the adjuvant setting.

Trial Design: APHINITY is a prospective, randomized, multicenter, double-blind, placebo-controlled study in pts with HER2-positive primary BC who have had an excision of their tumor. Pts will be randomized to one of 2 arms (1:1 ratio). The investigational arm will comprise of a course of adjuvant CT (investigators choice) consisting of either an anthracycline-taxane or taxane-platin containing regimen and T and P for 1 year. The comparator arm will consist of the same adjuvant CT backbone with T and placebo for 1 year.

Major Eligibility Criteria:
1. Non-metastatic primary BC histologically confirmed and adequately excised
2. Node-positive or node-negative: for patients with node-positive disease (pN ≥1), any pT except T0; for patients with node-negative disease (pN0), tumor size must be >1.0 cm OR for tumor size between >0.5 cm and ≤1.0 cm, at least one of the following features will be required: histologic grade 3 OR negative for ER and PgR OR age ≥35 years.
3. The interval between definitive surgery for BC and randomization must be at least 3 weeks but no more than 7 weeks.
4. Baseline LVEF ≥55%
5. HER2-positive BC confirmed by a central laboratory and defined as: IHC 3+ in >10% immunoreactive cells OR HER2 gene amplification by in situ hybridization [ISH] (ratio of HER2 gene signals to centromere 17 signals ≥2).

Aims: The primary objective is to compare invasive disease-free survival (IDFS) between both treatment arms. Secondary objectives include comparing IDFS including second non-BC, DFS, OS, recurrence-free interval (RFI), distant RFI, cardiac safety, overall safety and health-related quality of life in the two treatment arms.

Statistical Methods: Pts will be stratified based on nodal status, type of adjuvant CT regimen, hormone receptor status and geographical region. The study is designed to have an 80% power to test the null hypothesis of no true difference in risk of an IDFS event (HR = 1) versus the alternative hypothesis of a difference (HR = 0.75) in hazard rates with a 5%, 2-sided significance level.

Target accrual: 3806; Present accrual: Start Q4 2011
OTI-02-05
A Phase III Clinical Trial Comparing Trastuzumab Given Concurrently with Radiation Therapy to Radiation Therapy (RT) Alone for Women with HER2-Positive DCIS Resected by Lumpectomy: NSABP B-43,
Julian TB, Anderson SJ, Cobleigh MA, Sziopikou KP, Arthur DW, Zheng P, Mamounas EP, Pajon ER, Behrens RJ, Chu L, Leasure NC, Atkins JN, Poliakov J, Seay TE, McCaskill-Stevens W, Rabinovitch R, Wolmark N. National Surgical Breast & Bowel Project (NSABP); Pittsburgh, PA; Allegheny General Hospital, Pittsburgh, PA; University of Pittsburgh Graduate School of Public Health and Pittsburgh, PA; Allegheny General Hospital, Pittsburgh, PA; Northwestern University Feinberg School of Medicine, Chicago, IL; Virginia Commonwealth University, Richmond, VA; Aultman Health Foundation, Canton, OH; Colorado Cancer Research Program, Denver, CO; Iowa Oncology Research Association, Des Moines, IA; Florida Cancer Specialists, Sarasota, FL; Reading Regional Cancer Center, West Reading, PA; SCCCC-CCOP, Goldsboro, NC; Kaiser Permanente Southern California, San Diego, CA; Atlanta Regional Community Clinical Oncology Program, Atlanta, GA; National Cancer Institute, Rockville, MD; University of Colorado, Aurora, CO

Background: Because a substantial portion of DCIS is ER negative and overexpresses HER2, therapy targeting this protein is a promising strategy for HER2-overexpressing DCIS. Preclinical studies have shown that trastuzumab (T) boosts the effectiveness of RT in xenograft models and in cell lines with no detrimental effect on irradiated HER2-normal cells. Studies correlating clinical response with molecular markers in T-treated patients show that apoptosis occurs within 1 wk of starting single-agent T, with little effect on proliferation. Shorter duration treatments with this agent require investigation. Adjuvant trials using T during breast irradiation have already provided ample safety evidence. Will T administered during WBI improve lumpectomy + WBI results in women with HER2-positive DCIS? This trial will allow us to better understand the biology of breast cancer and its prevention and will extend the benefits of breast-conserving surgery for women with DCIS.

Trial Design: Post lumpectomy for DCIS without evidence of an invasive component, a central review of each patient’s pure DCIS is carried out for HER2 by IHC analysis. If the HER2 is 2+ or FISH analysis is done, and patients whose tumors are HER2 3+ or FISH positive can be randomly assigned to receive 2 doses of T 3 wk apart during WBI or to receive WBI alone.

Eligibility criteria: Women 18 years or older with an ECOG status of 0 or 1 who have undergone a margin-clear lumpectomy for DCIS and whose tumors are clinically or pathologically node negative are eligible. DCIS must be HER2 positive by central testing. ER and HER2 PR status must be known before random assignment.

Specific aims: The primary aim is to determine if T given concurrently with WBI is more beneficial in preventing IBC recurrence, ipsilateral skin cancer recurrence, or ipsilateral DCIS recurrence compared with WBI alone for HER2-positive DCIS resected by lumpectomy. Secondary aims are to compare the possible benefit of T given during WBI to that of WBI alone in preventing regional or distant recurrence and contralateral invasive or DCIS breast cancer. B-43 will determine if invasive or DCIS DFS, recurrence-free interval, and OS can be improved with the addition of T to WBI. The effects of T on ovarian function in premenopausal women will also be assessed.

Statistical methods and accrual: Our design calls for accrual of 2000 patients during a 7.9-year period. As of May 31, 2011, 578 patients have been entered. A definitive analysis of primary endpoints will be performed when 163 ipsilateral breast cancer events occur (7.5 and 8 years after protocol initiation). This number of events affords 80% power to detect a hazard reduction of 36%, from 1.73 ipsilateral breast cancer events per 100 patient-years to 1.11 events per 100 patient-years. The 36% observed reduction in the hazard of IBTR-SCR-DCIS on the T arm is based on a projection of 40% hazard reduction if the compliance were perfect, with a 10% noncompliance rate.

Supported by PHS grants NCI-U10-CA-69651, NCI-U10-CA-12027, and NCI P30-CA-14599 from the US NCI and Genentech, Inc.

OTI-02-06
DETECT III – A Multicenter, Randomized, Phase III Study To Compare Standard Therapy Alone Versus Standard Therapy Plus Lapatinib in Patients with Initially HER2-Negative Metastatic Breast Cancer and HER2-Positive Circulating Tumor Cells.
Melcher CA, Janni W, Ortmann U, Jäger B, Rack B, Müller V, Schneweiss A, Pantel K, Solomayer E-F, Fehm T. University Hospital Duesseldorf, Duesseldorf, Germany; University Hospital Munich, Munich, Germany; National Center for Tumor Diseases Heidelberg, Heidelberg, Germany; University Hospital Hamburg, Hamburg, Germany; University Hospital Hamburg, Hamburg/Saar, Germany; University Hospital Tuebingen, Tuebingen, Germany; University Hospital Hamburg-Eppendorf, Hamburg-Eppendorf, Germany

Background
In breast cancer patients, HER2 status may change over the course of the disease. Approximately 20-30% of initially HER2-negative patients have HER2-positive metastasis (Zidan et al. 2005, Tewes et al. 2009). Re-evaluation of HER2 status on metastatic tissue is warranted, but not always possible, especially during the course of therapy. Determining HER2 status on circulating tumor cells is one option for re-evaluating HER2 status at the time metastasis is diagnosed as described in our previous study DETECT I (Fehm et al. 2010). However, at present it is unclear if therapy based on the HER2 status of CTC offers a clinical benefit for patients. Therefore, the study DETECT III aims to assess whether lapatinib, as one of the HER2-targeted therapies, in initially HER2-negative breast cancer patients with HER2-positive CTC is effective at the time of distant disease.

Trial Design
DETECT III is a prospective, multicenter, randomized, open-label, two arm phase III study. As only half of the patients with HER2-negative MBC will be CTC-positive and approx. 32% will exhibit HER2-positive CTCs a screening of about 1420 patients will be needed. Approx. 228 patients will be enrolled in the study and randomized 1:1 to one of the following regimens Arm A (n=114): Standard Treatment, Arm B (n=114): Standard Treatment plus Lapatinib.

Planned duration of individual study participation
• Max. duration of randomized treatment period: 12 months
• Max. follow-up period: 24 months

Main eligibility criteria
1. Metastatic breast cancer
2. HER2-negative primary tumor tissue and/or biopsies from metastatic sites or locoregional recurrences
3. Evidence of HER2-positive CTCs
4. Indication for a standard chemotherapeutic regimen with lapatinib is either approved or has been investigated in prior clinical trials
5. Tumor evaluation within 6 weeks before randomization
6. ≥ 1 lesion that can be accurately measured according to RECIST
7. LVEF ≥ 50

www.aacrjournals.org Cancer Res; 71(24 Suppl.) December 15, 2011
Specific aims
Objective
The objective of the trial is to prove the clinical efficacy of lapatinib in patients with metastasizing breast cancer who exhibit HER2-positive circulating tumor cells (CTC) although the primary tumor tissue and/or biopsies from metastatic sites were investigated for HER2 status and showed HER2-negativity.

Primary endpoint:
• Progression free survival
Secondary endpoints:
• Overall response rate
• Clinical benefit rate
• Overall survival
• Dynamic of CTC
• Quality of life
• Safety and tolerability of lapatinib

Statistical methods
The primary endpoint will be analyzed by Kaplan-Meier method using the logrank test in order to compare the PFS distributions of the two arms. Efficacy, toxicity and other event rates are calculated, providing confidence intervals. In case of comparison between patient groups, these rates will be analyzed by Fisher’s exact test or χ² test. The Kaplan Meier analysis for all event related data will be carried out overall for the whole patient population. Furthermore a Cox regression analysis will be done using the following covariates
• Hormone receptor status (positive/negative)
• Number of prior chemotherapy lines for metastatic disease
• Prior endocrine therapy for metastatic disease
• Endocrine treatment vs. cytotoxic treatment
• One metastatic site vs. multiple metastatic sites
• Bone metastases vs. no bone involvement
• Performance status (0 / > 0)

OT1-02-07

Fehrenbacher L, Jeong J-H, Rastogi P, Geyer CE, Paik S, Ganz PA, Land SR, Costantino JP, Swain SM, Mamounas EP, Wolmark N. National Surgical Adjuvant Breast and Bowel Project (NSABP) Operations and Biostatistical Centers; Kaiser Permanente, Northern California; University of Pittsburgh Graduate School of Public Health; University of Pittsburgh Cancer Institute, University of Pittsburgh School of Medicine; Allegheny General Hospital; Jonsson Comprehensive Cancer Center at UCLA; Washington Cancer Institute, Washington Hospital Center; Aultman Health Foundation

Adjuvant studies utilizing trastuzumab in early HER2+ breast cancer demonstrated a large reduction in recurrence and death. Post-enrollment central testing showed HER2 non-amplified participants derived similar benefit. Among HER2-amplified patients, multiple studies showed no effect on benefit by degree of amplification. Extensive testing including blinded external review confirmed the non-amplified nature of the HER2 normal group. Detailed relevant background and confirmatory studies will be provided. As a result of these findings, NSABP study B-47, sponsored by the NCI, was activated January 2011. The study is NCI central IRB approved, open in the CTSU, and endorsed by SWOG as of April 2011.

Study: Selection of one of the two chemotherapy regimens is by physician choice: The non-anthracycline regimen is TC (docetaxel 75 mg/m2, cyclophosphamide 600 mg/m2) administered IV every 3 weeks for 6 cycles; the anthracycline regimen is AC followed by WP (doxorubicin 60 mg/m2 and cyclophosphamide 600 mg/m2 administered IV either every 3 weeks or every 2 weeks [per investigator discretion] for 4 cycles followed by paclitaxel 80 mg/m2 IV weekly for 12 doses). Patients will be randomly assigned to receive chemotherapy with or without trastuzumab therapy. For patients receiving the TC chemotherapy regimen, trastuzumab will be given every 3 weeks during and following chemotherapy until 1 year after the first trastuzumab dose (8 mg/kg loading dose; 6 mg/kg for the remaining doses). For patients receiving the AC followed by WP chemotherapy regimen, trastuzumab will begin with the first dose of weekly paclitaxel and will be given weekly for 12 doses (4 mg/kg loading dose; 2 mg/kg for the remaining weekly doses). Following completion of WP, trastuzumab therapy will continue with 6 mg/kg doses given every 3 weeks for a total of 1 year. Patients will also receive adjuvant radiation therapy and endocrine therapy, as clinically indicated.

Detailed menstrual history, concurrent medications, weight changes, and biomarkers (estrogen, stress, inflammation status) will be collected throughout the study. Collection of circulating tumor cells as an ancillary study is planned.

Eligibility: Eligibility includes: node positive or high risk node negative female breast cancer patients; HER2 IHC 1+ or 2+ scores, but non amplified by FISH; normal cardiac, renal, and liver function. Detailed eligibility will be provided.

Statistical: The primary aim is to determine whether the addition of trastuzumab to chemotherapy improves invasive disease-free survival (IDFS).

3260 patients will be enrolled to provide statistical power of 0.9 to detect a 33% reduction in the hazard rate of IDFS using a one-sided alpha level of 0.025. Projected accrual time is approximately 3 years.

Progress: Protocol was activated in January 2011. First patient was entered in February 2011. As of June 16, 2011, 115 of 3260 patients have been enrolled. Supported by NCI U10-12027, -37377, 69651, 69974, and Genentech, Inc.

OT1-02-08
The PERSEPHONE Trial: Duration of Trastuzumab with Chemotherapy in Women with HER2 Positive Early Breast Cancer. Changing the Randomisation Point To Address Potential Barriers to Recruitment.

Earl HM, Lai S, Vallier A-L, Hiller L, Ogburn-Storey E, Higgins H, Dunn J. Addenbrooke’s Hospital, Cambridge, United Kingdom; University of Warwick, Coventry, United Kingdom

Background: Persephone is a phase III randomised controlled trial comparing six months of trastuzumab (9 doses) to the standard 12 month duration (18 doses) in patients with HER2 positive early breast cancer in respect of disease free survival, safety and cost-effectiveness. The trial opened to recruitment in October 2007 but soon showed that meeting recruitment targets was challenging, reaching only 20-30 patients per month. A key issue seemed to be the mandatory requirement to randomise before patients started trastuzumab treatment. Successful accrual of patients in the PHARE trial, a Persephone sister study, run by the National Institute for Cancer, Paris had not incorporated this criteria.

Method: In September 2009, following accrual of 316 patients, this potential barrier to recruitment was addressed by a major
protocol amendment which relaxed the eligibility criteria to allow randomisation of patients who had received up to 9 doses of trastuzumab.

Results: To date, 1334 patients have been randomised into PERSEPHONE. After the amendment, monthly recruitment increased to 40-50 patients and, more recently, to 60-70 patients. Of the 1018 patients recruited since September 2009, 450 (44%) patients had received at least 1 dose of trastuzumab pre-randomisation (see Table).

Retrospective collection of pre-randomisation trastuzumab dose and toxicity information has proved successful, allowing analyses of dose intensity, toxicity and compliance to be carried out on all patients.

Conclusion: Relaxing the eligibility criteria has considerably improved recruitment into the PERSEPHONE trial without compromising the important endpoints the trial sets out to assess.

OTI-02-09
A Phase II Randomized Trial of Lapatinib with Either Vinorelbine or Capecitabine as First- and Second-Line Therapy for HER2-Overexpressing Metastatic Breast Cancer.

Janni W, Pikiel J, Sarosiek T, Karaszewska B, Papadimitriou CA, Schwedler K, Alavarez Gallego J, Caruso M, Herve RA, Lau MR, Williams LS, Briggs K, Sapunar FJ, Heinrich-Heine-Universität; Wojewódzkie Centrum Onkологии; Centrum Medyczne Ostrobramska; Przychodnia Lekarska KOMED; Alexandria Hospital; Johann-Wolfgang-Goethe-Universität; Hospital Provincial de Zama; Humanitas Centro Catanese di Oncologia; Centre Medical Claval; GlaxoSmithKline

Background: Lapatinib, a dual kinase inhibitor of epidermal growth factor receptor (EGFR) and the human epidermal growth factor receptor-2 (HER2/ErbB2), is approved for the treatment of HER2-overexpressing (HER2+) metastatic breast cancer (MBC) in combination with capecitabine following progression after trastuzumab, anthracyclines, and taxanes. Vinorelbine is an important chemotherapy option in MBC, and multiple Phase II trials in combination with trastuzumab have been conducted.

Methods: This randomized, open-label, multicenter, phase II study (VITAL, LAP112620, NCT01013740) is evaluating the efficacy and safety of lapatinib with either vinorelbine or capecitabine in women with HER2+ MBC. A total of 105 stage IV breast cancer patients with disease progression who have received ≤1 chemotherapy regimens in the metastatic setting with an ECOG performance status of ≤1 are randomized 2:1 to either: lapatinib 1250 mg orally once daily (QD) continuously plus vinorelbine 20 mg/m² intravenously on days 1 and 8 every third week; or lapatinib 1250 mg orally QD continuously plus capecitabine 2000 mg/m²/d orally in 2 doses 12 hours apart on days 1 to 14 every third week. Following progression in the randomized phase, patients will be given the option to cross over to the other arm. The primary endpoint is progression-free survival and will be analyzed with a descriptive intent since the study is not powered to detect differences between treatment arms. Secondary endpoints include overall response rate, overall survival, duration of response, time to response, and clinical benefit rate.

The study is currently recruiting in 8 countries in Europe (Bulgaria, France, Germany, Greece, Italy, Poland, Serbia, Spain) and 2 in Latin America (Chile, Mexico).

Funding Source: GlaxoSmithKline

OTI-02-10
Phase I-II Study of HER2 Vaccination with Poly(I) • Poly(C₃U) (Ampligen®) as an Adjuvant in Optimally Treated Breast Cancer Patients.

Higgins DM, Childs J, Parker S, Guthrie KA, Disis ML, Salazar LG. University of Washington, Seattle, WA; Fred Hutchinson Cancer Research Center, Seattle, WA

Background: Despite improved response rates and overall survival, many HER2+ breast cancer (BC) patients have disease relapse suggesting residual microscopic disease. HER2 vaccines given with adjuvants that can enhance, sustain, and skew antigen immunogenicity toward a Th1 phenotype could induce robust tumor-specific Th1 immunity resulting in immunologic eradication of residual tumor cells and potentially prevent relapse. One such adjuvant is Ampligen which is highly selective as a TLR-3 agonist. Our pre-clinical studies show a dose effect in the tumor prevention efficacy of Ampligen when given as an adjuvant with vaccines. We hypothesize HER2 peptide vaccination given with standard adjuvant 100mcg GMCSF and Ampligen can induce a higher incidence and magnitude of protective HER2-specific Th1 immunity than with GMCSF alone.

Trial design: Phase I-II randomized 2-stage HER2 vaccine study. Stage I will enroll 40 patients (10/arm) into one of 4 Ampligen dose arms (4, 20, 79, or 495 mcg + HER2 vaccine). The Ampligen “maximum biologic dose” (MBD), the dose with the highest incidence/magnitude of immune response and lowest incidence of toxicity will be defined. Stage II will enroll 48 patients (24/arm) receiving Ampligen MBD + HER2 vaccine + GMCSF or HER2 vaccine + GMCSF to evaluate if Ampligen MBD increases the incidence and magnitude of immunity vs HER2 vaccine + GMCSF alone. Patients will be enrolled sequentially and randomized equally into all arms via a permuted block design. Patients will receive 3 monthly vaccines. Toxicity and immune response will be assessed.

Aims: 1) To evaluate toxicity and define the MBD of Ampligen as an adjuvant with HER2 vaccination 2) determine if Ampligen MBD when combined with GMCSF as adjuvant and HER2 vaccination increases incidence/magnitude of HER2 Th1 immunity compared to standard GMCSF alone.

Eligibility criteria: Stage II--IV HER2+ BC patients who: 1) have completed definitive standard treatment, and in clinical remission 2) 14 days post chemotherapy and steroids 3) have adequate blood counts 4) are off trastuzumab 5) have no active autoimmune disease.

Statistical methods: In aim 1, we expect mild toxicity between the 4 dose arms, thus lack of efficacy based on incidence of immune response will be evaluated. Six responses must be observed within a dose arm to move forward based on historical 60% response rate (RR) with standard GMCSF (probability of continuing if true RR is 40% and 70% is 0.17, 0.85, respectively). In aim 2, 24 patients/arm provides 80% power to detect 40% difference in incidence of immune response between the 2 groups (Pearson chi-square test, two-sided alpha of 0.05) and 82% power to assess a 0.85 SD unit difference in change between control and MBD, based on a 2-sample t-test (p=0.05) and effect size defined as the difference in the means divided by the common SD. Incidences of HER2 Th1 immunity will be compared across treatment arms via Pearson chi-square test; magnitude of immune response will be compared across groups via linear regression model.
Study Accrual: Target accrual is 88 patients: Stage I (n=40) and Stage II (n=48). There has been no accrual at this time.

OT1-02-11
MotHER: A Registry Developed for Women with Breast Cancer Who Have Received Trastuzumab within 6 Months Prior to Conception or during Pregnancy.

Background: Trastuzumab is a humanized monoclonal antibody that targets HER2, a protein that is overexpressed in approximately 20% of patients with breast cancer (BC). Trastuzumab is approved for the treatment of HER2-positive BC in both the metastatic and adjuvant settings, and is classified as US Food and Drug Administration (FDA) Pregnancy Category D, which indicates evidence of fetal harm, but benefit may outweigh risk. In the postmarketing setting, oligohydramnios has been reported in patients who received trastuzumab during pregnancy either alone, or in combination with chemotherapy. As a result, this registry was requested by the FDA and was established as part of a post-marketing commitment.

Study Design: MotHER uses a prospective, observational cohort design to evaluate the outcomes of pregnancies in women exposed to trastuzumab within 6 months prior to conception or during pregnancy. Women are followed until pregnancy outcome is known; infants are followed through the first year of life. Medical information is primarily collected from the patient’s healthcare providers (HCPs) (ob/gyn, oncologist, pediatrician). Using a standardized recording and coding system, information collected on potential defects noted at birth or during the pediatric follow-up period is evaluated and classified by a birth defect evaluator/clinical geneticist.

Eligibility Criteria: Enrollment is voluntary and must be initiated by the patient before the pregnancy outcome. Enrollment may be suggested by an HCP. A verbal informed consent process is used. Patients with known prenatal testing results may enroll; however, to reduce the potential for bias, patients with knowledge of prenatal testing results (either normal or abnormal) will be analyzed as a separate subset.

Aims: The aim of this study is to evaluate the effects of trastuzumab therapy on pregnancy outcome in women who were administered trastuzumab while pregnant. The MotHER registry is the first prospective cohort study to be established for investigating the effects of a targeted cancer therapy on pregnancy outcome. The greatest challenge for this registry is to enroll a sufficient number of patients from the relatively small population of trastuzumab-exposed women who become pregnant.

Analysis Methods: Primary outcome measures are the occurrences of oligohydramnios, live births, fetal deaths/stillbirths (≥20 weeks gestation), and fetal/infant major malformations, deformations, disruptions or functional deficits. Secondary outcomes include pre-term births, elective terminations, miscarriages, fetal growth abnormalities, and pregnancy or delivery complications. The sample size has not been pre-specified. The study is descriptive: event proportions and associated confidence intervals will be calculated; statistical testing is inappropriate.

Accrual: This registry was activated in December 2008 and will accrue in the US over a 10-year period. As of June 20, 2011, 5 patients had been enrolled.

Contact Information: Patient and HCP awareness of the registry and willingness to participate are crucial to its ultimate success.

OT1-02-12
Early Detection of Cardiotoxicity by Advanced Cardiac Imaging and a Novel Biomarker in Breast Cancer Patients Undergoing Chemotherapy.

Background
The survival rate of breast cancer patients has increased due to improvements in cancer treatment. However, many survivors develop irreversible or reversible cardiotoxicity associated with anthracycline or trastuzumab therapy, respectively. To detect cardiac damage, the currently accepted method is to measure left ventricular ejection fraction (LVEF) by echocardiography, which lacks the sensitivity to predict early cardiac dysfunction.

Early identification of cardiotoxicity is essential to cancer survivors, as development of cardiomyopathy carries a worse outcome independent of cancer prognosis. Currently, there are no accepted guidelines for the early detection of myocardial injury. The use of cardiac biomarkers and more sensitive echocardiographic techniques have expanded options for monitoring, but have yet to reach a consensus.

Hence, our study will evaluate the potential predictive value of novel cardiac biomarkers and advanced echocardiographic and cardiac magnetic resonance imaging (CMR) techniques to detect subclinical myocardial damage. Our findings may be applicable for monitoring new antineoplastic agents during food and drug administration (FDA) clinical trials.

Trial Design
Prospective cohort study with internal control of 20 patients newly diagnosed with breast cancer. The trial will assess endpoints at baseline, 2 weeks after initiation of therapy, and 2 weeks and 6 months after chemotherapy completion.

1. Primary Endpoint
   a. Decline in left ventricular ejection fraction assessed by CMR and 3D-echo not detected by conventional methods
   b. Presence of either myocardial fibrosis or edema detected by CMR
   c. Changes in myocardial deformation detected by echo or CMR strain
   d. Increase in cardiac biomarkers (Serum caspase-3 p17 peptide, Troponin I, B-type natriuretic peptide) and possible correlation with imaging parameters

2. Secondary Endpoint
   a. Development New York Heart Association class 1 to 4 symptoms
   b. Decrease in LVEF of ≥5% to ≤50% with or without symptoms

Eligibility Criteria
Inclusion Criteria:
1. Newly diagnosed stage I, II, or III breast cancer
2. Age between 18 and 75 years old.
3. Treatment with trastuzumab or anthracycline-based chemotherapy

Exclusion Criteria:
1. History of cardiovascular disease
2. Pacemaker
3. History of mediastinal radiotherapy
4. Creatinine clearance <30 ml/min
5. Serum bilirubin >2.0 mg/dl, ALT and AST > 100 U/l
6. Hypertension, uncontrolled >140/90
7. LVEF <55% per 2-D echocardiogram
8. Claustrophobia

Specific Aims
1. Detect early myocardial injury.
2. Evaluate early predictors of left ventricular dysfunction.
3. Evaluate timing of monitoring during or post treatment
Statistical Method
This is a pilot study and 20 patients are required to reach statistical significance with 85% power. All values will be analyzed as mean±SD or n (%). Categorical indicators will be analyzed using nonparametric statistics such as Cochran’s Q. Changes in imaging and biomarker parameters will be assessed using analysis of variance, while correlation between the two will be assessed using mixed models appropriate for binary outcome. Significance will be accepted at p ≤0.05 for all tests.

Present accrual and target accrual
Nine subjects are enrolled with a goal of 20.

Contact for people interested in trial:
1. Dr. Erick Avelar, eavelar@uchc.edu
2. Dr. Susan Tannenbaum, stannenbaum@uchc.edu

OT1-02-13
Cardiac Biomarkers on Trastuzumab (Cabot Trial): Determining the Cardiac Biomarker Profile in Breast Cancer Patients Receiving Adjuvant Trastuzumab Therapy.
Kumar VNC, Kavask P, Rask S, Mukherjee SD, Ellis P; Dhesy-Thind B. Sunnybrook Odette Cancer Centre, Toronto, ON, Canada; Juravinski Hospital, Hamilton, ON, Canada; Juravinski Cancer Centre, Hamilton, ON, Canada

Background: Trastuzumab is a humanized anti-HER2 monoclonal antibody that has demonstrated a 50% reduction in the risk of HER2+ breast cancer recurrence. This benefit is at the risk of possible cardiac dysfunction. Detecting trastuzumab-related cardiotoxicity based on physical examination and assessment of left ventricular ejection fraction (LVEF) by serial echocardiography or multi gated acquisition (MUGA) scan, has low diagnostic sensitivity and low predictive power in detecting subclinical myocardial injury. There is interest in developing simple, non-invasive, and cost-effective tools for early identification of trastuzumab-related cardiotoxicity. Use of easily detectable cardiac biomarkers in blood, such as cardiac troponins (cTnT and cTnI) and natriuretic peptides (NPs), are being evaluated. Kavask et al. have studied a high-sensitivity cTn (hs-cTn) assay that is 10-fold more sensitive, and may be able to identify evolving injury earlier when compared to the conventional cTn assays. B-type natriuretic peptide (BNP) has been established as an indicator for heart failure. Pro-BNP is secreted from the cardiac ventricles in response to increased pressure and volume and is divided into NT-pro-BNP and BNP. The longer half-life of NT-proBNP may make it a more accurate predictor of ventricular stress. Trial design: This is a pilot single institution, prospective cohort study of 25 patients. Breast cancer patients will be seen at the Juravinski Cancer Centre, Hamilton, Canada. Biomarkers will be collected at baseline, then days 1 and 2 of every 21 day cycle for the first 3 months, then every 42 days for the next 3 months. LVEF will be measured at baseline and then every 3 months while on trastuzumab. Eligibility criteria: Patients with stage I-III, HER2 positive (3+ by immunohistochemistry or FISH+) breast cancer receiving adjuvant trastuzumab therapy. Patients who have received prior trastuzumab therapy or are unable to provide informed consent will be excluded. Specific aims: To determine the biological profile of cardiac biomarkers – cTnT, hs-cTn, and NT-proBNP – in patients on adjuvant trastuzumab; and, to determine if elevations in these biomarkers correlate with LVEF. Statistical methods: A convenient sample size of 25 patients will be entered into this pilot study. The minimum of 20 patients is a requirement by the Clinical Laboratory Standards Institute (CLSI) to formally accept existing reference ranges for the cardiac biomarkers to be used in the HER2 breast cancer population (National Committee for Clinical Laboratory Standards (NCCLS)). Present accrual and target accrual: 8 patients have enrolled to date.

OT1-03-01
A Randomized Phase III Clinical Trial of Standard Adjuvant Endocrine Therapy +/- Chemotherapy in Patients (pts) with 1-3 Positive Nodes, Hormone Receptor (HR)-Positive and HER2-Negative Breast Cancer with Recurrence Score (RS) of 25 or Less: SWOG S1007.
Gonzalez-Angulo AM, Barlow WE, Gralow JR, Meric-Bernstam F, Hayes DF, Moinpour CM, Ramsey SD, Schott AF, Sparks DB, Albain KS, Hortobagyi GN. MD Anderson Cancer Center; Houston, TX; Cancer Research And Biostatistics, Seattle, WA; Seattle Cancer Care Alliance/University of Washington, Seattle, WA; University of Michigan, Ann Arbor, MI; Fred Hutchinson Cancer Research Ctr, Seattle, WA; University of Michigan and SWOG, Ann Arbor, MI; SWOG, San Antonio, TX; Loyola Univ Chicago Stritch School of Medicine, Maywood, IL

Background: Multi-gene tumor assays have provided clinically useful prognostic information for pts with HR receptor and node-positive breast cancer. The 21-gene RS was shown to be prognostic for pts treated with tamoxifen alone, and exploratory studies suggested that it may be predictive of benefit from chemotherapy. In retrospective analyses from SWOG S8814, pts with low RS appeared to get no benefit from adjuvantCAF chemotherapy, while those with higher RS did. These retrospective data require validation, especially since more modern chemotherapy might be more effective than the regimen used in S8814.

Specific Aims/Trial Design: In January 2011, SWOG activated a phase III randomized clinical trial (registration number NCT01272037) to test the efficacy of using modern chemotherapy regimens in node positive pts with low RS, whose prognosis is still moderately poor but may not benefit from adjuvant chemotherapy based on tumor biology predicted by the RS value. The trial is similar to the Tailor RX study, but focuses on a node-positive population with low and intermediate RS.

Eligibility Criteria: Pts with 1 to 3 positive lymph nodes, HR-positive and HER2-negative invasive breast cancer with RS ≤ 25 are eligible for randomization. Pts will be informed of their RS, Target and Present Accrual: Approximately 9400 patients will be screened to randomize 4000, stratified by RS (0-13 vs. 14-25), menopausal status, and axillary surgery (sentinel node vs. complete dissection); 46 are presently registered. Statistical Methods: The trial is powered to find a significant interaction of treatment assignment and the continuous RS value and, subsequently, derive a cut point for using the assay to guide treatment decisions. Pts who consent to screening are required to consent to banking of the tumor tissue and blood for further studies. Patient Reported Outcomes will be collected pre, post-screening and post-randomization. The study also has a cost-effectiveness analysis. Funding: Supported in part by National Cancer Institute grants CA32102 & CA38926, and in part by the Susan G. Komen for the Cure® Research Program, and the Breast Cancer Research Foundation.
OT1-03-02
SAFIR01: A Molecular Screening Trial for Metastatic Breast Cancer Patients.
Andre F, Peletkian C, Jimenez M, Ferrero JM, Delaloge S, Roman Roman S, Dessen P, Bonnefoi H. Gustave Roussy Institute; Unicancer; Curie Institute; Bergonie Institute; Centre antoine lacassagne, Nice, France

Background: High number of new drugs are targeting molecular alterations that occur in a few number of patients. Molecular screening that consists in the assessment of single molecular alteration during the screening phase of the therapeutic trial is not suitable. Indeed, this modality of screening is associated with a high rate of screen failure due to the low incidence of the molecular alteration. In order to optimize molecular screening, we have launched a clinical trial that aims at performing array CGH and hot spot mutations in patients with metastatic breast cancer.

Patients and Methods. The trial plans to include 400 patients with metastatic breast cancer and included the first patient in may 2011. This trial is being sponsored by French federation of Cancer centers (UNICANCER) and involves 20 centers. Biopsy is being performed on metastatic site. Both frozen and FFPE samples are obtained. DNA extraction is being performed in the investigation center after control for the % of cancer cells. Array CGH and PIK3CA/AKT mutations (SANGE method) are being performed in four genomic platforms. A pilot study that included 106 patients has shown the feasibility of such technologies in the context of daily practice. Data from array CGH are being sent to a bioinformatician who forward the results on both pre-selected targets, DNA instability and some targets of interest selected based on log2(ratio) and function. Recommendations for trials are then being sent to each investigator. There is no limitation for previous lines and it is recommended to perform biopsy in patients who do not present progressive disease. This trial is being funded by French NCI (750 000 euros)

Conclusion: SAFIR01 is a trial that aims at using high throughput technologies in order to drive patients with molecular alterations to specific therapeutic trials. Further amendments are being planned including implementation of high throughput sequencing and performance of functional testing. Further trial will compare this high throughput approach to standard methods for target identification.

OT1-03-03
Effect of Tamoxifen Therapy on Inhibition of Tumor Suppressor p53 by Estrogen Receptor.
Kulkarni S, Fetterly GJ, Morrison CD, Adjei AA, Andrews C, Edge SP, Mukhopadhyay UK, Swezigg WM, Das GM. Roswell Park Cancer Institute, Buffalo, NY

Background: A large number of patients with estrogen receptor (ER)-positive tumors are resistant to tamoxifen (TAM). Although several plausible reasons for such resistance have been suggested, the mechanisms remain unclear. ER mediates effects of estrogen by promoting proliferation of breast cancer cells. Tumor suppressor protein p53 guards against tumorigenesis by preventing proliferation of cells with genomic damage. Dr. Das’s laboratory previously reported that ER binds and functionally suppresses wild type p53 in human breast cancer cells and xenograft tumor tissue, and TAM is capable of inhibiting this interaction. We hypothesize that relieving suppression of wild type p53 by ER could be an important mechanism underlying TAM action in breast cancer. To test this hypothesis, we have initiated a pilot randomized clinical trial of 50 women with newly diagnosed ERα-positive breast cancer.

Specific Aims: 1) To investigate the effect of a short pre-surgical intervention with TAM on the ER-p53 interaction in ER-positive, p53 wild type breast tumors and 2) To confirm the wild type status of p53 and analyze the functional status of the p53 pathway by monitoring expression of selected p53 target genes in tumors that have and have not been treated with TAM.

Trial design: A randomized clinical trial in the pre-surgical setting was proposed with either TAM 20mg for four weeks vs. no intervention. Patients randomized to the TAM arm will undergo multiple pharmacokinetic and pharmacodynamic measurements of TAM metabolites and genotyping for common polymorphisms of TAM metabolism genes, CYP2D6 and CYP3A4/5. Fresh tumor tissue will be harvested from all patients at the time of surgery for analysis of ER-p53 protein interaction using tissue chromatin immunoprecipitation (tissue ChIP) assay. p53 gene status will be determined by sequencing. RNA and protein expression of ER, p53, and a selected group of ER and p53 target genes in the diagnostic core biopsy and surgical specimens will be analyzed by quantitative real-time PCR (qRTPCR) and immunohistochemistry (IHC). TAM metabolites will also be measured in the tumor and the surrounding benign tissue.

Eligibility criteria: Women greater or equal to eighteen years of age diagnosed with ER-positive invasive breast cancer (approximately 1cm in size) who will undergo primary surgical excision for their initial therapy are eligible. Women must not be pregnant, be on current hormonal therapy, or have a history of hypercoagulable syndrome or prior arterial or venous thrombosis.

Statistical methods: Descriptive statistics such as frequencies and relative frequencies will be computed for all categorical variables. Numeric variables will be summarized using simple descriptive statistics such as mean, standard deviation, and quartiles. Ninety-five percent confidence intervals will be computed. ChIP data will be subjected to Fisher’s Exact Test. IHC date will be analyzed by Wilcoxon-Mann-Whitney test.

Present accrual and target accrual: We have accrued 17 patients to date and plan to accrue a total of 50 patients, 25 in each arm.

OT2-01-01
International Breast Cancer Study Group (IBCSG) Trial 22-00: Low-Dose Cytotoxics as Maintenance “Anti-Angiogenesis Treatment” Following Adjuvant Induction Chemotherapy for Patients with ER-Negative and PgR-Negative Breast Cancer.
Colleoni M. International Breast Cancer Study Group

Background
Patients with endocrine responsive disease benefit from five years of endocrine therapy after chemotherapy, but for patients with endocrine non-responsive disease there is no evidence of benefit of extending treatment beyond a standard duration (three to six months). The low-dose maintenance chemotherapy (metronomic cyclophosphamide and methotrexate (CM) given orally) regimen being tested in this trial was developed in advanced disease and resulted in tumor shrinkage even in heavily pretreated patients. The mechanism of this effect might be through anti-angiogenesis or by interference with progression of the stromal structure of metastases.

Trial Design
This randomized phase III trial compares 12 months of CM Maintenance chemotherapy (CMM) (cyclophosphamide 50/mg/day orally continuously for 1 year; methotrexate 2.5 mg/twice a day orally days 1 and 2 of every week for 1 year) vs. no CMM, following breast cancer surgery and standard induction chemotherapy. Stratification factors: institution, menopausal status, induction regimen. Concurrent trastuzumab is permitted for patients with HER2-positive disease.
Major Eligibility Criteria
-Histologically proven primary breast cancer
-Both estrogen and progesterone receptor status negative (<10% of tumor cells positive by IHC)
-Known HER2 status
-Approved induction chemotherapy must begin within 8 weeks after definitive surgery
-Pathological axillary staging
-

Specific Aim
To evaluate the efficacy of a low-dose chemotherapy regimen, hypothesized to have anti-angiogenic activity, administered following a standard chemotherapy program, in patients whose tumors are not endocrine therapy-responsive.

Statistical Methods
The primary analysis population will be intention-to-treat (all randomized patients). The primary endpoint, disease-free survival (DFS), will be compared between treatment arms using a two-sided stratified logrank test with an alpha level of 0.05. Based on results from ER-negative populations in other IBCSG trials, we assume that the overall five-year disease-free survival for the group receiving induction chemotherapy alone will be 70%. Due to a relatively high non-adherence rate (14% of early patients randomized to CMM did not start CM), the original sample size of 900 was increased to 1080 (October 2010), and the target number of events from 256 to 307. With this revision detection of a true hazard ratio of 0.70 will be achieved with a power of 72% despite a 15% non-adherence rate in the CMM group.

Present and Target Accrual
Target: 1080 patients. Present: 967 (as of June 1, 2011).

Related Research
Serum Substudy for 170 patients will evaluate differences from baseline to 18 months post baseline in serum VEGF, VCAM-1 and NRP protein values. Patient self-reported quality-of-life assessments are collected at baseline and months 9, 12, 18, 24 for all patients.

Central pathology review of histology, grade, ER, PgR, Her2, and Ki-67 for all patients is ongoing.

OT2-01-02
First-Line Bevacizumab in Combination with Capecitabine or Paclitaxel for HER2-Negative Locally Recurrent or Metastatic Breast Cancer (LR/MBC): A Randomized Phase III Trial.
Beslja S, Brodowicz T, Greil R, Inbar MJ, Kahán Z, Kaufman B, Lang I, Sieger GG, Stemmer SM, Zielinski C, Zvirbule Z, The CECOG TURANDOT Trialists. Institute of Oncology, Sarajevo, Bosnia and Herzegovina; Medical University of Vienna, Vienna, Austria; University Hospital Salzburg, Salzburg, Austria; Tel Aviv Sourasky Medical Centre, Tel Aviv, Israel; University of Szeged, Szeged, Hungary; Sheba Medical Center, Tel Hashomer, Israel; National Institute of Oncology, Budapest, Hungary; Rabin Medical Center, Petah Tikva, Israel; Riga Eastern Clinical University Hospital, Riga, Latvia

Background: A number of phase III studies have shown significant progression-free survival (PFS) benefits with the combination of bevacizumab (Bev) and either first-line capecitabine (X) or taxane therapy in LR/MBC. The ongoing open-label, randomized, phase III CECOG-sponsored TURANDOT study (CECOG/BC.1.3.005) is investigating the efficacy and safety of first-line Bev plus paclitaxel (P) versus Bev plus X in this setting.

Materials and methods: Eligible patients (pts) are aged ≥18 years with HER2-negative, chemonaive LR/MBC, an EOCG performance status of 0–2 and a life expectancy >12 weeks. Prior chemotherapy and concomitant hormonal therapy for LR/MBC are not permitted, but prior (neo)adjuvant chemotherapy is allowed if completed ≥6 months before randomization or ≥12 months if taxane based. Pts are randomized to receive Bev 10mg/kg days 1, 15 plus P90mg/m² days 1, 8, 15, q28d (Arm A) or Bev 15mg/kg day 1 plus X 1,000mg/m² bid days 1–14, q21d (Arm B) until disease progression, unacceptable toxicity or withdrawal of consent. The primary objective is to demonstrate non-inferiority in overall survival (OS) with Bev plus P versus Bev plus X (upper limit ≤1.33 for the two-sided confidence interval for hazard ratio [HR]). Secondary objectives are: comparison of overall response rate (RECIST criteria); PFS; time to response; duration of response; time to treatment failure; quality (CTCAE version 3); and quality of life (EORTC QLQ-30). The recruitment target is 560 pts. A sample size of 490 pts in the per-protocol population will be required to provide 80% power to reject the null hypothesis of inferiority at a one-sided significance level of 0.025, assuming a 24-month median OS with Bev plus P and an alternative hypothesis of HR=1. Data cut-off for adverse event reports was 12 Apr 2010. Interim and final efficacy analyses will be triggered after 175 and 389 events, respectively.

Results: Recruitment to the study began in Sep 2008 and was completed in Aug 2010, with 561 pts randomized. Follow-up is ongoing.

Conclusions: TURANDOT is the first study to examine the efficacy and safety of Bev plus P versus Bev plus X as first-line treatment for pts with LR/MBC.
≥4 cycles of anthracycline and/or taxane containing neoadjuvant chemotherapy regimen (+trastuzumab in HER2-positive tumors) are eligible. Pts must have failed to achieve a pCR following neoadjuvant treatment (i.e. residual invasive breast cancer >5mm) in the breast or lymph nodes at surgery [ypT1b-T4, N1-2, M0]). Additional eligibility criteria include: ECOG performance status of 0-1; adequate hematologic, hepatic and renal function. Pts with nonhealed surgical wounds, known or active cardiovascular disease, QTC interval > 480 ms, chronic use of QTc prolonging drugs, as well as previous breast cancer diagnosis <3 years prior to trial entry, are excluded.

**Trial Design:** Pts are stratified into three cohorts according to HER2 and hormone receptor status as follows: triple-negative (Cohort A, n=54), hormone-receptor-positive/HER2-negative (Cohort B, n=42) and HER2-positive (Cohort C, n=32). All pts receive eribulin mesylate 1.4mg/m² IV on days 1 & 8 of each 21–day treatment cycle for 6 cycles. Pts with HER2-positive tumors also receive trastuzumab 6mg/kg IV day 1 of each cycle. Locoregional radiotherapy and/or adjuvant hormonal therapy (Cohort B only) will be administered per institutional guidelines. With standard neoadjuvant therapy, the approximate median DFS of pts who do not achieve 2-pCR are as follows: triple-negative, 40%; hormone-receptor-positive/HER2-negative, 80%; and HER2-positive, 60%. For a one-sided test of hypothesis at alpha = 0.10 and power = 0.80, the required numbers of evaluable patients treated in each cohort are 49, 38, and 47, respectively, to demonstrate improvement in treatment outcome in these groups of at-risk pts.

The trial is currently enrolling and has an accrual goal of 148 patients.

**OT2-01-04**

**Cardiac Safety of Anthracycline-Containing Adjuvant Chemotherapy of Early Breast Cancer: OSCAR/ABC Ongoing, Observational, Multicentric Study.**

**Ricevuto E, Cocciolone V, Zilli M, Scognamiglio MT, Pistilli B, Di Menna G, Mancini M, Cattani K, Adinolfi MI, Ferrandina MG, Pancotti A, Recchia F, Latini L, Ficorella C, Iacobelli S. San Salvatore Hospital, University of L’Aquila, L’Aquila, Italy; SS. Annunziata Hospital and G. Bernabeo Hospital, University G. D’Annunzio, Chieti, Italy; Ospedale Civilie of Macerata, Macerata, Italy; E. Renzetti Hospital, Lanciano, Chieti, Italy; Catholic University of the Sacred Heart, Rome, Campobasso, Italy; Mazzini Hospital, Teramo, Italy; Ospedale Civilie of Avezzano, Avezzano, L’Aquila, Italy.

**BACKGROUND:** Among the different chemotherapeutic options available for adjuvant treatment of early breast cancer (EBC), anthracycline-containing regimens represent prevalent choices. OSCAR/ABC is an observational, prospective, multicentric study aimed at evaluating, in the clinical practice, the relevance of cardiac dysfunction and congestive heart failure (CHF) associated to “free choice”; anthracycline-containing adjuvant regimens and to identify patients at increased cardiac risk. **PATIENTS AND METHODS:** patients candidate to receive adjuvant anthracycline-containing chemotherapy, will be enrolled in the study. Data on demographic and clinical characteristics of patients (age, cardiovascular comorbidity) tumor features (TNM, histotype, ER and PgR status, Ki67, and HER2 status), type of adjuvant regimen and tolerability of treatment will be collected and centrally registered at the Consorzio Interuniversitario Nazionale per la Bio-Oncologia (CINBO) using e-CRFs. Data on type, sites and doses of radiotherapy performed will be collected, to evaluate the possible impact on cardiac function. Primary aim of the study is to evaluate the prevalence of cardiac dysfunction and CHF among the whole population enrolled, particularly according to risk criteria and type of administered chemotherapy. Cardiac dysfunction is defined as limiting cardio-vascular toxicity (≥ Grade 3 dyspnea, arrhythmia, hypertension) and/or asymptomatic LVEF reduction ≥20% (if >50% at the baseline) or ≥10% (if ≤50% at baseline); CHF is defined as clinical diagnosis and/or asymptomatic LVEF reduction ≥20% (if >50% at the baseline) or ≥10% (if ≤50% at baseline). Assessment of cardiac risk involves the evaluation of age (< vs ≥ 65 years), cardio-vascular comorbidities (requiring treatment or not) and Left-Ventricular Ejection Fraction LVEF (> vs ≤ 55%) at diagnosis. Clinical and instrumental cardiac evaluation (ECG, Echocardiography) will be performed at study entry, on-treatment and up to 5 years thereafter. Secondary objective of the study is to evaluate the clinical properness of different adjuvant anthracyclines-containing chemotherapy options, with regard to prevalence of therapeutic regimens, safety, efficacy (DFS and OS) and costs analysis. Cardiac safety and general toxicity on-treatment will be evaluated according to NCI criteria. The expected enrollment is 1,200 patients in 36 months. From September 2010 to May 2011, 7 of the 13 Centers involved in the study are active, with 65 enrolled patients.

**OT2-02-01**

**The SOLE Trial: International Breast Cancer Study Group (IBCSG 35-07) and Breast International Group (BIG 1-07) Study of Letrozole Extension.**

**Colleoni M. SOLE Collaborative Group and International Breast Cancer Study Group Group.**

**BACKGROUND:** The SOLE trial tests the hypothesis that treatment-free intervals during the course of five years of extended adjuvant letrozole will improve disease-free survival (DFS). The hypothesis is based on the observation in animal models that intermittent letrozole withdrawal will permit some estrogenic stimulation which makes residual resistant disease susceptible to letrozole reintroduction.

**Trial Design**

Randomized, Phase III trial comparing 5 years of continuous letrozole vs. 5 years of intermittent letrozole. The intermittent group receives letrozole daily for the first 9 months (followed by a 3-month gap) years 1-4, and 12 months year 5. Stratification factors are institution and prior endocrine therapy (SERM, AI or both).

**Major Eligibility Criteria**

-Postmenopausal
-Premenopausal
-Disease-free
-Received 4-6 years of prior adjuvant endocrine therapy (SERM and/or AI)
-Randomized within 12 months of last dose of prior endocrine therapy
-Endocrine-responsive breast cancer at diagnosis
-Node-positive breast cancer at diagnosis

**Specific Aim**

To compare continuous and intermittent letrozole given for a five year period for postmenopausal women who are disease-free following 4-6 years of prior adjuvant endocrine therapy with SERM(s) and/or AI(s) for endocrine-responsive node-positive operable breast cancer.

**Statistical Methods**

The primary analysis will be undertaken with the intention-to-treat population of all randomized patients. The primary endpoint DFS will be compared between treatment arms using a two-sided stratified logrank test with an overall experiment-wise alpha level equal to at most 0.05.

For the eligible population of patients with node positive disease at initial diagnosis, we assume 90% of patients who receive continuous extended letrozole will be alive and disease-free at 4 years from randomization (based on results of MA.17). The sample size was
determined to provide 80% power to detect a 20% reduction in the risk of an event defining DFS associated with intermittent letrozole compared with continuous letrozole (hazard ratio = 0.80; increase in 4-year DFS from 90% to 91.917%) using a two-sided 0.05 level test of significance.

**Present and Target Accrual**

Target: 4800; Present: 2655 (June 1, 2011)

**Related Research**

The SOLE-EST Substudy focuses on the changes in estrogen levels that occur on letrozole and during the three month treatment gap without letrozole; and relationships between changes in patient-reported musculoskeletal symptoms, grip strength and QL. The target accrual goal is 100 patients (75 intermittent and 25 continuous).

**The SOLE Quality of Life Substudy** compares differences in patient-reported symptoms and QL between continuous letrozole for 5 years and intermittent letrozole over a 2-year period. The target accrual goal is 834 patients.

**Central Pathology**

Review for all patients of histology, grade, ER, PgR, HER2, and Ki-67 is ongoing.

**Contact Information**

The SOLE trial is a worldwide collaboration among cooperative groups and large institutions primarily through the Breast International Group (BIG).

**OT2-03-01**

Incidence of Mastalgia as a Presenting Complaint in Iranian Population with Regard to Age, BMI, Education, Residency (City or Rural), State of Marriage and Compare with Western Countries.

Razavi S, Private Breast Clinic, Esfahan, Islamic Republic of Iran

As it is has usually been stated, breast pain (mastalgia) is among the most common (or the commonest) cause of women referring to a breast clinic. The incidence has been reported in different ranges, and some studies (e.g. Canadian groups) have stated that mastalgia has its lowest incidence in middle east (compared to western countries). Based on this information I have recently planned a study to investigate this issue.

To evaluate this data, I planned a questionnaire for every new patient coming to my breast clinic randomly. Every questionnaire was double checked & if still incomplete, was completed by phone communication.

The only inclusion criteria were to be a new patient. In this way over 550 questioners were completed during over 4 months. The aim is to find if there is any statistical difference in incidence rate and if there is any, evaluate any demographic difference that can be a cause.

**OT2-03-02**

Prospective Neo-Adjuvant Registry Trial Linking MammaPrint, Subtyping and Treatment Response: Neo-adjuvant Breast Registry – Symphony Trial (NBRST).

Whitworth P, Beitsh P, Gittleman M, Akbari S. Nashville Breast Center, Nashville, TN; Dallas Surgical Group, Dallas, TX; Breast Care Specialists, Allentown, PA; Virginia Hospital Center, Arlington, VA

**Background**

MammaPrint is performed on a diagnostic multi-gene array featuring >4,500 genes. This platform enables additional gene expression profiles to be analyzed simultaneously on one tumor specimen. BluePrint, an eighty gene Molecular Subtyping Profile, discriminates between three distinctive subtypes; Basal-type, Luminal-type, and ERBB2 (HER2)-type. Studies have shown marked differences in response to neo-adjuvant treatment in groups stratified by MammaPrint and BluePrint.

**Trial design**

A prospective observational, case-only study linking MammaPrint, BluePrint, TargetPrint, TheraPrint (together referred to as the Symphony suite) and possible additional profiles of interest to neo-adjuvant treatment response and Distant Metastases Free Survival (DMFS) and Relapse Free Survival (RFS). 20-30 institutions in the US will be invited to contribute clinical patient data from enrolled patients after a MammaPrint, TargetPrint, BluePrint and TheraPrint (Symphony suite) has been successfully performed and the patient has started neo-adjuvant therapy. Treatment is at the discretion of the physician, adhering to NCCN approved regimens or a recognized alternative.

**Eligibility criteria**

- Women with histologically proven breast cancer, who have started or are scheduled to start neo-adjuvant chemotherapy therapy or neo-adjuvant hormone therapy, after successful Symphony suite assessment
- Age 18-90
- Written informed consent
- No excisional biopsy or axillary dissection
- No confirmed distant metastatic disease
- No prior therapy for the treatment of breast cancer

**Scope**

The scope of this registry study is to measure chemosensitivity as defined by pCR (primary endpoint), or endocrine sensitivity as defined by partial response, (a primary endpoint for neo-adjuvant endocrine therapy and a secondary endpoint for neoadjuvant chemotherapy), metastasis-free survival and relapse-free survival (secondary endpoints) in molecular subgroups, determined by the MammaPrint and BluePrint; as well as correlation to Targetprint and Theraprint read outs in addition to investigating novel response profiles.

**Statistical methods**

The response rate and corresponding confidence intervals will be presented as a proportion of all patients enrolled. The confidence intervals will be calculated using the normal approximation to the binomial distribution. Comparison of response rates between different molecular subgroups will be conducted using Pearson Chi-square test. Correlation of chemosensitivity and endocrine sensitivity (as defined by pCR) to TheraPrint will be determined using Pearson correlation and linear fit models. Kaplan-Meier curves for RFS and DMFS will be calculated for different molecular subgroups.

**Present accrual and target accrual**

The target accrual is to enroll approximately 500 patients in 4 years.

**OT2-03-03**

Spectroscopic Feature of Breast Cancer.

Ogura H, Yamashita D, Nasu H, Hosokawa Y, Koizumi K, Yamaki E, Yoshimoto K, Suzuki T, Ueda Y, Oda M, Yamashita Y, Sakahara H. Hamamatsu University School of Medicine, Hamamatsu, Shizuoka, Japan; Hamamatsu Photonics K.K., Hamamatsu, Shizuoka, Japan

**Objectives:** To examine optical properties of breast cancer by time-resolved spectroscopy.

Materials and Methods: We irradiated a pulsed laser of 760, 800, and 830 nm wave-length lights at multiple sites of both breasts including the site just above the cancer and detected the light transmitted through the breast with TRS-20SH (Hamamatsu Photonics K.K.). Absorption coefficient (μa), reduced scattering coefficient (μs’), total hemoglobin...
(\text{tHb})$, and oxygen saturation (SO2) of the breast were calculated by photon diffusion equation. The clinical trial started in January 2007. A total of one hundred nine breast cancer patients participated in the trial and written informed consent were obtained from all of the patients. Results: In 800 nm wave-length, absorption coefficient (\(\mu_a\)) of breast cancer tissue was significantly high, compared with contra-lateral normal breast (cancer:0.0677±0.0293, normal breast:0.0479±0.0161, \(p<0.001\)).

**Table 1**

<table>
<thead>

</tbody>
</table>

Absorption coefficient (\(\mu_a\)) and reduced scattering coefficient (\(\mu_s'\)) of cancer / normal breast

The result was the same in 760, and 830 nm. There was no difference in reduced scattering coefficient (\(\mu_s'\)) between breast cancer tissue and contra-lateral normal breast (800 nm cancer:9.07±1.217, normal breast:9.34±1.243, \(p=0.10\)). The \(\text{tHb}\) of breast cancer tissue was significantly high, compared with normal breast (cancer:31.0±14.7, normal breast:21.0±8.2, \(p=0.001\)). There was no difference in oxygen saturation (SO2) between breast cancer tissue and contra-lateral normal breast (cancer:72.8±4.1, normal breast:73.8±4.5, \(p=0.08\)).

Conclusion: Absorption coefficient (\(\mu_a\)) and \(\text{tHb}\) increased in breast cancer, whereas reduced scattering coefficient (\(\mu_s'\)) did not.

**OT2-03-04**

A Trial Model for the Future in the Search for Personalised Medicine – The UK POETIC and EPHOS-B Perioperative Trials Experience.

Bliss JM, Robison LE, Webster-Smith MF, Emson MA, Kilburn LS, Smith JE, Robertson J, Dowsett M, Bundred NJ, Cameron DA, Vidy R, Horgan K, Evans AA, Kokan JS, Pinhel I, A’Hern R, On Behalf of the POETIC & EPHOS-B Trialists. Institute of Cancer Research, Sutton, London, United Kingdom; Royal Marsden Hospital, London, United Kingdom; Nottingham University Hospitals, Nottingham, United Kingdom; Royal Marsden Hospital and Breakthrough Breast Cancer Centre, London, United Kingdom; Wythenshawe Hospital, Manchester, United Kingdom; Western General Hospital, Edinburgh, United Kingdom; Stafford Hospital, Stafford, United Kingdom; Leeds General Infirmary, Leeds, United Kingdom; Poole Hospital, Poole, United Kingdom; Macclesfield District General Hospital, Macclesfield, United Kingdom

**Background:** Perioperative therapy offers the opportunity to measure biological response to treatment in the primary tumor in early breast cancer (EBC), enhancing prospects for personalised medicine. Perioperative trials form an expanding component of the UK national breast cancer trials portfolio. Unlike traditional neoadjuvant studies, activity dovetails around timelines for standard treatment with no planned delay to primary surgery. Tissue samples collected prior to randomisation (baseline) & again at surgery address key biological endpoints & are essential for perioperative studies.

**Methods:** As the UK’s largest perioperative trial, POETIC (ER+ve postmenopausal EBC, +/- aromatase inhibitor therapy, biomarker & disease outcome) aims to recruit 4000 patients from 100+ centres. EPHOS-B (HER2+ve EBC, +/- lapatinib or trastuzumab) focuses on biomarker endpoints & aims to recruit 250 patients. Barriers to recruitment included 1) integration of research protocols into busy breast surgical clinics, extending a clinical trials culture across a multidisciplinary breast diagnostic team, & ensuring appropriate GCP training, 2) satisfying requirements for storing research tissue, 3) complying with government cancer wait times, 4) obtaining biomarker results within required timelines 5) ensuring completeness & quality of tissue samples. Additional challenges for EPHOS-B include managing requirements for scheduling of oncological therapy (e.g. trastuzumab) in pre-operative setting, delivery of such therapy outside the randomising hospital & rapid access to cardiac screening before randomisation.

**Results:** The following strategies were developed to overcome barriers 1) increasing collaborative working at sites & adopting a pragmatic approach to type of tissue required. Centres choose to provide both FFPE tissue & tissue in RNA-later, or FFPE tissue only; 2) working with national regulators to agree interpretation of current legislation in designation of when tissue is “in transit” (enabling it to reside outside a tissue bank) & “research” tissue (where transfer to a tissue bank is required); 3) agreement with government that procedures integral to perioperative trials comply with cancer wait times; 4) promoting reorganisation of site processes for obtaining essential biomarker results; 5) pilot lab work to inform site guidance on tissue collection procedures to ensure quality of samples received. A tracking database allows completeness of tissue samples to be monitored. Work to improve timelines for HER2 testing in EPHOS-B is ongoing, & challenges of delivering anti-HER2 therapy in this setting have been addressed.

**Conclusions:** Assessment of biological response to therapy in the primary tumor in EBC within national trials is feasible. Many barriers faced by POETIC have been overcome, & with recruitment now 100+ patients per month, newer centres benefit from earlier experience. Lessons learnt in POETIC apply to EPHOS-B, allowing investigators to focus on resolving more challenging issues specific to that trial. In many centres both trials have been important drivers in improving timeliness of molecular testing & therefore benefited the patient pathway in general as well as securing high quality trial data.

**OT2-03-05**

Evaluation of the Prevalence and Prognostic Significance of VEGF\(_{165b}\) in Breast Cancer Patients Compared to Healthy Women.

Guenthner-Biller MM, Rademacher A, Mayr D, Engelstädter V, Fries K, Jeschke U, Rack B. Ludwig-Maximilians-University, Munich, Bavaria, Germany

Background: VEGF\(_{165b}\) mRNA was first isolated in 2002 by RT-PCR out of renal cortex tissue which resulted in a shorter PCR product than predicted from previously identified isoforms. This isoform was subsequently identified and cloned in both primary epithelial cells as well as in stable immortalized podocyte cell lines. Because of the nature of this splice variant and its distal splicing of the 3’-untranslated region of the VEGF mRNA, most previously investigated expression studies will not have distinguished VEGF\(_{165b}\) but no in vivo data regarding the level of expression of VEGF\(_{165b}\) in breast cancer or its possible correlation with disease progression.

**Methods:** As the UK’s largest perioperative trial, POETIC (ER+ve postmenopausal EBC, +/- aromatase inhibitor therapy, biomarker & disease outcome) aims to recruit 4000 patients from 100+ centres. EPHOS-B (HER2+ve EBC, +/- lapatinib or trastuzumab) focuses on biomarker endpoints & aims to recruit 250 patients. Barriers to recruitment included 1) integration of research protocols into busy breast surgical clinics, extending a clinical trials culture across a multidisciplinary breast diagnostic team, & ensuring appropriate GCP training, 2) satisfying requirements for storing research tissue, 3) complying with government cancer wait times, 4) obtaining biomarker results within required timelines 5) ensuring completeness & quality of tissue samples. Additional challenges for EPHOS-B include managing requirements for scheduling of oncological therapy (e.g. trastuzumab) in pre-operative setting, delivery of such therapy outside the randomising hospital & rapid access to cardiac screening before randomisation.

**Results:** The following strategies were developed to overcome barriers 1) increasing collaborative working at sites & adopting a pragmatic approach to type of tissue required. Centres choose to provide both FFPE tissue & tissue in RNA-later, or FFPE tissue only; 2) working with national regulators to agree interpretation of current legislation in designation of when tissue is “in transit” (enabling it to reside outside a tissue bank) & “research” tissue (where transfer to a tissue bank is required); 3) agreement with government that procedures integral to perioperative trials comply with cancer wait times; 4) promoting reorganisation of site processes for obtaining essential biomarker results; 5) pilot lab work to inform site guidance on tissue collection procedures to ensure quality of samples received. A tracking database allows completeness of tissue samples to be monitored. Work to improve timelines for HER2 testing in EPHOS-B is ongoing, & challenges of delivering anti-HER2 therapy in this setting have been addressed.

**Conclusions:** Assessment of biological response to therapy in the primary tumor in EBC within national trials is feasible. Many barriers faced by POETIC have been overcome, & with recruitment now 100+ patients per month, newer centres benefit from earlier experience. Lessons learnt in POETIC apply to EPHOS-B, allowing investigators to focus on resolving more challenging issues specific to that trial. In many centres both trials have been important drivers in improving timeliness of molecular testing & therefore benefited the patient pathway in general as well as securing high quality trial data.
existing clinical data. There are two groups of patients included in this study; patients with newly diagnosed breast cancer and healthy volunteers.

Eligibility criteria: The eligibility criteria for the breast cancer group are newly diagnosed ductal, lobular or inflammatory breast cancer at stage I-IV, no prior treatment, above 18 years of age. The eligibility criteria for the healthy volunteers are healthy women with no history of cancer with no current medical therapies and above 18 years of age.

Specific aims: The primary objective of this trial is to estimate the prevalence of VEGF_165b in breast cancer patients and healthy volunteers. The secondary objective is the correlation of VEGF_165b with clinical characteristics over time.

Statistical method: The statistical analysis being used in this study will be primarily descriptive with the calculation of mean and median and confidence intervals. The difference in distribution of the values will be examined in a one way variant analysis. We will also correlate results from different biospecimens and correlate the prevalence of variant presence or absence.

Material and methods: The samples will be analysed using a specific ELISA as well as immunohistochemistry. The accuracy and sensitivity of the available ELISA are of utmost importance in this setting. Bates et al have done previous work evaluating the ELISA used in this study and have shown that it underestimates the value for VEGF_165b but that it is specific for VEGF_165b. Since we will rather look at individual variation over the course of time, it will not have an effect regarding the expected results but it prohibits a direct comparison of the measured levels of VEGF_165b to VEGF_165b if they are not corrected for this lack in sensitivity.

OT2-03-06

Hylton NM, Partridge SC, Rosen M, Kim E, L’Heureux DZ, Edsman L, University of California at San Francisco, San Francisco, CA; University of Washington, Seattle, WA; Hospital of the University of Pennsylvania, Philadelphia, PA; Brown University, Providence, RI; American College of Radiology Imaging Network, Philadelphia, PA

Background: Functional MRI techniques may be utilized for characterizing breast tumors and measuring response to neoadjuvant chemotherapy (NAC). Dynamic contrast enhanced (DCE) MRI is the most common functional breast MRI technique. Fitting DCE MRI data to an appropriate pharmacokinetic model allows noninvasive, in vivo measurement of physiological parameters related to tissue perfusion, microvascular permeability, and extracellular/extravascular volume fraction. Diffusion weighted imaging (DWI) MRI is an alternative technique that measures the mobility of water molecules in vivo and is sensitive to tissue characteristics such as cell density, membrane permeability, and microstructure. DWI provides complementary information to DCE MRI about tumor biology and has shown promise for early prediction of response. The master ISPY2 multi-center study is a process targeting the rapid, focused clinical development of paired oncologic therapies and biomarkers. Its framework is an adaptive phase II clinical trial design in the neoadjuvant setting for women with locally advanced breast cancer. As a sub-study, ACRIN 6698 will combine both DCE and DWI MRI data to generate novel imaging biomarkers that correlate with treatment response. The two studies will provide a rich data set that can be used to elucidate molecular pathways and tumor responses to novel investigational drugs with standard chemotherapy. **Trial design**: ACRIN 6698 will perform advanced DCE and DWI MR imaging as part of the I-SPY TRIAL. The ISPY 2 adaptive therapy design will use different tumor biomarker assays to identify patients with high risk of recurrence. Patients will receive NAC doublet chemotherapy and trastuzumab (if Her2+). Patients will be randomized and stratified into different arms receiving investigational agents of different drug classes. ACRIN 6698 patients will receive four advanced MRI exams (both DCE and DWI) at baseline, early therapy, mid therapy and prior to surgery.

**Specific aims**: The primary aim will determine if the % change in tumor apparent diffusion coefficient (ADC) measured on DWI from baseline to early treatment timepoint is predictive of pathologic complete response (pCR). The secondary aim will determine if the combined measurement of percentage change in tumor ADC on DWI, and percentage change in tumor volume and peak signal enhancement ratio (SER) on DCE MRI is predictive of pCR. **Statistical methods**: Receiver operating characteristic (ROC) curve and corresponding area under the ROC curves (AUC) for the individual marker, % change in tumor ADC, and % change in tumor volume and peak SER, will be estimated. Linear score of the 3 markers will be derived by fitting the multivariate logistic regression model, where the outcome is a binary variable for pCR and the predictors are the 3 measurements. The ROC curve for the derived linear score will be constructed and its AUC value will be estimated. **Target accrual**: ACRIN 6698 is open to ISPY 2 sites. The target accrual is 200 of ISPY 2’s planned enrollment of 800 participants.

OT2-04-01
A Randomized Phase II Trial of Vitamin D vs Placebo in Premenopausal Women: CALGB 70806.

Wood ME, Kingsley F, Ambaye AB, Yee L, Jung S-H, Marshall JR, Paskett E. University of Vermont, Burlington, VT; Ohio State University; Roswell Park Cancer Institute; Duke University

**Background**: Chemoprevention studies are long and expensive. Gaining information about the feasibility of an agent using biomarker endpoints can save money and ensure that only the most promising agents move forward. There is strong evidence to suggest breast cancer prevention properties for vitamin D. The safety and tolerability of this agent makes it a perfect candidate for a chemopreventive agent. This clinical trial will evaluate the effect of vitamin d on several breast cancer; providing important information regarding the feasibility of a larger chemoprevention study using cancer development as the endpoint. Successful completion of this study will also validate this design of biomarker testing of potential chemoprevention agents within a cooperative group setting and add to data validating these specific biomarkers.

**Methods**: This is a randomized placebo controlled trial of one year of 2000 units of vitamin D (cholecalciferol) for premenopausal women (≥ 35 years) with increased breast density. The primary aim of this study is to evaluate the effect of vitamin D on breast density. Secondary aims include evaluation of vitamin D effects on IGF1 and markers of cellular proliferation (Ki-67 and atypia). In addition 3 methods of density analysis (Breast Imaging Reporting and Data System (BI-RADS), Visual Analogue Scale (VAS), and the Boyd method) will be compared. For the primary endpoint of change in mammographic density we will have an 87% power to detect a standardized effect size (difference in means divided by standard deviation) of 0.4 in change of mammographic density between...
two arms. The target effect size is 2.64%. This study was activated 10/15/2010 and has been opened at 75 sites with 15 patients enrolled. Target accrual is 250.
Funding: This study is sponsored by the NCI and CALGB.

**OT2-04-02**  
**Metformin for Breast Cancer Prevention: A Pilot Study.**  
Ledgerwood MM, Ojeda-Fournier H, Patterson R, Hastei F, Andre MP, Cadmus L, Blair S. University of California, San Diego, CA

**Background:** There is a body of accumulating evidence connecting metformin, a biguanide derivative which reduces hepatic gluconeogenesis and improves skeletal muscle insulin sensitivity, to reduced breast cancer risk. This, in addition to a well-established drug safety record among diabetics and non-diabetics, has provoked an interest in further study of metformin’s effects on breast cancer risk indicators. In our study, we examine the effects of metformin on breast density and proliferative cell marker Ki67, both indicators of breast cancer risk. This is a small observational pilot study to determine the feasibility of subject recruitment, data collection through fine-needle aspiration, and breast density measurement.

**Trial Design:** Recruitment of 10 breast surgery patients with high risk histology to: 1. Undergo peri-areolar fine needle aspiration (RPFNA) used to collect breast cells for analysis of proliferative marker Ki67. 2. Breast density assessment by a) mammography (the standard method) and b) whole-breast ultrasound (an innovative method recently developed at UCSD).

Each subject will undergo a single view mammogram, whole-breast ultrasound, and intra-operative RPFNA. No drug or therapeutic intervention will take place in this pilot study.

**Eligibility:** Female undergoing excisional high risk breast surgery.

**Specific Aims:** Aim 1. To determine the feasibility of recruiting high risk breast surgery patients to an observational study involving RPFNA, mammography, and whole-breast ultrasound. Aim 2. a) To compare mammography and whole-breast ultrasound for measurement of breast density. b) To examine potential for detecting biomarkers of cell proliferation through RPFNA.

**Statistical Method:** Breast density will be determined by the ratio of fibroglandular tissue to fat measured on mammogram and WBU. Cell proliferation will be assessed by the percentage of positivity for biomarkers of cell proliferation through RPFNA.

**Accrual and target accrual:** Five of ten breast excisional high risk breast surgery subjects have been accrued at this time.

**OT2-04-03**  
**Uptake of a Randomized Breast Cancer Prevention Trial Comparing Letrozole to Placebo in BRCA1/2 Mutation Carriers:**  
The FNCLCC ONCO-03/LIBER Trial.

Pujol P, Lasset C, Berthet P, Dugas C, Delalorge S, Fricker JP, Chabbert Buffet N, Lemonnier J, Roca L, Mijonet S, Baudry K, Martin AL. University Hospital CHU Arnaud de Villeneuve, Montpellier, France; Centre Léon Bérard, Lyon and University of Lyon 1; CNRS; UMR 5558, Villeurbanne, France; Centre François Baclesse, Caen, France; Institut Gustave Roussy, Villejuif; Centre Paul Strauss, Strasbourg; AP HP Hôpital Tenon; Fédération Nationale Française des Centres de Lutte contre le Cancer

**Background:** Women with germline BRCA1 or BRCA2 (BRCA1/2) mutations are an extreme risk population for developing breast cancer, with a life-time risk of 56-80%. Prophylactic mastectomy provides a valid option to reduce such risk, but it considerably affects the quality of life. Medical prevention by aromatase inhibitor that has been recently shown to have preventive effect may thus be an alternative.

LIBER is an ongoing, double-blind, randomized phase III trial to evaluate the efficacy of five-years letrozole versus placebo to decrease breast cancer incidence in post-menopausal BRCA1/2 mutation carriers (NCT00673335). We present data on the uptake of this trial. Methods: To evaluate theoretical feasibility, we compared inclusion criteria of women in the LIBER trial (n=113) to characteristics of women entered in the prospective ongoing national GENEPSO cohort (n=1505). Uptake was evaluated through a survey sent to all active centres, with responses obtained from 17 of the 20 (85%) centres. Results: According to characteristics of the women included in GENEPSO cohort (n=1505) and the survey, approximately one third of BRCA1/2 mutation carriers are eligible for this study. From November 2009 to May 2010, 534 women eligible from chart review have been informed by mail of the trial and were invited to an oral information by participating centres. Of them, 44% of women came to the dedicated medical visit. Uptake of drug prevention trial was 32% of orally informed women and 15% of overall eligible women. Main reasons of refusal were: potential side effects, probability to receive the placebo and lack of support from the women’s physicians. Prior prophylactic oophorectomy and history of previous unilateral breast cancer were more frequent in women enrolled in the ONCO-03/LIBER trial than in the French cohort (93% versus 60% and 50 % versus 39 %, respectively), suggesting a higher motivation for medical prevention in these subgroups of patients. Conclusion: One third of women with a BRCA1/2 mutation are eligible to the ONCO-03/LIBER prevention trial. 32 % of orally informed women and, only 15% of overall eligible women entered the trial. To reach accrual objective (n=308), a greater information of the trial should be offered to women with BRCA1/2 mutation and the trial has been proposed to other countries.
brain metastasis or without brain metastases. Two positron emission tomography (PET) scans will be performed in each patient following intravenous administration of a microdose of [11C] lapatinib: in lapatinib-naïve patients and at steady-state lapatinib, after treatment with unlabelled oral lapatinib 1500 mg once daily for 8 days. [11C] lapatinib time-activity curves will be generated for normal brain and brain metastases, the PET volume of distribution in the brain calculated and penetration of [11C] lapatinib into the brain quantified. Analysis of brain PET data is explorative as [11C] lapatinib is a new tracer. Therefore, this study investigates both the difference in lapatinib brain penetration between patients with and without brain metastases, as well as the effect of low and high concentrations of lapatinib on the BBB efflux system. The study is currently recruiting in one center in the United Kingdom.

OT2-05-02
ACRIN 6691 Monitoring and Predicting Breast Cancer Neoadjuvant Chemotherapy Response Using Diffuse Optical Spectroscopic Imaging (DOSI).

Tromberg BJ, L’Heureux DZ, Mankoff DA, Zhang Z, Cervusi A, Mehta R, Carpenter PM, Butler JA, Hylton NM, Kaufman P, Pogue BW, Paulsen K, Yodh AG, Boas D, Isakoff S. University of California, Irvine, CA; American College of Radiology Imaging Network, Philadelphia, PA; University of Washington, Seattle, WA; Brown University, Providence, RI; University of California at San Francisco, San Francisco, CA; Dartmouth University, Lebanon, NH; University of Pennsylvania, Philadelphia, PA; Massachusetts General Hospital, Charlestown, MA; Massachusetts General Hospital, Boston, MA

Background: Imaging technologies monitoring and predicting breast cancer response to neoadjuvant chemotherapy (NAC) are of increasing interest. The utility of conventional imaging approaches varies and identifies the need for alternate functional imaging strategies. The use of model-based photon migration methods to quantitatively separate light absorption from scattering in multiply-scattering tissues is a type of near-infrared spectroscopy (NIRS) broadly referred to as diffuse optical spectroscopy (DOSI) [Buvlewac, et al. Applied Optics, 2000; Jakubowski, et al., J of Applied Optics, 2009]. DOSI is a promising experimental technology that allows patients undergoing NAC to be followed with a “no significant risk” device meeting Food and Drug Administration criteria for exempt status. The current design is a mobile device which offers increased accessibility and is relatively simple to perform and interpret, as compared to mammography, magnetic resonance imaging, and positron emission tomography. Due to its size and portability, DOSI is a low barrier-to-access technology, creating new opportunities for patients to receive personalized treatment and for physicians to gain new insight into response mechanisms. The long-term goal is to provide oncologists with a relatively simple, risk-free bedside tool that can be used to help inform medical decisions on chemotherapy regimen, duration, and timing of surgery, thereby maximizing therapeutic response and minimizing unnecessary toxicity. Trial design: In this phase I/II prospective single arm study, patients will receive SOC NAC at five (5) NCI Network for Translational Research in Optical Imaging (NTROI) clinical sites with identical DOSI instruments and procedures. Patients will receive four DOSI exams: at baseline before chemotherapy, at early therapy 5-10 days after NAC initiation, at mid therapy, and at post therapy prior to surgery. The protocol will evaluate a harmonized DOSI technology platform that has been standardized for NAC monitoring. Eligibility: Women who have been diagnosed with breast cancer, have had confirmation by pre-treatment biopsy, and are scheduled to receive NAC followed by surgery are eligible for this trial. Specific aims: The primary aim of this clinical trial is to determine whether the baseline to mid-therapy changes in the DOSI measurement of the quantitative tumor tissue optical index can predict final pathologic complete response in patients with breast cancer undergoing NAC. The secondary aims investigate the correlation between additional DOSI quantitative measurements of tumor biochemical composition obtained at other timepoints, the full range of pathologic response (i.e. complete, partial, and non-response), and any corresponding imaging measurements. Statistical methods: Logistic regression models will be used to study the relationships between pathological complete response and percent change in tissue optical index tumor to normal ratio at different imaging time points. Study size: A total of sixty (60) patients will be enrolled in this imaging study. Currently, one patient has accrued.

OT2-05-03
ACRIN 6688 Phase II Study of Fluorine-18 3’-Deoxy-3’ Fluorothymidine (FLT) in Invasive Breast Cancer.

Jolles PJ, Kostakoglu L, Bear HD, Idowu MO, Kurdziel K, Shankar L, Mankoff DA, Duan F, L’Heureux DZ. Virginia Commonwealth University, Richmond, VA; Mount Sinai School of Medicine, New York, NY; National Cancer Institute, Bethesda, MD; University of Washington, Seattle, WA; Brown University, Providence, RI; American College of Radiology Imaging Network, Philadelphia, PA

Background: Neoadjuvant chemotherapy (NAC) prior to surgery provides enhanced options for locoregional management and has become an integral component of primary breast cancer management. Initial tumor response in patients receiving NAC is generally determined at therapy completion. This evaluation is determined by either the presence/absence of palpable tumor as a clinical response and/or presence/absence of invasive tumor cells in the breast and nodes as a pathological response. The ability to evaluate the effectiveness of neoadjuvant therapy early during treatment would be of significant importance. FDG PET imaging has been shown to be predictive of subsequent tumor response, but the tendency of FDG to accumulate in inflammatory tissues can complicates image interpretation. MRI changes have also been touted as predictors of response. Preliminary data suggest that early FLT PET is better able to predict response to therapy, as FLT uptake has been shown to correlate with cellular proliferation, and does not significantly accumulate in inflammatory tissue (Kenny et al, Eur J Nucl Med Mol Imaging 2007:1339-1347). The analysis of these data may provide a better understanding of early treatment response and improve the clinical management of breast cancer in the future. Trial design and eligibility: In this phase II multi-institutional study, breast cancer patients with locally advanced disease with a tumor size ≥2cm (measured on imaging or estimated by physical exam) are eligible. Participants will receive standard of care NAC at their respective institutions. Participants will have 3 FLT imaging sessions to evaluate therapy response: at baseline, early-treatment (5-10 days after initiating treatment), and post-treatment prior to surgery. Specific aims: The primary objective is to correlate the percentage change in the standardized uptake value between baseline and early therapy FLT in the primary tumor with pathologic response. Correlatively, FLT PET parameters will be compared with proliferative indices from the initial biopsy and residual tumor surgical samples using Ki-67 staining, mitotic index, and residual cancer burden. Potential safety issues and the physiologic effects associated with FLT administration will also be evaluated. Statistical methods: To evaluate the relationship between an uptake parameter and pathologic complete response, a ROC curve
will be estimated and the area under the curve, along with its 95% confidence interval, will be determined. **Accrual:** Currently, 45/67 patients have accrued to the study.

### OT2-05-04

**ACRIN PA 4006: Comparison of Full-Field Digital Mammography with Digital Breast Tomosynthesis Image Acquisition in Relation to Screening Call-Back Rate.**

Conant EF, Maidment A, Copit D, Olson CB, Heckel ML, Gatsonis C. Hospital of the University of Pennsylvania, Philadelphia, PA; Albert Einstein Medical Center, Philadelphia, PA; American College of Radiology Imaging Network, Philadelphia, PA; Brown University, Providence, RI

**Background:** With competing parameters of specificity and sensitivity, breast cancer screening must limit both missed cancers and false-positive call-backs (with potential to biopsy) to reduce cost and unnecessary anxiety to patients. Full-field digital mammography (FFDM) has been shown to provide improved sensitivity over analog mammography in the detection of breast cancers, particularly in women with dense breasts. Unfortunately, call-back rates for both digital and analog screening mammography have similar, elevated rates of approximately 10% (E. Pisano et al, NEJM, 2005). Incorporation of digital breast tomosynthesis (DBT), a novel 3-D reconstruction of multiple low-dose digital mammographic images, may reduce the number of call-back visits needed by providing many of the benefits of diagnostic imaging at screening. This study will assess variations in DBT image acquisition while limiting radiation dose to women with varying breast sizes and densities, to define parameters to be used in a larger national screening tomosynthesis trial.

**Eligibility:** Asymptomatic women 25 years and older with no breast cancer history are eligible for Group A or B (see below). Pregnant women, women unable to tolerate compression of the breast associated with mammography, women with implants, and women with breasts too large for DBT are excluded from participation. **Trial design/target accrual:** This multicenter trial uses Hologic digital mammography units at two institutions in Philadelphia, Pennsylvania. The timing of the study-related imaging visits are segregated into two cohorts, screening (Group A) and diagnostic (Group B). Group A comprises 500 women who will undergo both FFDM and DBT at screening. Initial independent interpretations of the FFDM and DBT from local readers will determine call back. Enriched Group B comprises 50 women who have been informed of abnormal findings from a FFDM screening within 30 days of enrollment. They will be recruited prior to their diagnostic imaging and consent to DBT of both breasts as part of their diagnostic imaging. Participants from both Groups will be followed or biopsied as recommended by their treating physician. Follow up includes medical record review and images collection at approximately 1-year. Follow-up data may be collected up to 18 months. **Specific aims and statistical methods:** ACRIN PA 4006 will evaluate the specificity of 2-D FFDM versus a combination of 2-D and 3-D tomosynthesis imaging in breast cancer screening. Specificity will be measured by the participant call-back rate by each modality. Sensitivity and specificity by lesion-type characteristics, especially focused on DBT assessment of calcifications, will be compared. **Current accrual:** Currently, the trial accrual has reached 259 of 550.

### OT2-05-05

**Phase I/II Study of Adoptive T Cell Therapy Following In Vivo Priming with a HER2 Peptide-Based Vaccine in Patients with Stage IV Breast Cancer.**

Parker SL, Higgins DM, Childs JS, Dang Y, Guthrie KA, Disis ML, Salazar LG, Coveler A. University of Washington, Seattle, WA; Fred Hutchinson Cancer Research Center, Seattle, WA

**Background:** Adoptive T cell therapy has evolved from preclinical setting to a potentially feasible treatment strategy for advanced breast cancer (BC). However, the ability to expand tumor antigen specific T cells ex vivo has been one of the major hurdles that has limited clinical translation of adoptive T cell therapy. Tumor specific T cells are rare in unprimed patients and generating large bulk cultures from rare precursor frequencies is difficult. We have found immunizing HER2+ patients to increase tumor specific T cell precursor frequencies to the levels of a vaccinated foreign antigen markedly improves the ability to generate large numbers of tumor specific T cells in vitro. We hypothesize that T cell expansion strategies that are facilitated by prior immunization will be clinically useful in the treatment of advanced BC.

**Design:** A Phase I/II non-randomized, single arm study. Priming with a HER2 ICD vaccine will be performed at 1 week intervals for a total of 3 vaccines. Patients will undergo leukapheresis 2 weeks after the 3rd vaccine to collect PBMC for T cell expansion. Patients will be pre-treated with cyclophosphamide 24 hours prior to 1st T cell infusion and then receive up to 3 dose-escalating infusions of T cells given 7-10 days apart. Three HER2 vaccine booster immunizations will then be administered at 1, 2, and 4 months after the final T cell infusion. Follow-up for persistent and continued immunity will then ensue.

**Aims:** To evaluate the safety of infusing escalating doses of HER2 specific T cells into patients with advanced HER2+ BC using ex vivo expanded autologous T cells, to investigate to what extent HER2 specific T cell immunity can be boosted or generated in individuals after infusion of HER2 specific T cells, to evaluate how long T cell immune augmentation persists in vivo after adoptive transfer of HER2 specific T cells and subsequent booster immunizations.

**Criteria:** Patients with HER2+ Stage IV BC who: have been maximally treated and not achieved a complete remission, have stable or slowly progressive disease, HER2+, and have adequate LVEF.

**Statistical Methods:** Toxicity will be determined by chemical and clinical parameters evaluated at various time points. If the true probability of a DLT is 0.11, then the probability of observing 0 DLT’s in 20 patients is 0.097. If the true probability of a DLT is 0.18, then the probability of observing ≤1 DLT’s in 20 patients is 0.102, and if the true probability of a DLT is 0.27, then the probability of observing ≤2 DLT’s in 20 patients is 0.064. Therefore, with low observed rates of DLT (<10%), we can be reasonably confident (~90%) with 20 patients that the true DLT rate is < 0.27. Immunologic response, defined as the successful boosting of precursor frequency with infusion of HER2-specific T cells, will be evaluated by assessing the change in T cell level from baseline. To assess the durability of the T cell response, we are primarily interested in estimating the proportion of patients whose T cells persist at a level the same or greater as the level after the final T cell infusion as long as 6 months following the final booster vaccine.

**Accrual:** Target=20/Actual=14
**OT2-05-06**

ACOSOG Z11101/ACRIN 6694: Effect of Preoperative Breast MRI on Surgical Outcomes, Costs and Quality of Life of Women with Breast Cancer.

**Bedrosian I, Suman VJ, Yao K, Shih Y-CT, Yen TWF, Comstock C, Newstead G, Birdwell R, Kim E, L’Heureux DZ, Gatsonis C. MD Anderson Cancer Center, Houston, TX; Mayo Clinic, Rochester, MN; University of Chicago, Evanston, IL; University of Chicago, Chicago, IL; Medical College of Wisconsin, Milwaukee, WI; Memorial Sloan-Kettering Cancer Center, New York City, NY; Harvard Medical School, Boston, MA; Brown University, Providence, RI; American College of Radiology Imaging Network, Philadelphia, PA**

**Background:** Surgical planning and local-regional treatment of breast cancer relies on accurate assessment of disease extent including the primary tumor size and the presence/absence of multiple tumor foci. As a staging modality for breast cancer, MRI has shown high sensitivity for detection of additional foci of diseases within the index breast. However, the impact of preoperative breast MRI on reducing re-excision rates and improving local control is less clear. Data from the COMICE trial in the UK suggested that routine use of pre-operative breast MRI did not alter rates of re-excision; however issues have been raised about the lack of quality standards for the MR imaging that may have resulted in the negative results of this trial. Retrospective data suggest that local recurrence is not impacted by use of breast MRI. In concert with data showing no improvement in clinical outcomes of breast cancer patients, concerns have been raised that routine use of preoperative breast MRI is associated with increased rates of mastectomy and delays to surgery. Therefore, the application of MRI for preoperative surgical staging remains controversial. In order to address this ongoing controversy, a joint effort has been launched by ACOSOG and ACRIN for a prospective clinical trial focused on evaluating the impact of preoperative breast MRI on clinically relevant patient outcomes. An important part of this collaboration is implementation of standards of how MRI findings should be clinically managed and used to direct localization methods and surgical planning, thereby creating guidelines for subsequent patient intervention. **Trial design/eligibility criteria:** A prospective multicenter trial will include women eligible for BCT by standard criteria and randomized between current standard of care, clinical examination and mammography (+/- ultrasound) and the same plus preoperative breast MRI. The study will focus on women at the highest risk of local recurrence: ER/PR/HER-2 negative (triple negative) and HER-2 amplified breast cancers. Specific aims: To compare the rates of local recurrence following breast conserving therapy in a cohort randomized to preoperative staging with mammography or mammography plus breast MRI. Additionally, a comparison of rates of re-operation, time to local recurrence, survival outcomes, contralateral breast cancer rates, rates of multicentric disease and other secondary aims will be performed. Costs and quality of life measures will also be investigated. **Statistical methods:** A stratified logrank test and Cox partial likelihood score test will be used to assess whether the distribution of LR times differs with respect to diagnostic work-up approach having adjusted for tumor stage. Cox modeling with the Cox partial likelihood score test will be used to examine the strength of association between these time to event distributions and such additional potential prognostic factors as menopausal status, chemotherapy, radiation therapy, ER, PR, number of positive lymph nodes, HER-2/neu expression, Nottingham grade, and Ki-67 expression. **Target Accrual:** 556 patients

**OT2-06-01**

A Phase III Randomized Multicentric French Study To Evaluate the Impact of a Localized 16-Gy Boost after Conservative Surgery and a 50-Gy Whole-Breast Irradiation in Breast Ductal Carcinoma In Situ (The BONBIS Trial).

**Azria D, Cowen D, De La Lande B, Bourjorgier C, Latorzeff I, Leblanc-Onfroy M, Douadi-Gaci Z, Pradier O, Peignaux K, Levy C, Ellis S, Lecouillerd I, Racadot S, Bontemps P, Benyoucef A, Lagarde P, Laharie-Mineur H, Cretin J, Marchal C, Serin D, Lemanski C. CRLC Val d’Aurelle, Montpellier, France; AP-HM, Marseille, France; Centre Rene Huguenin, Saint Cloud, France; IGR, Villejuif, France; Groupe ONCORAD, Toulouse, France; Centre Rene Gauducheau, Nantes, France; Centre Catherine de Sienne, Nantes, France; CHU Brest, Brest, France; CRLC G-F Leclerc, Dijon, France; CRLC Francois Baclesse, Caen, France; Centre Catalan d’Oncologie, Perpignan, France; CRLC Eugene Marquis, Rennes, France; Centre Leon Berard, Lyon, France; CHU Besancon, Besancon, France; Centre Henri Becquerel, Rouen, France; Institut Bergonie, Bordeaux, France; Clinique Tivoli, Bordeaux, France; Clinique Valdegour, Nimes, France; Centre Alexis Vautrin, Vandoeverlees Nancy, France; Institut Sainte Catherine, Avignon, France**

**Background:** Ductal carcinoma in situ is defined as breast cancer confined to the ducts of the breast without evidence of penetration of the basement membrane. Local treatment quality represents one of the most prognostic factors as half of recurrences are invasive diseases. The main goal of adjuvant radiotherapy after conservative surgery is to decrease local recurrences and to permit breast conservation with low treatment-induced sequelae. Several randomized trials have established the impact of 50 Gy to the whole breast (WB) in terms of local control. Nevertheless, no randomized trial is still available concerning the role of the boost in this disease. The phase III randomized trial “BONBIS” is elaborated to evaluate the impact of a 16-Gy boost after 50 Gy delivered to the whole breast in 25 fractions and 33 days.

**Methods:** A total of 1950 patients DCIS breast cancer patients are planned to be enrolled in this trial. Patients will receive the following treatment: (A) WB radiotherapy of 50 Gy in 25 fractions vs. (B) WB radiotherapy of 50 Gy in 25 fractions plus a localized 16-Gy boost in 8 fractions. The primary endpoint is local-relapse free survival (LRFS). This trial is designed to detect an expected rate in control arm of 7% and 4 % in experimental arm. With 90% power and a=0.05, 137 events are necessary to achieve the main goal. An interim analysis is planned after 50% of observed event. Stratifications are made based on recognized prognostic factors: age, hormonal treatment, differentiation, circumstance of diagnosis, surgical margin, centre. Secondary endpoints are relapse free survival, overall survival, acute and late toxicities, cosmetic results, and quality of life. Translational researches are also planned to identify intrinsic radiosensitivity of normal tissues (radiation-induced apoptosis assay, genome-wide association study) but also predictive models of tumor recurrences. Inclusions have started in November 2008 and are not so far than the planned estimation.

This trial is granted by the French National Cancer Institute (PHRC 2008) and supported by the French National Society of Radiation Oncology (SFRO).
**OT2-06-02**

A Randomized Phase III Study of Conventional Whole Breast Irradiation (WBI) vs Partial Breast Irradiation (PBI) for Women with Stage 0, 1, or 2 Breast Cancer: NSABP B-39/RTOG 0413. Julian TB, Costantino JP, Vicini FA, White JR, Cecchini RS, Winter KA, Arthur DW, Kurke R, Rabinoivitch R, Parda DS, Mamounas EP, Curran, Jr WJ, Wolmark N. National Surgical Adjuvant Breast & Bowel Project (NSABP), Pittsburgh, PA; Allegheny General Hospital, Pittsburgh, PA; NSABP Biostatistical Center, Pittsburgh, PA; University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA; Beaumont Health System, Royal Oak, MI; Radiation Therapy Oncology Group (RTOG), Philadelphia, PA; Medical College of Wisconsin, Milwaukee, WI; Virginia Commonwealth University, Richmond, VA; Arizona Breast Cancer Specialists, Scottsdale, AZ; University of Colorado Denver, Aurora, CO; Aultman Health Foundation, Canton, OH; Emory University, Atlanta, GA

**Background:** Breast-conserving therapy (BCT) with WBI is an accepted option in the treatment of most patients with stage 1 or 2 breast cancer, but not all eligible patients utilize it. This may be because of age, length of time required for WBI treatment and availability of this method, and burden of care. There is a large body of mature phase I and II data, and some preliminary phase III data, that relate to the replacement of WBI after lumpectomy with PBI delivered in 4-5 days and restricted to the region of the tumor bed. Can an acceptable outcome be achieved with radiation therapy (RT) delivered only to the region of the tumor?

**Trial design:** For the administration of WBI, we are using standard techniques delivered over 5-7 weeks as outlined in the B-39/0413 protocol. For the administration of PBI, we are using high-dose-rate multi-catheter brachytherapy, high-dose-rate single-entry intracavitary brachytherapy (MammoSite®, MammoSite® ML, Contura®, MLB, and SAVI®), and 3D conformal external beam RT. PBI is given twice a day, at least 6 hours apart, on 5 treatment days over a period of 5-10 days. The technique selected depends on technical considerations, radiation oncology facility technique credentialing, and patient preference. Before random assignment, patients must have a planning CT. Those randomized to WBI receive chemotherapy, if applicable, before their RT. Those randomized to PBI receive RT before chemotherapy, if applicable. All treatment sites must pass a rigorous QA and QC process for PBI before and during the duration of the study. We are using a QOL program to assess cosmesis, fatigue, symptoms, and perceived convenience of care.

**Eligibility criteria:** Patients must have stage 0 or stage 1 or 2 IBC with no evidence of metastatic disease. Tumor size must be 3 cm or less. Women must have undergone a lumpectomy with the margins of the resected specimen histologically free of cancer, including DCIS. Patients must have no more than 3 positive axillary nodes. Accrual is open to all premenopausal women and to postmenopausal women who have IBC that is ER/PR negative or node positive. Patients are stratified according to disease stage, menopausal status, hormone receptor status, and intention to receive chemotherapy. Following stratification, patients are randomly assigned to receive WBI or PBI.

**Specific aims:** The primary endpoint is the comparison of those receiving PBI and WBI for the diagnosis of in-breast tumor recurrence (IBTR). The study will also compare women receiving PBI and WBI for overall survival, recurrence-free survival, and distant disease-free survival. QOL aims are related to cosmesis, fatigue, treatment-related symptoms, and perceived convenience of care.

**Statistical analysis and accrual:** PBI and WBI will be declared equivalent if the estimated relative risk of IBTR falls between 0.86 and 1.17. Analysis will occur after 175 IBTRs are diagnosed. At the end of May 2011, accrual was 3962 of 4300 patients. Supported by PHS grants NCI-U10-CA-69651, NCI-U10-CA-12027, and NCI P30-CA-14599 from the US NCI.

**OT2-07-01**

**Background:** Lymphocele is the principal post-operative morbidity following axillary node dissection. According to the literature, incidence can vary from 4 to 89%. Encouraging results in terms of reducing postoperative lymphoceles as well as drainage duration and volume using octreotide have been recorded recently. A new molecule, namely pasireotide, developed by Novartis Pharma AG, Basle Switzerland, is a somatostatin analog possessing high binding affinity to 4 of the 5 somatostatin receptors. Trial design: We are performing a prospective, randomized 1:1, double blind, multicenter trial against placebo with a Bayesian design. Eligibility criteria: any female patient scheduled for breast surgery with mastectomy and axillary node dissection indicated at the pre-surgical stage. Specific aims: The purpose of this trial is to assess the efficacy of a single pre-surgical injection of pasireotide LAR 60 mg im in reducing the postoperative incidence of symptomatic lymphoceles following mastectomy with axillary node dissection for breast cancer. Patients are followed up for 4 weeks.

**Statistical methods:** The statistical analysis will be carried out sequentially after observing the principal criterion (i.e. success is defined as a total volume of lymphocele following single or repeated aspiration ≤60 cc in the 28 days following surgery or a routine aspiration volume on the 28th day ≤120cc) of each patient included for each randomization group, with or without treatment. It involves estimating the probability of a response in each group using a Bayesian design based on a beta-binomial model. With the Bayesian approach, the response rate in each group (\( \hat{p} \)) is considered as a random variable, with a priori density focused on the anticipated response rate of 80% in the group receiving treatment and 60% in the non-treatment group, which will be sequentially updated as the observations are made according to a so-called posteriori law. Present accrual and target accrual: The sample size consists of a total of 90 patients with 45 patients in the active treatment group and 45 patients in the placebo one. To date more than 50% of the patients have been included.
OT2-07-02
SWOG S0927: A Randomized Double Blind Placebo-Controlled Trial of Omega-3-Fatty Acid for the Control of Aromatase Inhibitor (AI)-Induced Musculoskeletal Pain in Women with Early Stage Breast Cancer.
Hershman DL, Unger JM, Crew KD, Moiinpour CM, Minasian LM, Hansen L, Lew DL, Kaberle K, Wade JL, Meyskens FL. Columbia University, New York, NY; SWOG, Seattle, WA; National Cancer Institute, Bethesda, MD; Legacy Good Samaritan Hosp & MC, Portland, OR; SWOG, San Antonio, TX; Cancer Care Specialists of Illinois, Decatur, IL; University of California, Irvine, Orange County, CA

Background: Despite the well-proven efficacy of aromatase inhibitors (AIs) for the treatment of hormone-sensitive breast cancer, a significant number of women suffer from musculoskeletal side-effects which can result in early discontinuation of this important medication. Given the proposed anti-inflammatory effects of omega-3-fatty acid and the paucity of therapeutic options for AI-induced arthralgia, it is therefore reasonable to test the efficacy of omega-3-fatty acid in women with breast cancer who have developed moderate to severe joint symptoms after initiating AIs.

Specific aims: To assess if omega-3-fatty acid as compared to placebo causes a reduction in worst joint pain/stiffness in women with AI-associated arthralgias at 12 weeks as measured by the modified Brief Pain Inventory (BPI). Additional measures will include the WOMAC, M-SACRAH, FACT-ES and global rating of change, which will be assessed at baseline, 6, 12 and 24 weeks. We will evaluate fasting lipids, hormone levels, serum inflammatory markers (TNF, IL2, CRP), and markers of joint destruction (CTX-II) at baseline, 12 and 24 weeks.

Eligibility criteria: Pts. must have histologically-confirmed stages I-III breast cancer, with no evidence of metastatic disease and undergone definitive breast cancer surgery. Pts must be post-menopausal and currently be taking a third-generation AI – anastrazole (Arimidex®), letrozole (Femara®), or exemestane (Aromasin®) for at least the previous 90 days prior to registration with plans to continue for at least an additional 180 days after registration. The patient must have a worse joint pain/stiffness score of 5 or greater on the 10-point scale of the BPI which started or increased after initiation of AI. Pts must not have taken omega-3-fatty acid supplements within the past 3 months prior to registration. Pts will be randomized to receive 6 capsules daily (at 1,000 mg each; ~600mg combination of ethyl esters EPA/DHA) of omega-3-fattyacid or matching placebo daily for 24 weeks.

Statistical methods: We stipulate an alpha=.05 two-sided test, with an estimated 5% non-adherence and 20% dropout rate at the primary endpoint evaluation time of 12 weeks after randomization. For a two point difference in worst joint pain/stiffness and a 3.5 point SD at 12 weeks, 222 eligible patients would be required for 90% power under a two-arm normal design. To allow ineligibility rate of 10%, 246 total pts will be enrolled. The study should be activated September 2011.

Funding: Supported by National Cancer Institute grant CA037429

OT3-01-01
Adelson KB, Raptis G, Sparano J, Germain D. Mount Sinai School of Medicine, New York, NY; Albert Einstein Cancer Center, Bronx, NY

Background: Bortezomib is a proteasome inhibitor that enhances fulvestrant-mediated aggregation of the ER in the cytoplasm without blocking ER degradation in the nucleus in ER+ human breast cancer cell lines, thereby promoting cytoplasmic ER aggresomes which activate a sustained unfolded protein response leading to apoptotic cell death; the combination also induces tumor regression in a tamoxifen resistant T47D-cyclin D1 xenograft model more effectively than either agent alone (Clin Cancer Res 2011; 17: 2292-2300).

Hypothesis: We hypothesize that the combination of fulvestrant and bortezomib will be more effective than fulvestrant alone in ER+, AI-resistant MBC.

Trial design: This is an open-label randomized phase II design in which patients with MBC are randomized to receive fulvestrant alone (500 mg IM day -14, day +1, and day +14 during cycle 1, then 500 mg every 4 weeks on day +1 during cycle 2 and thereafter) or in combination with bortezomib (1.6 mg/m2 IV days +1, +8, +15 every 28 days). Stratification factors for randomization include performance status (ECOG 0 vs. 1-2), measurable disease (yes vs. no), and prior chemotherapy for MBC (yes vs. no). Patients who progress on fulvestrant alone may cross over to the combination.

Eligibility criteria: Postmenopausal women with ER+, Her2-negative, MBC who have progressive disease during AI therapy for metastatic disease, or relapse while receiving adjuvant AI therapy. Up to one prior chemotherapy regimen for metastatic disease is permitted.

Specific aims:
Primary Objective: To determine if the addition of bortezomib to fulvestrant significantly improves median progression-free survival (PFS), defined as the time from cycle 1, day 1 of therapy until disease progression or death from any cause.

Secondary Objectives: To determine: (1) adverse event rates in both arms, (2) the clinical benefit rate (CBR – objective response [by RECIST 1.1] and/or progression free at 24 weeks), (3) the objective response and CBR after crossover from fulvestrant to fulvestrant plus bortezomib.

Translational Objectives: To perform an exploratory analysis of the effects of the combination on intratumoral nuclear/cytoplasmic ER ratio, unfolded protein response (BiP), apoptosis (cleaved caspase 3, Bcl-2 phospho JNK.)

Statistical methods: he median PFS for patients receiving fulvestrant alone is expected to be approximately 5.4 months based upon patients with AI-resistant disease enrolled on the CONFIRM trial ( J Clin Oncol 2010; 28: 4594-4600). The trial is designed to detect a 70% improved in median PFS to 9.0 months (alpha=0.10, beta =0.10), which will require 59 eligible patients in each arm.

Present accrual and target accrual: 24/118
OT3-01-02
Imatinib Mesylate in Combination with Vinorelbin for Patients with Metastatic Breast Cancer – An Ongoing Phase I/II Clinical Trial.
Mundhenke C, Schem C, Bauerschlag DO, Weigel MT, Hilpert F, Eidmann H, Tiemann K, Muth M, May C, Hanson S, Jonat W, Maass N, Kiel University, Kiel, SH, Germany; RWTH Aachen, Aachen, NRW, Germany; Novartis Pharma, Nuremberg, Bavaria, Germany; Institut fuer Haematopathologie Hamburg, Hamburg, HH, Germany

Background: Imatinib mesylate is a tyrosine kinase inhibitor which originally had been developed to block pathognomonic bcr-abl oncprotein in chronic myeloid leukemia. It is also an inhibitor of the receptor tyrosine kinases of platelet-derived growth factor (PDGF) and stem cell factor (SCF), c-Kit, and abl. Therefore it also inhibits PDGF- and SCF-mediated cellular events, as tumor cell proliferation in solid tumors. Additionally, inhibition of PDGF- b-receptor relieves tumor hypertension in solid tumors and thereby helps to deliver higher concentrations of cytotoxic drugs into the tumor cell. Vinorelbin is a semisynthetic vincaalcaloid with antitumor activity. As a single agent and as a combination partner of other cytotoxic drugs, it has proven good tolerability and high effectiveness in treatment of patients with metastatic breast cancer (MBC). This study was designed to evaluate the feasibility of the combination of imatinib mesylate and the cytotoxic drug of vinorelbin in different concentrations in patients with advanced and MBC.

Study design: This is a prospective open-label, single arm phase I/II study combining 400 mg Imatinib Mesylate p.o. daily (amended from 600 mg) with an escalating dose of vinorelbin i.v. weekly for patients with locally advanced or metastatic breast cancer. Patients must have tumors expressing PDGF-receptor-α and/or -β and/or c-kit and have received pretreatment with an anthracyclin containing regimen. Main study endpoints are feasibility and tolerability of this novel combination. In addition to the total toxicity and the incidences of hematological and non-hematological toxicity of grade 3 and 4, the clinical activity together with the clinical response rate and the time to disease progression will be evaluated. The quality of life is examined during the whole course of treatment. Recruitment started for level one with 10 mg/m² vinorelbin and proceeds to the next higher levels 15, 20 and 25 mg/m². Each dose level will be filled with at least five patients. Patients of one dose level will be followed for a minimum of 28 days during therapy, before enrolment of patients for the next dose level can start. For translational research multiple skin biopsies will be taken (skin wounding assays). When feasible tumor-biopsies are taken before and during therapy. Expression of tyrosine kinase receptors (c-kit and PDGF-receptor) will be correlated with treatment response.

Present accrual and target accrual: 33 patients have been enrolled into the study. Dose levels I-III have been fully recruited. In dose level IV two patients with visceral metastasis are ongoing on study medication. Safety and clinical data will be available after the last patient discontinues study treatment.

Information on the study protocol, the translational subprotocol and details on c-kit and PDGF-receptor expression analysis will be presented at the meeting.

OT3-01-03
Kalinsky K, Sparano JA, Kim M, Crew KD, Maurer MA, Taback B, Feldman SM, Hibshoosh H, Wiechmann LS, Adelson KB, Hershman DL, Columbia University Medical Center, New York, NY; Albert Einstein College of Medicine, New York, NY; Mount Sinai School of Medicine, New York, NY

Background: To serve as a bridge between pre-clinical and early clinical testing, pre-surgical studies are being designed to expose patients to a limited duration of an anti-cancer agent before launching a lengthy clinical trial program. In this model, modulation of predictive tissue and serum biomarkers are assessed. At Columbia University, we have completed 3 pre-surgical studies. The PI3K/Akt signaling pathway is an important signaling pathway in breast cancer (BC). The first allosteric Akt inhibitor to enter clinical development, MK-2206 is well-tolerated and has demonstrated anti-cancer properties in pre-clinical and early-phase clinical studies. The purpose of this study (NCI P8740) is to determine the effects of MK-2206 on women with newly diagnosed BC between breast biopsy and surgery. Trial Design: Patients (n=30) will receive 2 doses of weekly MK-2206 (200 mg): first dose at day -9 and second at day -2 from surgery. This drug administration consistency will decrease the potential for noise in detecting true biomarker response. This time period was selected based upon the pharmacokinetic profile of weekly MK-2206. The main eligibility criteria for this open-label pre-surgical trial include operable, clinical stage I (at least T1c) to IIIC invasive BC. Patients not considered for neoadjuvant chemotherapy are eligible. Specific Aims: Our hypothesis is that MK-2206 will decrease phospho-AktSer473 in tumor tissue after 2 weekly doses. To maintain sample quality and ensure that phospho-Akt evaluated on formalin-fixed paraffin-embedded (FFPE) tissue is comparable across samples (given the 20 minute half life of AKT), all samples will be processed rapidly by a standardized protocol. Secondary objectives include the following in FFPE: modulation of downstream PI3K/Akt pathway signaling [immunohistochemistry and reverse phase-protein microarray analysis (RPMA)]; change in tumor proliferation (Ki-67 staining); and exploration of whether PI3K/Akt signaling change depends upon tumor genetics (PIK3CA mutation or PTEN loss) or expression (Hormone Receptor/HER2 status). Pre- and post-MK-2206 blood will be collected for phospho-expression analysis in peripheral blood mononuclear cells (RPMA and western blotting). Statistical Methods: With the expectation that 20% of the matched pre- and post-treatment tissue samples will not be analyzable, we will enroll 30 patients to ensure that matched tumor samples from 24 patients are available for our primary analysis. A sample size of 24 patients will yield greater than 90% power to detect a difference in the mean score between pre-and-post treatment samples of 60 units, paired t-test (2-sided, 0.05 significance level). This trial was recently activated by the NCI and currently ready to accrue patients. Patients will be enrolled and treated at affiliated institutions in the New York Cancer Consortium.
OT3-01-04

TANIA: A Randomized Phase III Trial Evaluating Continuing and Reinstituted Bevacizumab (BEV) in Patients Previously Treated with 1st-Line BEV for Locally Recurrent/Metastatic Breast Cancer (LR/mBC).

von Minckwitz G, Cortés J, Gligorov J, Marschner NW, Puglisi F, Vrdoljak E, Duene A-A, Zielinski C. German Breast Group, GGB Forschungs GmbH, Neu-Isenburg, Germany; Vall d’Hebron University Hospital, Barcelona, Spain; APHP Tenon-APREC, Paris, France; Outpatient Cancer Centre, Freiburg, Germany; University Hospital of Udine, Udine, Italy; Centre of Oncology, Split, Croatia; F. Hoffmann-La Roche Ltd, Basel, Switzerland; Medical University of Vienna, Vienna, Austria

Background: BEV has repeatedly demonstrated improvements in progression-free survival (PFS) in randomized phase III trials, providing benefit in the 1st- and 2nd-line settings when combined with chemotherapy versus chemotherapy alone. However, the role of BEV in BEV-pretreated LR/mBC is unclear. The TANIA trial (MO22998) was initiated to address this question.

Trial design: TANIA is an open-label randomized multicenter phase III trial. Eligible patients are aged ≥18 years with HER2-negative LR/mBC that has progressed during or after ≥12 weeks of 1st-line BEV combined with chemotherapy for LR/mBC. Maintenance therapy with BEV and/or endocrine therapy before study enrollment is permitted. Patients who have previously received anti-angiogenic therapy other than BEV in the 1st-line LR/mBC setting are not eligible. BEV-specific exclusion criteria are similar to previous randomized trials (e.g. inadequately controlled hypertension; history of nephrotic syndrome, hypertensive crisis, gastrointestinal perforation, or grade ≥3 venous thromboembolism; significant vascular disease). All patients must provide written informed consent. After stratification according to hormone receptor status, time to 1st progression (<6 vs ≥6 months), choice of chemotherapy (taxane vs non-taxane vs vinorelbine), and LDH level (≤1.5 vs >1.5 × upper normal limit), eligible patients are randomized 1:1 to 2nd-line treatment with either standard single-agent chemotherapy alone (arm 1) or standard single-agent chemotherapy combined with BEV (15 mg/kg q3w or 10 mg/kg q2w, depending on the chosen chemotherapy regimen; arm 2). 2nd-line therapy is continued until disease progression, unacceptable toxicity, or patient withdrawal. At progression, patients in arm 1 receive 3rd-line chemotherapy without BEV (ie no crossover permitted) and those in arm 2 receive 3rd-line chemotherapy in combination with BEV (unless prevented by unacceptable toxicity). Maintenance endocrine therapy is permitted in both arms (in combination with BEV in arm 2). At 3rd progression, BEV is permitted in all patients. The primary objective is to determine the therapeutic benefit of continued or reintroduced BEV in combination with 2nd-line chemotherapy for patients previously treated with 1st-line BEV plus chemotherapy, determined by the duration of PFS from the time of randomization to 2nd progression (or death). Additional objectives include evaluation of the interval between 2nd and 3rd progression, the interval between randomization and 3rd progression, PFS in stratified subgroups, overall response rate to 2nd-line therapy, overall survival (OS), 1-year OS rate, safety, quality of life (FACT-B and EQ-5D), and translational research. The sample size of 488 patients is calculated assuming median PFS of 7 months in arm 1, a hazard ratio of 0.75, a recruitment period of 30 months, and a 5% dropout rate (ie 439 eligible patients), providing ≥80% power at two-sided α=0.05. As of 15th June 2011, 23 patients have been enrolled. The primary analysis is planned after 384 patients have shown progression on 2nd-line therapy.

OT3-01-05

PARP Inhibition after Preoperative Chemotherapy in Patients with Triple-Negative Breast Cancer (TNBC) or Known BRCA 1/2 Mutations: Hoosier Oncology Group BRE09-146.

Miller KD, Perkins SM, Badve SS, Sledge GW, Schneider BP. Indiana University Melvin and Bren Simon Cancer Center

Background: Based on recently reported I-SPY trial, TNBC patients who had residual disease category II or III had 2-year disease free survival (%) of only ~40% (J Clin Oncol 2009;27:18s). Currently, no standard systemic therapy exists for this high-risk group. It represents a real opportunity to explore the potential impact of novel therapies. Recent laboratory and early clinical studies (Nature 2005;434:913) identified a unique sensitivity to DNA-damaging chemotherapy and PARP inhibition. We initiated a randomized phase II trial of DNA-damaging chemotherapy (cisplatin) or PARP-inhibition + cisplatin in TNBC patients with substantial residual invasive disease after standard anthracycline and/or taxane containing neoadjuvant chemotherapy. Methods: To ensure a high-risk population, patients must have residual disease category 0-2 based on the Miller-Payne classification system, residual cancer burden classification II or III, residual lymph node involvement, or at least 2 cm of residual invasive disease in the breast. After completion of standard radiation therapy (when indicated), patients are randomized 1:1 to cisplatin (75 mg/m2 IV Day 1 every 3 weeks x 4 cycles) alone or in combination with PARP inhibition (PF-01367338 - 24 mg IV D1, 2, 3 of each 3 week cycle with a single dose escalation to 30 mg in the absence of significant toxicity in cycle 1 followed by maintenance PARP inhibition weekly x 24 weeks). The primary objective is 2-year DFS. To detect an improvement in 2-year DFS from 40% with cisplatin alone to 63.2% in the cisplatin + PF-01367338 arm (corresponding to HR=0.5), with 80% power using a one-side log-rank test with 0.10 level of significance, 102 patients are required in the primary analysis. Secondary objectives include safety, 1-year DFS, overall survival, and biomarkers of tumor recurrence, resistance to chemotherapy and/or PARP inhibition. Two dose escalation safety cohorts (N=13) were completed without dose limiting toxicity; the randomized portion began enrolment in 11/2010 has enrolled 20 patients as of 05/2011.

OT3-01-06

A Phase 2 Study Investigating the Safety, Efficacy and Surrogate Biomarkers of Response of 5-Azacitidine (5-AZA) and Entinostat (MS-275) in Patients with Advanced Breast Cancer.

Connor RM, Jankowitz RC, Andreopoulos E, Alred JB, Jeter SC, Zorzi J, Adam BM, Espinoza-Delgado I, Baylin SB, Zahnow CA, Ahuja N, Davidson NE, Stearns V, Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD; University of Pittsburgh Cancer Institute, Pittsburgh, PA; Albert Einstein College of Medicine, Montefiore Medical Center, New York, NY; Mayo Clinic, Rochester, MN; National Cancer Institute, Bethesda, MD

Background: Epigenetic alterations in the genome, including abnormal DNA methylation and histone hypoacetylation, initiate and promote cancerous changes via several mechanisms, including inactivation of tumor suppressor genes. Preclinical investigations in breast cancer suggest that use of epigenetic modifiers results in re-expression of aberrantly silenced genes and proteins that represent important therapeutic targets (e.g. estrogen receptor alpha, ER). Combination therapy with a DNA methyltransferase inhibitor (DNMTI) and a histone deacetylase inhibitor (HDACI) has yielded superior ER re-
expression and greater restoration of tamoxifen responsiveness than with HDACI alone. We hypothesize that clinically tolerable doses of the DNMTI 5-azacitidine (5-AZA) and the HDACI entinostat may not only effect changes in DNA methylation and gene expression, but also yield objective disease responses in women with advanced breast cancer. 

Trial design: 
This multicenter phase II study (NCT01349959) is enrolling patients with advanced human epidermal growth factor receptor 2 (HER2)-negative breast cancer with triple negative (ER/PR/HER2-negative, Cohort A) or hormone-resistant (Cohort B) disease. Patients will receive 5-AZA 40 mg/m2 subcutaneously days 1-5 and 8-10 and entinostat 7 mg orally days 3 and 10 every 28 days. Because of the potential for re-expression of the ER with epigenetic agents, patients will be offered continuation of 5-AZA and entinostat at progression with the addition of hormonal therapy (investigator discretion). Mandatory tumor biopsies will be performed at baseline and after 8 weeks of therapy to evaluate correlative biomarkers. 

Eligibility Criteria: 
Eligible patients must be ≥ 18 years, have measurable locally advanced/metastatic triple-negative (at least one prior chemotherapy received adjuvant/metastatic setting) or hormone-resistant (must have received two prior hormonal agents and one prior chemotherapy) disease, adequate organ function and ECOG PS ≤ 2. 

Specific Aims: 
1. Objective response rate (ORR) by RECIST 1.1 criteria. 
2. Safety and tolerability 
3. Progression-free survival, overall survival and clinical benefit rate. 
4. Safety and toxicity data, feasibility and response rate where hormonal therapy is added to the combination under investigation at the time of progressive disease. 
5. Pharmacokinetics, cytidine deaminase, changes from baseline of candidate gene methylation and expression in circulating deoxyribonucleic acid (DNA) and malignant tissue. 

Statistical Methods: 
Using a two-stage three-outcome design to assess the efficacy of the combination, a maximum of 30 patients (requiring 27 evaluable) will be accrued to each cohort unless undue toxicity is encountered for a maximum sample size of 60 patients. The study design tests the null hypothesis that the ORR is at most 5% against the alternative hypothesis that it is at least 20% with a type I error of 4% and power of 90%. Present and Targeted Accrual: This study has just opened to patient enrollment. We anticipate a rapid accrual of 60 patients within 1 year. 

Funding from Stand Up to Cancer and CTEP). 

OT3-01-07 
The BEACON Study (BrEAst Cancer Outcomes with NKTR-102): A Phase 3 Open-Label, Randomized, Multicenter Study of NKTR-102 Versus Treatment of Physician’s Choice (TPC) in Patients (pts) with Locally Recurrent or Metastatic Breast Cancer (MBC) Previously Treated with an Anthracycline, a Taxane, and Capecitabine (ATC). 

Awada A, Leung ACF, Zhao C, Hannah AL, Perez EA. Universite Libre de Bruxelles, Brussels, Belgium; Nektar Therapeutics, San Francisco, CA; Mayo Clinic, Jacksonville, FL 

Background: NKTR-102 is a next-generation topoisomerase I inhibitor-polymer conjugate with a markedly reduced Cmax and a continuous exposure profile compared to irinotecan. A phase 2 trial of single-agent NKTR-102 compared a dose of 145 mg/m2 every 2w or every 3w in 3rd-line MBC (Awada et al, ASCO 2011). Overall the ORR was 29% (including 3% CR) with the prior ATC subset demonstrating an ORR of 31%. Dosing every 3w was better tolerated; in this arm, median PFS equaled 5.3m and median OS equaled 13.1m. 

Trial Design: NKTR-102 will be compared to TPC in an open-label, randomized, parallel, two arm multicenter Phase 3 pivotal study in pts with previously treated locally recurrent or metastatic breast cancer. 

Key Entry Criteria: Adult females, with ECOG 0 or 1 with adequate liver, kidney and marrow function. All patients must have received prior therapy with an anthracycline (in neo/adjuvant or metastatic setting or both), a taxane (in neo/adjuvant or metastatic setting or both) and capecitabine (in neo/adjuvant or locally advanced/metastatic setting or both) unless not medically appropriate or explicitly contraindicated for the patient. All chemotherapy- and radiation-related toxicities must have resolved to ≤ Grade 1, except for stable sensory neuropathy ≤ Grade 2 and alopecia. 

Funding from Stand Up to Cancer and CTEP). 

OT3-01-08 
Phase II Study of S-1 Combined with Cisplatin in the First-Line Treatment of Triple Negative Breast Cancer. 

Fan Y, Xu BH. Cancer Hospital & Institute, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China 

Rationale: There is no standard choice of first-line treatment for triple negative breast cancer (TNBC). It is supposed that TNBC may be more sensitive to DNA damage agents such as platinum but resistant to cell cycle specific agents including taxanes and 5-fluorouracil. Currently these hypotheses are under investigation in several ongoing clinical trials. S-1 is an orally administered fluorinated pyrimidine with high activity in non-small-cell lung cancer and gastric cancer. Recently single agent S-1 has been reported to be effective in capecitabine-resistant metastatic breast cancer with a response rate of 27.8% and median TTP of 6.2 months. So it is intriguing to find whether S-1 plus cisplatin would be a valuable regimen in TNBC patients with limited choices of management. 

Design: This is a prospective, single-arm phase II study. Eligible patients are treated first with S-1 (80mg/m2, 2 weeks on and 1 week off) and cisplatin (75mg/m2 intravenously day1) every 3 weeks as a cycle for up to 6 cycles, until disease progression, unacceptable toxicity or patient consent withdrawal. If no PD was observed after 6 cycles, patients can remain on S-1 until disease progression, unacceptable toxicity or patient consent withdrawal. 

Eligibility: Major inclusion criteria includes: 1. histologically confirmed triple negative breast cancer; 2. advanced patients without
prior treatment for locally recurrent or metastatic disease; 3. patients must have received anthracyclines and taxanes in neo/adjuvant setting; 4. at least one measurable disease according to RECIST 1.1; 5. adequate organ function within acceptable range.

Endpoints: The primary endpoint is objective response rate (ORR) and secondary endpoints include progression free survival (PFS), overall survival (OS) and safety profile. Exploratory biomarks will be studied for TS and DPD enzyme expression and genotyping.

Statistical considerations: The expected response rate is around 50% based on the literature, and the null hypothesis is based on a response rate no greater than 30%. According to Simon’s two stage phase II design with errors of 0.05 and 0.20 respectively, a minimum of 15 patients would be required in the first stage and totally 46 patients after the second stage. Since a non-compliance rate of 10% is expected, we plan to enroll a total of 50 patients.

Recruitment: Currently it has just been initiated with 1 patient still on screening. The target accrual, as stated above, is 50 patients.

OT3-01-09
Phase 3 Trial Comparing Capericitabine in Combination with Sorafenib or Placebo for Treatment of Locally Advanced or Metastatic HER2-Negative Breast Cancer (RESILIENCE).

Baselga J, Schwartzberg LS, Petrenciu O, Shan M, Gradihar WJ. Massachusetts General Hospital Cancer Center; West Clinic; Bayer HealthCare Pharmaceuticals; Feinberg School of Medicine, Northwestern University

Sorafenib (SOR) is an oral multikinase inhibitor with antiangiogenic and antiproliferative activity. SOR is currently indicated for renal cell and hepatocellular carcinoma, with indications in other tumor types being explored. In a double-blind, randomized phase 2b screening trial (SOLT-0701) in patients with advanced HER2-negative breast cancer (BC), the addition of SOR to capecitabine (CAP) showed a statistically significant improvement in the primary endpoint of progression-free survival (PFS) compared with placebo (PL)+CAP (median 6.4 vs 4.1 mo; hazard ratio=0.58; 1-sided P=0.0006). The combination was tolerable. Grade 3/4 adverse events were comparable between treatment arms with the exception of grade 3 hand-foot skin reaction/syndrome (HFSR/HFS) (44% in SOR+CAP vs 14% in PL+CAP). The SOLT-0701 results indicate a potential role for the oral combination of SOR+CAP in the treatment of BC and support a phase 3 trial.

Design: RESILIENCE is an ongoing multinational, double-blind, PL-controlled, randomized phase 3 trial designed to assess SOR+CAP as a first- or second-line therapy in advanced HER2-negative BC. Eligibility criteria include: ≥18 years of age; ≤1 prior chemotherapy regimen for advanced BC; and resistant to/failed taxane and anthracycline or no indication for further anthracycline treatment. Prior hormonal or radiation therapy is allowed, but prior use of VEGF inhibitors is not. Patients with significant cardiovascular disease or active brain metastases are not eligible. Patients are stratified by hormone receptor status, geographic region, and prior chemotherapy for advanced BC and randomized (1:1) to CAP (1000 mg/m² po twice daily [BID], days 1–14 of a 21-day cycle) in combination with SOR (po BID, days 1–21, total dose 600 mg/day) or matching PL. CAP and SOR/PL doses can be escalated to 2500 mg/m² per day and 800 mg/day, respectively, as tolerated. The protocol outlines strategies to manage toxicities with dose interruption and reduction. Dose re-escalation after reduction is allowed for SOR/PL (per protocol guidance) but not for capecitabine. Guidelines are provided for prophylactic and symptomatic treatment of HFSR/HFS. Radiographic assessment is every 6 wk for the first 36 wk, and every 9 wk thereafter.

The primary endpoint is PFS. Assuming a 1-sided alpha of 0.005 and a power of 98.9%, the sample size is estimated at ~519 patients, with primary analysis planned after 363 events. Secondary endpoints include overall survival, time to progression, overall response rate (RECIST 1.1 criteria), duration of response, and safety. In addition, patient reported outcomes will be assessed, and the trial will include an exploratory analysis of biomarkers. Enrollment began in Nov 2010. The trial is registered at ClinicalTrials.gov (NCT01234337).

Conclusions: RESILIENCE will provide definitive PFS data for SOR+CAP as a first- or second-line therapy in HER2-negative locally advanced or metastatic BC. The phase 3 design and improved dosing guidance since SOLT-0701 will better characterize the benefit-to-risk profile of this regimen.

OT3-01-11
A Randomized, Phase II Multicenter, Double-Blind, Placebo-Controlled Trial Evaluating MetMAb and/or Bevacizumab in Combination with Weekly Paclitaxel in Patients with Metastatic Triple-Negative Breast Cancer.

Daniel BR, Campone M, Dieras V, Ervin T, Yu W, Paton VE, Xia Q, Peterson A. Chattanooga Oncology Hematology Associates - SCRI, Chattanooga, TN; Centre Rene Gauducheau, Nantes-Saint Herblain, France; Institute Curie, Paris, France; Florida Cancer Specialists, Englewood, FL; Genentech Inc., South San Francisco, CA

Background: Dysregulation of the HGF/Met pathway has been associated with tumorigenesis in many malignancies, including the basal sub-type of triple-negative breast cancer. MetMAb (RG3638) is a recombinant, humanized, monovalent monoclonal antibody directed against Met. By binding to the extracellular domain of Met, MetMAb selectively blocks ligand binding and subsequent activation by HGF. Pre-clinical data support the efficacy of combining MetMAb with numerous chemotherapy agents and with targeted agents including bevacizumab and erlotinib. In clinic, MetMAb has been generally well tolerated as a single agent (Phase I), in combination with bevacizumab (Phase Ib) and with bevacizumab in a dose escalation/expansion study (Phase Ib') as well as in combination with erlotinib in patients with previously treated NSCLC. The combination of MetMAb + erlotinib in NSCLC demonstrated significant benefit in both PFS and OS in patients with Met diagnostic positive tumors whereas those patients with Met diagnostic negative tumors demonstrated a detrimental effect in both PFS and OS. The most commonly reported adverse events associated with MetMAb are peripheral edema and fatigue.

Methods: This clinical trial is a randomized three-arm Phase II study in patients with triple-negative metastatic breast cancer, which makes up the majority of basal sub-type breast cancer. Patients will be randomized (1:1:1) to either paclitaxel + bevacizumab + placebo; paclitaxel + placebo + MetMAb; or paclitaxel + bevacizumab + MetMAb. The primary endpoint of this study is PFS in all patients and by Met diagnostic status. Secondary endpoints include an evaluation of OS, ORR, safety, and pharmacokinetics. To date, 11 patients have been enrolled, and 10 patients have been treated.

Primary and secondary analyses will include all randomized patients, with patients analyzed according to the treatment arm to which they were assigned. Kaplan-Meier methodology will be used to estimate the median PFS for each treatment arm. An estimate of the HR with 95% CI will be determined using a Cox regression model with an
indicator variable for the MetMAb-containing arm. Safety will be assessed through summaries of adverse events and will include all patients who receive any amount of study treatment. This study remains open for accrual; further details on the trial can be found on the ClinicalTrials.gov website under NCT01186991.

OT3-01-13
Phase One Trial of Combined Temsirolimus, Erlotinib, and Cisplatin in Advanced Solid Tumors.

Background: A large subset of triple negative breast cancers (TNBC) are driven in part by a combination of activated growth factor signaling and downstream constitutive activation of the PI3K pathway. One therapeutic strategy is to target each driver simultaneously, requiring an understanding of drug interactions and combined toxicities. There is a strong correlation between loss of PTEN and both expression of EGFR and mutation of p53 in a subset of TNBC. Single agent trials targeting EGFR in breast cancer have been a disappointment likely, in part, due to constitutive downstream activation of PI3K, AKT and mTOR signaling, mainly through loss of PTEN expression. Preclinical studies have demonstrated 1) that resistance to EGFR-targeted therapy in the setting of an activated PI3K pathway can be overcome with rapamycin (which inhibits the TORC1 mTOR complex), and 2) that a subset of TNBC cells with p53 mutations are particularly sensitive to the DNA damaging agent cisplatin due to their high expression of p63 and p73. We have hypothesized that targeting the EGFR, PTEN and DNA damage pathways simultaneously with the rapalog temsirolimus, the EGFR inhibitor erlotinib, and cisplatin will provide therapeutic benefit in a definable subset of TNBC patients.

Design: Single institution phase one dose escalation trial of combined temsirolimus, erlotinib, and cisplatin in advanced solid tumor patients. Cisplatin and temsirolimus are given on day 1 and day 8 of 21 day cycles and erlotinib is taken daily without interruption. Patients are dose escalated using a standard 3+3 design. Cisplatin is given at a fixed dose of 30 mg/m². Erlotinib was started at 100 mg and will be escalated to 150 mg. Temsirolimus was started at 15 mg, and after erlotinib escalation, will be escalated to 25 mg. The objectives of the study are: 1) characterize toxicity of the regimen and establish combined maximal tolerated dosing, 2) measure drug target inhibition by assessing EGFR, AKT, and mTOR activation in serial assessments of peripheral blood mononuclear cells and skin biopsies, 3) measure the pharmacokinetics of all three drugs in combination, and 4) exploratory assessment of molecular measures of PTEN, EGFR, and p53 status, and markers of activated downstream pathways in patient’s archived pathology specimens to assess feasibility of identifying candidate biomarkers in future trials involving patients with TNBC. Eligibility criteria include one prior treatment for advanced disease, ECOG PS=0-1, measurable or non-measurable disease, available archived tumor sample, non-smoking, normal renal function, and lack of concurrent use of strong CYP3A4 inhibitors or inducers. Because of significant rash encountered in prior combination trials of EGFR and TORC1 inhibitors, a prophylactic oral doxycycline strategy supported by randomized trials is being employed. Current accrual is 6 out of a possible 18 patients.

OT3-01-14
N0937: Phase II Trial of Brostallicin and Cisplatin in Patients with Metastatic Triple Negative Breast Cancer.

Moreno-Aspitia A, Rowland KM, Liu H, Hillman DW, Stella PJ, Perez EA. Mayo Clinic, Jacksonville, FL; Mayo Clinic, Rochester, MN; Carle Cancer Center, Urbana, IL; St. Joseph Mercy Cancer Center, Ypsilanti, MI

Background: Tumors that are negative for estrogen and progesterone receptors and do not over express HER2 are referred as “triple negative” breast cancer (TNBC). These tumors are characterized by unique molecular profiles on gene expression arrays, aggressive behavior with a high recurrence rate, an increased risk of visceral metastases, poor prognosis and lack of targeted therapies. Brostallicin is a novel synthetic compound from the class of DNA minor groove binding (MGB) anti-cancer agents. It retains activity in cancer cells resistant to alkylating agents, topoisomerase I inhibitors and is fully active against DNA-mismatch repair deficient tumor cells. Cells expressing relatively high glutathione/glutathione S-transferase (GSH/GST) levels are more susceptible to brostallicin antitumor efficacy. Cisplatin administration increases expression of GST in tumor cells leading to an increased anti-tumor efficacy of brostallicin.

Trial design: Single-stage phase II study - based on the effects of cisplatin on GSH/GST levels in preclinical models, the most reasonable sequence to explore was cisplatin on Day 1 followed by brostallicin on Day 2 repeated every 21 days.

Eligibility criteria: Women or men ≥18 years of age with confirmed adenocarcinoma of the breast with clinical evidence of measurable metastatic disease and triple negative subtype according to current ASCO CAP guidelines [ER/PR ≤1%; HER2 negative], who received 0-4 prior chemotherapy regimens in the metastatic setting; with adequate hematologic, renal and hepatic functions; and no active CNS metastases.

Aims: To study the efficacy of the novel drug, brostallicin, as well as to serve as proof of concept of its mechanism of action in TNBC. The primary endpoint is to evaluate clinical efficacy of the combination of brostallicin and cisplatin in the treatment of patients with metastatic TNBC, as measured by progression-free survival (PFS) at 3 months with 89% power (0.10 significance level) to detect an absolute difference of 20%. Secondary endpoints include ORR by RECIST, duration of response, 6-month PFS, overall survival (OS) and adverse event profile. Tertiary endpoints include assessment of 1) GSH levels prior to the administration of cisplatin and of brostallicin; and 2) the prevalence of BCRA-1 mutation by IHC in the primary or metastatic tumor.

Statistical methods: The largest 3-month PFS proportion where the proposed treatment regimen would be considered ineffective in this population was estimated at 35% based on the median PFS of 60 days in patients with metastatic TNBC enrolled in the N0234 trial (erlotinib and gemcitabine as 1/2nd line), and the smallest 3-month PFS success proportion that may warrant subsequent studies with the proposed regimen in this patient population was estimated at 55%. The interim analysis will be reported when the 20th eligible patient has been followed for 3 months.

Present accrual and target accrual: 21 patients have been accrued at the time of abstract submission (June 2011). Target accrual is 42 evaluable patients.
**OT3-01-15**

**Phase III Trial Evaluating the Addition of Bevacizumab to Endocrine Therapy as First-Line Treatment for Advanced Breast Cancer: The LEA Study.**

*De la Haba-Rodriguez JR, von Minckwitz G, Martin M, Morales S, Crespo C, Guerrero A, Anton-Torres A, Gil M, Muñoz M, Carrasco E, Rodríguez-Martin C, Porras I, Aktas B, Schoeneegg W, Tio J, Mehta K, Loibl S, On Behalf of GEICAM and GBG. University Reina Sofia Hospital, Córdoba, Spain; German Breast Group, Neus-Isenberg, Germany; Universitario Gregorio Marañon, Spain; Hospital Arzum de Vilanova de Lleida, Spain; Hospital U. Ciudad de Murcia, Spain; Hospital University Hospital, Spain; Hospital Universitario Ramón y Cajal, Spain; Instituto Valenciano de Oncologia, Spain; Miguel Servet University Hospital, Spain; Institut Catala d’Oncologia, Spain; Provincial Hospital Clinic, Barcelona, Spain; GEICAM Headquarters, Madrid, Spain; University Hospital, Essen, Germany; Praxis Dr Schnoenegg, Berlin, Germany; Universitätsklinikum Muenster, Germany*

**Background:** Retrospective clinical data suggest that high vascular endothelial growth factor (VEGF) levels in breast tumors are associated with a decreased response to endocrine therapy. We designed the randomized phase III LEA study of first-line bevacizumab in combination with endocrine therapy, to address the hypothesis that anti-VEGF treatment can prevent resistance to endocrine therapy in patients with advanced breast cancer sensitive to such treatment.

**Methods:** Postmenopausal patients with evaluable locally recurrent or metastatic breast cancer, HER2-negative and estrogen receptor (ER)- and/or progesterone receptor (PgR)-positive disease, and eligible to receive hormonal treatment are candidates for this study. Patients are randomized to receive letrozole 2.5mg daily or fulvestrant, 250mg every 4 weeks (Arm A) or the same hormonal therapy plus bevacizumab 15mg/kg every 3 weeks (Arm B). The primary objective is to compare progression-free survival (PFS) between the treatment arms. Secondary endpoints are overall survival, time to treatment failure, overall response rate, response duration, clinical benefit rate and safety. In total, 344 patients (172 in each treatment arm) will be randomized to receive letrozole or fulvestrant.

**Results:** Recruitment began in November 2007. To date, 348 patients have been included in the study in Spain (n=244) and Germany (n=104). We anticipate completing recruitment by September 2011. Baseline characteristics of the first 334 randomized patients are shown in the table.

**Conclusions:** LEA is the first study to explore the use of an antiangiogenic drug in combination with endocrine therapy in the context of a phase III study.

**OT3-01-16**

**A Phase 2 Study of Ridaforolimus (RIDA) and Dalotuzumab (DALO) in Estrogen Receptor Positive (ER+) Breast Cancer.**

*Lu BD, Blum JL, Cortes J, Rugo HS, Swanton C, Eaton L, Song Y, Zhang T, Ebbinghaus SW, Baselga J, Merck Research Laboratories, Kenilworth, NJ; Texas Oncology, Dallas, TX; Vall D’Hebron University Hospital, Barcelona, Spain; UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, CA; The Royal Marsden Hospital, Sutton, United Kingdom; Merck Research Laboratories, North Wales, PA; Merck Research Laboratories, Boston, MA; Massachusetts General Hospital, Boston, MA*

**Background:** Activation of the PI3K/AKT/mTOR pathway is common in breast cancer. Preclinical studies indicate that the dual inhibition of IGFR and mTOR may be additive or synergistic and abrogate the feedback activation of AKT due to rapamycin analog mTOR inhibitors. A phase 1 study of the mTOR inhibitor RIDA and the anti-IGFR antibody DALO demonstrated that the combination was feasible and well-tolerated at doses that were nearly those used for the two single agents and with dose limiting toxicity of stomatitis, similar to RIDA as monotherapy. A preliminary signal of anti-tumor activity, including partial responses and prolonged progression free survival, was observed in ER+ breast cancer, especially in high proliferation tumors. This observation is supported by data from tumor profiling including partial responses and prolonged progression free survival, was observed in ER+ breast cancer, especially in high proliferation tumors. This observation is supported by data from tumor profiling and preclinical data suggesting that ER+ high proliferation breast cancer may be responsive to the RIDA-DALO combination. Methods: This is a two-part, adaptive design study intended to first test the combination of RIDA-DALO against a standard agent, exemestane, for ER+ positive breast cancer that has progressed after aromatase inhibitors. The trial is a multi-center, international, randomized study for ER+ positive breast cancer that has progressed after aromatase inhibitors. The trial is a multi-center, international, randomized study with PFS as the primary endpoint. Patients (pts) are stratified into high and low proliferation strata based on baseline Ki67, and the low proliferation stratum is capped to ensure adequate enrollment of high proliferation pts. If Part A shows a PFS benefit for RIDA-DALO, Part B is intended to show the PFS benefit of the combination over the single agents by comparing RIDA-DALO to RIDA and DALO. Part B will be further adapted based on whether the PFS benefit in Part A is observed in all-comers or the high proliferation subset. Tumor tissue is collected for molecular profiling and analysis of intrinsic subtype, with an efficacy analysis based on classification.
of tumors using the genomic grade index (GGI) as an exploratory objective. This trial design is intended to establish proof of concept that RIDA-DALO can prolong PFS in ER+ breast cancer in all-comers or a high proliferation subset by Ki67, while efficiently addressing the development of two investigational agents in combination and leading to a two-arm Phase 3 design.

OT3-01-17
Randomized, Double-Blind, Placebo-Controlled Phase II Trial of Low-Dose Metronomic Cyclophosphamide Alone or in Combination with Veliparib (ABT-888) in Chemotherapy-Resistant ER and/or PR-Positive, HER2/neu-Negative Metastatic Breast Cancer: New York Cancer Consortium Trial P8853.

Andreopoulou E, Chen AP, Zujewski JA, Kalinsky K, Vahdat L, Raptis G, Hershman D, Novic Y, Muggia F, Sparano J. Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, NY; National Cancer Institute, Bethesda, MD; Columbia University Medical Center, New York, NY; Weill Cornell Medical College, New York, NY; Mount Sinai School of Medicine, New York, NY; New York University Langone Medical Center, New York, NY

Background: Veliparib is an orally available, small molecule inhibitor of poly(ADP-ribose) polymerase (PARP). PARP is an essential nuclear enzyme that plays a role in recognition of DNA damage and facilitation of DNA repair. PARP inhibitors potentiate the cytotoxicity of DNA-damaging agents, including cyclophosphamide (C). The rationale for the proposed trial is as follows: (1) low-dose, continuous metronomic C (50 mg PO daily) has activity in refractory metastatic breast cancer (MBC), (2) PARP is induced by DNA damaging agents, (3) PARP expression is comparable in ER-positive and ER-negative disease, (4) some ER-positive breast cancers exhibit defective homologous recombination pathway repair genes (eg, RAD51 and XRCC3), (5) the PARP inhibitor iniparib appears to be more effective when used in chemotherapy resistant disease. Taken together, these findings suggest that veliparib-C combination may be more effective than metronomic C alone in chemotherapy resistant MBC.

Trial design: A randomized Phase II trial design 1:1: S. Blocked randomization will be performed at all participating sites. Patients are randomized to oral C (50mg PO daily) plus either veliparib (60mg PO daily) or matching placebo.

Eligibility criteria: (1) ER- and/or PR-positive, HER2-negative MBC, (2) ECOG PS 0-1, (3) at least 2 prior chemotherapy regimens for MBC, including a taxane and capcetabine. 4) at least 1 line of endocrine therapy for metastatic disease (includes relapse while receiving endocrine therapy).

Specific aims: Primary: To determine if the addition of veliparib to metronomic dose C improves median progression free survival (PFS) compared with C alone in patients with ER and/or PR-positive, HER2-negative MBC who progressed on at least two lines of prior chemotherapy and one line of prior endocrine therapy.

Secondary: 1) To determine if the addition veliparib to C chemotherapy improves a) response rate b) clinical benefit rate (defined as objective response plus stable disease for at least 24 weeks from day +1) 2) Survival in patients treated with C alone and C plus veliparib. 3) Adverse event profile in patients treated with C alone and C plus veliparib.

Translational: Exploratory analyses will evaluate whether the macroH2A1.1 and PARP1 expression status in archival paraffin, or veliparib-induced PARP downregulation in peripheral blood mononuclear cells, is predictive of benefit from veliparib.

Statistical methods: The primary endpoint is PFS, and the trial is powered to detect an increase in median PFS from 3 to 6 months (alpha=0.10, beta=0.10), which will require enrollment of 62 eligible patients over 12 months.

Enrollment: The study is active and open to enrollment.

Clinical trials.gov NCT01351909

OT3-01-18
Combination Immunotherapy with Trastuzumab and the HER2 Vaccine E75 in Low and Intermediate HER2-Expressing Breast Cancer Patients To Prevent Recurrence.

Sears AK, Clifton GT, Vreeland TJ, Hale DF, Ponniah S, Mittendorf EA, Peoples GE. Brooke Army Medical Center; Ft. Sam Houston, TX; Uniformed Services University of the Health Sciences, USMCI, Bethesda, MD; UT M.D. Anderson Cancer Center, Houston, TX

Background: In a phase II trial, the HER2-derived E75 vaccine administered with the immunoadjuvant GM-CSF has been shown to reduce breast cancer recurrence in the adjuvant setting, with a greater benefit seen in patients with low levels of HER2 expression (IHC 1+ or 2+). There has also been recent suggestion that patients with low HER2 expression may also benefit from trastuzumab. Preclinical testing of the combination of trastuzumab and the E75 vaccine has shown a synergism with combinational therapy. Finally, from our phase II trials of cytotoxic T cell-eliciting peptide vaccines, sequential treatment with trastuzumab and HER2 vaccination has resulted in no recurrences in 30 patients with a median follow-up of 48 months. Based on these results, we have designed a trial to evaluate the ability of the combination of trastuzumab and the E75 vaccine to prevent breast cancer recurrence.

Trial Design: This study will be a multi-center, prospective, randomized, single-blinded, phase II trial evaluating trastuzumab + E75 + GM-CSF (immunoadjuvant) vs. trastuzumab + GM-CSF alone (no E75) in the adjuvant setting in breast cancer patients. Eligible patients include node positive (or node negative if negative for both ER and PR) disease-free breast cancer patients with low or intermediate levels of HER2 expression (IHC 1+ or 2+) and adequate cardiac function (LVEF >50%). Patients must be HLA-A2/A3 restricted. Patients will be enrolled after completing standard of care multi-modal therapy and randomized between the two treatment arms with stratification by HER2 expression (1+ or 2+) and nodal status (N0, N1, N2, or N3). Vaccinations (E75+GM-CSF or GM-CSF alone) will be administered as six monthly intradermal inoculations concurrently with trastuzumab therapy. The primary efficacy endpoint is to compare disease-free survival (DFS) between treatment arms at 24 months. Secondary Objectives will include evaluation of cardiac toxicity from combination therapy (periodic cardiac assessment with MUGA or ECHO), DFS at 36 months, and immunologic responses to vaccination. From previously published experience with trastuzumab, we expect a recurrence rate of 15% in trastuzumab (plus GM-CSF) treated patients and anticipate that the combination of trastuzumab with E75+GM-CSF will reduce this recurrence rate to 5%. In order to show a statistical difference between these recurrence rates, we plan to enroll 150 patients per treatment arm (300 total) with a type I error rate of 5% and 80% power to detect the primary endpoint. Trial accrual is anticipated to begin in January 2012, with a two year period of enrollment followed by a three year follow-up period.

Conclusion: We hypothesize that combination adjuvant immunotherapy with trastuzumab and E75 vaccination will result in a greater reduction in breast cancer recurrence than trastuzumab therapy alone and have designed a multi-center, prospective, randomized, single-blinded, phase II trial evaluating the efficacy of
this immunotherapy combination. Contact Information: This trial is sponsored by Genentech and RXi Pharmaceuticals through the Henry M. Jackson Foundation.

OT3-01-19
Phase II Study of Topical Imiquimod and Weekly Abraxane for the Treatment of Breast Cancer Cutaneous Metastases.
Higgins DM, Childs J, Parker S, Disis ML, Salazar LG. University of Washington, Seattle, WA

Background: Breast cancer (BC) cutaneous lesions present as local chest wall recurrence or as isolated sites of metastatic disease. The treatment of cutaneous lesions is challenging and includes chest wall resection, local radiation therapy, and/or salvage chemotherapy which is not curative, associated with significant morbidity, and results in overall response rates of 20-30%. Thus, investigation of novel treatment strategies is warranted. This study incorporates multimodality treatment with topical imiquimod, a TLR-7 agonist which generates an immune signal similar to that of pathogenic bacteria and Abraxane, a conventional systemic chemotherapy with potential immunostimulatory effects. Combined, these two agents provide local and systemic strategies which are potentially synergistic; and more effective than as single-agents in treating and controlling cutaneous disease.

Trial design: A Phase II single arm, non-randomized study. Patients will be sequentially enrolled and receive a maximum of 3 treatment cycles. A treatment cycle consists of topical imiquimod daily to target lesions for 4 days/week for 4 weeks in addition to Abraxane on Days 1, 8, and 15 every 28 days. Toxicity will be evaluated weekly during treatment then monthly for four months. Defined lesions are assessed at baseline and monthly. Skin biopsies are obtained pre and post treatment for histologic analysis and RT-PCR analysis of a 7 IFN-related gene signature previously associated with tumor inhibition. Immunity to BC antigens and serum TGF-β levels are also evaluated.

Aims: To evaluate the safety and anti-tumor effects of chemoimmunotherapy with topical imiquimod and Abraxane.

Eligibility criteria: Patients with progressive or relapsed BC after standard therapy who 1) have measurable cutaneous metastatic lesions, 2) are at least 7 days from last chemotherapy, 30 days from local radiotherapy and/or systemic steroids, 3) have adequate blood counts and 4) no history of active autoimmune disease. Bisphosphonates, trastuzumab, and/or hormonal therapy is allowed.

Statistical methods: Antitumor activity of target lesions will be assessed per modified WHO criteria. Complete response (CR)-complete clearance of lesions; Partial response (PR) ≥ 50% decrease in lesion size; Stable disease (SD) < 50% decrease in lesion size; Progressive disease (PD) increase in ≥ 25% lesion size. Historical overall response rates (ORR) with second and third line salvage chemotherapy range from 20-30%, with CR rates less than 2%. Based on these numbers, an ORR of 50% or a CR rate of 10% will be used as benchmarks for success (i.e., ≥ 8 responses or ≥ 2 CRs among 15 patients (observed ORR of ≥ 53% or observed CR rate of ≥ 13%) to consider the treatment worthy of further study. As a measure of the precision of the estimate of ORR achievable with 15 patients, if the response rate is 60%, we will be 80% confident that the observed RR is within 0.16 of the true RR with 15 patients treated. Toxicity will be evaluated by CTC/3E v. 3.0 and descriptive statistics will be used to summarize changes from baseline and for reporting of immunological parameters.

Accrual: 10 patients received treatment with a target accrual of 15.

OT3-02-01
A 1-Year Prospective Longitudinal Study of the Role of Psychosocial Factors in Adherence to Adjuvant Endocrine Therapy in Early Breast Cancer.
Song X, Verma S, Dent S, Clemons M, Graham N, Bedard M, Paquet L. The Ottawa Hospital Cancer Centre, Ottawa, ON, Canada; Carleton University, Ottawa, ON, Canada

Background: Extensive evidence suggests that endocrine therapy (ET) and adherence to adjuvant ET directly impacts on disease-free and overall survival in women with hormone receptor positive (HR+) early stage breast cancer (EBC). Despite this, adherence to ET is suboptimal, with 35%-50% of patients discontinuing therapy earlier than recommended. Interventions to improve adherence are lacking, due in part to a poor understanding of the modifiable risk factors influencing adherence. Virtually all authors have focused on educational needs of patients and side effect management of ET but there remains a paucity of data on how potentially modifiable psychosocial factors present at outset of treatment initiation influence adherence. We believe that a better understanding of these factors may lead to interventions which enable women to adhere to long term life-saving therapies. This study aims to identify such factors guided by the Common-Sense Model of Self-Regulation which proposes that cognitive, emotional, coping and interpersonal factors are modifiable determinants of adherence.

Study Design: The study is a single centre prospective longitudinal quantitative study. Women diagnosed with HR+ EBC for which endocrine therapy is intended will be enrolled. Participants will complete questionnaires prior to initiating ET, then at 3, 6 and 12 months. The predictor variables are: 1) modifiable factors including illness and treatment cognitions, self-efficacy in coping with side effects anticipated or experienced, fear of breast cancer recurrence, trait anxiety, patient-physician interaction, 2) treatment-induced toxicities and 3) clinical factors including ET, chemotherapy, radiation, cancer stage and menopausal status. The outcome variable is adherence measured at each assessment post-treatment initiation with pill counts and participants’ self-report.

Inclusion criteria: 1) Histologically proven Stage I, II, IIIa EBC; 2) Treatment with ET (tamoxifen or an aromatase inhibitor).

Specific Aims: To evaluate the impact on adherence to ET by 1) potentially modifiable psychosocial factors 2) side effects and 3) clinical factors.

Statistical Method: Adherence responses will be transformed into dummy coded variables (0=take ET as prescribed; 1=does not take ET as prescribed). For each assessment, several separate univariate logistic regressions will be conducted with demographic (age, education, work and marital status, ethnicity), cognitive (illness and treatment perception), emotional (fear of recurrence and anxiety), coping (self-efficacy), and patient-physician relationship (role preference, trust and satisfaction), severity of side effects and clinical factors, as independent predictors of adherence. Only predictors which are significant at the 0.25 level will be entered in subsequent hierarchical multiple regression models to identify the main determinants of adherence.

Accrual: Expected study accrual is 200 over 12-18 months. Accrual started in May of 2011 and 36 patients have been accrued to the study.
OT3-02-02
Yoga Compared to Exercise as a Therapeutic Intervention during (Neo)adjuvant Chemotherapy in Women with Stage I-III Breast Cancer.

Wiedemann F, Büssing A, Halle M, Kiechle M, Kohls N, Ostermann T, Satllter D, Ettl J. Technische Universität München, Munich, Germany; Universität Witten/Herdecke, Herdecke, Germany; Praxis Gynäkologie Arabella, Munich, Germany; Ludwig-Maximilians-Universität München, Bad Tölz, Germany.

Background: Psychological and physical distress is high in breast cancer patients receiving neoadjuvant or adjuvant chemotherapy. The patients’ ability to cope with this distress has an impact on treatment variables, i.e. deliverable chemotherapy dose, tolerability of side effects, and finally treatment completion rate. Exercise intervention studies have shown physiological and psychological benefits when undertaken during cancer treatment. There is also evidence that mind/ body interventions such as yoga are useful to manage treatment-related symptoms and anxiety in breast cancer patients. Considering the specific theoretical background of mind/body interventions this ongoing trial aims to elucidate the different effects of yoga and conventional exercise on physical and psychological factors in breast cancer patients undergoing neoadjuvant or adjuvant chemotherapy.

Trial design: Longitudinal data collection within an open, prospective, randomized trial using standardized questionnaires about inner correspondence and peacefulness with practices (ICPH), health-related quality of life (EORTC QLC C-30), fatigue (Cancer Fatigue Scale, CFS-D), mindfulness (Freiburg Mindfulness Inventory, FMI), spiritual/religious attitudes and disease coping (SpREUK), and life satisfaction (Brief Multidimensional Life Satisfaction Scale, BMLSS). Patients with newly diagnosed stage I-III breast cancer undergoing neoadjuvant or adjuvant chemotherapy are randomly assigned to receive yoga or conventional exercise on a 1:1 ratio. The yoga intervention consists of a weekly 60-minute iyengar-Yoga group-session together with individual home-based, self-contained 20-minute sessions twice a week. The conventional exercise intervention consists of a weekly 60-minute physiotherapy exercise session together with individual home-based, self-contained 20-minute sessions twice a week. Data assessments via questionnaires are done at baseline, right after the 12-week intervention period and 2 months after the end of intervention. Statistical analysis includes analyses of variance with all collected parameters and analysis of correlation between ICPH and above parameters. For statistical power 1-β=0.8 and two-sided probability of error α=0.05 the target accrual is 120 patients. Patient accrual within two breast care units started in April 2011 with 12 patients being on study to date (2011, June 21). Planned period of accrual is 20 months.

OT3-02-03
Patient Empowerment by Group Medical Consultations in the Follow-Up of Breast Cancer Survivors and Surveillance of Women with a BRCA Mutation.

Background: During usual follow-up care for breast cancer patients only little time is left for psychosocial support, while most patients experience several complaints, which may increase levels of distress or effect the quality of life. BRCA mutation carriers have a 40-80% life-time risk of developing breast cancer. They have a complex choice to make between yearly breast cancer surveillance or prophylactic mastectomy. Both options show increased survival rates.

To fulfill the needs for psychosocial support and information we have introduced group medical consultations (GMCs). A GMC provides individual medical visits conducted within a group. This 90 minute group-visit with 8-12 patients gives patients the opportunity to spend more time with their clinician and a behavioral health professional and learn from other patients experiencing similar topics. However, it should be noted that group sessions may increase fear in some patients.

Trial design: This multicenter randomized controlled trial will assess the effect of GMCs compared to individual visits for patients in the follow-up after breast cancer and for women with a BRCA mutation. The intervention group will participate in a GMC once, while the control group will have usual care.

Eligibility criteria: Inclusion criteria for the follow-up of breast cancer patients are: histologically proven breast cancer; age ≥18 years; primary treatment completed maximally 5 years ago. For BRCA mutation carriers inclusion criteria are: carrier of a BRCA1 or BRCA2 mutation; diagnosed maximally 2 years ago; age ≥25 years. Exclusion criteria for both groups are: currently involved in a diagnostic work-up because of a suspicion of breast cancer; metastatic breast cancer; current psychiatric disorder; insufficient command of the Dutch language. A history of prophylactic mastectomy is an exclusion criteria only for BRCA mutation carriers.

Study endpoints: Primary outcomes in this study are empowerment and psychological distress. In addition, the effects on cancer worry, information needs and information giving, self-examination of the breasts, treatment compliance, patient satisfaction, quality of life and costs of care (secondary outcome measures) will be studied.

Statistical methods: To assess a clinically relevant effect of GMCs on psychological distress with a power of 80%, a two-side significance of 5%, and a standard deviation of 45, 80 patients need to be included in each group. Randomization will take place per patient in blocks of 16 patients. Differences between baseline and post-test between the two groups will be compared by using ANCOVA for primary outcomes and ANOVA or mixed model for secondary analysis.

Accrual: Patients are currently being recruited at the Radboud University Nijmegen Medical Center. In the future other centers in the Netherlands will participate. Presently (21st June 2011) a total number of 37 patients have been included since start of the study (April 2011). The expected end of accrual of 320 patients will be December 2012.

OT3-02-04
TBCRC 012: ABCDE, a Phase II Randomized Study of Adjuvant Bevacizumab, Metronomic Chemotherapy (CM), Diet and Exercise after Preoperative Chemotherapy for Breast Cancer.

Mayer EL, Ligibel JA, Burstein JJ, Peppercorn JM, Miller KD, Carey LA, Dickler MN, Mayer IA, Forero A, Eng-Wong J, Pletcher PJ, Ryabin N, Gelman R, Wolff AC, Winer EP. Dana-Farber Cancer Institute, Boston, MA; Duke University Medical Center, Durham, NC; Indiana University Melvin and Bren Simon Cancer Center, Indianapolis, IN; University of North Carolina at Chapel Hill, Durham, NC; Memorial Sloan-Kettering Cancer Center, New York, NY; Vanderbilt University, Nashville, TN; University of Alabama, Birmingham, AL; Georgetown University Lombardi Comprehensive Cancer Center, Washington, DC; Hoosier Oncology Group, Indianapolis, IN; Johns Hopkins Kimmel Cancer Center, Baltimore, MD.

exploring the efficacy of adjuvant combination chemotherapy and B. DFCI 05-055 (Mayer et al, ASCO 2007, 2008) demonstrated the feasibility of 1 year B after preoperative chemotherapy. Also, increasing data support risk reduction through lifestyle interventions (Segal, Ligibel et al, ASCO 2011). The ABCDE trial was designed to evaluate extended adjuvant B in a high risk post-preoperative cohort, and also assess the contribution of exercise to a dietary intervention.

**Eligibility Criteria**
Eligible pts have HER2- breast cancer and have received preoperative anthracycline and/or taxane-based chemotherapy with residual invasive disease at surgery. Acceptable stages include: triple negative if preop stages I-III, or ER+/PR+ if stage III preop or IIIB postop. Acceptable organ function and standard B exclusions apply. Registration must occur between 28-180 days after last surgery.

**Specific Aims**
Primary endpoint is recurrence-free survival at a median follow-up of 6 years. Secondary endpoints include B pharmacogenomics, evaluation of the impact of exercise on quality of life and biomarkers associated with recurrence, and prospective examination of cardiac toxicity. Residual tissue-based predictors of outcome will be extensively explored, including PAM50, Ki67, and VEGF hypoxia signature.

**Methods**
This is a 2 x 2 randomized study with a first randomization to 6 months (mo) B 15 mg/kg every 3 weeks (wks) plus 6 mo CM (C 50 mg daily, M 2.5 mg twice daily days 1, 2 each wk), followed by 2.5 years B 15 mg/kg every 6-8 wks, versus observation. A second randomization is to a 1 year telephone-based lifestyle intervention, offering dietary modification alone, or in combination with a structured exercise program.

**Statistical Methods and Accrual**
Total sample size is 660 pts within the Translational Breast Cancer Research Consortium. Overall power is 0.80 to detect a hazard ratio of 0.59-0.68, depending on pt population. Accrual initiated early 2011 and is expected to continue for the next 36 months.

**Conclusions**
Patients with residual disease after preoperative chemotherapy are at high risk of recurrence and have unmet medical needs. To our knowledge, this is the only trial testing a prolonged but less intensive adjuvant B schedule in this clinical setting. Results of this study could have critical implications for the management of this patient population and for the design of future clinical trials with anti-angiogenic agents.
